        android:textAppearance="?android:attr/textAppearanceLarge"
```

## ADVANCED CONSTRAINTLAYOUT

```
app:layout_constraintBottom_toBottomOf="parent"  
app:layout_constraintEnd_toEndOf="parent"  
app:layout_constraintHeight_min="80sp"  
app:layout_constraintHeight_max="160sp"  
app:layout_constraintStart_toStartOf="parent"  
app:layout_constraintTop_toBottomOf="@id/first"  
app:layout_constraintWidth_max="160sp" />  
</android.support.constraint.ConstraintLayout>
```

(from [Containers/Sampler/app/src/main/res/layout/childsize\\_cl.xml](#))

Both have their text set to a passage from Lewis Carroll’s “The Jabberwocky”:

'Twas brillig, and the slithy toves, Did gyre and gimble in the wabe; All  
mimsy were the borogoves, And the mome raths outgrabe.

The top widget has its height set to `wrap_content` and its width set to `0dp`. It also has constraints to tie it to the top, start, and end of the `ConstraintLayout`. As a result, it happily occupies the space needed to show the entire text:

*Figure 443: ConstraintLayout, with Constrained Size of Second Child*

The bottom widget has its height and width both set to `0dp`. It has constraints to tie it to the start, end, and bottom of the `ConstraintLayout`, plus positioning it below the top `TextView`. Given the `0dp` width and height, you would expect it to fill all remaining space and show the entire snippet of prose.

## ADVANCED CONSTRAINTLAYOUT

---

However, this widget *also* has three size constraints:

- `app:layout_constraintHeight_min="80sp"`
- `app:layout_constraintHeight_max="160sp"`
- `app:layout_constraintWidth_max="160sp"`

As a result, the `TextView` is kept within those bounds, and as a result not all of the text can be seen. It is not clear exactly how `ConstraintLayout` chooses the actual size between the minimum and maximum values though.

### ...of the `ConstraintLayout` Itself

To control the size of the `ConstraintLayout` itself, we can use the following attributes:

If This Is <code>wrap_content</code> ...	...Then You Can Use
<code>android:layout_width</code>	<code>android:minWidth</code> and <code>android:maxWidth</code>
<code>android:layout_height</code>	<code>android:minHeight</code> and <code>android:maxHeight</code>

Each takes a dimension and works pretty much as you might expect from the attribute names.

This layout uses all four of those:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <android.support.constraint.ConstraintLayout
    android:id="@+id/first"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center"
    android:layout_marginEnd="8dp"
    android:layout_marginLeft="8dp"
    android:layout_marginRight="8dp"
    android:layout_marginStart="8dp"
    android:layout_marginTop="8dp"
    android:maxHeight="160dp">
```

## ADVANCED CONSTRAINTLAYOUT

```
android:maxWidth="160dp"
android:minHeight="80dp"
android:minWidth="80dp">

<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:ellipsize="end"
    android:text="@string/jabberwocky"
    android:textAppearance="?android:attr/textAppearanceLarge"
    app:layout_constraintBottom_toBottomOf="parent"
    app:layout_constraintEnd_toEndOf="parent"
    app:layout_constraintStart_toStartOf="parent"
    app:layout_constraintTop_toTopOf="parent" />
</android.support.constraint.ConstraintLayout>
</FrameLayout>
```

(from [Containers/Sampler/app/src/main/res/layout/size\\_cl.xml](#))

Here, the `ConstraintLayout` is centered within a `FrameLayout`. The width and height officially are `wrap_content`, but the minimum and maximum for each is set to 80dp and 160dp, respectively.

The results are somewhat unexpected:

Figure 444: `ConstraintLayout`, with Constrained Size

Given that there is more text, and that the `TextView` itself is not limited by `android:maxLines` or something, one might expect a 160dp x 160dp allocation for the `ConstraintLayout`. Instead, the height is left at 80dp, for unclear reasons.

## Chains, Without the Whips

Chains represent a linked series of widgets in a row or column inside of a `ConstraintLayout`. You can then set up some rules for how the entire chain should be rendered, such as how to handle whitespace between those widgets.

### How Do We Set up a Chain?

A chain is an implicit structure. There is no `app:chainId` or similar mechanism to identify chains.

Rather, a chain is defined any time there are 2 widgets with mutual constraints, such as the left side of one widget being tied to the right side of the other widget, and vice-versa.

A chain itself can be as many widgets as needed, so long as pair-wise they have the mutual constraints. So, for example, here is a chain containing three `Button` widgets:

```
<Button
    android:id="@+id/button1a"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="1"
    app:layout_constraintBottom_toBottomOf="parent"
    app:layout_constraintHorizontal_chainStyle="spread"
    app:layout_constraintEnd_toStartOf="@+id/button2a"
    app:layout_constraintStart_toStartOf="parent"
    app:layout_constraintTop_toTopOf="parent"
    app:layout_constraintVertical_bias="0.1" />

<Button
    android:id="@+id/button2a"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="2"
    app:layout_constraintBaseline_toBaselineOf="@+id/button1a"
    app:layout_constraintStart_toEndOf="@+id/button1a"
    app:layout_constraintEnd_toStartOf="@+id/button3a" />
```

```
<Button
    android:id="@+id/button3a"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="3"
    app:layout_constraintBaseline_toBaselineOf="@+id/button2a"
    app:layout_constraintStart_toEndOf="@+id/button2a"
    app:layout_constraintEnd_toEndOf="parent" />
```

(from [Containers/Sampler/app/src/main/res/layout/chains.cl.xml](#))

button1a and button2a have their horizontal constraints connected to each other, as do button2a and button3a. Hence, the three widgets represent a single chain.

### Styles of Chains

Configuring a chain comes in part by adding a “chain style” attribute to the head of the chain. The head is defined as the left-most widget in a horizontal chain (e.g., button1a) or the top-most widget in a vertical chain.

### Spread

If you do not otherwise specify on a chain, the chain style is “spread”. By default, this means that whitespace should be allocated between the widgets in the chain and outside the ends of the chain. And, by default, that allocation is even, so the space between each widget in the chain is the same, and the same amount of space appears outside the chain on either side.

That’s what we get from the chain shown above:

The chain head (button1a) has `app:layout_constraintHorizontal_chainStyle="spread"` to positively declare that this chain has a spread style, though this is unnecessary, as this is the default chain behavior.

### Spread-Inside

A `spread_inside` chain style is similar to `spread`, except that there is no whitespace added to either end of the chain. All whitespace goes between the pairs of widgets.

*Figure 446: Spread-Inside Chain*

### Packed

Conversely, a packed chain style puts all the whitespace on either end of the chain, having the widgets directly adjacent to each other:

*Figure 447: Packed Chain*

### Chains and Biases

Spread and packed chains — ones where there is whitespace outside the chain — respond to biases, where a bias slides the entire chain to a given side by allocating the whitespace non-equally.

For example, here is a biased packed chain:

```
<Button
  android:id="@+id/button1e"
  android:layout_width="wrap_content"
  android:layout_height="wrap_content"
  android:text="1"
  app:layout_constraintBottom_toBottomOf="parent"
  app:layout_constraintHorizontal_bias="0.8"
  app:layout_constraintHorizontal_chainStyle="packed"
  app:layout_constraintEnd_toStartOf="@+id/button2e"
  app:layout_constraintStart_toStartOf="parent"
  app:layout_constraintTop_toTopOf="parent"
  app:layout_constraintVertical_bias="0.9" />

<Button
```

## ADVANCED CONSTRAINTLAYOUT

---

```
android:id="@+id/button2e"  
android:layout_width="wrap_content"  
android:layout_height="wrap_content"  
android:text="2"  
app:layout_constraintBaseline_toBaselineOf="@+id/button1e"  
app:layout_constraintStart_toEndOf="@+id/button1e"  
app:layout_constraintEnd_toStartOf="@+id/button3e" />  
  
<Button  
android:id="@+id/button3e"  
android:layout_width="wrap_content"  
android:layout_height="wrap_content"  
android:text="3"  
app:layout_constraintBaseline_toBaselineOf="@+id/button2e"  
app:layout_constraintStart_toEndOf="@+id/button2e"  
app:layout_constraintEnd_toEndOf="parent" />
```

(from [Containers/Sampler/app/src/main/res/layout/chains\\_cl.xml](#))

Here, the chain head has `app:layout_constraintHorizontal_bias="0.8"`, sliding the entire packed chain to the right:

Figure 448: Packed Chain with Horizontal Bias

## Chains and Weights

Spread and spread-inside chains — ones where there is whitespace inside the chain — respond to weights, reminiscent of the weights used with `LinearLayout`.

Simply marking the widget as having a width (or height, for vertical chains) of `0dp` causes that widget to absorb the whitespace:

```
<Button  
android:id="@+id/button1c"  
android:layout_width="wrap_content"  
android:layout_height="wrap_content"  
android:text="1"  
app:layout_constraintBottom_toBottomOf="parent"  
app:layout_constraintHorizontal_chainStyle="spread_inside"  
app:layout_constraintEnd_toStartOf="@+id/button2c"  
app:layout_constraintStart_toStartOf="parent"
```

## ADVANCED CONSTRAINTLAYOUT

---

```
app:layout_constraintTop_toTopOf="parent"
app:layout_constraintVertical_bias="0.5" />

<Button
    android:id="@+id/button2c"
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:text="2"
    app:layout_constraintBaseline_toBaselineOf="@+id/button1c"
    app:layout_constraintStart_toEndOf="@+id/button1c"
    app:layout_constraintEnd_toStartOf="@+id/button3c" />

<Button
    android:id="@+id/button3c"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="3"
    app:layout_constraintBaseline_toBaselineOf="@+id/button2c"
    app:layout_constraintStart_toEndOf="@+id/button2c"
    app:layout_constraintEnd_toEndOf="parent" />
```

(from [Containers/Sampler/app/src/main/res/layout/chains\\_cl.xml](#))

*Figure 449: Spread-Inside Chain, With Middle Button Filling Space*

If two or more widgets use 0dp this way, they will divide the space equally, by default. Using `app:layout_constraintHorizontal_weight` or `app:layout_constraintVertical_weight` on the affected widgets can be used to divide the space on a weighted basis (e.g., giving one widget twice the space of another).

## Going in a Circle

Ordinary constraints work on the classic X/Y axes that dominate most of 2D UI design.

ConstraintLayout adds circular constraints, which allow you to position widgets based on angles and radii. Most apps will have no need for this, though a few will.

## ADVANCED CONSTRAINTLAYOUT

For example, maybe you need something akin to a compass rose:

*Figure 450: ConstraintLayout, Showing Circular Constraints*

Setting up the four cardinal directions (north, south, east, west) using X/Y axes would be trivial. Setting up the other four directions would be a bit more complicated. And setting up widgets in other positions — such as the twelve positions of a classic analog clock dial — would get you into some trigonometry to work out the X/Y positions to use.

With ConstraintLayout, it is much simpler.

Each child to be constrained using circular constraints need three attributes:

- `app:layout_constraintCircle`, providing the ID of the widget that is at the center of the circle
- `app:layout_constraintCircleRadius`, with a dimension indicating how far away the widget is from that center
- `app:layout_constraintCircleAngle`, with a value between 0 and 359, measuring the angle in degrees, with 0 representing “up” or “north”

This crude compass rose has a single circle, so all of the `app:layout_constraintCircle` and `app:layout_constraintCircleRadius` values

## ADVANCED CONSTRAINTLAYOUT

---

can remain the same. The only thing that varies is the angle:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.constraint.ConstraintLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ImageView
        android:id="@+id/compass"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginBottom="8dp"
        android:layout_marginEnd="8dp"
        android:layout_marginLeft="8dp"
        android:layout_marginRight="8dp"
        android:layout_marginStart="8dp"
        android:layout_marginTop="8dp"
        android:src="@drawable/ic_location_searching_black_24dp"
        app:layout_constraintBottom_toBottomOf="parent"
        app:layout_constraintEnd_toEndOf="parent"
        app:layout_constraintStart_toStartOf="parent"
        app:layout_constraintTop_toTopOf="parent" />

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/northeast"
        android:textAppearance="?android:attr/textAppearanceLarge"
        app:layout_constraintCircle="@id/compass"
        app:layout_constraintCircleAngle="45"
        app:layout_constraintCircleRadius="@dimen/radius" />

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/east"
        android:textAppearance="?android:attr/textAppearanceLarge"
        app:layout_constraintCircle="@id/compass"
        app:layout_constraintCircleAngle="90"
        app:layout_constraintCircleRadius="@dimen/radius" />

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/southeast"
        android:textAppearance="?android:attr/textAppearanceLarge"
        app:layout_constraintCircle="@id/compass"
        app:layout_constraintCircleAngle="135"
        app:layout_constraintCircleRadius="@dimen/radius" />

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/south"
        android:textAppearance="?android:attr/textAppearanceLarge"
        app:layout_constraintCircle="@id/compass"
        app:layout_constraintCircleAngle="180"
        app:layout_constraintCircleRadius="@dimen/radius" />
</android.support.constraint.ConstraintLayout>
```

```
<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/southwest"
    android:textAppearance="?android:attr/textAppearanceLarge"
    app:layout_constraintCircle="@id/compass"
    app:layout_constraintCircleAngle="225"
    app:layout_constraintCircleRadius="@dimen/radius" />

<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/west"
    android:textAppearance="?android:attr/textAppearanceLarge"
    app:layout_constraintCircle="@id/compass"
    app:layout_constraintCircleAngle="270"
    app:layout_constraintCircleRadius="@dimen/radius" />

<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/northwest"
    android:textAppearance="?android:attr/textAppearanceLarge"
    app:layout_constraintCircle="@id/compass"
    app:layout_constraintCircleAngle="315"
    app:layout_constraintCircleRadius="@dimen/radius" />

<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/north"
    android:textAppearance="?android:attr/textAppearanceLarge"
    app:layout_constraintCircle="@id/compass"
    app:layout_constraintCircleAngle="0"
    app:layout_constraintCircleRadius="@dimen/radius" />
</android.support.constraint.ConstraintLayout>
```

(from [Containers/Sampler/app/src/main/res/layout/circle\\_cl.xml](#))

## Groups of Views... But Not ViewGroups

One of the side benefits of having widgets be in a container is that you can toggle the visibility of the container, thereby affecting the visibility of all of those widgets. However, this only works if the contents of the container are exactly what need to be toggled this way, with no extra widgets or widgets that are outside of the container.

ConstraintLayout offers a Group facility that allows you to logically group widgets together for visibility control, but does not otherwise affect their layout rules. To do this, simply have a Group in your layout with an `app:constraint_referenced_ids` attribute that lists the widgets that belong to the group. As we saw in [the section on barriers](#), `app:constraint_referenced_ids` contains a comma-delimited list of widget names, without the `@id/` or `@+id/` prefixes. If you give the Group its own ID,

## ADVANCED CONSTRAINTLAYOUT

---

you can retrieve it via `findViewById()` at runtime and toggle the visibility.

For example, this layout is a near-clone of the circular constraints one from above. The difference is that the center is now an `ImageButton` and a `Group` appears at the bottom:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.constraint.ConstraintLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ImageButton
        android:id="@+id/compassButton"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginBottom="8dp"
        android:layout_marginEnd="8dp"
        android:layout_marginLeft="8dp"
        android:layout_marginRight="8dp"
        android:layout_marginStart="8dp"
        android:layout_marginTop="8dp"
        android:src="@drawable/ic_location_searching_black_24dp"
        app:layout_constraintBottom_toBottomOf="parent"
        app:layout_constraintEnd_toEndOf="parent"
        app:layout_constraintStart_toStartOf="parent"
        app:layout_constraintTop_toTopOf="parent" />

    <TextView android:id="@+id/northeast"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/northeast"
        android:textAppearance="?android:attr/textAppearanceLarge"
        app:layout_constraintCircle="@id/compassButton"
        app:layout_constraintCircleAngle="45"
        app:layout_constraintCircleRadius="@dimen/radius" />

    <TextView android:id="@+id/east"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/east"
        android:textAppearance="?android:attr/textAppearanceLarge"
        app:layout_constraintCircle="@id/compassButton"
        app:layout_constraintCircleAngle="90"
        app:layout_constraintCircleRadius="@dimen/radius" />

    <TextView android:id="@+id/southeast"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/southeast"
        android:textAppearance="?android:attr/textAppearanceLarge"
        app:layout_constraintCircle="@id/compassButton"
        app:layout_constraintCircleAngle="135"
        app:layout_constraintCircleRadius="@dimen/radius" />

    <TextView android:id="@+id/south"
        android:layout_width="wrap_content"
```

## ADVANCED CONSTRAINTLAYOUT

---

```
    android:layout_height="wrap_content"
    android:text="@string/south"
    android:textAppearance="?android:attr/textAppearanceLarge"
    app:layout_constraintCircle="@id/compassButton"
    app:layout_constraintCircleAngle="180"
    app:layout_constraintCircleRadius="@dimen/radius" />

<TextView android:id="@+id/southwest"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/southwest"
    android:textAppearance="?android:attr/textAppearanceLarge"
    app:layout_constraintCircle="@id/compassButton"
    app:layout_constraintCircleAngle="225"
    app:layout_constraintCircleRadius="@dimen/radius" />

<TextView android:id="@+id/west"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/west"
    android:textAppearance="?android:attr/textAppearanceLarge"
    app:layout_constraintCircle="@id/compassButton"
    app:layout_constraintCircleAngle="270"
    app:layout_constraintCircleRadius="@dimen/radius" />

<TextView android:id="@+id/northwest"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/northwest"
    android:textAppearance="?android:attr/textAppearanceLarge"
    app:layout_constraintCircle="@id/compassButton"
    app:layout_constraintCircleAngle="315"
    app:layout_constraintCircleRadius="@dimen/radius" />

<TextView android:id="@+id/north"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/north"
    android:textAppearance="?android:attr/textAppearanceLarge"
    app:layout_constraintCircle="@id/compassButton"
    app:layout_constraintCircleAngle="0"
    app:layout_constraintCircleRadius="@dimen/radius" />

<android.support.constraint.Group android:id="@+id/directions"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:visibility="visible"
    app:constraint_referenced_ids="north,northeast,east,southeast,south,southwest,west,northwest"/>
</android.support.constraint.ConstraintLayout>
```

(from [Containers/Sampler/app/src/main/res/layout/group\\_cl.xml](#))

This app uses a ViewPager, with fragments for each page, with one page per layout. As part of setting up that fragment, we check to see if there is a compassButton widget and, if so, set up an OnClickListener (via a lambda expression) to toggle the group visibility:

## ADVANCED CONSTRAINTLAYOUT

---

```
@Override
public void onViewCreated(@NonNull View view,
                          @Nullable Bundle savedInstanceState) {
    View compassButton=view.findViewById(R.id.compassButton);

    if (compassButton!=null) {
        compassButton.setOnClickListener(v -> {
            View group=view.findViewById(R.id.directions);

            if (group.getVisibility()==View.VISIBLE) {
                group.setVisibility(View.GONE);
            }
            else {
                group.setVisibility(View.VISIBLE);
            }
        });
    }
}
```

(from [Containers/Sampler/app/src/main/java/com/commonsware/android/containers/sampler/MainActivity.java](#))

The result is that when the user clicks the button, the eight direction labels either disappear or re-appear, as appropriate.

Note that there is [a bug](#) that limits Group to VISIBLE and GONE visibility states. It does not work with INVISIBLE.

# GridLayout

---

In 2011, Google added `GridLayout` to our roster of available container classes (a.k.a., layout managers). `GridLayout` is an attempt to make setting up complex Android layouts a bit easier, particularly with an eye towards working well with IDE graphical layout editors. In this chapter, we will examine why `GridLayout` was added and how we can use it in our projects.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## Issues with the Classic Containers

Most layouts are implemented using a combination of `LinearLayout`, `RelativeLayout`, and `TableLayout`. Almost everything you would want to be able to create can be accomplished using one, or sometimes more than one, of those containers.

However, there are issues with the classic containers. The two most prominent might be the over-reliance upon nested containers and issues with drag-and-drop GUI building capability.

## Nested Containers

`LinearLayout` and `TableLayout` suffer from a tendency to put too many containers inside of other containers. For example, implementing some sort of 2x2 grid would involve:

## GRIDLAYOUT

---

- A vertical `LinearLayout` holding onto a pair of horizontal `LinearLayout`s, or
- A `TableLayout` holding onto a pair of `TableRows`

On the surface, this does not seem that bad. And, in many cases, it is not that bad.

However, views and containers are relatively heavyweight items. They consume a fair bit of heap space, and when it comes time to lay them out on the screen, they consume a fair bit of processing power. In particular, the fact that a container can hold onto *any* type of widget or container means that it is difficult to optimize common scenarios (e.g., a 2x2 grid) for faster processing. Instead, a container treats its children more or less as “black boxes”, requiring lots of method invocations up and down the call stack to calculate sizes and complete the layout process.

Moreover, the call stack itself can be an issue. The stack size of the main application thread has historically been rather small (8KB was the last reported value). If you have a complex UI, with more than ~15 nested containers, you are likely to run into a `StackOverflowError`. Android itself will contribute some of these containers, exacerbating this problem.

`RelativeLayout`, by comparison, can implement some UI patterns without any nested containers, simply by positioning widgets relative to the container’s bounds and relative to each other.

### Drag-and-Drop

Where `RelativeLayout` falls down is with the drag-and-drop capability of the graphical layout editor in IDEs like Android Studio.

When you release the mouse button when dropping a widget into the preview area, the tools need to determine what that really means in terms of layout rules.

`LinearLayout` works fairly well: it will either insert your widget in between two other widgets or add it to the end of the row or column you dropped into. `TableLayout` behaves similarly.

`RelativeLayout`, though, has a more difficult time guessing what particular combination of rules you really mean by this particular drop target. Are you trying to attach the widget to another widget? If so, which one? Are you trying to attach the widget to the bounds of the `RelativeLayout`? While sometimes it will guess properly, sometimes it will not, with potentially confusing results. It is reasonably likely that you will need to tweak the layout rules manually, either via the Attributes

pane or via the raw XML.

## The New Contender: GridLayout

GridLayout tries to cull the best of the capabilities of the classic containers and drop as many of their limitations as possible.

GridLayout works a bit like `TableLayout`, insofar as it sets things up in a grid, with rows and columns, where the row and column sizes are computed based upon what is placed into those rows and columns. However, unlike `TableLayout`, which relies upon a separate `TableRow` container to manage the rows, `GridLayout` takes the `RelativeLayout` approach of putting rules on the individual widgets (or containers) in the grid, where those rules steer the layout processing. For example, with `GridLayout`, widgets can declare specifically which row and column they should slot into.

`GridLayout` also goes a bit beyond what `TableLayout` offers in terms of capabilities. Notably, it supports row spans as well as column spans, whereas `TableRow` only supports a column span. This gives you greater flexibility when designing your layout to fit the grid-style positioning rules. You can also:

- Explicitly state how many columns there are, rather than having that value be inferred by row contents
- Allow Android to determine where to place a widget without specifying any row or column, with it finding the next available set of grid cells capable of holding the widget, based upon its requested row span and column span values
- Have control over orientation: whereas `TableLayout` always was a column of rows, you could have a `GridLayout` be a row of columns, if that makes implementing the design easier
- And so on

## GridLayout and the Android Support Package

`GridLayout` was natively added to the Android SDK in API Level 14 (Android 4.0). Fortunately, the Android Support package has a backport of `GridLayout`. However, the backport is not in one of the JAR files, such as `support-v4`, as `GridLayout` requires some resources. Hence, it is in an Android library project that you must add to your project, known as `gridlayout-v7`.

## GRIDLAYOUT

---

Android Studio users can simply add a implementation 'com.android.support:gridlayout-v7:...' statement to their top-level dependencies closure, for some version identified by .... So long as those users have the Android Support Repository set up in the SDK Manager, Gradle will be able to find and incorporate the artifact.

When using the backported GridLayout, you will need to declare another XML namespace in your layout XML resources. That namespace will be `http://schemas.android.com/apk/res-auto`. If you use an IDE to add the GridLayout to the layout resource, it will automatically add this namespace, under the prefix of `app`, such as:

```
<android.support.v7.widget.GridLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="2">
</android.support.v7.widget.GridLayout>
```

That namespace is required for GridLayout-specific attributes. For example, we can have a `columnCount` attribute, indicating how many columns the GridLayout should contain. For the native API Level 14 GridLayout, that attribute would be `android:columnCount`. For the backport, it will be `app:columnCount`, assuming that you gave the namespace the prefix of `app`.

When citing GridLayout-specific attributes, the rest of this chapter will use the `app` prefix, to clarify which attributes need that prefix for the backport. If you are using the native API Level 14 implementation of GridLayout, and you are manually working with the XML, just remember to use `android` as a prefix instead of `app`.

The sample app shows *both* the native and the backport implementations of GridLayout: on API Level 14+ devices/emulators it will use native implementations from `res/layout-v14/`, and it will use the backport on older environments.

## Our Test App

To look at a series of GridLayout-based layouts, let's turn our attention to the [GridLayout/Sampler](#) sample project. This has the same ViewPager and PagerTabStrip as did the second sample app from [the chapter on ViewPager](#). However, rather than use a list of 10 EditText widgets managed by fragments, in this

## GRIDLAYOUT

---

case, our fragments will manage layouts containing GridLayout. Each page of our pager will contain a TrivialFragment, whose contents are based on a Sample class that is a simple pair of a layout resource ID and a string resource ID for the fragment's title:

```
package com.commonware.android.gridlayout;

class Sample {
    int layoutId;
    int titleId;

    Sample(int layoutId, int titleId) {
        this.layoutId=layoutId;
        this.titleId=titleId;
    }
}
```

(from [GridLayout/Sampler/app/src/main/java/com/commonware/android/gridlayout/Sample.java](#))

Our revised SampleAdapter maintains a static ArrayList of these Sample objects, one per layout we wish to examine, and uses those values to populate our ViewPager title:

```
package com.commonware.android.gridlayout;

import android.content.Context;
import android.support.v4.app.Fragment;
import android.support.v4.app.FragmentManager;
import android.support.v4.app.FragmentPagerAdapter;
import java.util.ArrayList;

public class SampleAdapter extends FragmentPagerAdapter {
    static ArrayList<Sample> SAMPLES=new ArrayList<Sample>();
    private Context ctxt=null;

    static {
        SAMPLES.add(new Sample(R.layout.row, R.string.row));
        SAMPLES.add(new Sample(R.layout.column, R.string.column));
        SAMPLES.add(new Sample(R.layout.table, R.string.table));
        SAMPLES.add(new Sample(R.layout.table_flex, R.string.flexible_table));
        SAMPLES.add(new Sample(R.layout.implicit, R.string.implicit));
        SAMPLES.add(new Sample(R.layout.spans, R.string.spans));
    }

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }
}
```

## GRIDLAYOUT

---

```
}

@Override
public int getCount() {
    return(SAMPLES.size());
}

@Override
public Fragment getItem(int position) {
    return(TrivialFragment.newInstance(getSample(position).layoutId));
}

@Override
public String getPageTitle(int position) {
    return(ctxt.getString(getSample(position).titleId));
}

private Sample getSample(int position) {
    return(SAMPLES.get(position));
}
}
```

(from [GridLayout/Sampler/app/src/main/java/com/commonsware/android/gridlayout/SampleAdapter.java](#))

TrivialFragment just inflates our desired layout, having received the layout resource ID as a parameter to its factory method:

```
package com.commonsware.android.gridlayout;

import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class TrivialFragment extends Fragment {
    private static final String KEY_LAYOUT_ID="layoutId";

    static TrivialFragment newInstance(int layoutId) {
        TrivialFragment frag=new TrivialFragment();
        Bundle args=new Bundle();

        args.putInt(KEY_LAYOUT_ID, layoutId);
        frag.setArguments(args);

        return(frag);
    }
}
```

## GRIDLAYOUT

---

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    return(inflater.inflate(getArguments().getInt(KEY_LAYOUT_ID, -1),
                          container, false));
}
}
```

(from [GridLayout/Sampler/app/src/main/java/com/commonsware/android/gridlayout/TrivialFragment.java](#))

Note that if you load this project from the GitHub repository, you will need to update it for your copy of the GridLayout library project.

## Replacing the Classics

Let's first examine the behavior of GridLayout by seeing how it can replace some of the classic layouts we would get from LinearLayout and TableLayout. Each of the following sub-sections will examine one GridLayout-based layout XML resource, how it can be constructed, and what the result looks like when viewed in the sample project.

### Horizontal LinearLayout

The classic way to create a row of widgets is to use a horizontal LinearLayout. The LinearLayout will put each of its children, one after the next, within the row.

The GridLayout equivalent is to specify one that has an `app:columnCount` equal to the number of widgets in the row. Then, each widget will have `app:layout_column` set to its specific column index (starting at 0) and `app:layout_row` set to 0, as seen in `res/layout/row.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="2">

    <Button
        app:layout_column="0"
        app:layout_row="0"
        android:text="@string/button"/>

    <Button
        app:layout_column="1"
        app:layout_row="0"
        android:text="@string/button"/>

```

## GRIDLAYOUT

---

```
</android.support.v7.widget.GridLayout>
```

(from [GridLayout/Sampler/app/src/main/res/layout/row.xml](#))

Unlike `LinearLayout`, though, we do not specify sizes of the children, in terms of `android:layout_width` and `android:layout_height`. `GridLayout` works a bit like `TableLayout` in this regard, supplying default values for these attributes. In the case of `GridLayout`, the defaults are `wrap_content`, and this cannot be overridden (akin to the behavior of immediate children of a `TableRow`). Instead, you will control size via row and column spans, as will be illustrated later in this chapter.

Given the above layout, we get:

*Figure 451: Row Using GridLayout, on a 4.0.3 Emulator*

### Vertical LinearLayout

Similarly, the conventional way you would specify a column is to use a vertical `LinearLayout`, which would position its children one after the next. The `GridLayout` equivalent would be to have `app:columnCount` set to 1, and to place the widgets in each required row via `app:layout_row` attributes, as seen in `res/layout/column.xml`:

## GRIDLAYOUT

---

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  app:columnCount="1">

  <Button
    app:layout_column="0"
    app:layout_row="0"
    android:text="@string/button"/>

  <Button
    app:layout_column="0"
    app:layout_row="1"
    android:text="@string/button"/>

</android.support.v7.widget.GridLayout>
```

(from [GridLayout/Sampler/app/src/main/res/layout/column.xml](#))

*Figure 452: Column Using GridLayout, on a 4.0.3 Emulator*

All that being said, it is still probably better to use `LinearLayout` in these cases, rather than mess with `GridLayout`.

## TableLayout

The big key to a `TableLayout` is column width, where columns expand to fill their

## GRIDLAYOUT

---

contents, assuming there is sufficient room in the table. GridLayout also expands its columns to address the sizes of its contents.

For example, here is a simple 2x2 table, with TextView widgets in the left column and EditText widgets in the right column, as seen in `res/layout/table.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  app:columnCount="2">

  <TextView
    app:layout_column="0"
    app:layout_row="0"
    android:text="@string/name"
    android:textAppearance="?android:attr/textAppearanceLarge"/>

  <EditText
    app:layout_column="1"
    app:layout_row="0"
    android:inputType="textPersonName">

    <requestFocus/>
  </EditText>

  <TextView
    app:layout_column="0"
    app:layout_row="1"
    android:text="@string/address"
    android:textAppearance="?android:attr/textAppearanceLarge"/>

  <EditText
    app:layout_column="1"
    app:layout_row="1"
    android:inputType="textPostalAddress"/>

</android.support.v7.widget.GridLayout>
```

(from [GridLayout/Sampler/app/src/main/res/layout/table.xml](#))

However, our EditText widgets are small, because nothing is causing them to fill the available space. To do that, we can use `android:layout_gravity`, to ask the GridLayout to let the widgets fill the available horizontal space, as seen in `res/layout/table_flex.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  app:columnCount="2">

  <TextView
    app:layout_column="0"
    app:layout_row="0"
```

## GRIDLAYOUT

---

```
    android:text="@string/name"
    android:textAppearance="?android:attr/textAppearanceLarge"/>

    <EditText
        app:layout_column="1"
        app:layout_row="0"
        app:layout_gravity="fill_horizontal"
        android:inputType="textPersonName">

        <requestFocus/>
    </EditText>

    <TextView
        app:layout_column="0"
        app:layout_row="1"
        android:text="@string/address"
        android:textAppearance="?android:attr/textAppearanceLarge"/>

    <EditText
        app:layout_column="1"
        app:layout_row="1"
        app:layout_gravity="fill_horizontal"
        android:inputType="textPostalAddress"/>
</android.support.v7.widget.GridLayout>
```

(from [GridLayout/Sampler/app/src/main/res/layout/table\\_flex.xml](#))

## GRIDLAYOUT

---

This allows the EditText widgets to fill the width of the column:

*Figure 453: Table Using GridLayout, on a 4.0.3 Emulator*

That holds true regardless of how wide that column is:

## Implicit Rows and Columns

While all the previous samples showed the row and column of each widget being defined explicitly via `app:layout_row` and `app:layout_column` attributes, that is not your only option.

If you have `app:columnCount` on the `GridLayout` element itself, you can allow `GridLayout` to assign rows and columns. In this respect, `GridLayout` behaves a bit like a “flow layout”: it assigns widgets to cells in the first row, starting from the first column and working its way across, wrapping to the next row when it runs out of room. This makes for a more terse layout file, at the cost of perhaps introducing a bit of confusion when you add or remove a widget and everything after it in the layout file shifts location.

For example, `res/layout/implicit.xml` is the same as `res/layout/table_flex.xml`, except that it skips the `app:layout_row` and `app:layout_column` attributes, allowing `GridLayout` to assign the positions:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
```

## GRIDLAYOUT

---

```
app:columnCount="2"
app:orientation="horizontal">

<TextView
    android:text="@string/name"
    android:textAppearance="?android:attr/textAppearanceLarge" />

<EditText
    app:layout_gravity="fill_horizontal"
    android:inputType="textPersonName">

    <requestFocus/>
</EditText>

<TextView
    android:text="@string/address"
    android:textAppearance="?android:attr/textAppearanceLarge" />

<EditText
    app:layout_gravity="fill_horizontal"
    android:inputType="textPostalAddress" />

</android.support.v7.widget.GridLayout>
```

(from [GridLayout/Sampler/app/src/main/res/layout/implicit.xml](#))

Visually, this sample is identical to the last one:

*Figure 455: Table Using GridLayout and Implicit Positions, on a 4.0.3 Emulator*

---

## GRIDLAYOUT

---

The “across columns, then down rows” model holds for `GridLayout` in the default orientation: horizontal. You can add an `app:orientation` attribute to the `GridLayout`, setting it to vertical. Then, based on an `app:rowCount` value, `GridLayout` will automatically assign positions, working down the first column, then across to the next column when it runs out of rows.

### Row and Column Spans

Like `TableLayout`, `GridLayout` supports the notion of column spans. You can use `app:layout_columnSpan` to indicate how many columns a particular widget should span in the resulting grid.

However, `GridLayout` also supports row spans, in the form of `app:layout_rowSpan` attributes. A widget can span rows, columns, or both, as needed.

If you are using implicit positions, per the previous section, `GridLayout` will seek the next available space that has sufficient rows and columns for a widget’s set of spans.

For example, the following diagram depicts five buttons placed in a `GridLayout` with various spans, and an attempt to add a sixth button that should span two columns:

*Figure 456: Span Sample (image courtesy of Android Open Source Project)*

Assuming the first five buttons were added in sequence and with implicit positioning, `GridLayout` ordinarily would drop the sixth button into the fourth column of the third row. However, there is only a one-column-wide space available there, given that the third button intrudes into the third row. Hence, `GridLayout` will skip over the smaller space and put the sixth button into the sixth column in the third row.

## GRIDLAYOUT

---

A GridLayout-based layout that implements the above diagram can be found in `res/layout/spans.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="9"
    app:orientation="horizontal"
    app:rowCount="5">

    <Button
        app:layout_gravity="fill"
        app:layout_columnSpan="2"
        app:layout_rowSpan="2"
        android:text="@string/string_1"/>

    <Button
        app:layout_gravity="fill_horizontal"
        app:layout_columnSpan="2"
        android:text="@string/string_2"/>

    <Button
        app:layout_gravity="fill_vertical"
        app:layout_rowSpan="4"
        android:text="@string/string_3"/>

    <Button
        app:layout_gravity="fill"
        app:layout_columnSpan="3"
        app:layout_rowSpan="2"
        android:text="@string/string_4"/>

    <Button
        app:layout_gravity="fill_horizontal"
        app:layout_columnSpan="3"
        android:text="@string/string_5"/>

    <Button
        app:layout_gravity="fill_horizontal"
        app:layout_columnSpan="2"
        android:text="@string/string_6"/>

    <android.support.v7.widget.Space
        android:layout_width="36dp"
        app:layout_column="0"
        app:layout_row="4" />

    <android.support.v7.widget.Space
        android:layout_width="36dp"
        app:layout_column="1"
        app:layout_row="4" />

    <android.support.v7.widget.Space
        android:layout_width="36dp"
        app:layout_column="2"
        app:layout_row="4" />
```

## GRIDLAYOUT

---

```
<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="3"
    app:layout_row="4" />

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="4"
    app:layout_row="4" />

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="5"
    app:layout_row="4" />

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="6"
    app:layout_row="4" />

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="7"
    app:layout_row="4" />

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
    app:layout_row="0" />

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
    app:layout_row="1" />

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
    app:layout_row="2" />

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
    app:layout_row="3" />

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
    app:layout_row="4" />

</android.support.v7.widget.GridLayout>
```

(from [GridLayout/Sampler/app/src/main/res/layout/spans.xml](#))

This layout shows one of the limitations of `GridLayout`: its columns and rows will have a size of 0 by default. Hence, to ensure that each row and column has a minimum size, this layout uses `Space` elements (in an eighth column and fifth row) to establish those minimums. This makes the layout file fairly verbose, but it gives

## GRIDLAYOUT

---

the desired results:

*Figure 457: GridLayout Spans, on a 4.0.3 Emulator*

## GRIDLAYOUT

---

However, the fixed-sized Space elements break the fluidity of the layout:

*Figure 458: GridLayout Spans, in Landscape, on a 4.0.3 Emulator*

Perhaps someday someone will create a PercentSpace widget, occupying a percentage of the parent's size, that could be used instead.

The author would like to give thanks to [those on Stack Overflow who assisted in getting the span layout to work](#).

# Dialogs and DialogFragments

---

Generally speaking, modal dialogs are considered to offer poor UX, particularly on mobile devices. You want to give the user more choices, not fewer, and so locking them into “deal with this dialog right now, or else” is not especially friendly. That being said, from time to time, there will be cases where that sort of modal interface is necessary, and to help with that, Android does have a dialog framework that you can use.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## DatePickerDialog and TimePickerDialog

Android has a pair of built-in dialogs that handle the common operations of allowing the user to select a date (`DatePickerDialog`) or a time (`TimePickerDialog`). These are simply dialog wrappers around the [DatePicker](#) and [TimePicker](#) widgets, as are described in this book’s Widget Catalog.

The `DatePickerDialog` allows you to set the starting date for the selection, in the form of a year, month, and day of month value. Note that the month runs from 0 for January through 11 for December. Most importantly, both let you provide a callback object (`OnDateChangeListener` or `OnDateSetListener`) where you are informed of a new date selected by the user. It is up to you to store that date someplace, particularly if you are using the dialog, since there is no other way for you to get at the chosen date later on.

Similarly, `TimePickerDialog` lets you:

- Set the initial time the user can adjust, in the form of an hour (0 through 23) and a minute (0 through 59)
- Indicate if the selection should be in 12-hour mode with an AM/PM toggle, or in 24-hour mode (what in the US is thought of as “military time” and what in much of the rest of the world is thought of as “the way times are supposed to be”)
- Provide a callback object (`OnTimeChangeListener` or `OnTimeSetListener`) to be notified of when the user has chosen a new time, which is supplied to you in the form of an hour and minute

For example, from the [Dialogs/Chrono](#) sample project, here’s a trivial layout containing a label and two buttons — the buttons will pop up the dialog flavors of the date and time pickers:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <TextView android:id="@+id/dateAndTime"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    />
  <Button android:id="@+id/dateBtn"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="Set the Date"
    android:onClick="chooseDate"
    />
  <Button android:id="@+id/timeBtn"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="Set the Time"
    android:onClick="chooseTime"
    />
</LinearLayout>
```

(from [Dialogs/Chrono/app/src/main/res/layout/main.xml](#))

The more interesting stuff comes in the Java source:

## DIALOGS AND DIALOGFRAGMENTS

---

```
package com.commonware.android.chrono;

import android.app.Activity;
import android.app.DatePickerDialog;
import android.app.TimePickerDialog;
import android.os.Bundle;
import android.text.format.DateUtils;
import android.view.View;
import android.widget.DatePicker;
import android.widget.TextView;
import android.widget.TimePicker;
import java.util.Calendar;

public class ChronoDemo extends Activity {
    TextView dateAndTimeLabel;
    Calendar dateAndTime=Calendar.getInstance();

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        dateAndTimeLabel=(TextView)findViewById(R.id.dateAndTime);

        updateLabel();
    }

    public void chooseDate(View v) {
        new DatePickerDialog(this, d,
            dateAndTime.get(Calendar.YEAR),
            dateAndTime.get(Calendar.MONTH),
            dateAndTime.get(Calendar.DAY_OF_MONTH))
            .show();
    }

    public void chooseTime(View v) {
        new TimePickerDialog(this, t,
            dateAndTime.get(Calendar.HOUR_OF_DAY),
            dateAndTime.get(Calendar.MINUTE),
            true)
            .show();
    }

    private void updateLabel() {
        dateAndTimeLabel
            .setText(DateUtils
                .formatDateTime(this,
                    dateAndTime.getTimeInMillis(),
                    DateUtils.FORMAT_SHOW_DATE|DateUtils.FORMAT_SHOW_TIME));
    }

    DatePickerDialog.OnDateSetListener d=new DatePickerDialog.OnDateSetListener() {
        public void onDateSet(DatePicker view, int year, int monthOfYear,
            int dayOfMonth) {
            dateAndTime.set(Calendar.YEAR, year);
            dateAndTime.set(Calendar.MONTH, monthOfYear);
            dateAndTime.set(Calendar.DAY_OF_MONTH, dayOfMonth);
            updateLabel();
        }
    };
};
```

## DIALOGS AND DIALOGFRAGMENTS

---

```
TimePickerDialog.OnTimeSetListener t=new TimePickerDialog.OnTimeSetListener() {
    public void onTimeSet(TimePicker view, int hourOfDay,
        int minute) {
        dateAndTime.set(Calendar.HOUR_OF_DAY, hourOfDay);
        dateAndTime.set(Calendar.MINUTE, minute);
        updateLabel();
    }
};
}
```

(from [Dialogs/Chrono/app/src/main/java/com/commonsware/android/chrono/ChronoDemo.java](#))

The “model” for this activity is just a Calendar instance, initially set to be the current date and time. In the `updateLabel()` method, we take the current Calendar, format it using `DateUtils` and `formatDateTime()`, and put it in the `TextView`. The nice thing about using Android’s `DateUtils` class is that it will format dates and times using the user’s choice of date formatting, determined through the Settings application.

Each button has a corresponding method that will get control when the user clicks it (`chooseDate()` and `chooseTime()`). When the button is clicked, either a `DatePickerDialog` or a `TimePickerDialog` is shown. In the case of the `DatePickerDialog`, we give it an `OnDateSetListener` callback that updates the Calendar with the new date (year, month, day of month). We also give the dialog the last-selected date, getting the values out of the Calendar. In the case of the `TimePickerDialog`, it gets an `OnTimeSetListener` callback to update the time portion of the Calendar, the last-selected time, and a true indicating we want 24-hour mode on the time selector

## DIALOGS AND DIALOGFRAGMENTS

---

With all this wired together, the resulting activity looks like this:

*Figure 459: ChronoDemo, As Initially Launched, on Android 7.1*

## DIALOGS AND DIALOGFRAGMENTS

---

Figure 460: ChronoDemo, Showing DatePickerDialog

Figure 461: ChronoDemo, Showing TimePickerDialog

### Changes and Bugs

Android 4.1 through 4.4 have some changes in behavior from what came before and what came after.

First, the “Cancel” button was removed, unless you specifically add a negative button listener to the underlying DatePicker or TimePicker widget:

*Figure 462: ChronoDemo, Showing DatePickerDialog, on Android 4.1*

The user can press BACK to exit the dialog, so all functionality is still there, but you may need to craft your documentation to accommodate this difference. And, on Android 5.0+, the Cancel button returned.

Second, your OnDateSetListener or OnTimeSetListener will be called an extra time. If the user presses BACK to leave the dialog, your onDateSet() or onTimeSet() will be called. If the user clicks the positive button of the dialog, you are called *twice*. There is a workaround [documented on Stack Overflow](#). This too was repaired in Android 5.0.

## AlertDialog

For your own custom dialogs, you could extend the `Dialog` base class, as do `DatePickerDialog` and `TimePickerDialog`. More commonly, though, developers create custom dialogs via `AlertDialog`, in large part due to the existence of `AlertDialog.Builder`. This builder class allows you to construct a custom dialog using a single (albeit long) Java statement, rather than having to create your own custom subclass. `Builder` offers a series of methods to configure an `AlertDialog`, each method returning the `Builder` for easy chaining.

Commonly-used configuration methods on `Builder` include:

- `setMessage()` if you want the “body” of the dialog to be a simple textual message, from either a supplied `String` or a supplied string resource ID.
- `setTitle()` and `setIcon()`, to configure the text and/or icon to appear in the title bar of the dialog box.
- `setPositiveButton()`, `setNeutralButton()`, and `setNegativeButton()`, to indicate which button(s) should appear across the bottom of the dialog, where they should be positioned (left, center, or right, respectively), what their captions should be, and what logic should be invoked when the button is clicked (besides dismissing the dialog).

Calling `create()` on the `Builder` will give you the `AlertDialog`, built according to your specifications. You can use additional methods on `AlertDialog` itself to perhaps configure things beyond what `Builder` happens to support.

Note, though, that calling `create()` does not actually display the dialog. The modern way to display the dialog is to tie it to a `DialogFragment`, as will be discussed in the next section.

## DialogFragments

One challenge with dialogs comes with configuration changes, notably screen rotations. If they pivot the device from portrait to landscape (or vice versa), presumably the dialog should remain on the screen after the change. However, since Android wants to destroy and recreate the activity, that would have dire impacts on your dialog.

Pre-fragments, Android had a “managed dialog” facility that would attempt to help with this. However, with the introduction of fragments came the `DialogFragment`,

## DIALOGS AND DIALOGFRAGMENTS

---

which handles the configuration change process.

You have two ways of supplying the dialog to the DialogFragment:

1. You can override `onCreateDialog()` and return a Dialog, such as AlertDialog created via an `AlertDialog.Builder`
2. You can override `onCreateView()`, as you would with an ordinary fragment, and the View that you return will be placed inside of a dialog

The [Dialogs/DialogFragment](#) sample project demonstrates the use of a DialogFragment in conjunction with an AlertDialog in this fashion.

Here is our DialogFragment, named `SampleDialogFragment`:

```
package com.commonware.android.dlgfrag;

import android.app.AlertDialog;
import android.app.Dialog;
import android.content.DialogInterface;
import android.os.Bundle;
import android.support.v4.app.DialogFragment;
import android.util.Log;
import android.view.View;
import android.widget.EditText;
import android.widget.Toast;

public class SampleDialogFragment extends DialogFragment implements
    DialogInterface.OnClickListener {
    private View form=null;

    @Override
    public Dialog onCreateDialog(Bundle savedInstanceState) {
        form=
            getActivity().getLayoutInflater()
                .inflate(R.layout.dialog, null);

        AlertDialog.Builder builder=new AlertDialog.Builder(getActivity());

        return(builder.setTitle(R.string.dlg_title).setView(form)
            .setPositiveButton(android.R.string.ok, this)
            .setNegativeButton(android.R.string.cancel, null).create());
    }

    @Override
    public void onClick(DialogInterface dialog, int which) {
        String template=getActivity().getString(R.string.toast);
```

## DIALOGS AND DIALOGFRAGMENTS

---

```
EditText name=(EditText)form.findViewById(R.id.title);
EditText value=(EditText)form.findViewById(R.id.value);
String msg=
    String.format(template, name.getText().toString(),
        value.getText().toString());

Toast.makeText(getActivity(), msg, Toast.LENGTH_LONG).show();
}

@Override
public void onDismiss(DialogInterface unused) {
    super.onDismiss(unused);

    Log.d(getClass().getSimpleName(), "Goodbye!");
}

@Override
public void onCancel(DialogInterface unused) {
    super.onCancel(unused);

    Toast.makeText(getActivity(), R.string.back, Toast.LENGTH_LONG).show();
}
}
```

(from [Dialogs/DialogFragment/app/src/main/java/com/commonsware/android/dlgfrag/SampleDialogFragment.java](#))

In `onCreateDialog()`, we inflate a custom layout (`R.layout.dialog`) that consists of some `TextView` labels and `EditText` fields:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_margin="4dp"
        android:orientation="horizontal">

        <TextView
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/display_name"/>

        <EditText
            android:id="@+id/title"
```

```
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:inputType="text"/>
</LinearLayout>

<LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    android:orientation="horizontal">

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/value"/>

    <EditText
        android:id="@+id/value"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:inputType="number"/>
</LinearLayout>
</LinearLayout>
```

(from [Dialogs/DialogFragment/app/src/main/res/layout/dialog.xml](#))

We then create an instance of `AlertDialog.Builder`, then start configuring the dialog by calling a series of methods on the Builder:

- `setTitle()` to supply the text to appear in the title bar of the dialog
- `setView()` to define the contents of the dialog, in the form of our inflated `View`
- `setPositiveButton()` to define the caption of one button (set here to the Android-supplied “OK” string resource) and to arrange to get control when that button is clicked (via this as the second parameter and our activity implementing `DialogInterface.OnClickListener`)
- `setNegativeButton()` to define the caption of the other button (set here to the Android-supplied “Cancel” resource)

We do not supply a listener to `setNegativeButton()`, because we do not need one in this case. Whenever the user clicks on *any* of the buttons, the dialog will be dismissed automatically. Hence, you only need a listener if you intend to do something special beyond dismissing the dialog when a button is clicked.

## DIALOGS AND DIALOGFRAGMENTS

---

At that point, we call `create()` to construct the actual `AlertDialog` instance and hand that back to Android.

If the user taps our positive button, we are called with `onClick()` and can collect information from our form and do something with it, in this case displaying a `Toast`.

We also override:

- `onCancel()`, which is called if the user presses the `BACK` button to exit the dialog
- `onDismiss()`, which is called whenever the dialog goes away for any reason (`BACK` or a button click)

Our activity (`MainActivity`), has a big button tied to a `showMe()` method, which calls `show()` on a newly-created instance of our `SampleDialogFragment`:

```
public void showMe(View v) {  
    new SampleDialogFragment().show(getSupportFragmentManager(), "sample");  
}
```

(from [Dialogs/DialogFragment/app/src/main/java/com/commonsware/android/dlgfrag/MainActivity.java](#))

The second parameter to `show()` is a tag that can be used to retrieve this fragment again later from the `FragmentManager` via `findFragmentByTag()`.

When you click the big button in the activity, our dialog is displayed:

*Figure 463: SampleDialogFragment, As Initially Launched, on Android 4.0.3*

Android will handle the configuration change, and so long as our dialog uses typical widgets like `EditText`, the standard configuration change logic will carry our data forward from the old activity's dialog to the new activity's dialog.

## DialogFragment: The Other Flavor

If you do not override `onCreateDialog()`, Android will assume that you want the `View` returned by `onCreateView()` to be poured into an ordinary `Dialog`, which `DialogFragment` will create for you automatically.

One advantage of this approach is that you can selectively show the fragment as a dialog *or* show it as a regular fragment as part of your main UI.

To show the fragment as a dialog, use the same `show()` technique as was outlined in the previous section. To display the fragment as part of the main UI, use a `FragmentManager` to `add()` it, the way you would for any other dynamic fragment.

This is one alternative to the normal fragment approach of having dedicated activities for each fragment on smaller screen sizes.

We will also see this approach used when we try to apply fragments to display content on a secondary screen using Android 4.2's `Presentation` class, covered [elsewhere in this book](#).

### **Dialogs: Modal, Not Blocking**

Dialogs in Android are modal in terms of UI. The user cannot proceed in your activity until they complete or dismiss the dialog.

Dialogs in Android are not blocking in terms of the programming model. When you call `show()` to display a dialog — either directly or by means of adding a `DialogFragment` to the screen — this is not a blocking call. The dialog will be displayed sometime after the call to `show()`, asynchronously. You use callbacks, such as the button event listeners, to find out about events going on with respect to the dialog that you care about.

This runs counter to a couple of GUI toolkits, where displaying the dialog blocks the thread that does the displaying. In those toolkits, the call to `show()` would not return until the dialog had been displayed and dealt with by the user. That being said, most modern GUI toolkits take the approach Android does and have dialogs be non-blocking. Some developers try to figure out some way of hacking a blocking approach on top of Android's non-blocking dialogs — their time would be far better spent learning modern event-driven programming.

# Advanced ListViews

---

The humble `ListView` is the backbone of many an Android application. On phone-sized screens, the screen may be dominated by a single `ListView`, to allow the user to choose something to examine in more detail (e.g., pick a contact). On larger screens, the `ListView` may be shown side-by-side with the details of the selected item, to minimize the “pogo stick” effect seen on phones as users bounce back and forth between the list and the details.

While we have covered the basics of `ListView` in the core chapters of this book, there is a lot more that you can do if you so choose, to make your lists that much more interesting — this chapter will cover some of these techniques.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on `Adapter` and `AdapterView`](#).

## Multiple Row Types, and Self Inflation

When we originally looked at `ListView`, we had all of our rows come from a common layout. Hence, while the data in each row would vary, the row structure itself would be consistent for all rows. This is very easy to set up, but it is not always what you want. Sometimes, you want a mix of row structures, such as header rows versus detail rows, or detail rows that vary a bit in structure based on the data:

Figure 464: *ListView with Row Structure Mix (image courtesy of Google)*

Here, we see some header rows (e.g., “SINGLE LINE LIST”) along with detail rows. While the detail rows visually vary a bit, they might still be all inflated from the same layout, simply making some pieces (second line of text, thumbnail, etc.) visible or invisible as needed. However, the header rows are sufficiently visually distinct that they really ought to come from separate layouts.

The good news is that Android supports multiple row types. However, this comes at a cost: you will need to handle the row creation yourself, rather than chaining to the superclass.

Our sample project, [Selection/HeaderDetailList](#) will demonstrate this, along with showing how you can create your own custom adapter straight from `BaseAdapter`, for data models that do not quite line up with what Android supports natively.

## Our Data Model and Planned UI

The HeaderDetailList project is based on the ViewHolderDemo project from [the chapter on ListView](#). However, this time, we have our list of 25 Latin words broken down into five groups of five, as seen in the HeaderDetailList activity:

```
private static final String[][] items= {
    { "lorem", "ipsum", "dolor", "sit", "amet" },
    { "consectetuer", "adipiscing", "elit", "morbi", "vel" },
    { "ligula", "vitae", "arcu", "aliquet", "mollis" },
    { "etiam", "vel", "erat", "placerat", "ante" },
    { "porttitor", "sodales", "pellentesque", "augue", "purus" } };
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

We want to display a header row for each batch:

Figure 465: HeaderDetailList, on Android 4.0.3

## The Basic BaseAdapter

Once again, we have a custom ListAdapter named IconicAdapter. However, this time, instead of inheriting from ArrayAdapter, or even CursorAdapter, we are

## ADVANCED LISTVIEWS

---

inheriting from `BaseAdapter`. As the name suggests, `BaseAdapter` is a basic implementation of the `ListAdapter` interface, with stock implementations of many of the `ListAdapter` methods. However, `BaseAdapter` is abstract, and so there are a few methods that we need to implement:

- `getCount()` returns the total number of rows that would be in the list. In our case, we total up the sizes of each of the batches, plus add one for each batch for our header rows:

```
@Override
public int getCount() {
    int count=0;

    for (String[] batch : items) {
        count+=1 + batch.length;
    }

    return(count);
}
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

- `getItem()` needs to return the data model for a given position, passed in as the typical `int` index. An `ArrayAdapter` would return the value out of the array at that index; a `CursorAdapter` would return the `Cursor` positioned at that row. In our case, we will return one of two objects: either the `String` for rows that are to display a Latin word, or an `Integer` containing our batch's index for rows that are to be a header:

```
@Override
public Object getItem(int position) {
    int offset=position;
    int batchIndex=0;

    for (String[] batch : items) {
        if (offset == 0) {
            return(Integer.valueOf(batchIndex));
        }

        offset--;

        if (offset < batch.length) {
            return(batch[offset]);
        }
    }
}
```

## ADVANCED LISTVIEWS

---

```
        offset -= batch.length;
        batchIndex++;
    }

    throw new IllegalArgumentException("Invalid position: "
        + String.valueOf(position));
}
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

- `getItemId()` needs to return a unique long value for a given position. A `CursorAdapter` would find the `_id` value in the `Cursor` for that position and return it. In our case, lacking anything else, we simply return the position itself:

```
@Override
public long getItemId(int position) {
    return(position);
}
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

- `getView()`, which returns the `View` to use for a given row. This is the method that we overrode on our `IconicAdapter` in some previous incarnations to tailor the way the rows were populated. Our `getView()` implementation will be a bit more complex in this case, due to our multiple-row-type requirement, so we will examine it a bit later in this section.

### Requesting Multiple Row Types

The methods listed above are the abstract ones that you have no choice but to implement yourself. Anything else on the `ListAdapter` interface that you wish to override you can, to replace the stub implementation supplied by `BaseAdapter`.

If you wish to have more than one type of row, there are two such methods that you will wish to override:

- `getViewTypeCount()` needs to return the number of distinct row types you will use. In our case, there are just two:

```
@Override
public int getViewTypeCount() {
    return(2);
}
```

## ADVANCED LISTVIEWS

---

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

- `getItemViewType()` needs to return a value from 0 to `getViewTypeCount()-1`, indicating the index of the particular row type to use for a particular row position. In our case, we need to return different values for headers (0) and detail rows (1). To determine which is which, we use `getItem()` — if we get an `Integer` back, we need to use a header row for that position:

```
@Override
public int getItemViewType(int position) {
    if (getItem(position) instanceof Integer) {
        return(0);
    }

    return(1);
}
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

The reason for supplying this information is for row recycling. The `View` that is passed into `getView()` is either `null` or a row that we had previously created that has scrolled off the screen. By passing us this now-unused `View`, Android is asking us to reuse it if possible. By specifying the row type for each position, Android will ensure that it hands us the right type of row for recycling — we will not be passed in a header row to recycle when we need to be returning a detail row, for example.

## Creating and Recycling the Rows

Our `getView()` implementation, then, needs to have two key enhancements over previous versions:

1. We need to create the rows ourselves, particularly using the appropriate layout for the required row type (header or detail)
2. We need to recycle the rows when they are provided, as this has a **major** impact on the scrolling speed of our `ListView`

To help simplify the logic, we will have `getView()` focus on the detail rows, with a separate `getHeaderView()` to create/recycle and populate the header rows. Our `getView()` determines up front whether the row required is a header and, if so, delegates the work to `getHeaderView()`:

```
@Override
```

---

## ADVANCED LISTVIEWS

---

```
public View getView(int position, View convertView, ViewGroup parent) {
    if (getItemViewType(position) == 0) {
        return(getHeaderView(position, convertView, parent));
    }

    View row=convertView;

    if (row == null) {
        row=getLayoutInflater().inflate(R.layout.row, parent, false);
    }

    ViewHolder holder=(ViewHolder)row.getTag();

    if (holder == null) {
        holder=new ViewHolder(row);
        row.setTag(holder);
    }

    String word=(String)getItem(position);

    if (word.length() > 4) {
        holder.icon.setImageResource(R.drawable.delete);
    }
    else {
        holder.icon.setImageResource(R.drawable.ok);
    }

    holder.label.setText(word);
    holder.size.setText(String.format(getString(R.string.size_template),
        word.length()));

    return(row);
}
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

Assuming that we are to create a detail row, we then check to see if we were passed in a non-null View. If we were passed in null, we cannot recycle that row, so we have to inflate a new one via a call to `inflate()` on a `LayoutInflater` we get via `getLayoutInflater()`. But, if we were passed in an actual View to recycle, we can skip this step.

From here, the `getView()` implementation is largely the way it was before, including dealing with the `ViewHolder`. The only change of significance is that we have to manage the label `TextView` ourselves — before, we chained to the superclass and let `ArrayAdapter` handle that. So our `ViewHolder` now has a `label` data member with

## ADVANCED LISTVIEWS

our label `TextView`, and we fill it in along with the size and icon. Also, we use `getItem()` to retrieve our Latin word, so it can find the right word for the given position out of our various word batches.

Our `getHeaderView()` does much the same thing, except it uses `getItem()` to retrieve our batch index, and we use that for constructing our header:

```
private View getHeaderView(int position, View convertView,
                           ViewGroup parent) {
    View row=convertView;

    if (row == null) {
        row=getLayoutInflater().inflate(R.layout.header, parent, false);
    }

    Integer batchIndex=(Integer)getItem(position);
    TextView label=(TextView)row.findViewById(R.id.label);

    label.setText(String.format(getString(R.string.batch),
                                1 + batchIndex.intValue()));

    return(row);
}
```

(from [Selection/HeaderDetailList/app/src/main/java/com/commonsware/android/headerdetail/HeaderDetailListDemo.java](#))

## Choice Modes and the Activated Style

Sometimes, our `ListView` is alongside other content, such as in the “master-detail” UI pattern:

Figure 466: Master-Detail UI Pattern

---

## ADVANCED LISTVIEWS

---

In that case, the `ListView` should have a durable indication of what the user last clicked on, since the detail widgets will contain details of that particular item. A typical approach for this is to use the “activated” style for `ListView` rows. In [the chapter on styles](#), we saw an example of an “activated” style that referred to a device-specific color to use for an activated background. With `ListView`, you can show a selection by marking the selected row as “activated”, so its style-specified “activated” background shows up.

Hence, the recipe for using activated notation for a `ListView` adjacent to details on the last-clicked-upon `ListView` row is:

- Use `CHOICE_MODE_SINGLE` (or `android:choiceMode="singleChoice"`) on the `ListView`.
- Have a style resource, in `res/values-v11/`, that references the device-specific activated background:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="activated" parent="android:Theme.Holo">
    <item name="android:background"?android:attr/activatedBackgroundIndicator</item>
  </style>
</resources>
```

- Have the same style resource also defined in `res/values` if you are supporting pre-Honeycomb devices, where you skip the parent and the background color override, as neither of those specific values existed before API Level 11:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="activated">
  </style>
</resources>
```

- Use that style as the background of your `ListView` row (e.g., `style="@style/activated"`)

Android will automatically color the row background based upon the last row clicked, instead of checking a `RadioButton` as you might ordinarily see with `CHOICE_MODE_SINGLE` lists.

## Custom Mutable Row Contents

Lists with pretty icons next to them are all fine and well. But, can we create `ListView` widgets whose rows contain interactive child widgets instead of just passive widgets like `TextView` and `ImageView`? For example, there is a `RatingBar` widget that allows users to assign a rating by clicking on a set of star icons. Could we combine the `RatingBar` with text in order to allow people to scroll a list of, say, songs and rate them right inside the list?

There is good news and bad news.

The good news is that interactive widgets in rows work just fine. The bad news is that it is a little tricky, specifically when it comes to taking action when the interactive widget's state changes (e.g., a value is typed into a field). We need to store that state somewhere, since our `RatingBar` widget will be recycled when the `ListView` is scrolled. We need to be able to set the `RatingBar` state based upon the actual word we are viewing as the `RatingBar` is recycled, and we need to save the state when it changes so it can be restored when this particular row is scrolled back into view.

What makes this interesting is that, by default, the `RatingBar` has absolutely no idea what item in the `ArrayAdapter` it represents. After all, the `RatingBar` is just a widget, used in a row of a `ListView`. We need to teach the rows which item in the `ArrayAdapter` they are currently displaying, so when their `RatingBar` is checked, they know which item's state to modify.

So, let's see how this is done, using the activity in the [Selection/RateList](#) sample project. We will use the same basic classes as in most of our `ListView` samples, where we are showing a list of Latin words. In this case, you can rate the words on a three-star rating. Words given a top rating are put in all caps:

```
package com.commonware.android.ratelist;

import android.app.ListActivity;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.LinearLayout;
import android.widget.RatingBar;
import android.widget.TextView;
import java.util.ArrayList;
```

## ADVANCED LISTVIEWS

---

```
public class RateListDemo extends ListActivity {
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        ArrayList<RowModel> list=new ArrayList<RowModel>();

        for (String s : items) {
            list.add(new RowModel(s));
        }

        setListAdapter(new RatingAdapter(list));
    }

    private RowModel getModel(int position) {
        return(((RatingAdapter)getListAdapter()).getItem(position));
    }

    class RatingAdapter extends ArrayAdapter<RowModel> {
        RatingAdapter(ArrayList<RowModel> list) {
            super(RateListDemo.this, R.layout.row, R.id.label, list);
        }

        public View getView(int position, View convertView,
            ViewGroup parent) {
            View row=super.getView(position, convertView, parent);
            RatingBar bar=(RatingBar)row.getTag();

            if (bar==null) {
                bar=(RatingBar)row.findViewById(R.id.rate);
                row.setTag(bar);
            }

            RatingBar.OnRatingBarChangeListener l=
                new RatingBar.OnRatingBarChangeListener() {
                    public void onRatingChanged(RatingBar ratingBar,
                        float rating,
                        boolean fromTouch) {
                        Integer myPosition=(Integer)ratingBar.getTag();
                        RowModel model=getModel(myPosition);
                    }
                };
        }
    }
}
```

## ADVANCED LISTVIEWS

---

```
        model.rating=rating;

        LinearLayout parent=(LinearLayout)ratingBar.getParent();
        TextView label=(TextView)parent.findViewById(R.id.label);

        label.setText(model.toString());
    }
};

    bar.setOnRatingBarChangeListener(l);
}

    RowModel model=getModel(position);

    bar.setTag(Integer.valueOf(position));
    bar.setRating(model.rating);

    return(row);
}
}

class RowModel {
    String label;
    float rating=2.0f;

    RowModel(String label) {
        this.label=label;
    }

    public String toString() {
        if (rating>=3.0) {
            return(label.toUpperCase());
        }

        return(label);
    }
}
}
```

(from [Selection/RateList/app/src/main/java/com/commonsware/android/ratelist/RateListDemo.java](#))

Here is what is different in this activity and `getView()` implementation than in earlier, simpler samples:

1. While we are still using `String` array items as the list of Latin words, rather than pour that `String` array straight into an `ArrayAdapter`, we turn it into a list of `RowModel` objects. `RowModel` is the mutable model: it holds the Latin

## ADVANCED LISTVIEWS

---

- word plus the current rating. In a real system, these might be objects populated from a database, and the properties would have more business meaning.
2. Utility methods like `onListItemClick()` had to be updated to reflect the change from a pure-String model to use a `RowModel`.
  3. The `ArrayAdapter` subclass (`RatingAdapter`), in `getView()`, lets `ArrayAdapter` inflate and recycle the row, then checks to see if we have a `ViewHolder` in the row's tag. If not, we create a new `ViewHolder` and associate it with the row. For the row's `RatingBar`, we add an anonymous `onRatingChanged()` listener that looks at the row's tag (`getTag()`) and converts that into an `Integer`, representing the position within the `ArrayAdapter` that this row is displaying. Using that, the rating bar can get the actual `RowModel` for the row and update the model based upon the new state of the rating bar. It also updates the text adjacent to the `RatingBar` when checked to match the rating bar state.
  4. We always make sure that the `RatingBar` has the proper contents and has a tag (via `setTag()`) pointing to the position in the adapter the row is displaying.

The row layout is very simple: just a `RatingBar` and a `TextView` inside a `LinearLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    >
    <RatingBar
        android:id="@+id/rate"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:numStars="3"
        android:stepSize="1"
        android:rating="2" />
    <TextView
        android:id="@+id/label"
        android:padding="2dip"
        android:textSize="18sp"
        android:layout_gravity="left|center_vertical"
        android:layout_width="match_parent"
        android:layout_height="wrap_content" />
</LinearLayout>
```

## ADVANCED LISTVIEWS

(from [Selection/RateList/app/src/main/res/layout/row.xml](#))

And the result is what you would expect, visually:

Figure 467: RateList, As Initially Shown

This includes the toggled rating bars turning their words into all caps:

Figure 468: RateList, With a Three-Star Word

## From Head To Toe

Perhaps you do not need section headers scattered throughout your list. If you only need extra “fake rows” at the beginning or end of your list, you can use header and footer views.

`ListView` supports `addHeaderView()` and `addFooterView()` methods that allow you to add `View` objects to the beginning and end of the list, respectively. These `View` objects otherwise behave like regular rows, in that they are part of the scrolled area and will scroll off the screen if the list is long enough. If you want fixed headers or footers, rather than put them in the `ListView` itself, put them outside the `ListView`, perhaps using a `LinearLayout`.

To demonstrate header and footer views, take a peek at the [Selection/HeaderFooter](#) sample project, particularly the `HeaderFooterDemo` class:

```
package com.commonware.android.header;

import java.util.Arrays;
import java.util.Collections;
import java.util.List;
import android.app.ListActivity;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;
import android.widget.ArrayAdapter;
import android.widget.Button;
import android.widget.TextView;

public class HeaderFooterDemo extends ListActivity {
    private static String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer",
        "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae",
        "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat",
        "placerat", "ante",
        "porttitor", "sodales",
        "pellentesque", "augue",
        "purus"};

    private long startTime=SystemClock.uptimeMillis();
    private boolean areWeDeadYet=false;

    @Override
    public void onCreate(Bundle state) {
```

## ADVANCED LISTVIEWS

---

```
super.onCreate(state);
setContentView(R.layout.main);
getListView().addHeaderView(buildHeader());
getListView().addFooterView(buildFooter());
setListAdapter(new ArrayAdapter<String>(this,
    android.R.layout.simple_list_item_1,
    items));
}

@Override
public void onDestroy() {
    super.onDestroy();

    areWeDeadYet=true;
}

private View buildHeader() {
    Button btn=new Button(this);

    btn.setText("Randomize!");
    btn.setOnClickListener(new View.OnClickListener() {
        public void onClick(View v) {
            List<String> list=Arrays.asList(items);

            Collections.shuffle(list);

            setListAdapter(new ArrayAdapter<String>(HeaderFooterDemo.this,
                android.R.layout.simple_list_item_1,
                list));
        }
    });

    return(btn);
}

private View buildFooter() {
    TextView txt=new TextView(this);

    updateFooter(txt);

    return(txt);
}

private void updateFooter(final TextView txt) {
    long runtime=(SystemClock.uptimeMillis()-startTime)/1000;

    txt.setText(String.valueOf(runtime)+" seconds since activity launched");
}
```

## ADVANCED LISTVIEWS

---

```
if (!areWeDeadYet) {
    listView().postDelayed(new Runnable() {
        public void run() {
            updateFooter(txt);
        }
    }, 1000);
}
}
```

(from [Selection/HeaderFooter/app/src/main/java/com/commonsware/android/header/HeaderFooterDemo.java](#))

Here, we add a header View built via `buildHeader()`, returning a Button that, when clicked, will shuffle the contents of the list. We also add a footer View built via `buildFooter()`, returning a TextView that shows how long the activity has been running, updated every second. The list itself is the ever-popular list of *lorem ipsum* words.

When initially displayed, the header is visible but the footer is not, because the list is too long:

Figure 469: A ListView with a header view shown

If you scroll downward, the header will slide off the top, and eventually the footer

will scroll into view:

*Figure 470: A ListView with a footer view shown*

## Enter RecyclerView

RecyclerView is a more powerful (and more complex) replacement for ListView and GridView. You can read more about [what it does and how you can use it](#).

# Action Modes

---

If you have spent much time on an Android 3.0+ device, then you probably have run into a curious phenomenon. Sometimes, when you select an item in a list or other widget, the action bar magically transforms from its normal look:

*Figure 471: Regular Action Bar for Activity with EditText*

to one designed to perform operations on what you have selected:

The good news is that this is not some sort of magic limited only to built-in widgets like `EditText`. You too can have this effect in your application, by triggering an “action mode”.

In this chapter, we will explore how you can set up and respond to action modes.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

## A Matter of Context

Most desktop operating systems have had the notion of a “context menu” for some time, typically triggered by a click of the right mouse button. In particular, a right-click over some selected item might bring up a context menu of operations to perform on that item:

- Selecting text in a text editor, then right-clicking, might bring up a context menu for cut/copy/paste of the text
- Right-clicking over a file in some sort of file explorer might bring up a context menu for cut/copy/paste of the file
- Etc.

Android supports context menus, driven by a long-tap on a widget rather than a right-click. You will find a few applications that offer such menus, particularly on lists of things. However, context menus are a very old UI design pattern in Android, and modern apps rarely use them.

Instead, contextual operations are raised via an action mode, so when the user specifies a context (e.g., selects a word in an `EditText`), the action bar changes to show operations relevant for the selection.

## Manual Action Modes

A common pattern will be to activate an action mode when the user checks off something in a multiple-choice `ListView`. If you want to go that route, there is some built-in scaffolding to make that work, described [later in this chapter](#).

You can, if you wish, move the action bar into an action mode whenever you want. This would be particularly important if your UI is not based on a `ListView`. For example, tapping on an image in a `GridView` might activate it and move you into an action mode for operations upon that particular image.

In this section, we will examine the [ActionMode/ManualNative](#) sample project. This is another variation on the “show a list of Latin words in a list” sample used elsewhere in this book.

## Choosing Your Trigger

As mentioned above, selecting a word or passage in an `EditText` (e.g., via a long-tap) brings up an action mode for cut/copy/paste operations. Other apps might bring up an action mode when you check an item in a checklist. Yet others might bring up an action mode when you long-tap on an item in a regular list. And so on.

You will need to choose, for your own UI, what trigger mechanism will bring up an action mode. It should be some trigger that makes it obvious to the user what the action mode will be acting upon. For example:

## ACTION MODES

---

- If the user long-taps on an item in a `GridView`, bring up an action mode, and treat future taps on `GridView` items as adding or removing items from the “selection” while that action mode is visible
- If the user “rubber-bands” some figures in your vector art drawing `View`, bring up an action mode for operations on those figures (e.g., rotate, resize)
- And so on

In the case of the sample project, we stick with the classic long-tap on a `ListView` row to bring up an action mode:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    initAdapter();
    getListView().setLongClickable(true);
    getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
    getListView().setOnItemLongClickListener(new ActionModeHelper(
                                                this,
                                                getListView()));
}
```

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeDemo.java](#))

## Starting the Action Mode

Starting an action mode is trivially easy: just call `startActionMode()` on your `Activity`, passing in an implementation of `ActionMode.Callback`, which will be called with various lifecycle methods for the action mode itself.

In the case of the `ActionMode` sample project, `ActionModeHelper` – our `OnItemLongClickListener` from the preceding section – also is our `ActionMode.Callback` implementation. Hence, when the user long-clicks on an item in the `ListView`, the `ActionModeHelper` establishes itself as the action mode:

```
@Override
public boolean onItemLongClick(AdapterView<?> view, View row,
                                int position, long id) {

    modeView.clearChoices();
    modeView.setItemChecked(position, true);

    if (activeMode == null) {
        activeMode=host.startActionMode(this);
    }

    return(true);
}
```

## ACTION MODES

---

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeHelper.java](#))

Note that `startActionMode()` returns an `ActionMode` object, which we can use later on to configure the mode's behavior, by stashing it in an `actionMode` data member.

Also, we make the long-clicked-upon item be “checked”, to show which item the action mode will act upon. Our row layout will make a checked row show up with the “activated” style, courtesy of Android's `simple_list_item_activated_1` stock layout.

Also note that we only start the action mode if it is not already started.

### Implementing the Action Mode

The real logic behind the action mode lies in your `ActionMode.Callback` implementation. It is in these four lifecycle methods where you define what the action mode should look like and what should happen when choices are made in it.

#### `onCreateActionMode()`

The `onCreateActionMode()` method will be called shortly after you call `startActionMode()`. Here, you get to define what goes in the action mode. You get the `ActionMode` object itself (in case you do not already have a reference to it). More importantly, you are passed a `Menu` object, just as you get in `onCreateOptionsMenu()`. And, just like with `onCreateOptionsMenu()`, you can inflate a menu resource into the `Menu` object to define the contents of the action mode:

```
@Override
public boolean onCreateActionMode(ActionMode mode, Menu menu) {
    MenuInflater inflater=host.getMenuInflater();

    inflater.inflate(R.menu.context, menu);
    mode.setTitle(R.string.context_title);

    return(true);
}
```

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeHelper.java](#))

## ACTION MODES

---

In addition to inflating our menu resource into the action mode's menu, we also set the title of the `ActionMode`, which shows up to the right of the Done button:

### `onPrepareActionMode()`

If you determine that you need to change the contents of your action mode, you can call `invalidate()` on the `ActionMode` object. That, in turn, will trigger a call to `onPrepareActionMode()`, where you once again have an opportunity to configure the `Menu` object. If you do make changes, return `true` — otherwise, return `false`. In the case of `ActionModeHelper`, we take the latter approach:

```
@Override
public boolean onPrepareActionMode(ActionMode mode, Menu menu) {
    return(false);
}
```

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeHelper.java](#))

### `onActionItemClicked()`

Just as `onCreateActionMode()` is the action mode analogue to `onCreateOptionsMenu()`, `onActionItemClicked()` is the action mode analogue to `onOptionsItemSelected()`. This will be called if the user clicks on something related to your action mode. You are passed in the corresponding `MenuItem` object (plus the

## ACTION MODES

---

ActionMode itself), and you can take whatever steps are necessary to do whatever the work is.

On the ActionModeDemo class, we have the business logic for handling the data-change operations in a performAction() method:

```
public boolean performAction(int itemId, int position) {
    switch (itemId) {
        case R.id.cap:
            String word=words.get(position);

            word=word.toUpperCase();

            adapter.remove(words.get(position));
            adapter.insert(word, position);

            return(true);

        case R.id.remove:
            adapter.remove(words.get(position));

            return(true);
    }

    return(false);
}
```

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeDemo.java](#))

And, the onItemClick() method calls performAction():

```
@Override
public boolean onItemClick(ActionMode mode, MenuItem item) {
    boolean result=
        host.performAction(item.getItemId(),
            modeView.getCheckedItemPosition());

    if (item.getItemId() == R.id.remove) {
        activeMode.finish();
    }

    return(result);
}
```

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeHelper.java](#))

onItemClick() also dismisses the action mode if the user chose the

---

## ACTION MODES

---

“remove” item, since the action mode is no longer needed. You get rid of an active action mode by calling `finish()` on it.

### `onDestroyActionMode()`

The `onDestroyActionMode()` callback will be invoked when the action mode goes away, for any reason, such as:

1. The user clicks the Done button on the left
2. The user clicks the BACK button
3. You call `finish()` on the `ActionMode`

Here, you can do any necessary cleanup. `ActionModeHelper` tries to clean things up, notably the “checked” state of the last item long-tapped-upon:

```
@Override
public void onDestroyActionMode(ActionMode mode) {
    activeMode=null;
    modeView.clearChoices();
    modeView.requestLayout();
}
```

(from [ActionMode/ManualNative/app/src/main/java/com/commonsware/android/actionmode/ActionModeHelper.java](#))

However, for reasons that are not yet clear, `clearChoices()` does not update the UI when called from `onDestroyActionMode()` unless you also call `requestLayout()`.

## Multiple-Choice-Modal Action Modes

For many cases, the best user experience will be for you to have a multiple-choice `ListView`, where checking items in that list enables an action mode for performing operations on the checked items. For this scenario, API Level 11+ has a built-in `ListView` choice mode, `CHOICE_MODE_MULTIPLE_MODAL`, that automatically sets up an `ActionMode` for you as the user checks and unchecks items.

To see how this works, let’s examine the [ActionMode/ActionModeMC](#) sample project. This is the same project as in the preceding section, but altered to have a multiple-choice `ListView`, utilizing an action mode on API Level 11+.

Once again, in `onCreate()`, we need to set up the smarts for our `ListView`. This time, though, we will use `CHOICE_MODE_MULTIPLE_MODAL`:

## ACTION MODES

---

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    initAdapter();

    getListView().setChoiceMode(ListView.CHOICE_MODE_MULTIPLE_MODAL);
    getListView().setMultiChoiceModeListener(new HCMultiChoiceModeListener(
        this, getListView()));
}
```

(from [ActionMode/ActionModeMC/app/src/main/java/com/commonsware/android/actionmodemc/ActionModeDemo.java](#))

We enable `CHOICE_MODE_MULTIPLE_MODAL` for the `ListView`, and register an instance of an `HCMultiChoiceModeListener` object via `setMultiChoiceModeListener()`. This object is an implementation of the `MultiChoiceModeListener` interface that we will examine shortly.

Since we now may have multiple checked items, our `performAction()` method must take this into account, capitalizing or removing all checked words:

```
public boolean performActions(MenuItem item) {
    SparseBooleanArray checked=getListView().getCheckedItemPositions();

    switch (item.getItemId()) {
        case R.id.cap:
            for (int i=0; i < checked.size(); i++) {
                if (checked.valueAt(i)) {
                    int position=checked.keyAt(i);
                    String word=words.get(position);

                    word=word.toUpperCase(Locale.ENGLISH);

                    adapter.remove(words.get(position));
                    adapter.insert(word, position);
                }
            }

            return(true);

        case R.id.remove:
            ArrayList<Integer> positions=new ArrayList<Integer>();

            for (int i=0; i < checked.size(); i++) {
                if (checked.valueAt(i)) {
                    positions.add(checked.keyAt(i));
                }
            }
    }
}
```

## ACTION MODES

---

```
    }

    Collections.sort(positions, Collections.reverseOrder());

    for (int position : positions) {
        adapter.remove(words.get(position));
    }

    getListView().clearChoices();

    return(true);
}

return(false);
}
```

(from [ActionMode/ActionModeMC/app/src/main/java/com/commonsware/android/actionmodemc/ActionModeDemo.java](#))

MultiChoiceModeListener extends the ActionMode.Callback interface we used with our manual action mode earlier in this book. Hence, we need to implement all the standard ActionMode.Callback methods, plus a new onItemCheckedStateChanged() method introduced by MultiChoiceModeListener:

```
package com.commonsware.android.actionmodemc;

import android.annotation.TargetApi;
import android.os.Build;
import android.view.ActionMode;
import android.view.Menu;
import android.view.MenuInflater;
import android.view.MenuItem;
import android.widget.AbsListView;
import android.widget.ListView;

@TargetApi(Build.VERSION_CODES.HONEYCOMB)
public class HCMultiChoiceModeListener implements
    AbsListView.MultiChoiceModeListener {
    ActionModeDemo host;
    ActionMode activeMode;
    ListView lv;

    HCMultiChoiceModeListener(ActionModeDemo host, ListView lv) {
        this.host=host;
        this.lv=lv;
    }

    @Override
```

## ACTION MODES

---

```
public boolean onCreateActionMode(ActionMode mode, Menu menu) {
    MenuInflater inflater=host.getMenuInflater();

    inflater.inflate(R.menu.context, menu);
    mode.setTitle(R.string.context_title);
    mode.setSubtitle("(1)");
    activeMode=mode;

    return(true);
}

@Override
public boolean onPrepareActionMode(ActionMode mode, Menu menu) {
    return(false);
}

@Override
public boolean onActionItemClicked(ActionMode mode, MenuItem item) {
    boolean result=host.performActions(item);

    updateSubtitle(activeMode);

    return(result);
}

@Override
public void onDestroyActionMode(ActionMode mode) {
    activeMode=null;
}

@Override
public void onItemCheckedStateChanged(ActionMode mode, int position,
                                       long id, boolean checked) {
    updateSubtitle(mode);
}

private void updateSubtitle(ActionMode mode) {
    mode.setSubtitle("(" + lv.getCheckedItemCount() + ")");
}
}
```

(from [ActionMode/ActionModeMC/app/src/main/java/com/commonsware/android/actionmodemc/HCMultiChoiceModeListener.java](#))

Android will automatically start our action mode for us when the user checks the first item in the list, using our `MultiChoiceModeListener` as the callback. Android will also automatically finish the action mode if the user unchecks all previously-checked items.

## ACTION MODES

---

In `onCreateActionMode()`, we populate the menu, plus set up a title and subtitle on the `ActionMode`. The subtitle appears below the title, as you might expect. In this case, we are indicating how many words are checked and therefore will be affected by the actions the user chooses in the action mode:

*Figure 474: The ActionModeMC Sample App, Showing the Action Mode*

Then, in `onActionItemClicked()`, we both call `performActions()` to affect the desired changes, plus update the subtitle in case the user removed words (which means they are no longer checked).

The new `onItemCheckedStateChanged()` will be called whenever the user checks or unchecks an item, up until the last item is unchecked. `HCMultiChoiceModeListener` simply updates the subtitle to reflect the new count of checked items.

On the whole, using `CHOICE_MODE_MULTIPLE_MODAL` is simpler than setting up your own trigger mechanism and managing the action mode yourself. That being said, both are completely valid options, which is particularly important for situations where a multiple-choice `ListView` is not the desired user interface.

## Long-Click To Initiate an Action Mode

However, rather than having checkboxes or the like always in the `ListView`, a more modern approach is to move into multiple-selection mode based on a long-click.

---

## ACTION MODES

---

Before then, clicks on rows behave like with any other `ListView`, but after a long-click, the action mode appears and the user can tap on rows to select which of them to operate upon.

The [ActionMode/LongPress](#) sample project is a variation on the preceding project, with some slight simplifications, and adopting the long-click as the means to enter the action mode.

### Setting Up the Listeners

In `onCreate()`, we set up listeners for both a long click (via `setOnItemLongClickListener()`) and for multiple-choice mode (via `setMultiChoiceModeListener()`). Both times, we supply the activity as the listener, as it implements the appropriate interfaces:

```
getListView().setOnItemLongClickListener(this);
getListView().setMultiChoiceModeListener(this);
```

(from [ActionMode/LongPress/app/src/main/java/com/commonsware/android/actionmode/longpress/ActionModeDemo.java](#))

### Handling the Long Click

By default, the `ListView` is in no-choice mode, where clicks on rows simply trigger `onItemClickListener()` or the equivalent. However, if the user long-clicks on a row, our `onItemLongClick()` method will be called, and we can both switch into multiple-choice mode and mark the long-clicked row as being checked:

```
@Override
public boolean onItemLongClick(AdapterView<?> parent, View view,
                               int position, long id) {
    getListView().setChoiceMode(ListView.CHOICE_MODE_MULTIPLE_MODAL);
    getListView().setItemChecked(position, true);

    return true;
}
```

(from [ActionMode/LongPress/app/src/main/java/com/commonsware/android/actionmode/longpress/ActionModeDemo.java](#))

At this point, the action mode will also start up, courtesy of having called `setMultiChoiceModeListener()`.

### Addressing Configuration Changes

If we undergo a configuration change, we want:

1. To keep the current set of words, including any that were added
2. To keep the action mode going, if the user had long-clicked to enter the action mode
3. To keep our checked item states, if the action mode is active

Keeping the checked item states will be handled for us by the built-in instance-state management of `ListView` and `ListActivity`. However, the rest we need to handle ourselves. So, we have an `onSaveInstanceState()` implementation in the activity, which saves the current choice mode, plus the current word list:

```
@Override
public void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);
    state.putInt(STATE_CHOICE_MODE, getListView().getChoiceMode());
    state.putStringArrayList(STATE_MODEL, words);
}
```

(from [ActionMode/LongPress/app/src/main/java/com/commonsware/android/actionmode/longpress/ActionModeDemo.java](#))

Plus, in `onCreate()`, after setting up the listeners, we set up the choice mode of the `ListView` based upon the passed in instance state `Bundle`, if there is one:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    if (state == null) {
        initAdapter(null);
    }
    else {
        initAdapter(state.getStringArrayList(STATE_MODEL));
    }

    getListView().setOnItemLongClickListener(this);
    getListView().setMultiChoiceModeListener(this);

    int choiceMode=
        (state == null ? ListView.CHOICE_MODE_NONE
         : state.getInt(STATE_CHOICE_MODE));

    getListView().setChoiceMode(choiceMode);
}
```

## ACTION MODES

---

```
}
```

(from [ActionMode/LongPress/app/src/main/java/com/commonsware/android/actionmode/longpress/ActionModeDemo.java](#))

Once we call `setChoiceMode()` with the previous activity instance's choice mode, if that was `CHOICE_MODE_MULTIPLE_MODAL`, Android will automatically open up the action mode again and restore our checked items.

### Resetting the Choice Mode

Where things get a bit interesting is when the user dismisses the action mode, at which point we need to move back to no-choice mode.

You might think that this would merely be a matter of calling `setChoiceMode()` on the `ListView`, asking for `CHOICE_MODE_NONE`. Indeed, that is part of the solution. However, there are two problems:

1. If you call that in `onDestroyActionMode()` directly, you wind up with infinite recursion and a `StackOverflowError`, as changing the choice mode while the action mode is still technically active will cause it to destroy the action mode again.
2. Switching the choice mode back to “none” enables some optimizations within `ListView` that ignore the checked state of our rows. However, those rows still already checked will show up as activated, even after calling `setChoiceMode()` to return to the normal “none” mode. `clearChoices()` also does not have a worthwhile effect, for whatever reason.

Hence, in `onDestroyActionMode()`, not only do we need to call `setChoiceMode()`, but we need to “smack around” the `ListView` enough to get it to clear our checked rows, and the easiest way to do that is to call `setAdapter()` on it, passing in its existing adapter:

```
@Override
public void onDestroyActionMode(ActionMode mode) {
    if (activeMode != null) {
        activeMode=null;
        listView.setChoiceMode(ListView.CHOICE_MODE_NONE);
        listView.setAdapter(listView.getAdapter());
    }
}
```

(from [ActionMode/LongPress/app/src/main/java/com/commonsware/android/actionmode/longpress/ActionModeDemo.java](#))

---

## ACTION MODES

---

And, we only do that while our action mode is active (i.e., `activeMode` is not null), to avoid the infinite recursion.

This is a bit clunky, but it works.

### The Results

When initially launched, the activity looks like a simple `ListActivity`:

*Figure 475: Action Mode Long Press Demo, As Initially Launched*

Tapping on a row provides the normal momentary highlight.

## ACTION MODES

---

However, if the user long-clicks a row, we move into the action mode and a multiple-choice ListView:

*Figure 476: Action Mode Long Press Demo, with Action Mode Activated*

## ACTION MODES

---

*Figure 477: Action Mode Long Press Demo, with Multiple Selections*

Dismissing the action mode returns the `ListView` to normal operation.

# Other Advanced Action Bar Techniques

---

The action bar offers a number of other features that developers can take advantage of, ones that do not necessarily fit into the other chapters. Hence, this chapter is a “catch all” for other things you may wish to do with your action bar. Note that this chapter is focused on the native action bar, not the [AppCompat](#) backport.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

## Action Layouts

What happens if you want something other than a button to appear as an action bar item? Suppose you want a field instead?

Fortunately, this is supported. Otherwise, this would be a completely pointless section of the book.

You can specify `android:actionLayout` on an `<item>` element in a menu resource. This will point to a reference to a layout XML resource that you want to have inflated into the action bar instead of a toolbar button. Then, in `onCreateOptionsMenu()`, you can call `findMenuItem()` on the `Menu` to retrieve the `MenuItem` associated with this `<item>` element, then call `getActionView()` to retrieve the root of your inflated layout. At that point, you can hook up event listeners to the widgets in that layout, as needed.

Obviously, since the action bar is only so big, you will need to be judicious about your use of space.

## Action Views and Action Providers

If all you need is a single widget to replace the toolbar button, rather than a whole layout resource, you can use `android:actionViewClass` instead of `android:actionLayout`. In `android:actionViewClass`, you provide the fully-qualified class name of the widget that you wish to use to replace the toolbar button. You still use `getActionView()` to retrieve a reference to this at runtime.

If the widget you use implements the `CollapsibleActionView` interface, then it has an additional behavior: the ability to collapse into a standard toolbar button or expand into its normal mode. The only example of this in the current Android SDK is `SearchView`, which can expand into a field for searching or collapse into a simple search icon (magnifying glass) as needed. We will see more about `SearchView`, and how it behaves as a `CollapsibleActionView`, [later in this chapter](#).

Yet another possible toolbar button replacement is an action provider. Whereas an action view or action layout provide the UI, and your code provides the handling of touch events, an action provider is an “all-in-one” solution. It is designed to be configured, then used by the user without any required additional intervention by the developer. That being said, an action provider can have its own listener interfaces to let developers know about various events that have occurred. The two primary implementations of the `ActionProvider` base class are:

- `MediaRouteActionProvider`, covered [later elsewhere in the book](#), is used to allow users to control the destination for media, such as routing audio to Bluetooth headphones instead of the device speaker or playing content back on a Chromecast
- `ShareActionProvider` can simplify sharing content via `ACTION_SEND`, as is covered [elsewhere in the book](#)

To use an `ActionProvider`, you add the `android:actionProviderClass` attribute to an `<item>` in the `<menu>` resource, providing the fully-qualified class name of the `ActionProvider` implementation. You can call `getActionProvider()` on the `MenuItem` to retrieve the `ActionProvider` instance, for configuration at runtime.

## Searching with SearchView

Many apps employ a SearchView in their action bar. The user typically sees the search icon as a regular toolbar button:

Figure 478: SearchView Demo, Showing Collapsed Action View

Tapping that opens a search field, taking over more of the action bar:

Figure 479: SearchView Demo, Showing Expanded Action View

Typing something in initiates some sort of search, as defined by the activity that is using the SearchView. BACK or the app icon in the action bar will “collapse” the SearchView back into its iconified state.

The [ActionBar/SearchView](#) sample project, profiled in this section, shows how you can use SearchView within your app. This sample is a clone of one of the previous action bar samples, where we have the list of 25 words, hosted in a ListFragment, with action bar items to add a word and reset the word list. In this section, we will augment the sample with a SearchView and a filtered ListView.

### SearchView... in the Menu Resource

The project’s menu resource (res/menu/actions.xml) contains a regular action item (reset), an action item employing an action layout (add), and an action item containing our SearchView (search):

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

  <item
    android:id="@+id/search"
    android:actionViewClass="android.widget.SearchView"
    android:icon="@drawable/ic_action_search"
    android:showAsAction="ifRoom|collapseActionView"
    android:title="@string/filter">
```

---

## OTHER ADVANCED ACTION BAR TECHNIQUES

---

```
</item>
</menu>
```

(from [ActionBar/SearchView/app/src/main/res/menu/actions.xml](#))

Note that the search item not only has `android:actionViewClass="android.widget.SearchView"` to tie in our action view, but it also has `android:showAsAction="ifRoom|collapseActionView"`, to indicate that this action view should support collapsing and expanding.

### SearchView... in the Action Bar Configuration

In `onCreateOptionsMenu()` of our `ActionBarFragment`, in addition to inflating the menu resource to configure the add action layout, we now also call a `configureSearchView()` method to configure the `SearchView`:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.actions, menu);

    configureSearchView(menu);

    super.onCreateOptionsMenu(menu, inflater);
}
```

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

In `configureSearchView()`, surprisingly enough, we configure the `SearchView`:

```
private void configureSearchView(Menu menu) {
    MenuItem search=menu.findItem(R.id.search);

    sv=(SearchView)search.getActionView();
    sv.setOnQueryTextListener(this);
    sv.setOnCloseListener(this);
    sv.setSubmitButtonEnabled(false);
    sv.setIconifiedByDefault(true);

    if (initialQuery != null) {
        sv.setIconified(false);
        search.expandActionView();
        sv.setQuery(initialQuery, true);
    }
}
```

## OTHER ADVANCED ACTION BAR TECHNIQUES

---

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

Specifically, we:

- Register our fragment as the `QueryTextListener` and the `OnCloseListener`, which will be covered in greater detail [later in this chapter](#)
- Disable the submit button, as we will be using the `SearchView` for filtering rather than querying
- Indicate that the `SearchView` should be collapsed (“iconified”) as the default state

Also, our fragment has an `initialQuery` data member, and if that is not null, we expand the `SearchView` and fill in `initialQuery` as the query to be shown in the `SearchView`, also submitting it.

`initialQuery` comes from our configuration change logic, as if the user fills in something in the `SearchView` in one configuration (e.g., portrait), we do not want to lose it on a configuration change (e.g., to landscape). In our `onSaveInstanceState()` method, we save both the query from the `SearchView` and the words currently in our list:

```
@Override
public void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);

    if (!sv.isIconified()) {
        state.putCharSequence(STATE_QUERY, sv.getQuery());
    }

    state.putStringArrayList(STATE_MODEL, words);
}
```

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

In `onViewCreated()`, we use the saved `InstanceState` `Bundle` to populate the adapter with the previous set of words, plus store the old `SearchView`'s query in `initialQuery`:

```
@Override
public void onViewCreated(@NonNull View view,
    @Nullable Bundle savedInstanceState) {
    if (savedInstanceState == null) {
        initAdapter(null);
    }
}
```

---

## OTHER ADVANCED ACTION BAR TECHNIQUES

---

```
else {
    initAdapter(savedInstanceState.getStringArrayList(STATE_MODEL));
    initialQuery=savedInstanceState.getCharSequence(STATE_QUERY);
}
}
```

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

Hence, on a configuration change, by the time `configureSearchView()` is called, we will have our `initialQuery`, if there is one, and we can set up the UI to be the same as it was in the old configuration.

### SearchView... And Filtering a ListView

The `ActionBarFragment` implements the `SearchView.OnQueryTextListener` and `SearchView.OnCloseListener` interfaces, which is why we can pass this to `setOnQueryTextListener()` and `setOnCloseListener()` in `configureSearchView()`.

Those two interfaces require a total of three methods, described below.

#### onQueryTextChange()

The `onQueryTextChange()` method — required by `SearchView.OnQueryTextListener` – will be called whenever the user has changed the contents of the expanded `SearchView`, such as by typing a character. This is used when you want to employ the `SearchView` for filtering, updating the filter as the user types, rather than for searching, in which case you would wait until the user “submits” the search request.

Our implementation takes advantage of `ArrayAdapter`’s built-in filtering capability:

```
@Override
public boolean onQueryTextChange(String newText) {
    if (TextUtils.isEmpty(newText)) {
        adapter.getFilter().filter("");
    }
    else {
        adapter.getFilter().filter(newText.toString());
    }

    return(true);
}
```

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

---

## OTHER ADVANCED ACTION BAR TECHNIQUES

---

Adapters that implement the `Filterable` interface can be filtered, automatically restricting the displayed items to ones that match the filter. Calling `getFilter()` on a `Filterable` returns a `Filter`. The default implementation of a `Filter` filters on the leading characters of `toString()` of `getItem()` from the Adapter. Hence, filtering an `ArrayAdapter` on our roster of 25 words, where the filter string is 'm', would show `morbi` and `mollis` but skip `amet`, let alone other words not beginning with `m`.

So, our `onQueryTextChange()` method simply updates the `Filter` with whatever the user has typed into the `SearchView`, setting the filter to the empty string if the `SearchView` is either empty or has null contents.

### **onQueryTextSubmit()**

The `onQueryTextSubmit()` method — required by `SearchView.OnQueryTextListener` — would be called if the user tapped on the submit button within the expanded `SearchView`, to ask us to perform the search. In this sample, we have disabled that button, as we are filtering our list on the fly, rather than performing a query once the `SearchView` is filled out. Hence, `ActionBarFragment` has a do-nothing implementation of `onQueryTextSubmit()`, simply returning `false` to indicate that we have not consumed the event:

```
@Override
public boolean onQueryTextSubmit(String query) {
    return(false);
}
```

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

The chapter on advanced database techniques has [a section on full-text indexing](#), and the sample app in that chapter demonstrates the use of the submit button in a `SearchView` and `onQueryTextSubmit()`.

### **onClose()**

The `onClose()` method — required by `SearchView.OnCloseListener` — in theory will be called when the `SearchView` is collapsed. Here, we simply clear out the filter that we are using to limit the contents of the `ListView`, plus return `true` to say that we have handled the event:

```
@Override
public boolean onClose() {
```

## OTHER ADVANCED ACTION BAR TECHNIQUES

---

```
adapter.getFilter().filter("");  
  
return(true);  
}
```

(from [ActionBar/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

According to the `SearchView` source code, it will only be called if:

- The query text is empty, and
- The `SearchView` is iconified by default (`setIconifiedByDefault(true)`)

In practice, not even that works very well.

Hence, if you really need to find out when the `SearchView` is collapsed, you will probably need to use the more generic `OnActionExpandListener` interface, attached to the `SearchView` via `setOnActionExpandListener()`. `onMenuItemActionCollapse()` should be called when the `SearchView` is collapsed. This also works for other types of collapsible action views, not just `SearchView`.

## SearchView... From the User's Perspective

If the user taps on the search icon, then starts typing into the SearchView's editing area, the ListView is filtered based upon the typed-in prefix:

## Floating Action Bars

By default, your action bar will be separate from the main content area of your activity. Normally, that is what you want.

## OTHER ADVANCED ACTION BAR TECHNIQUES

---

But, sometimes, you may want to have the action bar(s) float over the top of your activity, as can be seen in Google Maps:

Figure 481: Google Maps, with Floating Action Bar (image courtesy of Google)

To accomplish this, you can use `FEATURE_ACTION_BAR_OVERLAY`, as is illustrated in the [ActionBar/OverlayNative](#) sample project.

This is nearly identical to the `ActionBar/ActionBarDemoNative` sample project, with just a few changes, mostly in the `onCreate()` method of our activity:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    getWindow().requestFeature(Window.FEATURE_ACTION_BAR_OVERLAY);

    initAdapter();

    Drawable d=
        getResources().getDrawable(R.drawable.action_bar_background);

    getActionBar().setBackgroundDrawable(d);
}
```

## OTHER ADVANCED ACTION BAR TECHNIQUES

---

(from [ActionBar/OverlayNative/app/src/main/java/com/commonsware/android/actionbaroverlay/ActionBarDemoActivity.java](#))

In addition to the original logic, we:

- Call `requestFeature()` on our `Window` (obtained via a call to `getWindow()`), asking for `FEATURE_ACTION_BAR_OVERLAY`
- Call `setBackgroundDrawable()` on our `ActionBar`, supplying a reference to a drawable resource to use for the background of the floating action bar

The drawable resource is a `ShapeDrawable`, defined in XML:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <solid android:color="#AAFFFFFF" />

</shape>
```

(from [ActionBar/OverlayNative/app/src/main/res/drawable/action\\_bar\\_background.xml](#))

We will discuss `ShapeDrawable` in much greater detail [later in this book](#) . For the moment, take it on faith that our resource is defining a rectangle, with a translucent white fill. The alpha channel (AA) for our translucence is important, so the user can see a bit of our activity underneath the floating action bar.

## OTHER ADVANCED ACTION BAR TECHNIQUES

---

The result is that our action bars float over the top of the list:

*Figure 482: Floating Action Bar*

In this case, the effect is not very good, as the words will blend in too strongly with the overlaid action bars. However, that is a question of organizing the screen content and using this overlay feature only in cases where you will see good results, such as in the Google Maps example shown above.

# Toolbar

---

Android 5.0 introduced a `Toolbar` widget, offering functionality akin to the action bar, but in the form of a `ViewGroup` that can be positioned where you need it. You can even use a `Toolbar` as an outright replacement for the action bar, for cases where you need a bit more control over the action bar implementation than you get by default.

In this chapter, we will explore the use of `Toolbar`. Note that [an upcoming chapter](#) will cover the use of [a backport of `Toolbar`](#) that works back to API Level 7... albeit with some issues.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

Note that the examples in this chapter are clones of a couple from the core chapters. This chapter's prose was written assuming that you were familiar with those samples, so you may need to go back and review them as needed.

One of the samples relies upon using a custom `Parcelable` class, which is covered [in another chapter](#).

## Basic `Toolbar` Mechanics

As noted earlier, a `Toolbar` is an ordinary `ViewGroup`. While it does not support placing arbitrary children in it the way a `LinearLayout` might, it otherwise can be used like any other `ViewGroup`. In particular, you can put it in a layout resource and

position it wherever it makes sense, such as in a lower quadrant of a tablet-sized screen, tied to some specific part of your UI.

However, the `Toolbar` is not the action bar... at least, not by default. As such, you will use somewhat different methods for interacting with it, particularly for dealing with menu items:

- You will call `inflateMenu()` when you want to pour action items into the menu, as a counterpart to the work you do in `onOptionsItemSelected()` for the action bar
- You will call `setOnMenuItemClickListener()` to set a listener to be invoked when the user taps on a menu item in the `Toolbar`, as a counterpart to the work you do in `onOptionsItemSelected()`

A `Toolbar` does not automatically adopt much in the way of styling from your activity's theme. In particular, it does not set the background color to be the primary color of a `Theme.Material` theme, the way the action bar does. However, whether via a style resource, XML attributes in a layout file, or Java code, you can affect these same sorts of capabilities.

## Use Case: Split Action Bar

In Android 4.x, and in the original implementation of [the appcompat-v7 action bar backport](#), we had the notion of the “split action bar”. On phone-sized screens in portrait orientation, the action bar could easily get too crowded. We could opt into having a split action bar in these cases, where action items and the overflow would go into a bar at the bottom of the screen, leaving the top for the app's title, icon, and navigation items.

However, `Theme.Material` and modern editions of `appcompat-v7` have dropped support for the split action bar. To achieve the same basic effect, you can use a `Toolbar` that you position yourself at the bottom of the screen.

The [Toolbar/SplitActionBar](#) sample project demonstrates both the original Android 4.x way of getting a split action bar and using `Toolbar` to get the same basic visual effect on Android 5.0+. This is a clone of the `ActionBar/VersionedColor` sample app from [a previous chapter](#), supporting a tinted action bar on Android 4.x (via a custom theme based off of `Theme.Holo`) and Android 5.0+ (via a custom theme based off of `Theme.Material`).

### Enabling Stock Android 4.x Behavior

Getting a split action bar on Android 4.x was easy: just add `android:uiOptions="splitActionBarWhenNarrow"` to the `<activity>` or `<application>` in the manifest. Putting it on `<application>` will affect the default for all activities; putting it on a single `<activity>` affects only that activity.

The sample app's manifest uses `android:uiOptions="splitActionBarWhenNarrow"` on the one-and-only activity:

```
<activity
  android:name="ActionBarDemoActivity"
  android:label="@string/app_name"
  android:uiOptions="splitActionBarWhenNarrow">
  <intent-filter>
    <action android:name="android.intent.action.MAIN"/>

    <category android:name="android.intent.category.LAUNCHER"/>
  </intent-filter>
</activity>
```

(from [Toolbar/SplitActionBar/app/src/main/AndroidManifest.xml](#))

## TOOLBAR

---

The result is, as the name suggests, a split action bar:

Note that the bottom bar retains the tinting rules applied via our theme, created via [the Action Bar Style Generator](#).

### Adding the Toolbar

Since Toolbar is an ordinary ViewGroup, we can put one in a layout resource, such as `res/layout-v21/main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <ListView
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="1"/>
```

## TOOLBAR

---

```
<Toolbar
  android:id="@+id/toolbar"
  style="@style/SplitActionBar"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"/>
</LinearLayout>
```

(from [Toolbar/SplitActionBar/app/src/main/res/layout-v21/main.xml](#))

Here, we allocate `wrap_content` height for the Toolbar and give all remaining space to the `ListView` (by means of `android:layout_weight="1"` and no weight on the Toolbar).

The style attribute on the Toolbar points to a custom style resource, in `res/values-v21/styles.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
  <style name="SplitActionBar">
    <item name="android:background">@color/primary</item>
  </style>
</resources>
```

(from [Toolbar/SplitActionBar/app/src/main/res/values-v21/styles.xml](#))

This sets the background color of the Toolbar to be the same background color that we are using for the `colorPrimary` tint for our `Theme.Material`-based custom theme. By default, Toolbar has a black background, despite setting `colorPrimary` on the theme.

## Using the Layout

In `onCreate()` of the activity, we load up the layout file if we are on Android 5.0 or higher:

```
@Override
public void onCreate(Bundle state) {
  super.onCreate(state);
```

## TOOLBAR

---

```
if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
    setContentView(R.layout.main);
}

initAdapter();
}
```

(from [Toolbar/SplitActionBar/app/src/main/java/com/commonsware/android/toolbar/sab/ActionBarDemoActivity.java](#))

Note that we could have had a separate `res/layout/main.xml` resource, containing just the `ListView`. Then, we could call `setContentView()` regardless of API level, with the resource system pulling in the right one based on the device's API level. In this case, since we are using `ListActivity`, we do not need a layout for Android 4.x. Having two lines of Java versus a separate layout resource is a tradeoff that could be made either way.

This gives us a `Toolbar`, but by default it will be empty, making it less than useful.

### Populating and Using the Toolbar

On Android 4.x, we can just implement `onOptionsItemSelected()` and `onOptionsItemSelected()`, and the items will work, whether we chose a split action bar or not. On Android 5.0+, we need to explicitly put the action bar items into the `Toolbar` and explicitly register a listener to find out when those items are tapped.

We handle all of that in `onOptionsItemSelected()` itself, using different behavior based on API level:

```
@Override
public boolean onOptionsItemSelected(Menu menu) {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
        Toolbar tb = (Toolbar) findViewById(R.id.toolbar);

        tb.inflateMenu(R.menu.actions);
        tb.setOnMenuItemClickListener(new Toolbar.OnMenuItemClickListener() {
            @Override
            public boolean onMenuItemClick(MenuItem item) {
                return onOptionsItemSelected(item);
            }
        });
    }
    else {
        getMenuInflater().inflate(R.menu.actions, menu);
    }
}
```

## TOOLBAR

---

```
return(super.onCreateOptionsMenu(menu));  
}
```

(from [Toolbar/SplitActionBar/app/src/main/java/com/commonsware/android/toolbar/sab/ActionBarDemoActivity.java](#))

If we are on an Android 4.x device, we just `inflate()` a menu resource into the supplied `Menu` for the action bar. If we are on an Android 5.0+ device, we:

- Retrieve the `Toolbar` from the inflated layout
- Inflate our menu resource into the `Toolbar` via `inflateMenu()`
- Register an `OnMenuItemClickListener` with the `Toolbar`, routing the menu item click over to our `onOptionsItemSelected()` method, so we can have one common implementation of logic for handling action items that are either in the action bar or the `Toolbar`

## Results and Changes

Running this sample on Android 5.0+ gives us a split “action bar” implemented as a `Toolbar`:

*Figure 484: Split “Action Bar”, Via a Toolbar, on Android 5.1*

One significant visual difference is the horizontal placement of the action items. In a true split action bar, they are evenly spaced across the bar. In a Toolbar, they are flush right (or, more accurately, flush “end”, to handle right-to-left languages). There is nothing built into Toolbar to spread the items out. While there are [hacks to make this happen](#), they rely on internal implementation of Toolbar and may prove unreliable over time.

## Use Case #2: Replacement Action Bar

Another thing that you can do with a Toolbar is make it serve as your action bar. The net effect is that you can position your activity’s action bar wherever you like, rather than have it be anchored at the top of the screen. Also, you can control the Toolbar more than you can the original action bar, for things like animations. For example, if you have seen apps where the action bar slides out of the way while you are scrolling down a list, only to return when you scroll back up the list, that could be accomplished via a Toolbar as your action bar.

The basic mechanics of making a Toolbar serve as the action bar are not especially difficult. Primarily, you need to inherit from `Theme.Material.NoActionBar` (to suppress the regular action bar) and call `setActionBar()` to attach your Toolbar to the activity to serve as the activity’s action bar. As with all Toolbar-specific code, this will only work on API Level 21+, though the `appcompat-v7` backport offers similar capabilities.

The [Toolbar/SplitActionBar2](#) sample project is a clone of the `SplitActionBar` project from earlier in this chapter, except that the Toolbar is set up to serve as the activity’s action bar.

Our activity’s theme (`Theme.Apptheme`) now inherits from `Theme.Material.NoActionBar`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="android:Theme.Material.NoActionBar">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
  <style name="SplitActionBar">
    <item name="android:background">@color/primary</item>
  </style>
</resources>
```

## TOOLBAR

---

(from [Toolbar/SplitActionBar2/app/src/main/res/values-v21/styles.xml](#))

The `build.gradle` file sets the `minSdkVersion` to 21, so we dispense with the backwards-compatibility checks. So, in `onCreate()`, rather than conditionally using `main.xml` as our layout, we always use it, followed by a call to `setSupportActionBar()`:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setContentView(R.layout.main);
    setSupportActionBar((Toolbar) findViewById(R.id.toolbar));

    initAdapter();
}
```

(from [Toolbar/SplitActionBar2/app/src/main/java/com/commonsware/android/toolbar/sab2/ActionBarDemoActivity.java](#))

Our `onCreateOptionsMenu()` can also dispense with the conditional check to see if we are on API Level 21+. However, since we are using the `Toolbar` as our action bar, we can simply populate the action bar normally, and it will affect the `Toolbar`:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);

    return(super.onCreateOptionsMenu(menu));
}
```

(from [Toolbar/SplitActionBar2/app/src/main/java/com/commonsware/android/toolbar/sab2/ActionBarDemoActivity.java](#))

## TOOLBAR

---

The result is that we have a regular action bar, with its normal contents (e.g., title), but positioned where we put the Toolbar, at the bottom of the screen, where it used to serve as the bottom half of the split action bar:

*Figure 485: Toolbar as Action Bar on Android 5.1*

# AppCompat: The Official Action Bar Backport

---

Approximately 30 months after Google added the action bar to Android 3.0, Google released a backport for previous devices. Referred to here as AppCompat or, `appcompat-v7` (after its library name), this adds action bar support to Android apps, going all the way back to API Level 7.

The `appcompat-v7` Android Support Package artifact houses AppCompat. Version 21 and higher of this artifact change the way that AppCompat looks, to try to not only backport the action bar, but to backport a bit of the Material Design aesthetic.

This chapter will outline why you might want to use AppCompat and how to employ it in your Android applications.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

## Ummmm... Why?

You might wonder why we would bother with any of it. AppCompat is not required, and apps can work fine without it. And, in truth, most apps will be just fine using the native action bar implementation.

That being said, you may find some pressures nudging you towards using an action bar backport, and AppCompat specifically.

### Why an Action Bar Backport?

If your `minSdkVersion` is 11 or higher, you have an action bar on all Android versions that your app supports.

If, however, your `minSdkVersion` is below 11, by default you will get the old-style options menu on Android 1.x/2.x devices. That is not a crime. However, the action bar design pattern had been used in various Android apps prior to Android 3.0's formalization of the pattern. Many apps that users will see on older devices will have an action bar, courtesy of one of the backports. By adopting a backport, you will gain a measure of consistency in your UX across Android versions that you would otherwise miss by falling back to the options menu.

You might also adopt a backport because something else is steering you to use AppCompat, and therefore you elect to use it for those reasons.

### Why AppCompat?

AppCompat is a somewhat controversial library nowadays. It did not start that way when it was released in the Summer of 2013. But Google has been rather aggressive about trying to get developers to use AppCompat, and that aggressiveness has had its downsides.

#### Supported

The #1 reason for using AppCompat is because you decided, for other reasons, that you wanted an action bar backport, and AppCompat right now is the primary supported option.

The original backport, `ActionBarSherlock`, was officially deprecated by its author (Jake Wharton), who is steering you towards the native action bar or AppCompat as alternatives. While this does not prevent you from using `ActionBarSherlock`, it is probably not a great choice today given that Google is supporting AppCompat.

#### Materialistic

The current version of AppCompat does not only give you an action bar. It gives you an action bar that looks like the one that you get from `Theme.Material`. It also will attempt to apply your accent color to select widgets, the way Android 5.0 and `Theme.Material` do, to make your app abide a bit more by the Material Design

aesthetic.

[Whether or not this is a good thing is up to you.](#)

### Consistent

One hidden advantage of using AppCompat, particularly in concert with the fragments backport, is consistency across Android versions. By using the native action bar and fragments, you are at some risk of inconsistent behavior based upon:

- Android OS version, due to bug fixes, deprecations, and the like
- Manufacturer or ROM modder tweaks to the native implementations, which you do not control

Having your action bar and fragments be in a library in your app isolates you from those changes. AppCompat always uses its own implementation, so any changes in the native implementation will not affect your app.

This comes at a cost of additional complexity and APK size.

### Forced

Some things in the Android development ecosystem, like official support for the `MediaRouteActionProvider`, only work with the AppCompat action bar, as Google has either not shipped or has deprecated their native alternatives.

You may find some “cross-ports” of those things that work with the native action bar, but those are unlikely to be as well-supported as Google’s own editions.

Also, new projects created via Android Studio basically shove `appcompat-v7` down your throat. This is why this book’s tutorials have you start by importing an existing project, so you do not have to rip `appcompat-v7` and its references out by the roots to start a new project.

While it is theoretically possible that Google itself will eventually offer native action bar implementations of those things, it is unlikely. Hence, if you determine that you need one of those, you may be more inclined to use AppCompat, even if you do not need it for any other reason.

## The Basics of Using AppCompatActivity

The recipe for using the AppCompatActivity action bar requires no new skills beyond what you have learned so far in this book. However, there are some subtle and not-so-subtle differences in the approaches AppCompatActivity takes when compared to the native action bar.

To see the basic differences, we will take a look at the [AppCompatActivity/ActionBar](#) sample project. This is a port of the `fragments-and-action-bar` sample from [earlier in the book](#), where we have replaced the native action bar with AppCompatActivity.

### The Library Project

AppCompatActivity is provided by the `appcompat-v7` Android library project, part of the Android Support Package. Just add the implementation `'com.android.support:appcompat-v7:...'` line to your dependencies closure, replacing `...` with a suitable version number of the library. That will take care of downloading the library and adding it to your project.

To get the material effects described in this chapter, you will want to use version 21 or higher of `appcompat-v7` (e.g., `com.android.support:appcompat-v7:22.2.0`). And, due to a particular name change that we will examine shortly, using version 22 or higher is probably a good idea.

But, more importantly, you *really* want version 23 or higher. There are [changes to ART](#) – the Android runtime used on Android 5.0+ — that apparently will break the older versions of `appcompat-v7` when running on Android 6.0+ devices.

### Your Build Settings

If you are using version 22 or higher of AppCompatActivity, your build target must be API Level 22 or higher. Basically, for the Android Support libraries, your `compileSdkVersion` should match the major version of the library.

In Android Studio and the Android Gradle Plugin, this would be the `compileSdkVersion` found in your `build.gradle` file. In Eclipse, this would be the API level chosen in `Project > Properties > Android`.

### Your Theme

Rather than using `Theme.Holo` or `Theme.Material`, when using `AppCompatActivity` you will use `Theme.AppCompat`, whether you use that theme directly or create your own custom theme inheriting from it. There is also `Theme.AppCompat.Light` and `Theme.AppCompat.Light.DarkActionBar`, mirroring their native counterparts.

```
<application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.AppCompat">
```

(from [AppCompatActivity/ActionBar/app/src/main/AndroidManifest.xml](#))

### Your Menu Resources

Where things start to get a bit strange with `AppCompatActivity` comes with our menu resources. `AppCompatActivity` forces you to use a *different namespace* for any action bar-related attributes, those added in API Level 11 or higher.

So, we started with:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/add"
        android:icon="@drawable/ic_action_new"
        android:showAsAction="always"
        android:title="@string/add"/>
    <item
        android:id="@+id/reset"
        android:icon="@drawable/ic_action_refresh"
        android:showAsAction="always|withText"
        android:title="@string/reset"/>

</menu>
```

(from [Fragments/ActionBarNative/app/src/main/res/menu/actions.xml](#))

and we had to change it to:

```
<?xml version="1.0" encoding="utf-8"?>
<menu
```

```
xmlns:android="http://schemas.android.com/apk/res/android"
xmlns:app="http://schemas.android.com/apk/res-auto">

<item
    android:id="@+id/add"
    android:icon="@drawable/ic_action_new"
    app:showAsAction="always"
    android:title="@string/add"/>
<item
    android:id="@+id/reset"
    android:icon="@drawable/ic_action_refresh"
    app:showAsAction="always|withText"
    android:title="@string/reset"/>
<item
    android:id="@+id/about"
    android:icon="@drawable/ic_action_about"
    app:showAsAction="never"
    android:title="@string/about">
</item>
</menu>
```

(from [AppCompatActivity/src/main/res/menu/actions.xml](#))

Note that we have a new `xmlns:app="http://schemas.android.com/apk/res-auto"` namespace declaration in the root `<menu>` element, and that namespace is used for the `app:showAsAction` attribute. The actual prefix name, here shown as `app`, can be whatever you want. It just has to be unique within the document and a valid XML namespace prefix (e.g., no whitespace).

## Your Activity and Fragments

We have to inherit from an `AppCompatActivity` class to use `AppCompatActivity`. `AppCompatActivity` itself inherits from `FragmentActivity`, and so we can use the Android Support Package's backport of fragments without issue, so you have access to backported versions of `Fragment`, `ListFragment`, etc.

**NOTE:** Prior to version 22 of `appcompat-v7`, you would inherit from an `ActionBarActivity` class. That class is still available for backwards compatibility, but you are recommended to inherit from `AppCompatActivity` instead.

However, note that there are no other analogues of `AppCompatActivity` for other scenarios, such as `ListActivity`. In principle, you should be able to make your own mash-ups of `AppCompatActivity` and other base activity classes, though the proof of

this is left as an exercise for the reader. The sample app just uses AppCompatActivity directly for showing a ListView:

```
package com.commonware.android.inflation;

import android.os.Bundle;
import android.support.v7.app.AppCompatActivity;
import android.view.Menu;
import android.view.MenuItem;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.ArrayAdapter;
import android.widget.Toast;
import java.util.ArrayList;

public class ActionBarDemoActivity extends AppCompatActivity {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
    private ArrayList<String> words=null;
    private ArrayAdapter<String> adapter=null;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        setContentView(R.layout.list_content_simple);
        initAdapter();
    }

    @Override
    public boolean onCreateOptionsMenu(Menu menu) {
        getMenuInflater().inflate(R.menu.actions, menu);

        return(super.onCreateOptionsMenu(menu));
    }

    @Override
    public boolean onOptionsItemSelected(MenuItem item) {
        switch(item.getItemId()) {
            case R.id.add:
                addWord();

                return(true);
        }
    }
}
```

```
        case R.id.reset:
            initAdapter();

            return(true);

        case R.id.about:
            Toast.makeText(this, R.string.about_toast, Toast.LENGTH_LONG)
                .show();

            return(true);
    }

    return(super.onOptionsItemSelected(item));
}

private void initAdapter() {
    words=new ArrayList<String>();

    for (int i=0;i<5;i++) {
        words.add(items[i]);
    }

    adapter=
        new ArrayAdapter<String>(this,
                                android.R.layout.simple_list_item_1,
                                words);

    setListAdapter(adapter);
}

private void addWord() {
    if (adapter.getCount()<items.length) {
        adapter.add(items[adapter.getCount()]);
    }
}

private void setListAdapter(ListAdapter la) {
    ((ListView)findViewById(android.R.id.list)).setAdapter(la);
}
}
```

(from [AppCompat/ActionBar/app/src/main/java/com/commonsware/android/inflation/ActionBarDemoActivity.java](https://github.com/android/appcompat-v7/blob/master/android-support-v7-appcompat/src/main/java/com/commonsware/android/inflation/ActionBarDemoActivity.java))

The layout, `res/layout/list_content_simple.xml`, is cloned from the one used by `ListActivity` itself:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
```

## APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

/>
```

(from [AppCompat/ActionBar/app/src/main/res/layout/list\\_content\\_simple.xml](#))

### Your Callback Methods

In many cases, your `onCreateOptionsMenu()` and `onOptionsItemSelected()` methods will be the same for AppCompat as they would be for a regular Android app.

However, if you do need to manipulate action bar-specific attributes of your inflated menu resources, you will be unable to do so directly. The workaround is to use `MenuCompat` and `MenuItemCompat`, from the Android Support package, to give you access to newer `Menu` and `MenuItem` features in a backwards-compatible fashion.

## Your Results

Visually, the results are very similar to what we get from `Theme.Material`, whether we run on Android 5.0 itself:

*Figure 486: AppCompatActivity, on Android 5.0 Emulator*

...or on something older, like an Android 4.1 emulator:

*Figure 487: AppCompatActivity, on Android 4.1 Emulator*

## Other AppCompatActivity Effects

While the above recipe will give you the basics, you can go a lot further with AppCompatActivity, just as you can with the native action bar. Generally speaking, AppCompatActivity's backport includes all of the capabilities of the native action bar.

The biggest key is that when working with AppCompatActivity, if you need to access your ActionBar instance, call `getSupportActionBar()`, not `getActionBar()`. The latter will compile, but it will return `null` at runtime, as you are disabling the native action bar and using AppCompatActivity's instead.

## Tinting

The same basic tinting rules that apply for `Theme.Material` apply for `Theme.AppCompat` and AppCompatActivity, with two noteworthy differences.

First, the theme attributes do not have the `android` prefix, but instead are just the

bare names (e.g., `colorPrimary`). So, in the [AppCompat/ActionBarColor](#) sample project, the style resource becomes:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="Theme.AppCompat">
    <item name="colorPrimary">@color/primary</item>
    <item name="colorPrimaryDark">@color/primary_dark</item>
    <item name="colorAccent">@color/accent</item>
  </style>
</resources>
```

(from [AppCompat/ActionBarColor/app/src/main/res/values/styles.xml](#))

Second, not all widgets will have their colors affected by the theme. As of version 22 of `appcompat-v7`, the roster is limited to:

- `AutoCompleteTextView`
- `Button`
- `CheckBox`
- `CheckedTextView`
- `EditText`
- `MultiAutoCompleteTextView`
- `RadioButton`
- `RatingBar`
- `Spinner`
- `TextView`

Also, `Switch` adopts the colors, if you use the `SwitchCompat` backport discussed in the next section.

In the [AppCompat/Basic](#) directory you will find projects mirroring those from the `BasicMaterial` directory. In `BasicMaterial`, we saw how widgets were tinted based on a `Theme.Material`-based theme; in `AppCompat/Basic`, you will see how widgets are tinted based upon a `Theme.AppCompat`-based theme.

## Switch Backport

As mentioned above, there is an official backport of the Switch widget, known as `SwitchCompat`, added to the `appcompat-v7` library. This works back to API Level 7, as does everything in `appcompat-v7`. And, for better or worse, it provides a backport of the Material Design implementation of a Switch. So, rather than the `Theme.Holo.ON/OFF` toggle, we get the unlabeled “looks like a really tiny `SeekBar`” widget:

*Figure 488: SwitchCompat, on an Android 4.3 Emulator*

The above screenshot comes from the [AppCompat/Basic/Switch](#) sample project, which uses a layout specifying the `SwitchCompat` widget:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.SwitchCompat
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/toggle"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content" />
```

(from [AppCompat/Basic/Switch/app/src/main/res/layout/main.xml](#))

Also note that `SwitchCompat` only works inside an `AppCompatActivity`. It is not a

general backport of Switch that can be used in any activity.

### Overlay

AppCompat supports the same basic sort of [floating action bar](#) that is supported by the native action bar implementation. There are two slight changes in the recipe:

- Use `supportRequestWindowFeature()`, rather than `requestWindowFeature()`, to request `Window.FEATURE_ACTION_BAR_OVERLAY`
- Use `getSupportActionBar()`, rather than `getActionBar()`, to set the background

This is illustrated in `onCreate()` of the `ActionBarDemoActivity` version found in the [AppCompat/Overlay](#) sample project:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    supportRequestWindowFeature(Window.FEATURE_ACTION_BAR_OVERLAY);

    setContentView(R.layout.list_content_simple);

    initAdapter();

    Drawable d=
        getResources().getDrawable(R.drawable.action_bar_background);

    getSupportActionBar().setBackgroundDrawable(d);
    getSupportActionBar().setSplitBackgroundDrawable(d);
}
```

(from [AppCompat/Overlay/app/src/main/java/com/commonsware/android/actionbaroverlay/ActionBarDemoActivity.java](#))

And, you get the same basic results as with the native action bar:

*Figure 489: AppCompatActivity with FEATURE\_ACTION\_BAR\_OVERLAY on an Android 4.3 Emulator*

## SearchView

AppCompatActivity has its own implementation of SearchView, as `android.support.v7.widget.SearchView`. To use it, switch to that class in your menu resource, then use `MenuItemCompat.getActionView()` to retrieve the instance after your menu resource has been inflated.

For example, the [AppCompatActivity/SearchView](#) sample project uses the AppCompatActivity implementation of SearchView in its `res/menu/actions.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<menu
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto">

  <item
    android:id="@+id/search"
    app:actionViewClass="android.support.v7.widget.SearchView"
```

## APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

---

```
    android:icon="@drawable/ic_action_search"
    app:showAsAction="ifRoom|collapseActionView"
    android:title="@string/filter">
</item>
</menu>
```

(from [AppCompat/SearchView/app/src/main/res/menu/actions.xml](#))

Then, in `onCreateOptionsMenu()`, `ActionBarFragment` calls out to a private `configureSearchView()` method that retrieves the `SearchView` and sets it up, much as you saw with the native implementation of `SearchView` from [earlier in this book](#):

```
private void configureSearchView(Menu menu) {
    MenuItem search=menu.findItem(R.id.search);

    sv=(SearchView)MenuItemCompat.getActionView(search);
    sv.setOnQueryTextListener(this);
    sv.setOnCloseListener(this);
    sv.setSubmitButtonEnabled(false);
    sv.setIconifiedByDefault(true);

    if (initialQuery != null) {
        sv.setIconified(false);
        search.expandActionView();
        sv.setQuery(initialQuery, true);
    }
}
```

(from [AppCompat/SearchView/app/src/main/java/com/commonsware/android/ab/search/ActionBarFragment.java](#))

The resulting `SearchView` is tied into `AppBar` and offers a Material Design-esque look, applying your tints when opened:

*Figure 490: AppCompatActivity with SearchView on an Android 4.3 Emulator*

## ShareActionProvider

Similarly, `AppCompatActivity` has its own implementation of `ShareActionProvider`, as `android.support.v7.widget.ShareActionProvider`. The recipe for using it resembles that of using `SearchView`:

- Refer to the `AppCompatActivity` edition of the class in your menu resource
- Use `MenuItemCompat.getActionProvider()` to retrieve your `ShareActionProvider` instance after inflating the menu resource, to configure and use it

The [AppCompatActivity/Share](#) sample project is a clone of the `ShareActionProvider` project described [elsewhere in the book](#), converted to use `AppCompatActivity` and its edition of `ShareActionProvider`.

## Toolbar and AppCompatActivity

AppCompatActivity has its own backport of [the Toolbar widget](#). By and large, you use it in much the same way as you use the native Toolbar. On the plus side, the backported Toolbar works back to API Level 7, allowing you to take advantage of this on much older devices. However, it requires you to be using AppCompatActivity — you cannot use the backported Toolbar with a regular activity.

The [Toolbar/SupportActionBarCompat](#) sample project is a clone of the Toolbar/SupportActionBar sample. That sample uses the native Toolbar to replicate [the “split action bar” pattern](#), where there is a second “action bar” at the bottom of the screen, for actions that would not fit in the regular action bar. This clone uses the AppCompatActivity backport of Toolbar, and that requires some changes.

First, we now depend upon `appcompat-v7` in the `app/` module’s `build.gradle` file:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.android.support:appcompat-v7:22.2.1'
}

android {
    compileSdkVersion 22
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 14
        targetSdkVersion 22
    }
}
```

(from [Toolbar/SupportActionBarCompat/app/build.gradle](#))

Our styles and themes change to use `Theme.AppCompat` as a base:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

    <style name="Theme.Apptheme" parent="Theme.AppCompat">
        <item name="colorPrimary">@color/primary</item>
        <item name="colorPrimaryDark">@color/primary_dark</item>
        <item name="colorAccent">@color/accent</item>
    </style>
```

```
<style name="SplitActionBar">
  <item name="background">@color/primary</item>
</style>
</resources>
```

(from [Toolbar/SplitActionBarCompat/app/src/main/res/values/styles.xml](#))

Note that the `SplitActionBar` style, like `Theme.AppTheme`, drops the `android:` from the name attributes. That is because our `Toolbar` now comes from a library, and so we are no longer using system-defined attributes, but rather library-defined attributes.

The layout resource simply fully-qualifies the class name for the `Toolbar` widget to refer to the one from `AppCompatActivity`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <ListView
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="1"/>

  <android.support.v7.widget.Toolbar
    android:id="@+id/toolbar"
    style="@style/SplitActionBar"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"/>

</LinearLayout>
```

(from [Toolbar/SplitActionBarCompat/app/src/main/res/layout/main.xml](#))

`ActionBarDemoActivity` now needs to inherit from `AppCompatActivity`, rather than `ListActivity`. That means we no longer have any scenario in which we will get a `ListView` “for free” — we always have to inflate our layout resource:

```
@Override
public void onCreate(Bundle state) {
  super.onCreate(state);
```

## APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

---

```
setContentView(R.layout.main);
initAdapter();
}
```

(from [Toolbar/SplitActionBarCompat/app/src/main/java/com/commonsware/android/toolbar/sabc/ActionBarDemoActivity.java](#))

This also means we need our own `setListAdapter()` method, since we are no longer inheriting one:

```
private void setListAdapter(ListAdapter adapter) {
    ListView lv=(ListView)findViewById(android.R.id.list);

    lv.setAdapter(adapter);
}
```

(from [Toolbar/SplitActionBarCompat/app/src/main/java/com/commonsware/android/toolbar/sabc/ActionBarDemoActivity.java](#))

The only other change is to the `Toolbar` import statement, to pull in the backport:

```
import android.support.v7.widget.Toolbar;
```

(from [Toolbar/SplitActionBarCompat/app/src/main/java/com/commonsware/android/toolbar/sabc/ActionBarDemoActivity.java](#))

The result is visually very similar to what we would have had on Android 5.0+, but it works back to API Level 7:

*Figure 491: AppCompat Toolbar Backport, as a Split Action Bar*

## To Material, or Not to Material

(the following is adapted from [one of the author's blog posts](#))

There has been a lot of discussion regarding the adoption of Material Design aesthetics in Android apps. Newcomers to Android might conclude that Material Design must be The Most Important Thing in Android Development and therefore should be pursued immediately at all costs.

[Not everybody shares this opinion](#)

With that in mind, here are the author's recommendations on what to consider with Material Design:

**DO** start considering the effects of Material Design upon your Android app. Theme.Material is the dominant theme on Android 5.0 devices, and it should

remain the dominant theme on future Android versions, at least for a while. There will be hundreds of millions of these devices in use, eventually, and you will want your app to look like “it belongs” on those devices. On those devices, not only will Google’s apps be employing `Theme.Material`, but manufacturer-supplied apps should do so as well. While not everything on the device may necessarily adopt this theme, more than enough will that your app may stand out somewhat if your app does not and the user thinks that it should.

**DON’T** blindly assume that you should be using a Material-ish look on all versions of Android. Your objective should be having an app that looks like it belongs on the device. Material-themed apps are highly unlikely to achieve majority status, let alone dominance, on pre-Android 5.0 releases. After all, device manufacturers are not going to be shipping Material-themed updates to built-in apps *en masse*, and there are plenty of apps out there that are still using pre-Holo themes. This is all on top of app that have no identifiable Android theme (e.g., most games). Certainly, there will be Material-themed apps running on Android 4.x devices, courtesy of Google and some other developers. But there will be enough Holo-themed apps that your app will not look out of place on Android 4.x any time soon, if ever. Hence, you have your choice of adopting Material Design across the board or not — user pressure is unlikely to be a major criterion any time soon.

**DON’T** fall victim to the “our app must look the same across all devices” mindset. Again, your app should look like it belongs on the device, which is why trying to ape an iOS look-and-feel on Android is rarely a good move. Most people do not have two Android devices, and only a small subset of those will have an Android 5.x device and an Android 4.x (or older) device. Hence, most of the people who will care about your app appearing identical on those devices will be in your meeting room discussing the issue. Few of your users will notice — they want an app that works, does what the user wants, and looks like it belongs on their device.

**DO** consider whether adopting Material Design across the board may offer *engineering* benefits. For example, if you have been heavily customizing widget colors in a Holo-based theme, the tinting options provided by `appcompat-v7` may simplify your app a fair bit, reducing APK size, maintenance costs after the Material conversion, etc. Since your users are unlikely to be terribly concerned one way or the other, engineering considerations may help to “tip the scales” in one direction or another.

**DON’T** blindly assume that `appcompat-v7` will result in a simpler app, or that it should be the basis for all new apps. `appcompat-v7` has had a history of bugs. Not all of those bugs are Google’s fault (e.g., the Samsung device issue was really caused by

a screwy decision on Samsung's part), but that comes as cold comfort to developers trying to distribute `appcompat-v7` apps. And, if you are comfortable with using themes based on `Theme.Holo` for pre-Android 5.0 devices, `appcompat-v7` may be much more of an impediment than an advance. `appcompat-v7` is a tool, not a religion — use it where it clearly adds value *to you and your app*.

**DO** start planning for Google's next major theme overhaul. Google, of course, is portraying Material Design as being The One True UI Design. Google will probably get irritated when people point out that `Theme.Material` is the third major theme in the six-year production history of Android, and so assuming that `Theme.Material` is “the be-all and end-all” of themes is unrealistic. Whether the next-generation theme is a refinement on Material Design or a larger overhaul remains to be seen. But you should be taking into account that we may well wind up going through this same process in, say, early 2018. The more you can isolate the theme-related changes from the rest of your app, the more likely it is that you will be able to accommodate future theme changes with less work.

# The Android Design Support Library

In 2014, to much fanfare, Google released their first edition of [the Material Design guidelines](#).

What was missing was an actual implementation of most of these guidelines.

Beyond the obvious question of “how do you know that it will work well if you have not tried it?”, it put Android developers in the unenviable position of being pressured to make their apps “look more material” without having anything really to do that.

In the months that followed Google I/O 2014, various developers took this implementation gap as a challenge and created their own implementations of many bits of Material Design. Much of this was released in the form of open source components, easily added to an app via dependencies added to a project’s `build.gradle` file (at least, for Android Studio developers and other Gradle users).

In 2015, to a bit less fanfare, Google [released](#) the Android Design Support Library. The vision is that this would be the official implementation of many Material Design core components, like floating action buttons (FABs), snackbars, and the like.

This chapter explores some components from the Android Design Support Library. This chapter also explores some independent implementations of the same components, particularly ones that seem to be superior to what Google is offering at present.

## Prerequisites

Understanding this chapter requires that you have read the core chapters,

particularly [the one on the action bar](#). You also should read the chapter on [the appcompat-v7 action bar backport](#).

Note that the examples in this chapter are clones of a couple from the core chapters. This chapter's prose was written assuming that you were familiar with those samples, so you may need to go back and review them as needed.

One of the book samples makes use of [the animator framework](#).

## GUIs and the Support Package

Many developers think that the libraries in the Android Support Package are purely backports. They then get confused when they realize that certain classes, like `ViewPager`, are not part of the core Android framework for any API level and exist only in the Android Support Package.

In truth, a lot of what is in the Android Support Package consists of backports: fragments, the action bar, `NotificationCompat`, and so on. However, the Android Support Package really consists of code that Google wants to make available to developers that can be used right away, even on older devices.

Many pieces of the Android Support Package are GUI-related, yet are not backports:

- `support-v4` and `support-v13` have the aforementioned `ViewPager`
- `cardview-v7` has `CardView`
- `recyclerview-v7` has `RecyclerView`
- `leanback-v17` has classes for “the ten-foot UI” approach used for Android apps appearing on televisions, such as via Android TV boxes

Now, we can add the Android Design Support Library to that list. Right now, this library is focused on Material Design components, and that is likely to remain its near-term focus. It remains to be seen if other GUI components, not specifically tied to Material Design, wind up in the Android Design Support Library, in `support-v4/support-v13`, or in other libraries.

## Adding the Library... and What Comes With It

On the surface, Android Studio users can simply add `com.android.support:design:...` (for some version number for ..., such as `25.1.1`) as a dependency:

```
implementation 'com.android.support:design:25.1.1'
```

However, this library has a transitive dependency that pulls in `appcompat-v7`. Most pieces of the Android Design Support Library do indeed seem to require that you use `appcompat-v7`, using `Theme.AppCompat`, `AppCompatActivity`, and friends. This is true even if you planned on using `Theme.Material` itself, with a `minSdkVersion` of 21 or higher.

There are two ways to work around this `appcompat-v7` requirement:

- Use a third-party implementation of the same GUI element
- Use CWAC-CrossPort, described in the next section

## Introducing CWAC-CrossPort

[CWAC-CrossPort](#) is a library, published by the author of this book, that contains a subset of the GUI elements from the Design Support library. All references to `appcompat-v7` have been removed, replaced with equivalents from `Theme.Material`. As such, you can use CWAC-CrossPort on apps with a `minSdkVersion` of 21 or higher, to get the Material Design elements from the Design Support library, but without the `appcompat-v7` baggage.

CWAC-CrossPort does not include *everything* from the Design Support library, but it does include most of it.

As with the rest of the CWAC libraries, using it requires that you add the CWAC artifact repository to your Gradle configuration:

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}
```

Then, add a dependency on the artifact itself, for some version:

```
dependencies {
    implementation 'com.commonsware.cwac:crossport:0.3.0'
}
```

## Snackbars: Sweeter than Toasts

The Toast has been in Android since the beginning. It allows you to pop up a message to show the user, one that does not interfere with the rest of your activity layout. And, it is fairly easy to use.

However, some people get burned by Toast:

- A Toast is modeless, so you cannot get user input via a Toast
- Because a Toast is modeless, it is time-limited, and therefore the user might never see your message, because the user is not glancing at the screen during the short window your Toast is visible
- A Toast is a separate window from the window that is displaying your activity, so your Toast will remain visible even if the user navigates to some other activity, which can be annoying at times

The Material Design guidelines instead call for the use of a “snackbar”, and the Design Support Library offers a Snackbar implementation of this UI pattern. In contrast to a Toast:

- A Snackbar is part of your activity’s UI, and so it can collect input from the user, while it is around, usually in the form of some sort of “action”
- A Snackbar can be time-limited (for information notices) or durable (for errors or getting user input)
- While a Snackbar is part of your activity (and will go away when the user leaves your activity), you do not have to declare it in your layout files

With that in mind, let’s take a look at some use cases for a Snackbar and how they can be implemented.

### Alerts

The quintessential reason to use a Toast was to display a simple message to the user. You can use a Snackbar in the same role, with most of the same code.

Snackbar has a static `make()` method, mirroring the `makeText()` method on Toast. `make()` takes three parameters, only slightly different from those on `makeText()`:

1. A View in the activity that wishes to show the Snackbar
2. The message, in the form of a `CharSequence` (e.g., a `String`) or a string

resource ID

3. The duration of the Snackbar, which is either `Snackbar.LENGTH_SHORT`, `Snackbar.LENGTH_LONG`, or possibly something else (the documentation is inconsistent on this point)

As with `makeText()` on `Toast`, simply calling `make()` on `Snackbar` creates a `Snackbar` object for you, but does not display anything. You need to call `show()` on the `Snackbar` instance to get it to appear.

The [DesignSupport/Snackbar](#) sample project is a clone of the `Threads/AsyncDemo` sample from earlier in the book. The app shows a list of 25 Latin words, progressively added to the list via an `AsyncTask`. When the list is fully populated, the original sample would display a `Toast`, from `onPostExecute()` of the `AsyncTask`.

The revised sample substitutes a `Snackbar`:

```
@Override
protected void onPostExecute(Void unused) {
    Snackbar.make(getListView(), R.string.done,
        Snackbar.LENGTH_LONG).show();

    task=null;
}
```

(from [DesignSupport/Snackbar/app/src/main/java/com/commonsware/android/snackbar/async/AsyncDemoFragment.java](#))

The Snackbar will be centered along the bottom:

*Figure 492: Official Snackbar*

Unfortunately, there does not seem to be much support for styling the look of the Snackbar. To do this manually, you can obtain the actual View for the Snackbar via `getView()`. While you should make few assumptions about what this View actually is, you should be able to call setters on that View to change things like background colors.

Also note that the user can get rid of a Snackbar via a swipe gesture, in addition to allowing the Snackbar to time out on its own. This is not possible with Toast, as a Toast is modeless.

### **Action Bars. No, Not Those Action Bars.**

We can expand upon the user interaction with a Snackbar by adding an action to it. To do this, just call `setAction()` on the Snackbar after creating it, passing in the display string for the action (what the user will see on the Snackbar) and a `View.OnClickListener` that will get control when the user taps on that action. The look and feel of the action is up to the Snackbar implementation.

---

## THE ANDROID DESIGN SUPPORT LIBRARY

---

The [DesignSupport/SnackbarAction](#) sample project is a clone of the previous sample, adding one of these actions. Specifically, once the list is loaded, we want a “Restart” action to clear the list and load it again. Perhaps the user found loading the list to be exciting and wishes to see it happen all over again.

To that end, we should pull out the work of loading our list into a `loadModel()` method that can be used from multiple places:

```
private void loadModel() {
    task=new AddStringTask();
    task.execute();
}
```

(from [DesignSupport/SnackbarAction/app/src/main/java/com/commonsware/android/snackbar/action/AsyncDemoFragment.java](#))

The `onCreate()` method now delegates to `loadModel()`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    adapter=
        new ArrayAdapter<String>(getActivity(),
            android.R.layout.simple_list_item_1,
            model);

    loadModel();
}
```

(from [DesignSupport/SnackbarAction/app/src/main/java/com/commonsware/android/snackbar/action/AsyncDemoFragment.java](#))

And, more importantly for this section, we also call `loadModel()` from the `View.OnClickListener` of the action that we add to our Snackbar:

```
@Override
protected void onPostExecute(Void unused) {
    Snackbar munchie=Snackbar.make(getListView(), R.string.done,
        Snackbar.LENGTH_LONG);

    munchie.setAction(R.string.snackbar_action_restart,
        new View.OnClickListener() {
            @Override
            public void onClick(View view) {
                adapter.clear();
            }
        });
}
```

```
        loadModel();
    }
});

munchie.show();

task=null;
}
```

(from [DesignSupport/SnackbarAction/app/src/main/java/com/commonsware/android/snackbar/action/AsyncDemoFragment.java](#))

The action will appear on the Snackbar itself:

*Figure 493: Official Snackbar, with an Action*

Tapping the action triggers the listener, which in our case clears the list and starts the load all over again.

### CWAC-CrossPort

CWAC-CrossPort supports Snackbar, with all the same features as are in the original Design Support implementation. The [DesignSupport/SnackbarActionCP](#) sample project is a clone of the previous sample, where we have migrated to CWAC-CrossPort.

## THE ANDROID DESIGN SUPPORT LIBRARY

---

Our app/build.gradle file not only adds the CWAC-CrossPort dependency, but it sets the minSdkVersion to 21:

```
apply plugin: 'com.android.application'

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    implementation 'com.android.support:support-fragment:27.1.1'
    implementation 'com.commonsware.cwac:crossport:0.3.0'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 21
        targetSdkVersion 27
        applicationId 'com.commonsware.android.snackbar.action.crossport'
    }
}
```

(from [DesignSupport/SnackbarActionCP/app/build.gradle](#))

Removing appcompat-v7 has rippling effects across the rest of the code:

- We switch to inheriting from Theme.Material.Light.DarkActionBar in Theme.Apptheme, replacing the former Theme.AppCompat theme
- We change the theme colors to use the android: prefix (e.g., android:colorPrimary), instead of the bare names used by appcompat-v7
- Our activity now just inherits from Activity, instead of AppCompatActivity
- Our fragment now just inherits from android.app.Fragment, instead of android.support.v4.app.Fragment
- Our Snackbar import is now for com.commonsware.cwac.crossport.design.widget.Snackbar

Otherwise, the code is identical, and we get identical results, though with an inverse theme and adjusted title bar, to help distinguish the original from the CWAC-CrossPort edition:

*Figure 494: CWAC-CrossPort Snackbar*

## Absolutely FABulous

Perhaps no single element of the Material Design aesthetic has gotten more attention than has the floating action button, or FAB. These are round buttons, usually floating towards the bottom of the screen over top of the main UI:

Figure 495: Google Maps, with a Pair of FABs, on a Nexus 4

The job of the FAB is to provide rapid access to the primary action that users might take on that particular screen. Typically, in a master/detail sort of UI, the FAB will allow creating a new item for the collection:

- A voice recording app showing a list of previous recordings might have a FAB to make a new recording
- A blood pressure monitoring app showing a list of previous readings might have a FAB to take a new reading
- A to-do list app showing the current tasks might have a FAB to add a new task

However, the FAB does not have to be an “add” operation. The only real limitation is that it should be a screen-level operation, not affecting only some selected item on

that screen. So, for example, in the video recording app example, you would not use a FAB to play back one of the existing videos... at least on a screen listing those videos. If tapping a video in that list brings up some sort of detail screen, *that* screen could possibly have a FAB to play back the video.

The Design Support library has a rudimentary FAB implementation, and there are third-party alternatives that either add power or solve other FAB-related problems.

### FAB Mechanics

In many respects, setting up a FAB is not that different from setting up any other widget: put it in your layout, positioned where you want it, then access it in Java code to set up listeners. In particular, Google's FAB implementation supports a `View.OnClickListener` much like a regular `Button`.

The [DesignSupport/FAB](#) sample project is a clone of the first `Snackbar` sample from earlier in this chapter. The second `Snackbar` sample added a “restart” action to the `Snackbar`. In this sample, we instead have a “restart” action on a FAB.

Before, we did not need a layout resource for the `AsyncDemoFragment`, as it was an ordinary `ListFragment` and therefore would supply a `ListView` automatically. However, this time, we want to have a FAB as well, so we need our own layout file:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ListView
        android:id="@android:id/list"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:drawSelectorOnTop="false" />

    <android.support.design.widget.FloatingActionButton
        android:id="@+id/refresh"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_alignParentBottom="true"
        android:layout_alignParentEnd="true"
        android:layout_alignParentRight="true"
        android:layout_marginBottom="@dimen/fab_margin"
        android:layout_marginEnd="@dimen/fab_margin"
        android:layout_marginRight="@dimen/fab_margin"
    />
</RelativeLayout>
```

## THE ANDROID DESIGN SUPPORT LIBRARY

---

```
android:src="@drawable/ic_refresh_black_24dp" />
</RelativeLayout>
```

(from [DesignSupport/FAB/app/src/main/res/layout/main.xml](#))

Here, the FAB (a.k.a., `android.support.design.widget.FloatingActionButton`) is later in a `RelativeLayout` than is the `ListView`, so the FAB will have higher elevation and will appear to float over the `ListView`. The `android:src` attribute points to a drawable resource, much like how that attribute works on an `ImageButton`.

However, the interesting bit is the pair of margin attributes (`android:layout_marginRight` and `android:layout_marginBottom`). They point to a `fab_margin` dimension resource, one with some specific values required due to bugs (or curious implementation choices) in Google's FAB implementation.

By default, the `fab_margin` in `res/values/dimens.xml` is used, which has a dimension of `0dp`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="fab_margin">0dp</dimen>
</resources>
```

(from [DesignSupport/FAB/app/src/main/res/values/dimens.xml](#))

You might think that this would cause the FAB to be slammed up against the side and bottom of the `RelativeLayout`. However, the FAB has built-in margins... on older devices.

But, for whatever reason, on API Level 21+, that automatic margin vanishes. So, we have another definition of `fab_margin`, in `res/values-v21/dimens.xml`, setting it to `16dp`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="fab_margin">16dp</dimen>
</resources>
```

(from [DesignSupport/FAB/app/src/main/res/values-v21/dimens.xml](#))

Furthermore, Google's Material Design docs state that there should be `24dp` margin on tablets, not `16dp`. So, we have a *third* definition of `fab_margin`, in `res/values-sw720dp-v21`, to set the margin to `24dp`:

## THE ANDROID DESIGN SUPPORT LIBRARY

---

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="fab_margin">24dp</dimen>
</resources>
```

(from [DesignSupport/FAB/app/src/main/res/values-sw720dp-v21/dimens.xml](#))

It is possible that a full implementation of this would need a fourth `fab_margin` value, for Android 4.x tablets, where `fab_margin` would be set to something that gives a 24dp margin but takes into account the automatic margin that the FAB seems to have prior to API Level 21. This sample avoids this, going with the automatic margin on all tablets, regardless of API level.

The Java code is fairly straightforward, retrieving the FAB in `onViewCreated()` and hooking up a `View.OnClickListener` to the FAB, where that listener is the `AsyncDemoFragment` itself:

```
@Override
public void onViewCreated(View v, Bundle savedInstanceState) {
    super.onViewCreated(v, savedInstanceState);

    getListView().setScrollbarFadingEnabled(false);
    setListAdapter(adapter);

    FloatingActionButton fab=v.findViewById(R.id.refresh);

    fab.setOnClickListener(this);
}
```

(from [DesignSupport/FAB/app/src/main/java/com/commonsware/android/fab/async/AsyncDemoFragment.java](#))

In `onClick()`, if the `AsyncTask` is still running, we `cancel()` it. Then, we clear the list and kick off a fresh task via the same sort of `loadModel()` method as seen in the second `Snackbar` example:

```
@Override
public void onClick(View view) {
    if (task!=null) {
        task.cancel(false);
    }

    adapter.clear();
    loadModel();
}

void loadModel() {
```

```
task=new AddStringTask();
task.execute();
}
```

(from [DesignSupport/FAB/app/src/main/java/com/commonsware/android/fab/async/AsyncDemoFragment.java](#))

This gives us our FAB:

### Coordinating with Snackbars

However, what the above screenshots do *not* illustrate is what happens when our Snackbar appears:

*Figure 496: Official FAB, Conflicting with the Snackbar*

The fact that the Snackbar overlaps the FAB should not be much of a surprise. After all, the Snackbar overlaps the ListView as well. A Toast would also overlap the list and FAB. Hence, to some extent, the fact that there is this lack of coordination between the Snackbar and the FAB seems to be fairly normal.

That being said, the Design Support library has a container designed for coordinating between different children as those children animate and scroll. This container — CoordinatorLayout — is a subclass of FrameLayout, meaning other

than Z-axis ordering (elevation) and gravity, it has no other notable layout rules. It merely exists to perform this sort of coordination.

As it turns out, `CoordinatorLayout` has special awareness of `Snackbar` and the FAB, so simply using `CoordinatorLayout` will cause the FAB to slide upwards to make room for the `Snackbar`.

The [DesignSupport/CoordinatedFAB](#) sample project is a clone of the previous FAB example, except that we switch from a `RelativeLayout` root container to a `CoordinatorLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.design.widget.CoordinatorLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ListView
        android:id="@android:id/list"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:drawSelectorOnTop="false" />

    <android.support.design.widget.FloatingActionButton
        android:id="@+id/refresh"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="bottom|end"
        android:layout_marginBottom="@dimen/fab_margin"
        android:layout_marginEnd="@dimen/fab_margin"
        android:layout_marginRight="@dimen/fab_margin"
        android:src="@drawable/ic_refresh_black_24dp" />

</android.support.design.widget.CoordinatorLayout>
```

(from [DesignSupport/CoordinatedFAB/app/src/main/res/layout/main.xml](#))

Since `CoordinatorLayout` is based on `FrameLayout`, not `RelativeLayout`, we have to adjust the layout rules on the FAB to match, using `android:layout_gravity` to position the FAB towards the bottom right corner.

With no other changes, we now get coordinated movements of the FAB and the Snackbar as the Snackbar appears and disappears:

### CWAC-CrossPort

CWAC-CrossPort also has ports of `FloatingActionButton` and `CoordinatorLayout`, as can be seen in the [DesignSupport/CoordinatedFABCP](#) sample project.

In addition to the sorts of changes needed before (e.g., replace `appcompat-v7` with `crossport`, change imports, change the theme), our layout now uses `crossport` classes:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.design.widget.CoordinatorLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ListView
        android:id="@android:id/list"
        android:layout_width="match_parent"
```

```
    android:layout_height="match_parent"
    android:drawSelectorOnTop="false"
  />

  <com.commonsware.cwac.crossport.design.widget.FloatingActionButton
    android:id="@+id/refresh"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="bottom|end"
    android:layout_marginBottom="@dimen/fab_margin"
    android:layout_marginEnd="@dimen/fab_margin"
    android:src="@drawable/ic_refresh_black_24dp" />

</android.support.design.widget.CoordinatorLayout>
```

(from [DesignSupport/CoordinatedFABCP/app/src/main/res/layout/main.xml](#))

And, as before, we get the same results as with the official implements, just without the appcompat-v7 overhead:

*Figure 498: Coordinated FAB CrossPort Demo*

### Third-Party FABs... and FAMs

The Design Support implementation of a FAB works, and it works nicely “out of the box” with CoordinatorLayout. However, it implements only a subset of the Material

Design FAB capabilities, let alone related structures like the floating action menu (FAM).

As a result, there are [many FAB projects listed on the Android Arsenal](#), offering other implementations of a FAB.

In addition to complete FAB and FAM implementations, developers have been publishing libraries that add on other Material Design features to existing FAB implementations, such as:

- Wrapping [a progress bar around a FAB](#), perhaps to show the progress of some work triggered by a previous click on the FAB
- Using a [“material sheet”](#) or a [“floating action toolbar”](#) as an alternative to the FAM pattern

## Material Tabs with TabLayout

Android has had a myriad of tab implementations over the years:

- TabHost and TabWidget
- FragmentTabHost and TabWidget
- the now-deprecated action bar tabs
- PagerTabStrip, used in conjunction with a ViewPager

The Design Support library adds yet another tab implementation: TabLayout. Specifically, this implementation’s claim to fame is a faithful implementation of a subset of Google’s Material Design guidelines for how tabs should look and behave.

TabLayout can be used with or without a ViewPager. If you elect to skip the ViewPager, TabLayout works in a form reminiscent of action bar tabs, where it is responsible for the tab UI and you are responsible for updating the rest of your UI based upon the chosen tab (e.g., commit a FragmentTransaction). If you elect to use a ViewPager, TabLayout can lightly integrate with the ViewPager, so navigating by one means (e.g., swiping the pager) updates the other UI (e.g., changing the selected tab).

From a layout standpoint, you use TabLayout much like you would use TabWidget: put it where the tabs should go. Since Material Design wants the tabs on top, that means that typically you would put TabLayout inside a vertical LinearLayout, with the actual tabbed content beneath the TabLayout.

---

## THE ANDROID DESIGN SUPPORT LIBRARY

---

This is illustrated in the [DesignSupport/TabLayout](#) sample project. It is based on the original ViewPager samples, showing a set of editors in pages, this time using a TabLayout as the tab implementation (as opposed to PagerTabStrip or the TabPagerIndicator from the ViewPagerIndicator library).

The layout loaded by the activity has a setup much as described above: a vertical LinearLayout wrapped around a TabLayout and our ViewPager:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <android.support.design.widget.TabLayout
        android:id="@+id/tabs"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>

    <android.support.v4.view.ViewPager
        android:id="@+id/pager"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
    </android.support.v4.view.ViewPager>
</LinearLayout>
```

(from [DesignSupport/TabLayout/app/src/main/res/layout/main.xml](#))

TabLayout can have its tabs operate in one of two modes: fixed and scrollable. With fixed tabs, all tabs will be on the screen at all times, where they divide the available horizontal space between them. This works fine for just a few tabs. But for lots of tabs, each tab becomes very small, making it unlikely that the user can read the tab caption. Scrollable tabs each take up as much room as their caption requires, and if the roster of tabs becomes too wide for the screen, the user can swipe the tabs.

The sample app demonstrates both of these approaches, using a checkable action bar item to toggle between three editors with fixed tabs or ten editors with scrollable tabs. The default state is to be in fixed-tab mode:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">
    <item
        android:id="@+id/fixed"
        android:title="@string/menu_fixed"
```

## THE ANDROID DESIGN SUPPORT LIBRARY

---

```
    android:checkable="true"
    android:checked="true"
    app:showAsAction="never"/>
</menu>
```

(from [DesignSupport/TabLayout/app/src/main/res/menu/actions.xml](#))

The entire app was switched over to use AppCompatActivity and the fragment backport, as that is what the Design Support library requires. Beyond that, the EditorFragment is pretty much unchanged from the original implementations, just showing a large EditText widget with a hint based on the page number.

Our PagerAdapter — SamplePagerAdapter — has one change beyond the switch to the fragment backport. To accommodate switching between fixed and scrollable tabs, rather than hard-coding the number of pages, the adapter offers a setPageCount() method to stipulate the number of pages. The page count defaults to 3.

```
package com.commonware.android.tablayout;

import android.content.Context;
import android.support.v4.app.Fragment;
import android.support.v4.app.FragmentManager;
import android.support.v4.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
    private final Context ctxt;
    private int pageCount=3;

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);

        this.ctxt=ctxt;
    }

    @Override
    public int getCount() {
        return(pageCount);
    }

    @Override
    public Fragment getItem(int position) {
        return(EditorFragment.newInstance(position));
    }

    @Override
```

## THE ANDROID DESIGN SUPPORT LIBRARY

---

```
public String getPageTitle(int position) {
    return(EditorFragment.getTitle(ctxt, position));
}

void setPageCount(int pageCount) {
    this.pageCount=pageCount;
}
}
```

(from [DesignSupport/TabLayout/app/src/main/java/com/commonsware/android/tablayout/SampleAdapter.java](#))

In MainActivity, in onCreate(), we set up the ViewPager and the TabLayout:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    pager=(ViewPager)findViewById(R.id.pager);
    adapter=new SampleAdapter(this, getSupportFragmentManager());
    pager.setAdapter(adapter);

    tabs=(TabLayout)findViewById(R.id.tabs);
    tabs.setupWithViewPager(pager);
    tabs.setTabMode(TabLayout.MODE_FIXED);
}
```

(from [DesignSupport/TabLayout/app/src/main/java/com/commonsware/android/tablayout/MainActivity.java](#))

The bulk of the TabLayout setup work is handled with one call to `setupWithViewPager()`. This:

- Creates one tab for every page, based on whatever the PagerAdapter in the ViewPager is reporting at the time of this call
- Sets up the appropriate listeners, so that taps on a tab switches pages in the ViewPager, and swipes between pages update the selected tab

We also call `setTabMode(TabLayout.MODE_FIXED)`, as we are going with fixed tabs at the outset.

This gives us our three tabs:

*Figure 499: TabLayout Sample, As Initially Launched, Showing Three Fixed Tabs*

But we also have that menu resource, to allow the user to switch between fixed and scrollable tabs. We inflate() that resource in onCreateOptionsMenu() as usual, and we handle the checked state change in onOptionsItemSelected():

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);

    return(super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.fixed) {
        item.setChecked(!item.isChecked());

        if (item.isChecked()) {
            adapter.setPageCount(3);
            tabs.setTabMode(TabLayout.MODE_FIXED);
        }
    }
}
```

```
else {
    adapter.setPageCount(10);
    tabs.setTabMode(TabLayout.MODE_SCROLLABLE);
}

adapter.notifyDataSetChanged();

if (pager.getCurrentItem()>=3) {
    pager.setCurrentItem(2);
}

return(true);
}

return(super.onOptionsItemSelected(item));
}
```

(from [DesignSupport/TabLayout/app/src/main/java/com/commonsware/android/tablayout/MainActivity.java](#))

If the user taps on our checkable overflow item, we invert the item's checked state (which, unfortunately, does not happen automatically). Then, we call `setPageCount()` on the `SampleAdapter` and `setTabMode()` on the `TabLayout` based on the now-current checked state, to either have three fixed tabs or ten scrollable tabs.

Changing the page count of the `SampleAdapter` requires calling `notifyDataSetChanged()` to alert the `ViewPager` that the data set changed and it needs to repaint. However, while the associated `TabLayout` repaints, the selected page is left alone. That is fine when going from 3 pages to 10, but it could be a problem when going from 10 pages to 3, if the selected page is after those three. So, we use `setCurrentItem()` to manually move the selection to the last valid page, if that situation occurs.

Clicking on the “Fixed” checkable overflow item, and thereby unchecking it from its initial checked state, gives us ten scrollable tabs:

*Figure 500: TabLayout Sample, Showing Scrollable Tabs*

Note that while this particular sample app shows TabLayout working with a ViewPager, a ViewPager is not required to be able to use TabLayout. You can simply have the TabLayout plus your own system for whatever the tabs switch in your UI. Then, you can use methods like `addTab()` and `setOnTabSelectedListener()` to set up tabs and find out when the user taps on them, so you can adjust your UI to match the selected tab. That being said, many users may come to expect that they can horizontally swipe to move between pages of content, and so definitely consider using a ViewPager if practical.

### **CWAC-CrossPort**

CWAC-CrossPort has a port of TabLayout. The [DesignSupport/TabLayoutCP](#) sample project is identical to the `DesignSupport/TabLayout` sample app, except that it uses CWAC-CrossPort. The same sorts of modifications as seen earlier in this chapter are required, such as changing the layout to refer to the appropriate package for the ported TabLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <com.commonsware.cwac.crossport.design.widget.TabLayout
        android:id="@+id/tabs"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>

    <android.support.v4.view.ViewPager
        android:id="@+id/pager"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
    </android.support.v4.view.ViewPager>
</LinearLayout>
```

(from [DesignSupport/TabLayoutCP/app/src/main/res/layout/main.xml](#))

In this particular sample, since we are using menu resources, we have one additional change to make: switching from `app:showAsAction` to `android:showAsAction`, as we are using the native action bar:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">
    <item
        android:id="@+id/fixed"
        android:title="@string/menu_fixed"
        android:checkable="true"
        android:checked="true"
        android:showAsAction="never"/>
</menu>
```

(from [DesignSupport/TabLayoutCP/app/src/main/res/menu/actions.xml](#))

## Floating Labels

The `EditText` widget supports the `android:hint` attribute. The hint is shown in the `EditText` when the `EditText` is otherwise empty. However, if the `EditText` has actual text in it (whether typed by the user, loaded from a database, or whatever), the hint is not shown. This saves screen space compared to having a `TextView` label always visible; the hint itself serves as the label.

However, the hint-as-label pattern has a major drawback: the hint is not visible if there is text in the `EditText`. In the long term, as the user learns your UI, this is not a big problem. However, particularly early on, the user might look at a filled-in field and wonder what that field is for. This is even more likely in cases where the user is not the one who typed the text into the field in the first place, such as editing a database entry pulled from a server, where somebody (or something) else had created the entry in the first place.

The “floating label” pattern starts with a hint in the field. However, when the field is used, the hint animates out of the field itself and “floats” above the field in a shrunken form. This way, the label is always visible. However, in its smaller floating state, it takes up less screen space, yet while the field is otherwise empty, we can take advantage of that space to offer a “full-size” label instead.

The Design Support library offers `TextInputLayout` as a way of implementing the floating label pattern. This is not a subclass of `EditText`, but rather a `ViewGroup` that is wrapped around the `EditText`. This is convenient, insofar as it allows developers to use other `EditText` subclasses and still get the floating-label behavior.

`TextInputLayout` also supports an error state, where we can optionally show an error message below the `EditText`, such as an indication of an invalid bit of data entry.

### Using `TextInputLayout`

The [DesignSupport/FloatingLabel](#) sample project is a clone of [an earlier sample](#) where we allowed the user to enter in a URL and then, upon a button click, would parse the URL into a `Uri`, wrap that in an `ACTION_VIEW` Intent, then try to start an activity for that Intent.

The original sample’s layout looks like:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <EditText
        android:id="@+id/url"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
```

## THE ANDROID DESIGN SUPPORT LIBRARY

---

```
    android:hint="@string/url"
    android:inputType="textUri" />

<Button
    android:id="@+id/browse"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:onClick="showMe"
    android:text="@string/show_me" />

</LinearLayout>
```

(from [Activities/LaunchWeb/app/src/main/res/layout/main.xml](#))

In this revised sample, the original EditText is augmented with a TextInputLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:id="@+id/browse"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:onClick="showMe"
        android:text="@string/show_me">

        <requestFocus/>
    </Button>

    <android.support.design.widget.TextInputLayout
        android:id="@+id/til"
        android:layout_width="match_parent"
        android:layout_height="wrap_content">

        <EditText
            android:id="@+id/url"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:hint="@string/url"
            android:inputType="textUri" />
    </android.support.design.widget.TextInputLayout>

</LinearLayout>
```

(from [DesignSupport/FloatingLabel/app/src/main/res/layout/main.xml](#))

You will notice that there are a few changes here:

- The EditText is wrapped by an `android.support.design.widget.TextInputLayout` container that provides the actual floating label itself
- The Button is moved ahead of the EditText, in terms of the top-down organization of our vertical `LinearLayout`
- The Button has a `[requestFocus/]` child element, indicating to Android that this widget should get the focus first

Those latter two changes are due to one major limitation with `TextInputLayout`: the hint moves out of the EditText into the floating position when *either* there is text in the EditText *or* the EditText gains the focus. Strangely, simply putting the Button before the EditText is insufficient, as is simply adding `[requestFocus/]` on the Button. Both have to be implemented to cause the `TextInputLayout` to show the hint in its default location at the outset.

The Java code is also augmented a bit from the original sample, to take advantage of the error-reporting feature of `TextInputLayout`:

```
package com.commonsware.android.design.til;

import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.support.design.widget.TextInputLayout;
import android.support.v7.app.AppCompatActivity;
import android.util.Patterns;
import android.view.View;
import android.widget.EditText;

public class LaunchDemo extends AppCompatActivity {
    private TextInputLayout til;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        til=(TextInputLayout)findViewById(R.id.til);
        til.setErrorEnabled(true);
    }

    public void showMe(View v) {
        EditText urlField=(EditText)findViewById(R.id.url);
```

```
String url=urlField.getText().toString();

if (Patterns.WEB_URL.matcher(url).matches()) {
    startActivity(new Intent(Intent.ACTION_VIEW, Uri.parse(url)));
}
else {
    til.setError(getString(R.string.til_error));
}
}
}
```

(from [DesignSupport/FloatingLabel/app/src/main/java/com/commonsware/android/design/til/LaunchDemo.java](#))

The Patterns class in Android contains a series of stock regular expressions. One, WEB\_URL, is designed to see if the URL that was entered looks like a Web URL. When the user taps the button, if the pattern matches what the user entered in the field, we go ahead and try to start the activity. If not, we show an error.

To show the error, we need to do two things:

1. Up front, we call `setErrorEnabled()`, to tell `TextInputLayout` to reserve some space for an error message
2. At the point where we want to show the error, we call `setError()` on the `TextInputLayout`

When we run the app, the `TextInputLayout` leaves the hint in the `EditText` itself, as the `EditText` is empty and does not have the focus:

*Figure 501: FloatingLabel Sample, As Initially Launched*

Once the user taps on the field, though, the hint “floats” above the EditText:

*Figure 502: FloatingLabel Sample, After Focus Change*

And, if the user tries entering an invalid URL, the error message appears when the user taps the button to try to visit the invalid URL:

*Figure 503: FloatingLabel Sample, After Erroneous Data Entry*

### CWAC-CrossPort

CWAC-CrossPort has a port of `TextInputLayout` and `TextInputEditText`, the latter being the `EditText` subclass that actually winds up being used with a `TextInputLayout`.

The [DesignSupport/FloatingLabelCP](#) sample project is a port of the `FloatingLabel` sample, converted to using CWAC-CrossPort. The standard sorts of changes seen earlier in this chapter, such as artifact dependencies and themes, are needed. In addition, the layout needs to change to use the CWAC-CrossPort editions of the classes:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">
```

```
<Button
    android:id="@+id/browse"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:onClick="showMe"
    android:text="@string/show_me">

    <requestFocus />
</Button>

<com.commonsware.cwac.crossport.design.widget.TextInputLayout
    android:id="@+id/til"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <com.commonsware.cwac.crossport.design.widget.TextInputEditText
        android:id="@+id/url"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:hint="@string/url"
        android:inputType="textUri" />
</com.commonsware.cwac.crossport.design.widget.TextInputLayout>

</LinearLayout>
```

(from [DesignSupport/FloatingLabelCP/app/src/main/res/layout/main.xml](#))

### Third-Party Floating Labels

As with the rest of the Design Support library, `TextInputLayout` requires `appcompat-v7`. There are [other implementations of the floating label pattern](#) that do not require `appcompat-v7`, or perhaps offer additional features that you may want.

[FloatLabeledEditText](#) is one such implementation. It lacks the error message capability of `TextInputLayout`. However:

- It only floats the hint when there is text in the `EditText` widget, not when the `EditText` gets the focus, and
- It does not require `appcompat-v7`

The [DesignSupport/FloatingLabelNative](#) sample project is a clone of the previous sample, where the `TextInputLayout` is replaced by a `FloatLabeledEditText`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
```

```
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:orientation="vertical">

    <com.wrapp.floatlabeledittext.FloatLabeledEditText
        android:id="@+id/til"
        android:layout_width="match_parent"
        android:layout_height="wrap_content">

        <EditText
            android:id="@+id/url"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:hint="@string/url"
            android:inputType="textUri"/>
    </com.wrapp.floatlabeledittext.FloatLabeledEditText>

    <Button
        android:id="@+id/browse"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:onClick="showMe"
        android:text="@string/show_me"/>

</LinearLayout>
```

(from [DesignSupport/FloatingLabelNative/app/src/main/res/layout/main.xml](#))

As with `TextInputLayout`, `FloatLabeledEditText` is a decorating container around a regular `EditText`. Here, since the hint is left alone when the `EditText` gets focus, we have it back in its original position at the top of the form.

Visually, it is fairly similar to `TextInputLayout`, albeit with the native action bar:

*Figure 504: FloatingLabelNative Sample, As Initially Launched*

## THE ANDROID DESIGN SUPPORT LIBRARY

---

# Advanced RecyclerView

---

RecyclerView is the “Swiss army knife” of Android selection widgets. You can use it for a wide range of scenarios, well beyond what classic AdapterView widgets — like ListView or GridView — could handle.

In this chapter, we will “go outside the (AdapterView) box” and explore some advanced uses of RecyclerView.

## Prerequisites

Understanding this chapter requires that you have read [the core chapter on RecyclerView](#).

One section involves the use of [custom XML drawables](#). Another section demonstrates using content pulled from [the MediaStore ContentProvider](#).

This chapter also covers things like [action modes](#) and comparisons with other [advanced ListView techniques](#).

## What About Cursors?

So far, our model data has been a simple static array. Often times, though, we need to be working with model data culled from a database or ContentProvider. It may be that, for other reasons, we want to convert the Cursor we get back from queries into an array of ordinary Java objects. However, there is nothing stopping us from using a Cursor more directly as the model for a RecyclerView.

The RecyclerView.Adapter is responsible for teaching the

## ADVANCED RECYCLERVIEW

---

RecyclerView.ViewHolder the model data to bind against. The RecyclerView.Adapter base class is oblivious to how that model data is organized: array, ArrayList, Cursor, JSONArray, etc. And the actual bind-the-data logic for the RecyclerView.ViewHolder is our responsibility — again, the base class is oblivious to where the data is coming from. Hence, we can create our own protocol for passing the model data for the needed position from the RecyclerView.Adapter to the RecyclerView.ViewHolder. If we want to use a Cursor as the vehicle for doing this, we are welcome to do so.

This is illustrated in the [RecyclerView/VideoList](#) sample project, which is a clone of the VideoList project introduced in [the chapter on the MediaStore ContentProvider](#). In the original sample, the list was a ListView; in this sample, the list is a RecyclerView.

The core “plumbing” of the app is akin to the previous RecyclerView samples, such as using RecyclerViewActivity for handling getting the RecyclerView on the screen. However, our row layout is now based on the original VideoList row:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    android:padding="8dp"
    android:background="?android:attr/selectableItemBackground">

    <ImageView
        android:id="@+id/thumbnail"
        android:layout_width="64dp"
        android:layout_height="64dp"
        android:contentDescription="@string/thumbnail"/>

    <TextView
        android:id="@android:id/text1"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginLeft="8dp"
        android:layout_gravity="center_vertical"
        android:textSize="24sp"/>

</LinearLayout>
```

(from [RecyclerView/VideoList/app/src/main/res/layout/row.xml](#))

However, as we will now be accessing media, we need the READ\_EXTERNAL\_STORAGE permission, so we request that in the manifest:

## ADVANCED RECYCLERVIEW

---

```
<?xml version="1.0"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.recyclerview.videolist"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-permission android:name="android.permission.READ_EXTERNAL_STORAGE" />

    <application
        android:icon="@drawable/ic_launcher"
        android:theme="@style/Theme.Apptheme">
        <activity
            android:name=".MainActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

(from [RecyclerView/VideoList/app/src/main/AndroidManifest.xml](#))

And our app/build.gradle file gives us a targetSdkVersion of 23, requiring us to deal with runtime permissions on Android 6.0+:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.android.support:recyclerview-v7:27.1.1'
    implementation 'com.android.support:support-fragment:27.1.1'
    implementation 'com.squareup.picasso:picasso:2.5.2'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
```

## ADVANCED RECYCLERVIEW

---

```
        minSdkVersion 16
        targetSdkVersion 27
    }
}
```

(from [RecyclerView/VideoList/app/build.gradle](#))

`onCreate()` sets up the empty `RecyclerView` with a `LinearLayoutManager` and a `VideoAdapter` (that we will examine shortly). However, we also confirm whether we have `READ_EXTERNAL_STORAGE` already — if yes, we call `loadVideos()` to get the videos. If we do not have permission, and we are not in the middle of requesting permission, we ask for permission using `requestPermissions()`:

```
private static final String STATE_IN_PERMISSION="inPermission";
private static final int REQUEST_PERMS=137;
private boolean isInPermission=false;

@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setLayoutManager(new LinearLayoutManager(this));
    setAdapter(new VideoAdapter());

    if (state!=null) {
        isInPermission=
            state.getBoolean(STATE_IN_PERMISSION, false);
    }

    if (hasFilesPermission()) {
        loadVideos();
    }
    else if (!isInPermission) {
        isInPermission=true;

        ActivityCompat.requestPermissions(this,
            new String[] {Manifest.permission.READ_EXTERNAL_STORAGE},
            REQUEST_PERMS);
    }
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videlist/MainActivity.java](#))

`hasFilesPermission()` just uses `checkSelfPermission()` to see whether we can read external storage:

```
private boolean hasFilesPermission() {
```

## ADVANCED RECYCLERVIEW

---

```
return(ContextCompat.checkSelfPermission(this,
    Manifest.permission.READ_EXTERNAL_STORAGE)==
    PackageManager.PERMISSION_GRANTED);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

We then call `loadVideos()` once we have permission, plus keep track of whether or not we are in the process of requesting permissions (so we do not raise the permission dialog again if we undergo a configuration change while the permission dialog is already on-screen):

```
@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putBoolean(STATE_IN_PERMISSION, isInPermission);
}

@Override
public void onRequestPermissionsResult(int requestCode,
    String[] permissions,
    int[] grantResults) {

    isInPermission=false;

    if (requestCode==REQUEST_PERMS) {
        if (hasFilesPermission()) {
            loadVideos();
        }
        else {
            finish(); // denied permission, so we're done
        }
    }
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

`loadVideos()` just calls `initLoader()` to request that we load the videos from the `MediaStore`:

```
private void loadVideos() {
    getSupportLoaderManager().initLoader(0, null, this);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

The `CursorLoader` logic, for getting details about videos from the `MediaStore`, is

## ADVANCED RECYCLERVIEW

---

pretty much the same as before, other than providing the Cursor to the VideoAdapter when it is ready:

```
@Override
public Loader<Cursor> onCreateLoader(int arg0, Bundle arg1) {
    return(new CursorLoader(this,
        MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
        null, null, null,
        MediaStore.Video.Media.TITLE));
}

@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    ((VideoAdapter)getAdapter()).setVideos(c);
}

@Override
public void onLoaderReset(Loader<Cursor> loader) {
    ((VideoAdapter)getAdapter()).setVideos(null);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videlist/MainActivity.java](#))

VideoAdapter is another subclass of RecyclerView.Adapter, this time with smarts for dealing with a Cursor as the source of model data:

```
class VideoAdapter extends RecyclerView.Adapter<RowController> {
    Cursor videos=null;

    @Override
    public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new RowController(getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    void setVideos(Cursor videos) {
        this.videos=videos;
        notifyDataSetChanged();
    }

    @Override
    public void onBindViewHolder(RowController holder, int position) {
        videos.moveToPosition(position);
        holder.bindModel(videos);
    }

    @Override
```

## ADVANCED RECYCLERVIEW

---

```
public int getItemCount() {
    if (videos==null) {
        return(0);
    }

    return(videos.getCount());
}
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

Specifically:

- `getItemCount()` returns the count of videos from the Cursor, or 0 if the Cursor is null (mimicking the behavior of CursorAdapter, which also treats a null Cursor as merely being one that has no rows)
- `onCreateViewHolder()` creates the RowController
- `onBindViewHolder()` moves the Cursor to the desired position, then passes the Cursor over to the RowController

Also note that we have a `setVideos()` method that is used to associate our Cursor of video information with the adapter. This also triggers a call to `notifyDataSetChanged()`, to ensure that the RecyclerView knows that our model has changed and it should re-render its contents.

The RowController constructor retrieves the necessary widgets from the row and setting up an OnClickListener:

```
RowController(View row) {
    super(row);

    title=row.findViewById(android.R.id.text1);
    thumbnail=row.findViewById(R.id.thumbnail);

    row.setOnClickListener(this);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/RowController.java](#))

The `bindModel()` method invoked by `onBindViewHolder()` on VideoAdapter uses the same basic logic from the original VideoList sample to populate the row widgets, plus holds onto the Uri and MIME type of the video in data members for the current row:

```
void bindModel(Cursor row) {
```

---

## ADVANCED RECYCLERVIEW

---

```
title.setText(row.getString(
    row.getColumnIndex(MediaStore.Video.Media.TITLE)));

videoUri=
    ContentUris.withAppendedId(
        MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
        row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));

Picasso.with(thumbnail.getContext())
    .load(videoUri.toString())
    .fit().centerCrop()
    .placeholder(R.drawable.ic_media_video_poster)
    .into(thumbnail);

int mimeTypeColumn=
    row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);

videoMimeType=row.getString(mimeTypeColumn);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videlist/RowController.java](#))

The `onClick()` method uses those saved `Uri` and `MIME` type values for starting up the activity to play the selected video:

```
@Override
public void onClick(View v) {
    Intent i=new Intent(Intent.ACTION_VIEW);

    i.setDataAndType(videoUri, videoMimeType);
    title.getContext().startActivity(i);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videlist/RowController.java](#))

Other than the lack of dividers, the UI is very similar to the original `VideoList`.

This sample app is used as the basis for many other samples in this book, such as the [drag-and-drop examples](#).

## Grids

So far, we have focused on one visual representation of our collection of model data: a vertically-scrolling list. In the `AdapterView` family, a given `AdapterView` subclass has a specific visual representation (`ListView` for a vertically-scrolling list, `GridView`

for a two-dimensional grid, etc.). With RecyclerView, the choice of layout manager determines most of the visual representation, and so switching from a list to a grid can be as simple as a single-line change to our code.

The key, though, is the word *can* in the previous sentence. Depending upon what you want to do, a grid-styled RecyclerView can be more complicated, simply because you now have two dimensions' worth of power and configuration to play with.

### A Simple Grid

Making a RecyclerView use a grid is a matter of swapping out LinearLayoutManager for GridLayoutManager. In the [RecyclerView/Grid](#) sample project, you will see a clone of the CardRippleList3 sample app, where we are now using GridLayoutManager in onCreate() of MainActivity:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setLayoutManager(new GridLayoutManager(this, 2));
    setAdapter(new IconicAdapter());
}
```

(from [RecyclerView/Grid/app/src/main/java/com/commonsware/android/recyclerview/grid/MainActivity.java](#))

GridLayoutManager takes a number of “spans”, as well as a Context, as constructor parameters. In the simple case, as is with this app, “spans” will equate to “columns”: each item returned by the RecyclerView.Adapter will go into a single-row, single-span cell.

## ADVANCED RECYCLERVIEW

---

In our case, we requested two spans, and so our result resides in two columns:

*Figure 505: Grid RecyclerView Demo*

In this case, this is a “true” grid, with rows and columns of cells. Hence, the height of a row is determined by the tallest cell in that row. The “amet” cell in the left column of the third row is taller than required because of the word-wrap of the “consectetuer” cell in the right column of the same row, for example. [Later in this chapter](#), we will examine yet another option, `StaggeredGridLayoutManager`, where cells do not necessarily line up neatly in rows.

## Choosing the Number of Columns

If we rotate the screen for the above sample, you will see that the cells fit a bit better, since they are really repurposed list-style rows:

Figure 506: Grid RecyclerView Demo, Landscape

However, some apps may have smaller per-cell content. Plus, we have tablets to consider, and perhaps even televisions. It may be that you want to determine how many spans to use based on screen size and orientation.

One approach for doing that would be to use integer resources. You could have a `res/values/integers.xml` file with `<integer>` elements, giving the integer a name (name attribute) and value (text of the `<integer>` node). You could also have `res/values-w600dp/integers.xml` or other variations of the resource, where you provide different values to use for different screen sizes. Then, at runtime, call `getResources().getInteger()` to retrieve the correct value of the resource to use for the current device, and use that in your `GridLayoutManager` constructor. Now, you are in control over how many columns there are, by controlling how many spans are supplied to the constructor.

Another approach, [suggested by Chiu-Ki Chan](#), is to create a subclass of `RecyclerView`, on which you provide a custom attribute for a desired approximate column width. Then, in your subclass' `onMeasure()` method, you can *calculate* the number of spans to use to give you the desired column width.

Of course, another way to take advantage of screen space is to grow the cells. By default, they will grow evenly, as each cell takes up one span, and the spans are evenly sized. However, you can change that behavior, by attaching a `GridLayoutManager.SpanSizeLookup` to the `GridLayoutManager`. The `GridLayoutManager.SpanSizeLookup` is responsible for indicating, for a given item's position, how many spans it should take up in the grid. We will examine how this works [later in this chapter](#).

## Varying the Items

So far, all of the items in the `RecyclerView` have had the same basic structure, just with varying content in the widgets in those items. But, it is entirely possible that we will want to have some items be more substantively different, based on different layouts. `ListView` and kin handle this via `getViewTypeCount()` and `getItemViewType()` in the `ListAdapter`. `RecyclerView` and `RecyclerView.Adapter` offer a similar mechanism, including their own variant of the `getItemViewType()` method. In this section, we will examine how this works, both with lists and grids.

### A List with Headers

There are many cases where we want to have a list with some sort of section headers. The look of the headers usually is substantially different than the look of the rest of the rows, and therefore the best way to handle this is to teach the adapter about multiple row types.

This can be seen in the [RecyclerView/HeaderList](#) sample project. This is a clone of a similar project for `ListView`, where we want to put the 25 Latin words into 5 groups of 5 words each, with each group getting its own header.

Hence, our model data is now a two-dimensional `String` array:

```
private static final String[][] items= {
    { "lorem", "ipsum", "dolor", "sit", "amet" },
    { "consectetur", "adipiscing", "elit", "morbi", "vel" },
    { "ligula", "vitae", "arcu", "aliquet", "mollis" },
    { "etiam", "vel", "erat", "placerat", "ante" },
    { "porttitor", "sodales", "pellentesque", "augue", "purus" } };
```

(from [RecyclerView/HeaderList/app/src/main/java/com/commonsware/android/recyclerview/headerlist/MainActivity.java](#))

Our `getItemCount()` method now needs to take into account the headers, as well as the regular rows. There is one header row per batch of items, and so `getItemCount()`

## ADVANCED RECYCLERVIEW

---

sums up the sizes of the batches with the extra header rows:

```
@Override
public int getItemCount() {
    int count=0;

    for (String[] batch : items) {
        count+=1 + batch.length;
    }

    return(count);
}
```

(from [RecyclerView/HeaderList/app/src/main/java/com/commonsware/android/recyclerview/headerlist/MainActivity.java](#))

In order to teach RecyclerView about our different rows, we need to implement `getItemViewType()`. Unlike its counterpart on `ListAdapter`, `getItemViewType()` can return *any* int value, so long as it is unique for the row type. In fact, the recommendation is to use dedicated ID resources to ensure that uniqueness.

To that end, we define two ID resources, in a `res/values/ids.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <item type="id" name="header"/>
    <item type="id" name="detail"/>
</resources>
```

(from [RecyclerView/HeaderList/app/src/main/res/values/ids.xml](#))

Then, `getItemViewType()` can return `R.id.header` or `R.id.detail` to identify the two row types, and specifically which row type corresponds to the supplied position:

```
@Override
public int getItemViewType(int position) {
    if (getItem(position) instanceof Integer) {
        return(R.id.header);
    }

    return(R.id.detail);
}

private Object getItem(int position) {
    int offset=position;
    int batchIndex=0;
```

## ADVANCED RECYCLERVIEW

---

```
for (String[] batch : items) {
    if (offset == 0) {
        return(Integer.valueOf(batchIndex));
    }

    offset--;

    if (offset < batch.length) {
        return(batch[offset]);
    }

    offset-=batch.length;
    batchIndex++;
}

throw new IllegalArgumentException("Invalid position: "
    + String.valueOf(position));
}
```

(from [RecyclerView/HeaderList/app/src/main/java/com/commonsware/android/recyclerview/headerlist/MainActivity.java](#))

This leverages a copy of the `getItem()` method from the original `ListView` version of this sample, which returns an `Integer` for a header item (identifying which header it is) and a `String` for detail item (identifying what Latin word to use). Note that `getItem()` is not part of the `RecyclerView.Adapter` protocol, but you are certainly welcome to have one if you want it.

In `onCreateViewHolder()`, we can now start paying attention to the second parameter, which we have been studiously ignoring until now. That value, `viewType`, will be a value that we returned from `getItemViewType()`, and it indicates what sort of `RecyclerView.ViewHolder` we should return. In our case, there are only two possibilities, and so we just inflate the appropriate layout and use a dedicated controller class (`HeaderController` for headers, `RowController` for detail):

```
@Override
public RecyclerView.ViewHolder onCreateViewHolder(ViewGroup parent, int viewType) {
    if (viewType==R.id.detail) {
        return(new RowController(getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    return(new HeaderController(getLayoutInflater()
        .inflate(R.layout.header, parent, false)));
}
```

(from [RecyclerView/HeaderList/app/src/main/java/com/commonsware/android/recyclerview/headerlist/MainActivity.java](#))

## ADVANCED RECYCLERVIEW

---

Similarly, our binding logic in `onBindViewHolder()` needs to route the right sort of model information to the proper controller:

```
@Override
public void onBindViewHolder(RecyclerView.ViewHolder holder, int position) {
    if (holder instanceof RowController) {
        ((RowController)holder).bindModel((String)getItem(position));
    }
    else {
        ((HeaderController)holder).bindModel((Integer)getItem(position));
    }
}
```

(from [RecyclerView/HeaderList/app/src/main/java/com/commonsware/android/recyclerview/headerlist/MainActivity.java](#))

`RowController` is the same sort of setup as we have had in past examples. `HeaderController` is too, though it is far simpler, as we have only one widget needing to be updated (a `TextView` named `label`) and we do not care about click events:

```
package com.commonsware.android.recyclerview.headerlist;

import android.support.v7.widget.RecyclerView;
import android.view.View;
import android.widget.TextView;

class HeaderController extends RecyclerView.ViewHolder {
    TextView label=null;
    String template=null;

    HeaderController(View row) {
        super(row);

        label=(TextView)row.findViewById(R.id.label);

        template=label.getContext().getString(R.string.header_template);
    }

    void bindModel(Integer headerIndex) {
        label.setText(String.format(template, headerIndex.intValue()+1));
    }
}
```

(from [RecyclerView/HeaderList/app/src/main/java/com/commonsware/android/recyclerview/headerlist/HeaderController.java](#))

The results are header rows with one look-and-feel, and detail rows with a different look-and-feel:

Figure 507: HeaderList RecyclerView Demo

### A Grid-Style Table

In the discussion of RecyclerView grids, we saw that one way to take advantage of larger screens is to have more cells, in part by having more spans across the screen.

Another way to take advantage of screen space is to grow the cells. By default, they will grow evenly, as each cell takes up one span, and the spans are evenly sized. However, you can change that behavior, by attaching a `GridLayoutManager.SpanSizeLookup` to the `GridLayoutManager`. The `GridLayoutManager.SpanSizeLookup` is responsible for indicating, for a given item's position, how many spans it should take up in the grid.

One way of employing a `GridLayoutManager.SpanSizeLookup` is to make a table. If you want a table, but the user should only be able to select rows, that would be a matter of using a `LinearLayoutManager` and setting up the rows with "cells" that are of consistent size per row. For example, each row could be a horizontal `LinearLayout`, where the "column" widths are determined using

## ADVANCED RECYCLERVIEW

---

`android:layout_weight`. But sometimes you want a table where individual cells can be clicked upon (or selected via a five-way navigation option, like a trackball). In this case, `GridLayoutManager.SpanSizeLookup` will let you indicate, for a “column” of your output, how many spans the cell should take up. By using a consistent number of spans for each column, you can get the same sort of weighted column width that you might get with `LinearLayout`-based rows in a `LinearLayoutManager`-powered `RecyclerView`.

And that will make a lot more sense (hopefully) when you see an example.

The [RecyclerView/VideoTable](#) sample project is a clone of the `VideoList` sample project from earlier in the chapter, with a few changes:

- We are going to use a `GridLayoutManager`, yet still organize our output into logical rows, by having three cells per row (title, thumbnail, and video duration)
- We are going to use `GridLayoutManager.SpanSizeLookup` to control the widths of each column in our grid
- Because our cells have varying content (`ImageView` in one, `TextView` in others), we will use different controllers for those cells, each optimized for handling that cell’s sort of content

The two columns that will hold text (title and video duration) will use the following layout:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:background="?android:attr/selectableItemBackground"
    android:orientation="horizontal"
    android:padding="8dp">

    <TextView
        android:id="@android:id/text1"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:layout_marginLeft="8dp"
        android:layout_marginStart="8dp"
        android:textSize="20sp" />
</LinearLayout>
```

(from [RecyclerView/VideoTable/app/src/main/res/layout/label.xml](#))

---

## ADVANCED RECYCLERVIEW

---

The `LinearLayout` root element may seem superfluous, but we are using it for the `selectableItemBackground`, to provide a response when the cell is clicked upon.

Similarly, we have a layout dedicated to the thumbnail:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    android:padding="8dp"
    android:background="?android:attr/selectableItemBackground">

    <ImageView
        android:id="@+id/thumbnail"
        android:layout_width="96dp"
        android:layout_height="72dp"
        android:contentDescription="@string/thumbnail"/>

</LinearLayout>
```

(from [RecyclerView/VideoTable/app/src/main/res/layout/thumbnail.xml](#))

`onCreate()` of `MainActivity` is largely the same as before. This time, though, we are creating an instance of a `ColumnWeightSpanSizeLookup` class and using it for two things:

1. Calling its `getTotalSpans()` to tell the `GridLayoutManager` how many spans to use
2. Using it as a `GridLayoutManager.SpanSizeLookup`, attaching it to the `GridLayoutManager` via `setSpanSizeLookup()`:

```
ColumnWeightSpanSizeLookup spanSizer=new ColumnWeightSpanSizeLookup(COLUMN_WEIGHTS);
GridLayoutManager mgr=new GridLayoutManager(this, spanSizer.getTotalSpans());

mgr.setSpanSizeLookup(spanSizer);
setLayoutManager(mgr);
setAdapter(new VideoAdapter());
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/MainActivity.java](#))

The latter point means that `ColumnWeightSpanSizeLookup` is a subclass of the abstract `GridLayoutManager.SpanSizeLookup` base class. The one method that you need to override in a `GridLayoutManager.SpanSizeLookup` subclass is `getSpanSize()`. Given an item's position, `getSpanSize()` returns the number of spans that the item's cell should... um... span.

## ADVANCED RECYCLERVIEW

---

(we overload the word “span” a lot in Android...)

ColumnWeightSpanSizeLookup handles this via a set of column weights, which it gets as an int array in the constructor. onCreate() referenced a COLUMN\_WEIGHTS static data member for the weights:

```
private static final int[] COLUMN_WEIGHTS={1, 4, 1};
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/MainActivity.java](#))

This int array tells us both how many columns there are and how wide each column should be, in terms of spans.

Converting the position to a column index is a matter of applying the modulo (%) operator, so the implementation of getSpanSize() on ColumnWeightSpanSizeLookup just returns the columnWeights value for the desired column:

```
package com.commonsware.android.recyclerview.videotable;

import android.support.v7.widget.GridLayoutManager;

class ColumnWeightSpanSizeLookup extends GridLayoutManager.SpanSizeLookup {
    private final int[] columnWeights;

    ColumnWeightSpanSizeLookup(int[] columnWeights) {
        this.columnWeights=columnWeights;
    }

    @Override
    public int getSpanSize(int position) {
        return(columnWeights[position % columnWeights.length]);
    }

    int getTotalSpans() {
        int sum=0;

        for (int weight : columnWeights) {
            sum+=weight;
        }

        return(sum);
    }
}
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/ColumnWeightSpanSizeLookup.java](#))

---

## ADVANCED RECYCLERVIEW

---

`getTotalSpans()` is a convenience method, to sum all of the column weights. That is how many spans the `GridLayoutManager` will use overall, with each column getting its specific number of spans based upon the `int` array. Note that while we hard-coded the `int` array values in this case, there is nothing stopping us from using `<integer-array>` resources to pull these values out of the Java code, and perhaps even vary them by screen size or other configuration variations.

All of that will set up our grid with the correct number of spans and the right number of spans to use per column of the output. The combination will give us the row structure, as each row's worth of columns uses all of the spans for that row, forcing `GridLayoutManager` to put subsequent items on the next row.

The rest of the project is focused on having different widgets for those different cells, using `getItemViewType()` and so on.

The `VideoAdapter` implementation of `getItemViewType()` simply returns the position modulo 3, to return a unique value (in this case, 0, 1, or 2):

```
@Override
public int getItemViewType(int position) {
    return(position % 3);
}
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/MainActivity.java](#))

`getItemCount()` takes into account that there are three cells per video, and so the number of items being managed by this adapter is triple the number of videos:

```
@Override
public int getItemCount() {
    if (videos==null) {
        return(0);
    }

    return(videos.getCount()*3);
}
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/MainActivity.java](#))

The `onCreateViewHolder()` and `onBindViewHolder()` methods take into account those three item types, using a `VideoThumbnailController` or a `VideoTextController` depending on the item type. Both of those classes will inherit from a `BaseVideoController`, which defines a `bindModel()` method that `onBindViewHolder()` can use:

## ADVANCED RECYCLERVIEW

---

```
@Override
public BaseVideoController onCreateViewHolder(ViewGroup parent, int viewType) {
    BaseVideoController result=null;

    switch(viewType) {
        case 0:
            result=new VideoThumbnailController(getLayoutInflater()
                .inflate(R.layout.thumbnail,
                    parent, false));

            break;

        case 1:
            int cursorColumn=videos.getColumnIndex(MediaStore.Video.VideoColumns.DISPLAY_NAME);

            result=new VideoTextController(getLayoutInflater()
                .inflate(R.layout.label,
                    parent, false),
                android.R.id.text1,
                cursorColumn);

            break;

        case 2:
            cursorColumn=videos.getColumnIndex(MediaStore.Video.VideoColumns.DURATION);

            result=new VideoTextController(getLayoutInflater()
                .inflate(R.layout.label,
                    parent, false),
                android.R.id.text1,
                cursorColumn);

            break;
    }

    return(result);
}

@Override
public void onBindViewHolder(BaseVideoController holder, int position) {
    videos.moveToPosition(position/3);
    holder.bindModel(videos);
}
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/MainActivity.java](#))

BaseVideoController handles click events on the cell, along with collecting the Uri and MIME type of the video to use on click events:

```
package com.commonsware.android.recyclerview.videotable;

import android.content.ContentUris;
import android.content.Intent;
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;
import android.support.v7.widget.RecyclerView;
import android.view.View;
```

## ADVANCED RECYCLERVIEW

---

```
abstract class BaseVideoController extends RecyclerView.ViewHolder
    implements View.OnClickListener {
    protected Uri videoUri=null;
    private String videoMimeType=null;

    BaseVideoController(View cell) {
        super(cell);

        cell.setOnClickListener(this);
    }

    @Override
    public void onClick(View v) {
        Intent i=new Intent(Intent.ACTION_VIEW);

        i.setDataAndType(videoUri, videoMimeType);
        itemView.getContext().startActivity(i);
    }

    void bindModel(Cursor row) {
        int mimeTypeColumn=
            row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);

        videoUri=ContentUris.withAppendedId(
            MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
            row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));
        videoMimeType=row.getString(mimeTypeColumn);
    }
}
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/BaseVideoController.java](#))

VideoTextController extends BaseVideoController and handles binding some column from the MediaStore Cursor to a TextView with some ID:

```
package com.commonsware.android.recyclerview.videotable;

import android.database.Cursor;
import android.view.View;
import android.widget.TextView;

class VideoTextController extends BaseVideoController {
    private TextView label=null;
    private int cursorColumn;

    VideoTextController(View cell, int labelId, int cursorColumn) {
        super(cell);
        this.cursorColumn=cursorColumn;
    }
}
```

## ADVANCED RECYCLERVIEW

---

```
        label=(TextView)cell.findViewById(labelId);
    }

    @Override
    void bindModel(Cursor row) {
        super.bindModel(row);

        label.setText(row.getString(cursorColumn));
    }
}
```

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/VideoTextController.java](#))

VideoThumbnailController handles using Picasso to get the video thumbnail asynchronously and binding it to an ImageView in the inflated cell View:

```
package com.commonsware.android.recyclerview.videotable;

import android.content.ContentUri;
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;
import android.view.View;
import android.widget.ImageView;
import com.squareup.picasso.Picasso;

class VideoThumbnailController extends BaseVideoController {
    private ImageView thumbnail=null;

    VideoThumbnailController(View cell) {
        super(cell);

        thumbnail=(ImageView)cell.findViewById(R.id.thumbnail);
    }

    @Override
    void bindModel(Cursor row) {
        super.bindModel(row);

        Picasso.with(thumbnail.getContext())
            .load(videoUri.toString())
            .fit().centerCrop()
            .placeholder(R.drawable.ic_media_video_poster)
            .into(thumbnail);
    }
}
```

## ADVANCED RECYCLERVIEW

(from [RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/VideoThumbnailController.java](#))

The result is the same information as was in the original `VideoList` demo, but organized into a table, where each cell is clickable:

The duration is returned by `MediaStore` in milliseconds, which is not a great choice to present directly to the user. An improved version of this app might use a dedicated `RecyclerView.ViewHolder` that would convert the millisecond count into a duration measured in hours, minutes, and seconds (e.g., shown as `HH:MM:SS` to the user).

---

## ADVANCED RECYCLERVIEW

---

Also note that the cell sizes are purely driven by their weights, which will not necessarily handle all content in all configurations very well. The chosen weights barely work on a 10" tablet in portrait, for example:

Figure 509: VideoTable RecyclerView Demo, Portrait

## Mutable Row Contents

So far, all of the items we have used have been display-only. At most, they might respond to click events, along the lines of clicking a `ListView` row or `GridView` cell.

But, what about choice modes?

`ListView` and `GridView` — by way of their common `AbsListView` ancestor — have the concept of choice modes, where the user can “check” and “uncheck” items, and the list or grid will keep track of those states.

Well, as with lots of other things involving `RecyclerView`, `RecyclerView` does not offer choice modes... though you can implement that yourself. The [RecyclerView/ChoiceList](#) sample project turns our list-style `RecyclerView` into a checklist, with `CheckBox` widgets in each row, where the `RecyclerView.Adapter` will keep track of

the CheckBox checked states for us.

First, we need to add a CheckBox to the row:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.CardView
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:cardview="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    cardview:cardCornerRadius="4dp">

    <LinearLayout
        android:id="@+id/row_content"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal"
        android:background="?android:attr/selectableItemBackground">

        <ImageView
            android:id="@+id/icon"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_gravity="center_vertical"
            android:padding="2dip"
            android:src="@drawable/ok"
            android:contentDescription="@string/icon" />

        <LinearLayout
            android:layout_width="0dip"
            android:layout_height="wrap_content"
            android:layout_weight="1"
            android:orientation="vertical">

            <TextView
                android:id="@+id/label"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:textSize="25sp"
                android:textStyle="bold" />

            <TextView
                android:id="@+id/size"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:textSize="15sp" />

    </LinearLayout>

</CardView>
```

## ADVANCED RECYCLERVIEW

---

```
</LinearLayout>

<CheckBox
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:id="@+id/cb"
    android:layout_gravity="center_vertical"/>

</LinearLayout>
</android.support.v7.widget.CardView>
```

(from [RecyclerView/ChoiceList/app/src/main/res/layout/row.xml](#))

Our IconicAdapter is only slightly different than before:

- it inherits from a ChoiceCapableAdapter that we will examine shortly, and
- it supplies a MultiChoiceMode instance to ChoiceCapableAdapter as part of chaining to the ChoiceCapableAdapter constructor

```
class IconicAdapter extends ChoiceCapableAdapter<RowController> {
    IconicAdapter() {
        super(new MultiChoiceMode());
    }

    @Override
    public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new RowController(this, getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    @Override
    public void onBindViewHolder(RowController holder, int position) {
        holder.bindModel(items[position]);
    }

    @Override
    public int getItemCount() {
        return(items.length);
    }
}
```

(from [RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choicelist/MainActivity.java](#))

ChoiceCapableAdapter is simply a RecyclerView.Adapter that knows how to handle choice modes, as implemented via the ChoiceMode interface:

```
package com.commonsware.android.recyclerview.choicelist;
```

## ADVANCED RECYCLERVIEW

---

```
import android.os.Bundle;

public interface ChoiceMode {
    void setChecked(int position, boolean isChecked);
    boolean isChecked(int position);
    void onSaveInstanceState(Bundle state);
    void onRestoreInstanceState(Bundle state);
}
```

(from [RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choicelist/ChoiceMode.java](#))

A ChoiceMode is effectively a strategy class, responsible for tracking the checked states, not only for the current ChoiceCapableAdapter instance, but for future ones created as part of a configuration change. It requires four methods:

- setChecked() and isChecked() are getters and setters for whether or not a given position is checked
- onSaveInstanceState() and onRestoreInstanceState() manage storing and restoring those check states from the saved instance state Bundle of an activity or fragment

This project uses a MultiChoiceMode implementation of ChoiceMode:

```
package com.commonsware.android.recyclerview.choicelist;

import android.os.Bundle;

public class MultiChoiceMode implements ChoiceMode {
    private static final String STATE_CHECK_STATES="checkStates";
    private ParcelableSparseBooleanArray checkStates=new ParcelableSparseBooleanArray();

    @Override
    public void setChecked(int position, boolean isChecked) {
        checkStates.put(position, isChecked);
    }

    @Override
    public boolean isChecked(int position) {
        return(checkStates.get(position, false));
    }

    @Override
    public void onSaveInstanceState(Bundle state) {
        state.putParcelable(STATE_CHECK_STATES, checkStates);
    }

    @Override
    public void onRestoreInstanceState(Bundle state) {
        checkStates=state.getParcelable(STATE_CHECK_STATES);
    }
}
```

## ADVANCED RECYCLERVIEW

---

(from [RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choiceList/MultiChoiceMode.java](#))

MultiChoiceMode, in turn, is mostly handled by a ParcelableSparseBooleanArray. SparseBooleanArray is a class, supplied in the Android SDK, that is a space-efficient mapping of int values to boolean values, as opposed to using a HashMap and having to convert those primitives to Integer and Boolean objects. However, for inexplicable reasons, SparseBooleanArray was not [implemented to be Parcelable](#), and therefore it cannot be stored in a Bundle. ParcelableSparseBooleanArray is a subclass of SparseBooleanArray that handles the Parcelable aspects:

```
package com.commonsware.android.recyclerview.choiceList;

import android.os.Parcel;
import android.os.Parcelable;
import android.util.SparseBooleanArray;

public class ParcelableSparseBooleanArray extends SparseBooleanArray
    implements Parcelable {
    public static Parcelable.Creator<ParcelableSparseBooleanArray> CREATOR
        =new Parcelable.Creator<ParcelableSparseBooleanArray>() {
        @Override
        public ParcelableSparseBooleanArray createFromParcel(Parcel source) {
            return(new ParcelableSparseBooleanArray(source));
        }

        @Override
        public ParcelableSparseBooleanArray[] newArray(int size) {
            return(new ParcelableSparseBooleanArray[size]);
        }
    };

    public ParcelableSparseBooleanArray() {
        super();
    }

    private ParcelableSparseBooleanArray(Parcel source) {
        int size=source.readInt();

        for (int i=0; i < size; i++) {
            put(source.readInt(), (Boolean)source.readValue(null));
        }
    }

    @Override
    public int describeContents() {
        return(0);
    }
}
```

## ADVANCED RECYCLERVIEW

---

```
@Override
public void writeToParcel(Parcel dest, int flags) {
    dest.writeInt(size());

    for (int i=0;i<size();i++) {
        dest.writeInt(keyAt(i));
        dest.writeValue(valueAt(i));
    }
}
}
```

(from [RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choicelist/ParcelableSparseBooleanArray.java](#))

The net effect is that `MultiChoiceMode`, by means of `ParcelableSparseBooleanArray`, can track the checked/unchecked states of particular item position values.

`ChoiceCapableAdapter`, then, is a `RecyclerView.ViewHolder` that surfaces a `ChoiceMode` implementation:

```
package com.commonsware.android.recyclerview.choicelist;

import android.os.Bundle;
import android.support.v7.widget.RecyclerView;

abstract public class
    ChoiceCapableAdapter<T extends RecyclerView.ViewHolder>
    extends RecyclerView.Adapter<T> {
    private final ChoiceMode choiceMode;

    public ChoiceCapableAdapter(ChoiceMode choiceMode) {
        super();
        this.choiceMode=choiceMode;
    }

    void onChecked(int position, boolean isChecked) {
        choiceMode.setChecked(position, isChecked);
    }

    boolean isChecked(int position) {
        return(choiceMode.isChecked(position));
    }

    void onSaveInstanceState(Bundle state) {
        choiceMode.onSaveInstanceState(state);
    }
}
```

## ADVANCED RECYCLERVIEW

---

```
}  
  
void onRestoreInstanceState(Bundle state) {  
    choiceMode.onRestoreInstanceState(state);  
}  
}
```

(from [RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choicelist/ChoiceCapableAdapter.java](#))

The methods exposed by ChoiceCapableAdapter can then be used by outside parties. Specifically, MainActivity delegates onSaveInstanceState() and onRestoreInstanceState() to ChoiceCapableAdapter, so checked states can span configuration changes and the like. Plus, RowController can hook up on OnCheckedChangeListener and to update ChoiceCapableAdapter based on the state of checkbox changes:

```
package com.commonsware.android.recyclerview.choicelist;  
  
import android.annotation.TargetApi;  
import android.os.Build;  
import android.support.v7.widget.RecyclerView;  
import android.view.MotionEvent;  
import android.view.View;  
import android.widget.CheckBox;  
import android.widget.CompoundButton;  
import android.widget.ImageView;  
import android.widget.TextView;  
import android.widget.Toast;  
  
class RowController extends RecyclerView.ViewHolder  
    implements View.OnClickListener, CompoundButton.OnCheckedChangeListener {  
    private ChoiceCapableAdapter adapter;  
    private TextView label=null;  
    private TextView size=null;  
    private ImageView icon=null;  
    private String template=null;  
    private CheckBox cb=null;  
  
    RowController(ChoiceCapableAdapter adapter, View row) {  
        super(row);  
  
        this.adapter=adapter;  
        label=(TextView)row.findViewById(R.id.label);  
        size=(TextView)row.findViewById(R.id.size);  
        icon=(ImageView)row.findViewById(R.id.icon);  
        cb=(CheckBox)row.findViewById(R.id.cb);  
    }  
}
```

## ADVANCED RECYCLERVIEW

---

```
template=size.getContext().getString(R.string.size_template);

row.setOnClickListener(this);

if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
    row.setOnTouchListener(new View.OnTouchListener() {
        @TargetApi(Build.VERSION_CODES.LOLLIPOP)
        @Override
        public boolean onTouch(View v, MotionEvent event) {
            v
                .findViewById(R.id.row_content)
                .getBackground()
                .setHotspot(event.getX(), event.getY());

            return(false);
        }
    });
}

cb.setOnCheckedChangeListener(this);
}

@Override
public void onClick(View v) {
    Toast.makeText(v.getContext(),
        String.format("Clicked on position %d", getAdapterPosition()),
        Toast.LENGTH_SHORT).show();
}

@Override
public void onCheckedChanged(CompoundButton buttonView, boolean isChecked) {
    adapter.onChecked(getAdapterPosition(), isChecked);
}

void bindModel(String item) {
    label.setText(item);
    size.setText(String.format(template, item.length()));

    if (item.length()>4) {
        icon.setImageResource(R.drawable.delete);
    }
    else {
        icon.setImageResource(R.drawable.ok);
    }

    cb.setChecked(adapter.isChecked(getAdapterPosition()));
}
}
```

## ADVANCED RECYCLERVIEW

---

(from [RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choicelist/RowController.java](#))

Here, `bindModel()` updates the `CheckBox` based upon the `ChoiceCapableAdapter` `isChecked()` value for the `RecyclerView.ViewHolder` position (obtained via `getPosition()`). And, `onCheckedChanged()` updates the `ChoiceCapableAdapter` to keep track of whether this position is checked or unchecked, to handle row recycling, configuration changes, etc.

The result is much as you would expect: a version of our same sort of UI as before, except that if the user clicks the `CheckBox`, instead of the rest of the row, the `CheckBox` toggles its checked state, and that state survives row recycling, configuration changes, and so on:

Figure 510: ChoiceList RecyclerView Demo

Note that since this sample is using `Theme.Material` on Android 5.0+ devices, and since the screenshot is from an Android 5.0 emulator, the `CheckBox` styling is based on the accent color, here shown as bright yellow.

### Switching to the Activated Style

Also note that `ChoiceCapableAdapter`, `MultiChoiceMode`, and `kin` are oblivious to

---

## ADVANCED RECYCLERVIEW

---

how the user is informed about what is checked and unchecked. RowController in the previous sample happens to use a CheckBox. RowController could use some other widget, like a Switch.

Another approach is to use the activated state. Once again, this is the sort of thing that is automatically handled for us by ListView and its choice modes, but with some minor tweaks, we can get our RowController to use this approach. This is shown in the [RecyclerView/ActivatedList](#) sample project.

First, we need to give our row a background that has a StateListDrawable that supports the activated state. The simplest approach — and the one traditionally used with ListView — is to set up an activated style with the stock theme-supplied background drawable, then apply that style to the row.

So, this sample app defines activated in res/values/styles.xml:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

  <style name="Theme.Apptheme" parent="@android:style/Theme.Holo.Light.DarkActionBar">
  </style>

  <style name="activated" parent="Theme.Apptheme">
    <item name="android:background"?android:attr/activatedBackgroundIndicator</item>
  </style>
</resources>
```

(from [RecyclerView/ActivatedList/app/src/main/res/values/styles.xml](#))

Note that activated inherits from Theme.Apptheme. This means that we will get the Theme.Holo-flavored background normally, but on API Level 21+, we will get the Theme.Material-flavored background, courtesy of a res/values-v21/styles.xml override of Theme.Apptheme:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="android:Theme.Material.Light.DarkActionBar">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
</resources>
```

(from [RecyclerView/ActivatedList/app/src/main/res/values-v21/styles.xml](#))

Our row layout now dumps the CardView (whose own background may conflict with the activated one) and applies the activated style to the root LinearLayout:

## ADVANCED RECYCLERVIEW

---

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="horizontal"
  style="@style/activated">

  <ImageView
    android:id="@+id/icon"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:padding="2dip"
    android:src="@drawable/ok"
    android:contentDescription="@string/icon"/>

  <LinearLayout
    android:layout_width="0dip"
    android:layout_height="wrap_content"
    android:layout_weight="1"
    android:orientation="vertical">

    <TextView
      android:id="@+id/label"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:textSize="25sp"
      android:textStyle="bold"/>

    <TextView
      android:id="@+id/size"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:textSize="15sp"/>
  </LinearLayout>
</LinearLayout>
```

(from [RecyclerView/ActivatedList/app/src/main/res/layout/row.xml](#))

The row also no longer has the CheckBox, as it is no longer needed.

RowController now uses the OnClickListener interface to respond to clicks and use that to toggle the activated state for that row:

```
@Override
```

---

## ADVANCED RECYCLERVIEW

---

```
public void onClick(View v) {
    boolean isCheckedNow=adapter.isChecked(getAdapterPosition());

    adapter.onChecked(getAdapterPosition(), !isCheckedNow);
    row.setActivated(!isCheckedNow);
}
```

(from [RecyclerView/ActivatedList/app/src/main/java/com/commonsware/android/recyclerview/activatedlist/RowController.java](#))

`setActivated()`, applied to a `View`, indicates that it is (or is not) activated, affecting anything in that `View` that depends upon that state, such as the background.

Similarly, `bindModel()` uses `setActivated()` to update the activated state when binding our data:

```
void bindModel(String item) {
    label.setText(item);
    size.setText(String.format(template, item.length()));

    if (item.length()>4) {
        icon.setImageResource(R.drawable.delete);
    }
    else {
        icon.setImageResource(R.drawable.ok);
    }

    row.setActivated(adapter.isChecked(getAdapterPosition()));
}
```

(from [RecyclerView/ActivatedList/app/src/main/java/com/commonsware/android/recyclerview/activatedlist/RowController.java](#))

---

## ADVANCED RECYCLERVIEW

---

Everything else is the same as the original CheckBox version of the sample. But now, the “checked” state is indicated by the activated highlight:

Figure 511: *ActivatedList RecyclerView Demo*

And, since this demo is running on Android 5.0, the activated highlight color is the accent color, which in this case is set to be yellow.

### But, What About Single-Choice?

Both of the preceding examples illustrate multiple-choice behavior. Sometimes, though, single-choice behavior is the better option. For example, in a master-detail structure, in dual-pane mode (e.g., tablets, where the master and the detail are both visible), you probably normally want single-choice mode.

That is certainly possible, though, once again, RecyclerView does not offer it. It also adds a wrinkle: how do we arrange to uncheck a previously-checked item, when the user checks another item? Like RadioButton widgets in a RadioGroup, we need to ensure that only one item at a time is checked, and that will require us to update the UI of the formerly-checked-but-now-unchecked item.

With some tweaks, the last sample project, where we used the activated state for a

## ADVANCED RECYCLERVIEW

---

multiple-choice list, can be revised to limit the user to a single choice. Those tweaks are illustrated in the [RecyclerView/SingleActivatedList](#) sample project.

The ChoiceMode interface now has two new methods:

1. `isSingleChoice()` will return true for a single-choice ChoiceMode strategy, false otherwise
2. `getCheckedPosition()` will return the position of whatever the currently-checked item is

```
package com.commonware.android.recyclerview.singleactivatedlist;

import android.os.Bundle;

public interface ChoiceMode {
    boolean isSingleChoice();
    int getCheckedPosition();
    void setChecked(int position, boolean isChecked);
    boolean isChecked(int position);
    void onSaveInstanceState(Bundle state);
    void onRestoreInstanceState(Bundle state);
}
```

(from [RecyclerView/SingleActivatedList/app/src/main/java/com/commonware/android/recyclerview/singleactivatedlist/ChoiceMode.java](#))

SingleChoiceMode is now our implementation of ChoiceMode:

```
package com.commonware.android.recyclerview.singleactivatedlist;

import android.os.Bundle;

public class SingleChoiceMode implements ChoiceMode {
    private static final String STATE_CHECKED="checkedPosition";
    private int checkedPosition=-1;

    @Override
    public boolean isSingleChoice() {
        return(true);
    }

    @Override
    public int getCheckedPosition() {
        return(checkedPosition);
    }
}
```

## ADVANCED RECYCLERVIEW

---

```
@Override
public void setChecked(int position, boolean isChecked) {
    if (isChecked) {
        checkedPosition=position;
    }
    else if (isChecked(position)) {
        checkedPosition=-1;
    }
}

@Override
public boolean isChecked(int position) {
    return(checkedPosition==position);
}

@Override
public void onSaveInstanceState(Bundle state) {
    state.putInt(STATE_CHECKED, checkedPosition);
}

@Override
public void onRestoreInstanceState(Bundle state) {
    checkedPosition=state.getInt(STATE_CHECKED, -1);
}
}
```

(from [RecyclerView/SingleActivatedList/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/SingleChoiceMode.java](https://github.com/commonsware/android-recyclerview-singleactivatedlist/blob/master/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/SingleChoiceMode.java))

SingleChoiceMode tracks the currently-checked position, using -1 to indicate no position is checked. Of note, if a position was checked, then setChecked() unchecks it, SingleChoiceMode goes back to -1 and indicates that there is no currently-checked position.

ChoiceCapableAdapter also has a couple of modifications. First, it now accepts the RecyclerView itself as a constructor parameter, holding onto it in an rv data member. And, onChecked() needs to be modified to take care of removing the activated state from whatever item had been previously checked when some new item is checked:

```
package com.commonsware.android.recyclerview.singleactivatedlist;

import android.os.Bundle;
import android.support.v7.widget.RecyclerView;

abstract public class
```

## ADVANCED RECYCLERVIEW

---

```
ChoiceCapableAdapter<T extends RecyclerView.ViewHolder>
extends RecyclerView.Adapter<T> {
private final ChoiceMode choiceMode;
private final RecyclerView rv;

public ChoiceCapableAdapter(RecyclerView rv,
                             ChoiceMode choiceMode) {

    super();
    this.rv=rv;
    this.choiceMode=choiceMode;
}

void onChecked(int position, boolean isChecked) {
    if (choiceMode.isSingleChoice()) {
        int checked=choiceMode.getCheckedPosition();

        if (checked>=0) {
            RowController row=
                (RowController)rv.findViewByIdForAdapterPosition(checked);

            if (row!=null) {
                row.setChecked(false);
            }
        }
    }

    choiceMode.setChecked(position, isChecked);
}

boolean isChecked(int position) {
    return(choiceMode.isChecked(position));
}

void onSaveInstanceState(Bundle state) {
    choiceMode.onSaveInstanceState(state);
}

void onRestoreInstanceState(Bundle state) {
    choiceMode.onRestoreInstanceState(state);
}

@Override
public void onViewAttachedToWindow(T holder) {
    super.onViewAttachedToWindow(holder);

    if (holder.getAdapterPosition()!=choiceMode.getCheckedPosition()) {
        ((RowController)holder).setChecked(false);
    }
}
```

## ADVANCED RECYCLERVIEW

---

```
}  
}
```

(from [RecyclerView/SingleActivatedList/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/ChoiceCapableAdapter.java](https://github.com/commonsware/android-recyclerview/blob/master/singleactivatedlist/ChoiceCapableAdapter.java))

To do that, `onChecked()` asks the `ChoiceMode` if it is single choice. If yes, it gets the last checked position. If that position is plausible (0 or higher), it gets the `RecyclerView.ViewHolder` for that position via `findViewHolderForAdapterPosition()`, called on the `RecyclerView`. If this returns something other than null, then it must be a `RowController`, and so `onChecked()` calls `setChecked(false)` on that row to remove the activated state.

`findViewHolderForAdapterPosition()` and `findViewHolderForLayoutPosition()` replace the now-deprecated `findViewHolderForPosition()` method. All three methods do the same basic thing: given a position, return the `ViewHolder` for that position, if any. `findViewHolderForPosition()` and `findViewHolderForLayoutPosition()` have the same implementation, at least at the present time. The primary thing that `findViewHolderForAdapterPosition()` does differently is it always returns null if the data has been changed (e.g., `notifyDataSetChanged()` was called on the adapter) but those changes have not yet been laid out. In this sample app, that difference is academic, but `findViewHolderForAdapterPosition()` probably is a safer choice for most use cases.

However, these `find...()` methods have a wrinkle: they only return a `ViewHolder` if the row is *visible*. If the `ViewHolder` is cached, but not visible, `find...()` will still not return it. This causes a problem where we need to de-select a row that is not visible (and so `find...()` does not work) but will not be re-bound using `onBindViewHolder()` (as the `ViewHolder` is already set up). This requires us to implement `onViewAttachedToWindow()` — called whenever a `ViewHolder` contents are actually attached as children to the `RecyclerView` — and update the checked state there, as a fallback.

(and many thanks to Mahmoud Abou-Eita for [reporting that problem](#))

`setChecked()` did not exist in the previous sample, as the activated state was handled purely internally to `RowController`. So, now `RowController` has a `setChecked()` method to toggle the activated state:

```
void setChecked(boolean isChecked) {  
    row.setActivated(isChecked);  
}
```

---

## ADVANCED RECYCLERVIEW

---

(from [RecyclerView/SingleActivatedList/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/RowController.java](#))

MainActivity now must supply the RecyclerView to the IconicAdapter in onCreate():

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setLayoutManager(new LinearLayoutManager(this));
    adapter=new IconicAdapter(getRecyclerView());
    setAdapter(adapter);
}
```

(from [RecyclerView/SingleActivatedList/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/MainActivity.java](#))

...so that IconicAdapter() can supply it to the ChoiceCapableAdapter superclass constructor:

```
IconicAdapter(RecyclerView rv) {
    super(rv, new SingleChoiceMode());
}
```

(from [RecyclerView/SingleActivatedList/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/MainActivity.java](#))

Visually, the results are identical to the previous example, except that at most only one item can be checked at a time. The key is the phrase “at most” — this implementation allows the user to tap on a checked item to uncheck it. This may be fine, as your app may simply hide the detail in this scenario, still allowing the user to interact with action bar items (e.g., a “create new model” item). If you wanted to prevent that, have SingleChoiceMode *not* set checkedPosition to -1 when the user taps on a previously-checked item, to leave the currently-checked position intact.

## Keyboard Navigation

If you try using the RecyclerView/SingleActivatedList app — or any of the sample apps presented so far — on a device that has a physical keyboard or five-way navigation option (e.g., D-pad), you will find that RecyclerView has no built-in keyboard navigation. This is in contrast with standard AdapterView classes like ListView, where key events are handled automatically. Once again, if you want the behavior, you have to add it yourself.

## ADVANCED RECYCLERVIEW

---

The exact details of what you want to do when the user tries navigating with a keyboard will vary, based on lots of things:

- What sort of layout manager are you using? If it is a list, you only need to worry about moving up and down, while if it is a grid, you will need to handle movement along both axes.
- Do you have focusable widgets in your RecyclerView items? If so, how will navigation between those widgets blend with navigation through the RecyclerView overall?
- Are you using any sort of “selection” or “choice” model? If so, do you want keyboard navigation to change the choice? Or, do you want keyboard navigation to only make a choice when the user does something special (e.g., presses an Enter key or a center D-pad button), with the two-way or four-way navigation showing up as something separate from the user’s choice?

The [RecyclerView/SingleActivatedListKB](#) sample project is a clone of the `SingleActivatedList` sample, except that we now support keyboard events. Specifically, the user can use the up and down arrow keys to change the selected row in the list. This is perhaps the simplest scenario:

- We have no focusable widgets, so key events can just change the selected row
- It is just a list, so we only need to worry about two directions, not four
- We want either zero or one selected row, and so we do not need to have a distinction between navigation and selection, as we might with a multiple-choice list

And, the best part is that we only need to change `ChoiceCapableAdapter` — the rest of the app can remain unchanged.

First, we override another method on `RecyclerView.Adapter`: `onAttachedToRecyclerView()`. As the name suggests, this method is called when our adapter is assigned to a `RecyclerView` instance. Here, if we are in single-choice mode, we register an `OnKeyListener` on the `RecyclerView` itself, to find out when it receives key events:

```
// inspired by http://stackoverflow.com/a/28838834/115145  
  
@Override  
public void onAttachedToRecyclerView(RecyclerView rv) {  
    super.onAttachedToRecyclerView(rv);  
}
```

## ADVANCED RECYCLERVIEW

---

```
if (choiceMode.isSingleChoice()) {
    rv.setOnKeyListener(new View.OnKeyListener() {
        @Override
        public boolean onKey(View v, int keyCode, KeyEvent event) {
            if (event.getAction()==KeyEvent.ACTION_DOWN) {
                switch (keyCode) {
                    case KeyEvent.KEYCODE_DPAD_DOWN:
                        return(chooseNext());
                    case KeyEvent.KEYCODE_DPAD_UP:
                        return(choosePrevious());
                }
            }
            return(false);
        }
    });
}
```

(from [RecyclerView/SingleActivatedListKB/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/ChoiceCapableAdapter.java](#))

When the user presses down either the up or down arrow key (or equivalents on a D-pad), we call out to private `choosePrevious()` and `chooseNext()` methods, which will return `true` if we moved the selection in that direction, `false` otherwise. If the key event is not one of those, we return `false` to indicate that we are not consuming the key event.

The `choosePrevious()` and `chooseNext()` methods are responsible for determining what our next selection should be, assuming that the selection can change in the designated direction:

```
private boolean chooseNext() {
    long now=System.currentTimeMillis();
    boolean result=false;

    if (lastDownKeyTime==-1 || now-lastDownKeyTime>KEY_TIME_DELTA) {
        lastDownKeyTime=now;
        lastUpKeyTime=-1L;

        int checked=choiceMode.getCheckedPosition();

        if (checked<0) {
            onChecked(0, true, true);
            result=true;
        }
        else if (checked<getItemCount()-1) {
```

## ADVANCED RECYCLERVIEW

---

```
        onChecked(checked+1, true, true);
        result=true;
    }
}

return(result);
}

private boolean choosePrevious() {
    long now=System.currentTimeMillis();
    boolean result=false;

    if (lastUpKeyTime==-1 || now-lastUpKeyTime>KEY_TIME_DELTA) {
        lastUpKeyTime=now;
        lastDownKeyTime=-1L;

        int checked=choiceMode.getCheckedPosition();

        if (checked>0) {
            onChecked(checked-1, true, true);
            result=true;
        }
        else if (checked<0) {
            onChecked(0, true, true);
            result=true;
        }
    }

    return(result);
}
```

(from [RecyclerView/SingleActivatedListKB/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/ChoiceCapableAdapter.java](#))

In both cases, we find out what the current selection is. If it is a negative number, we do not have a selection yet, so we select the first row. Otherwise, if we can still move in the desired direction, add or subtract one from the current selection.

However, in this crude implementation, we need to slow down how frequently we change the selection. Simply changing which row is highlighted is fast, but if the list has to scroll to uncover that row, doing too many of those too quickly results in a “smearing” effect. The simplest way to avoid that smearing is to limit how many consecutive identical key events we process (e.g., user holds down an arrow key).

The approach taken in this code is to track the last time we were called to process an arrow key event for each direction, in `lastUpKeyTime` and `lastDownKeyTime` fields.

## ADVANCED RECYCLERVIEW

---

We use -1 to indicate that we have not just processed another one of that type. If, when we get a key event, either the related time value is -1 or is within `KEY_TIME_DELTA` of now, we go ahead and update the checked position (if needed), plus update the times. `KEY_TIME_DELTA` is defined as 250, limiting us to four updates per second.

We change the current selection, where needed, via a call to a new three-parameter `onChecked()` method:

```
void onChecked(int position, boolean isChecked) {
    onChecked(position, isChecked, false);
}

void onChecked(int position, boolean isChecked, boolean updateUI) {
    if (choiceMode.isSingleChoice()) {
        int checked=choiceMode.getCheckedPosition();

        if (checked>=0) {
            RowController row=
                (RowController)rv.findViewByIdForAdapterPosition(checked);

            if (row!=null) {
                row.setChecked(false);
            }
        }
    }

    choiceMode.setChecked(position, isChecked);

    if (updateUI) {
        notifyItemChanged(position);
        rv.scrollToPosition(position);
    }
}
```

(from [RecyclerView/SingleActivatedListKB/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/ChoiceCapableAdapter.java](#))

The third parameter indicates if we need to update the UI or not. For touchscreen events, activating rows and such is enough to ensure that the UI is properly updated. With key events, we need to:

- Make sure that Android is going to repaint the affected row and pick up the change in the activated state (`notifyItemChanged()`), and
- Make sure that the user can see the affected row, since they key event might

now select a row that is not visible on the screen (`scrollToPosition()`)

### Action Modes

Another thing that `ListView` gave us was support for action modes. In particular, the “multiple-choice modal” setting would automatically start and finish an action mode for us.

And, once again, `RecyclerView` has no hooks for action modes, though you can do it yourself if desired. We have to manually start and destroy the action mode, in addition to responding to the user’s interaction with the action mode (tapping on items, or dismissing the action mode manually).

Where things get interesting is in the connection between checked items and the action mode. There are two UX rules:

1. When there are no checked items, there should be no action mode
2. When there is no action mode, there should be no checked items

You might think that those two rules are the same, and to some extent they are. They are phrased this way to emphasize the state changes that are involved:

- When the user checks an item, an action mode should appear
- When the user unchecks the last checked item, and therefore there are no more checked items, the action mode should disappear
- When the user dismisses the action mode (e.g., presses BACK), all checked items should become unchecked

Handling these transitions takes a bit of work, demonstrated in the [RecyclerView/ActionModeList](#) sample project. This is a clone of the `ChoiceList` sample from earlier, augmented with an action mode when 1+ items are checked. The action mode logic is largely cloned from one of the book’s action mode samples, where we want to allow the user to capitalize or remove the checked items.

Once again, we have some tweaks to `ChoiceMode`, adding two methods:

1. `getCheckedCount()`, to return the number of checked items, which we will use for the subtitle of the action mode
2. `clearChecks()`, to uncheck all checked items

```
package com.commonware.android.recyclerview.actionmodelist;
```

## ADVANCED RECYCLERVIEW

---

```
import android.os.Bundle;

public interface ChoiceMode {
    void setChecked(int position, boolean isChecked);
    boolean isChecked(int position);
    void onSaveInstanceState(Bundle state);
    void onRestoreInstanceState(Bundle state);
    int getCheckedCount();
    void clearChecks();
}
```

(from [RecyclerView/ActionModelList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/ChoiceMode.java](#))

MultiChoiceMode implements those, plus adds a subtle change to `setChecked()`. Previous editions of `MultiChoiceMode` would simply put the checked state `boolean` into the `ParcelableSparseBooleanArray`, with `false` as a default value for any position not in the array. Now, we specifically *remove* items that are unchecked, so the only items in the `ParcelableSparseBooleanArray` are those that are checked. This makes `getCheckedCount()` and `clearChecks()` very simple to implement:

```
package com.commonsware.android.recyclerview.actionmodelist;

import android.os.Bundle;

public class MultiChoiceMode implements ChoiceMode {
    private static final String STATE_CHECK_STATES="checkStates";
    private ParcelableSparseBooleanArray checkStates=new ParcelableSparseBooleanArray();

    @Override
    public void setChecked(int position, boolean isChecked) {
        if (isChecked) {
            checkStates.put(position, isChecked);
        }
        else {
            checkStates.delete(position);
        }
    }

    @Override
    public boolean isChecked(int position) {
        return(checkStates.get(position, false));
    }

    @Override
    public void onSaveInstanceState(Bundle state) {
        state.putParcelable(STATE_CHECK_STATES, checkStates);
    }

    @Override
    public void onRestoreInstanceState(Bundle state) {
        checkStates=state.getParcelable(STATE_CHECK_STATES);
    }
}
```

## ADVANCED RECYCLERVIEW

---

```
@Override
public int getCheckedCount() {
    return(checkStates.size());
}

@Override
public void clearChecks() {
    checkStates.clear();
}
}
```

(from [RecyclerView/ActionModeList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/MultiChoiceMode.java](#))

ChoiceCapableAdapter exposes the two new ChoiceMode capabilities to its subclasses:

```
package com.commonsware.android.recyclerview.actionmodelist;

import android.os.Bundle;
import android.support.v7.widget.RecyclerView;

abstract public class
    ChoiceCapableAdapter<T extends RecyclerView.ViewHolder>
    extends RecyclerView.Adapter<T> {
    private final ChoiceMode choiceMode;

    public ChoiceCapableAdapter(ChoiceMode choiceMode) {
        super();
        this.choiceMode=choiceMode;
    }

    void onChecked(int position, boolean isChecked) {
        choiceMode.setChecked(position, isChecked);
    }

    boolean isChecked(int position) {
        return(choiceMode.isChecked(position));
    }

    void onSaveInstanceState(Bundle state) {
        choiceMode.onSaveInstanceState(state);
    }

    void onRestoreInstanceState(Bundle state) {
        choiceMode.onRestoreInstanceState(state);
    }

    int getCheckedCount() {
```

## ADVANCED RECYCLERVIEW

---

```
return(choiceMode.getCheckedCount());
}

void clearChecks() {
    choiceMode.clearChecks();
}
}
```

(from [RecyclerView/ActionModeList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/ChoiceCapableAdapter.java](#))

IconicAdapter now not only extends ChoiceCapableAdapter, but it implements the ActionMode.Callback interface, and therefore will be responsible for managing the action mode:

```
class IconicAdapter extends ChoiceCapableAdapter<RowController>
    implements ActionMode.Callback {
```

(from [RecyclerView/ActionModeList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/MainActivity.java](#))

IconicAdapter now overrides onChecked(), normally just handled by ChoiceCapableAdapter. In addition to chaining to the superclass for standard behavior, IconicAdapter manages the action mode:

- If we do not have any checked items, and we have an active action mode, finish() that action mode, as the user has unchecked the last checked item and the action mode is no longer needed
- Otherwise, update the subtitle, and if we are checking an item (isChecked is true), and if we do not already have an action mode going (tracked by an activeMode data member), start the action mode using startActionMode()

```
@Override
void onChecked(int position, boolean isChecked) {
    super.onChecked(position, isChecked);

    if (getCheckedCount()==0 && activeMode!=null) {
        activeMode.finish();
    }
    else {
        updateSubtitle(activeMode);

        if (isChecked) {
            if (activeMode==null) {
                activeMode=startActionMode(this);
            }
        }
    }
}
```

## ADVANCED RECYCLERVIEW

---

```
}  
}
```

(from [RecyclerView/ActionModeList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/MainActivity.java](#))

Because `IconicAdapter` implements `ActionMode.Callback`, it needs to implement the methods required by that interface. This includes:

- `onCreateActionMode()`, to set up the action mode
- `onPrepareActionMode()`, just because it is required by the interface
- `onActionItemClicked()`, where we should do some real work, but for the moment just have a `TODO` comment
- `onDestroyActionMode()`, where we make sure that all checked items are unchecked (`clearChecks()`) and tell the `RecyclerView.Adapter` that the data set changed, to force a repaint of all the visible rows, so they will now reflect the fact that they are no longer checked

```
@Override  
public boolean onCreateActionMode(ActionMode mode, Menu menu) {  
    MenuInflater inflater=getMenuInflater();  
  
    inflater.inflate(R.menu.context, menu);  
    mode.setTitle(R.string.context_title);  
    activeMode=mode;  
    updateSubtitle(activeMode);  
  
    return(true);  
}  
  
@Override  
public boolean onPrepareActionMode(ActionMode mode, Menu menu) {  
    return(false);  
}  
  
@Override  
public boolean onActionItemClicked(ActionMode mode, MenuItem item) {  
    // TODO: do something based on the action  
  
    updateSubtitle(activeMode);  
  
    return(true);  
}  
  
@Override  
public void onDestroyActionMode(ActionMode mode) {  
    if (activeMode != null) {
```

## ADVANCED RECYCLERVIEW

---

```
        activeMode=null;
        clearChecks();
        notifyDataSetChanged();
    }
}
```

(from [RecyclerView/ActionModeList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/MainActivity.java](#))

The `updateSubtitle()` method, referred to by some of the previous methods, just updates the subtitle of the action mode to reflect the current count of checked items:

```
private void updateSubtitle(ActionMode mode) {
    if (mode!=null) {
        mode.setSubtitle("(" + getCheckedCount() + ")");
    }
}
```

(from [RecyclerView/ActionModeList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/MainActivity.java](#))

The resulting app looks a lot like the original `ChoiceList` sample, until we check one or more items, at which point the action mode appears:

Figure 512: ActionModeList RecyclerView Demo

## Changing the Contents

The obvious problem with the preceding sample is that we are not actually doing anything in response to user clicks on action mode items. We really should be capitalizing and/or removing words. However, this involves modifying the model data and how that model data is being visually displayed by the `RecyclerView`.

The less-obvious problem is that we are calling `notifyDataSetChanged()` when the action mode is dismissed, to force a full repaint of the `RecyclerView` contents. While this works, it is overkill, as probably only a subset of the visible items are checked. Ideally, we would only update the specific positions that were checked and now, with the action mode finished, are unchecked. We could find the affected `RowController` instances, using `findViewHolderByPosition()` on `RecyclerView`, as we did in the single-choice list sample. But, really, updating the checked state is just another manifestation of the same problem that capitalizing or removing words causes: we need to ensure that the `RecyclerView` depicts the current model state, ideally with minimum work.

So, let's see how this is accomplished, by looking at the [RecyclerView/ActionModeList2](#) sample project. As the name suggests, this is a clone of the `ActionModeList` shown in the preceding section. This time, we will fully implement `onActionItemClicked()` and allow our model data to be mutable.

## Updating Existing Contents

With `AdapterView` and `Adapter` classes based on `BaseAdapter`, the only way we had to tell the `AdapterView` about model data changes was `notifyDataSetChanged()`. This would trigger a rebuild of the entire `AdapterView`, which is slow and expensive.

While `RecyclerView.Adapter` has its own `notifyDataSetChanged()`, that is really for total reloads of the model data, such as having gotten a fresh `Cursor` from a database and not knowing exactly what the changes are. If you are driving the changes yourself from the UI — and particularly if your model data is something like an `ArrayList` of model objects — you can use methods on `RecyclerView.Adapter` that are more fine-grained than is `notifyDataSetChanged()`.

If an item was updated in place — such as a word now being capitalized — you can use `notifyItemChanged()` on `RecyclerView.Adapter` to point out the specific position that changed. Alternatives include:

---

## ADVANCED RECYCLERVIEW

---

- `notifyItemMoved()`, to indicate that an item is still in the model data but now is in a new position
- `notifyItemRangeChanged()`, to indicate a range of positions that were modified, instead of having to repeatedly call `notifyItemChanged()`

`ActionModeList2` uses `notifyItemChanged()` when the user capitalizes words, to get those items repainted, if needed. It may not be needed immediately, if one or more of those items are not presently visible within the `RecyclerView`.

However, so far, our model data has been a static `String` array, and now we need a mutable model. So, we take the same approach as the `ListView` action mode samples use, converting our model to be an `ArrayList` that happens to be populated by a static `String` array.

The `items` data member of `MainActivity` is now an `ArrayList` of `String`, with the static `String` array being converted into `ORIGINAL_ITEMS`:

```
private static final String[] ORIGINAL_ITEMS={"lorem", "ipsum", "dolor",
    "sit", "amet",
    "consectetuer", "adipiscing", "elit", "morbi", "vel",
    "ligula", "vitae", "arcu", "aliquet", "mollis",
    "etiam", "vel", "erat", "placerat", "ante",
    "porttitor", "sodales", "pellentesque", "augue", "purus"};
private ArrayList<String> items;
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MainActivity.java](#))

Places that used to refer to items now use a private `getItems()` method, which lazy-instantiates the list if needed:

```
private ArrayList<String> getItems() {
    if (items==null) {
        items=new ArrayList<String>();

        for (String s : ORIGINAL_ITEMS) {
            items.add(s);
        }
    }

    return(items);
}
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MainActivity.java](#))

We also need to ensure that we hold onto the items across configuration changes,

## ADVANCED RECYCLERVIEW

---

since those items could be changed by the user. So, our `onSaveInstanceState()` and `onRestoreInstanceState()` methods on `MainActivity` now handle that chore, in addition to their original behavior of having the `ChoiceCapableAdapter` persist checked states:

```
@Override
public void onSaveInstanceState(Bundle state) {
    adapter.onSaveInstanceState(state);
    state.putStringArrayList(STATE_ITEMS, items);
}

@Override
public void onRestoreInstanceState(Bundle state) {
    adapter.onRestoreInstanceState(state);
    items=state.getStringArrayList(STATE_ITEMS);
}
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MainActivity.java](#))

(here, `STATE_ITEMS` is a static data member, serving as the constant key for the `Bundle` entry)

In order to be able to capitalize or remove the checked words from the list, we need to know which ones are checked. Rather than expose that data directly, `ChoiceMode` now has a `visitChecks()` method, where we can supply a `Visitor` to be invoked for every checked position:

```
package com.commonsware.android.recyclerview.actionmodelist2;

import android.os.Bundle;

public interface ChoiceMode {
    void setChecked(int position, boolean isChecked);
    boolean isChecked(int position);
    void onSaveInstanceState(Bundle state);
    void onRestoreInstanceState(Bundle state);
    int getCheckedCount();
    void clearChecks();
    void visitChecks(Visitor v);

    public interface Visitor {
        void onCheckedPosition(int position);
    }
}
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/ChoiceMode.java](#))

## ADVANCED RECYCLERVIEW

---

MultiChoiceMode implements `visitChecks()` by iterating over a *copy* of the `checkStates` `ParcelableSparseBooleanArray`. That way, if the visitor modifies `checkStates` (e.g., unchecks a position), our loop is unaffected.

```
@Override
public void visitChecks(Visitor v) {
    SparseBooleanArray copy=checkStates.clone();

    for (int i=0;i<copy.size();i++) {
        v.onCheckedPosition(copy.keyAt(i));
    }
}
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MultiChoiceMode.java](#))

`visitChecks()` is also exposed by `ChoiceCapableAdapter`, as are all the other methods on `ChoiceMode`.

Now, `IconicAdapter` can capitalize the words, by using `visitChecks()`:

```
case R.id.cap:
    visitChecks(new ChoiceMode.Visitor() {
        @Override
        public void onCheckedPosition(int position) {
            String word=getItems().get(position);

            word=word.toUpperCase(Locale.ENGLISH);
            getItems().set(position, word);
            notifyItemChanged(position);
        }
    });
    break;
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MainActivity.java](#))

Here, for each checked item, we capitalize the word, replace the original word with its capitalized equivalent, and call `notifyItemChanged()` to let the `RecyclerView` know that this position had its model data changed and therefore should be repainted, if needed.

We also use `visitChecks()` now in `onDestroyActionMode()`, to avoid the `notifyDataSetChanged()` call:

```
@Override
public void onDestroyActionMode(ActionMode mode) {
```

## ADVANCED RECYCLERVIEW

```
if (activeMode != null) {
    activeMode=null;
    visitChecks(new ChoiceMode.Visitor() {
        @Override
        public void onCheckedPosition(int position) {
            onChecked(position, false);
            notifyItemChanged(position);
        }
    });
}
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MainActivity.java](#))

Each item that was checked is unchecked, and we use `notifyItemChanged()` to ensure that the item is repainted if needed.

Now, checking some items and choosing “CAPITALIZE” from the action mode will capitalize those words:

Figure 513: ActionModeList2 RecyclerView Demo, with Capitalized Words

### Adding and Removing Items

There are also methods on RecyclerView.Adapter to specifically call out when you are adding or removing items from the adapter. Not only does this cause the RecyclerView to update itself, but it will animate the changes, if the relevant position(s) are visible.

Specifically, you can call:

- `notifyItemInserted()`, to indicate that a new item was inserted at a specified position, with everything else moving one position later in the roster
- `notifyItemRangeInserted()`, to insert several items in a block
- `notifyItemRemoved()`, to indicate a position that had an item removed from the roster, with later items moving up to take over earlier positions
- `notifyItemRangeRemoved()`, to remove several items in a block

The `ActionModeList2` sample uses `notifyItemRemoved()` as part of its handling of the remove action mode item:

```
case R.id.remove:
    final ArrayList<Integer> positions=new ArrayList<Integer>();

    visitChecks(new ChoiceMode.Visitor() {
        @Override
        public void onCheckedPosition(int position) {
            positions.add(position);
        }
    });

    Collections.sort(positions, Collections.reverseOrder());

    for (int position : positions) {
        getItem().remove(position);
        notifyItemRemoved(position);
    }

    clearChecks();
    activeMode.finish();
    break;
```

(from [RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MainActivity.java](#))

Because items slide up to take over vacated positions, when removing items, it is

important to remove the lowest items first and work your way up the roster. That is why this code:

- Aggregates the list of positions that are checked
- Sorts the checked items in reverse order
- Iterates over the checked items, removing each from the `ArrayList` and calling `notifyItemRemoved()` to inform the adapter that the old item at this position is now gone
- Clears all of the checks from the `ChoiceMode` (as all checked items are now removed) and finishes the action mode (as there are no more checked items)

The result is that when the user removes items, they rapidly fade out, then later items in the list slide up to occupy the now-vacated space. If you would prefer to use other animations, you can do so, by creating your own subclass of `RecyclerView.ItemAnimator` and attaching it to the `RecyclerView` with `setItemAnimator()`.

## The Order of Things

Version 22+ of `recyclerview-v7` offers `SortedList`. On the surface, the class appears to be a regular `List` that offers sorting. However, it also has a callback interface designed to be tied into `RecyclerView`, so that changes made to the `SortedList` can be reflected in the `RecyclerView` itself, complete with animations, optional batched processing, and so on.

This is illustrated in the [RecyclerView/SortedList](#) sample project. Along the way, we will also see how to use `RecyclerView` in a fragment and how to populate `RecyclerView` from the background thread.

## The Gradle Change

This project requires version 22 or higher of `recyclerview-v7`, as the original v21 release of `recyclerview-v7` did not have `SortedList`. So, the Gradle build file requests something appropriate:

```
implementation 'com.android.support:recyclerview-v7:27.0.2'  
implementation 'com.android.support:cardview-v7:27.0.2'
```

(from [RecyclerView/SortedList/app/build.gradle](#))

### The RecyclerViewFragment

Prior samples in this chapter used a RecyclerViewActivity for basic RecyclerView setup. However, in this sample, we want to use a retained fragment for managing the AsyncTask, which suggests putting the RecyclerView in a fragment, rather than having it be managed directly by the activity.

So, this project has a reworking of RecyclerViewActivity into RecyclerViewFragment:

```
package com.commonware.android.recyclerview.sorted;

import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.support.v7.widget.RecyclerView;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class RecyclerViewFragment extends Fragment {
    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup container,
        Bundle savedInstanceState) {
        RecyclerView rv=new RecyclerView(getActivity());

        rv.setHasFixedSize(true);

        return(rv);
    }

    public void setAdapter(RecyclerView.Adapter adapter) {
        getRecyclerView().setAdapter(adapter);
    }

    public RecyclerView.Adapter getAdapter() {
        return(getRecyclerView().getAdapter());
    }

    public void setLayoutManager(RecyclerView.LayoutManager mgr) {
        getRecyclerView().setLayoutManager(mgr);
    }

    public RecyclerView getRecyclerView() {
        return((RecyclerView)getView());
    }
}
```

---

## ADVANCED RECYCLERVIEW

---

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/RecyclerViewFragment.java](#))

Basically, what had been in `onCreate()` mostly moves into `onCreateView()`, where we set up the `RecyclerView`. The rest of the core API is unchanged.

The project has `SortedFragment`, which extends `RecyclerViewFragment` and handles loading of the data — we will examine more of it later in this chapter.

The revised `MainActivity` then just loads up `SortedFragment` via a `FragmentManager`:

```
package com.commonsware.android.recyclerview.sorted;

import android.support.v4.app.FragmentActivity;
import android.os.Bundle;

public class MainActivity extends FragmentActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
            getSupportFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new SortedFragment()).commit();
        }
    }
}
```

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/MainActivity.java](#))

## The SortedFragment

Most of `SortedFragment` is reminiscent of the original `AsyncTask` demo from [the chapter on threads](#), mashed up with one of the `CardView/RecyclerView` samples from earlier in this chapter. However, the `SortedList` gets weaved throughout.

## The SortedList

The model in the original `AsyncTask` demo was a simple `ArrayList`. Now it is a `SortedList`, initialized in `onCreate()` of the `SortedFragment`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);
}
```

## ADVANCED RECYCLERVIEW

---

```
model=new SortedList<String>(String.class, sortCallback);

task=new AddStringTask();
task.execute();
}
```

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java](#))

The `SortedList` constructor takes two parameters:

- the Java class object for the models inside the list (in this case, `String.class`)
- a `SortedList.Callback` object that will be invoked when the model changes based on `List` APIs (e.g., `add()`, `insert()`, `remove()`)

There is an optional third parameter for the capacity, unused in this sample.

We will take a peek at the `SortedList.Callback` implementation, named `sortCallback`, shortly.

### The `IconicAdapter`

The `IconicAdapter` from earlier `RecyclerView` samples worked directly off of the static array of `String` values. Now, we want it to work off of the model `SortedList`. Hence, `onBindViewHolder()` and `getItemCount()` need to be modified to refer to appropriate methods on the model:

```
class IconicAdapter extends RecyclerView.Adapter<RowController> {
    @Override
    public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new RowController(getActivity().getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    @Override
    public void onBindViewHolder(RowController holder, int position) {
        holder.bindModel(model.get(position));
    }

    @Override
    public int getItemCount() {
        return(model.size());
    }
}
```

---

## ADVANCED RECYCLERVIEW

---

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java](#))

Also note that when we create the adapter in `onViewCreated()`, that we hold onto it in an adapter data member of the fragment:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    setLayoutManager(new LinearLayoutManager(getActivity()));
    adapter=new IconicAdapter();
    setAdapter(adapter);
}
```

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java](#))

### The SortedList.Callback

The job of the `SortedList.Callback` is to serve as the bridge between the `SortedList` and the `RecyclerView.Adapter`.

`SortedList`, as the name suggests, sorts its contents. That means that any change to the `SortedList` contents can have different impacts on the `RecyclerView`. For example, while an `add()` to an `ArrayList` would just add a new row to the end of the `RecyclerView`, an `add()` on `SortedList` might need to insert a row in the middle of the `RecyclerView`, to maintain the sorted order.

Hence, your `SortedList.Callback` is responsible for two things:

- Helping with the sorting itself, by comparing elements
- Passing information about how the sorting is done out to the `RecyclerView.Adapter`, so the appropriate moves can be made there, complete with animations

With that in mind, here is the `sortedCB` implementation of `SortedList.Callback`:

```
private SortedList.Callback<String> sortCallback=new SortedList.Callback<String>() {
    @Override
    public int compare(String o1, String o2) {
        return o1.compareTo(o2);
    }

    @Override
    public boolean areContentsTheSame(String oldItem, String newItem) {
        return(areItemsTheSame(oldItem, newItem));
    }
}
```

## ADVANCED RECYCLERVIEW

---

```
@Override
public boolean areItemsTheSame(String oldItem, String newItem) {
    return(compare(oldItem, newItem)==0);
}

@Override
public void onInserted(int position, int count) {
    adapter.notifyItemRangeInserted(position, count);
}

@Override
public void onRemoved(int position, int count) {
    adapter.notifyItemRangeRemoved(position, count);
}

@Override
public void onMoved(int fromPosition, int toPosition) {
    adapter.notifyItemMoved(fromPosition, toPosition);
}

@Override
public void onChanged(int position, int count) {
    adapter.notifyItemRangeChanged(position, count);
}
};
```

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java](#))

The first method is your standard sort of `compare()` comparison method, as you might implement on a `Comparator`. It should return zero if the two model objects are the same from a sorting standpoint, a negative number if the first parameter sorts before the second parameter, or a positive number if the first parameter sorts after the second parameter.

Then there are two similarly-named methods that serve as more-or-less replacements for the `equals()` that you might have on a `Comparator`: `areContentsTheSame()` and `areItemsTheSame()`.

`areItemsTheSame()` should return `true` if the two passed-in values represent the same actual logical item. In the case of `SortedFragment`, that is simply whether or not the strings are equal. But, with a more complex data model, you might be comparing primary keys or some other form of immutable identifier.

`areContentsTheSame()` should return `true` if the visual representation of the items look the same, as this will be used to optimize the changes made to the `RecyclerView`.

For example, suppose a shopping cart fragment wanted to use `SortedList`. Further suppose that if you added three boxes of laundry detergent to the cart, rather than

## ADVANCED RECYCLERVIEW

---

having one row in the list with “Quantity: 3”, you were representing them as three rows in the RecyclerView. In this case:

- `compare()` returns a value to indicate the sorting rules of those shopping cart items, perhaps based on the title of the item
- `areItemsTheSame()` might return false for any combination of these three items, as they are logically distinct rows within the RecyclerView
- `areContentsTheSame()` might return true for any combination of these three items, as while they are three separate line items, each is visually identical in terms of what the RecyclerView rows look like

In many cases, `areContentsTheSame()` can simply invoke `areItemsTheSame()`, under the premise that different items *probably* have different visual representations. That is what is done in this sample, where `areItemsTheSame()` in turn uses `compare()` to see whether or not the items are the same.

Finally, there are four `on...()` methods that are simply forwarded along to their RecyclerView.Adapter counterparts, so changes to the SortedList make the corresponding changes to the RecyclerView contents.

Note that there is a `SortedListAdapterCallback` that takes a `RecyclerView.Adapter` as a constructor parameter and handles the `on...()` methods for you. However, since we want to retain the `SortedList` across configuration changes, and since `SortedList` does not allow us to change the `SortedList.Callback` object, we cannot readily switch the `SortedList` to the new fragment and new adapter after a configuration change.

### The AsyncTask

The `AddStringTask` is the same as with the original `AsyncTask` sample, except that now it adds the words to the `SortedList`, which (via its `Callback`) will update the `RecyclerView`:

```
private class AddStringTask extends AsyncTask<Void, String, Void> {
    @Override
    protected Void doInBackground(Void... unused) {
        for (String item : items) {
            if (isCancelled())
                break;

            publishProgress(item);
            SystemClock.sleep(400);
        }
    }
}
```

## ADVANCED RECYCLERVIEW

---

```
    }

    return(null);
}

@Override
protected void onProgressUpdate(String... item) {
    if (!isCancelled()) {
        model.add(item[0]);
    }
}

@Override
protected void onPostExecute(Void unused) {
    Toast.makeText(getActivity(), R.string.done, Toast.LENGTH_SHORT)
        .show();

    task=null;
}
}
```

(from [RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java](#))

### The Results

If you run this sample, you will see the words be added to the list, every 400ms. However, in the original `ListView`-based sample, new rows were appended to the end, and so you would not see new rows appear after the `ListView` space was filled. In this sample, the Latin words are sorted by `SortedList`, and you will see them animate into position at the appropriate spots as they are added. In the end, you get the same look as in earlier `CardView`-based `RecyclerView` implementations, except that the words are sorted:

*Figure 514: SortedList RecyclerView Demo*

### Other Bits of Goodness

To quote the infamous American infomercial line: “But wait! There’s more!”

In addition to `LinearLayoutManager` and `GridLayoutManager`, there is `StaggeredGridLayoutManager`. With a vertically-scrolling `GridLayoutManager`, rows are all a consistent height, but the cell widths might vary. With a vertically-scrolling `StaggeredGridLayoutManager`, the columns are all the same width, but the cell heights might vary.

All three of the standard layout managers support horizontal operation as well, through a boolean on a constructor. In these cases, the content will scroll horizontally, rather than vertically. This eliminates the need for third-party horizontal `ListView` implementations and the like.

And, of course, you can implement your own `RecyclerView.LayoutManager`, avoiding any of the built-in ones.

## Animating the Deltas

`SortedList` is interesting, but it is inflexible. For example, you cannot readily change the sort order, without completely replacing the `SortedList`.

Moreover, it assumes that the changes that you want to make are simply to keep a list in sorted order. There are plenty of other possible changes to your data set that might occur, such as from the results of some Web service call to synchronize your local data with that on a server. You would have to somehow perform your own “diff” on the data shown in your `RecyclerView` and the new roster of data, to determine what changed, what did not change, and how those changes affect things like item positions within the list or grid.

We have two options for handling this:

- The low-level approach offered by `DiffUtil`
- The simplified approach [offered by `ListAdapter`](#)

First, let’s look at `DiffUtil`. This handles all of the difference calculations to identify the specific changes needed to switch the `RecyclerView` from one list to another. You hand it two collections (old and new), plus an object that can help determine what the changes are (one reminiscent of a `SortedList.Callback`). It gives you a results object that, in turn, can update the `RecyclerView` to affect those changes.

The [Java8/VideoLambda](#) sample project is yet another rendition of the “list of videos” sample app from earlier in this chapter. However, it shows the list in sorted order, but using `DiffUtil` rather than `SortedList`. This allows us to offer the user the ability to change the sort order (ascending or descending).

## Model

The original version of this sample used a `Cursor` directly, wrapping it in a

## ADVANCED RECYCLERVIEW

---

RecyclerView.Adapter. That is fine, but we cannot readily sort a Cursor. It is simpler to convert the Cursor into a list of model objects, so we can sort the list.

To that end, the VideoLambda sample app has a Video class, with a constructor that can populate itself from a Cursor positioned on a valid row:

```
package com.commonware.android.recyclerview.videolist;

import android.content.ContentUris;
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;

class Video implements Comparable<Video> {
    final String title;
    final Uri videoUri;
    final String mimeType;

    Video(Cursor row) {
        this.title=
            row.getString(row.getColumnIndex(MediaStore.Video.Media.TITLE));
        this.videoUri=ContentUris.withAppendedId(
            MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
            row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));
        this.mimeType=
            row.getString(row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE));
    }

    @Override
    public boolean equals(Object obj) {
        if (!(obj instanceof Video)) {
            return(false);
        }

        return(videoUri.equals(((Video)obj).videoUri));
    }

    @Override
    public int hashCode() {
        return(videoUri.hashCode());
    }

    @Override
    public int compareTo(Video video) {
        return(title.compareTo(video.title));
    }
}
```

---

## ADVANCED RECYCLERVIEW

---

(from [Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/Video.java](#))

Note that Video has an implementation of equals() considering two Video objects to be equal if they point to the same Uri. That will be important when we use DiffUtil, as DiffUtil (and our helper code) need to know when two Video objects logically represent the same video.

Video also implements Comparable and therefore has a compareTo() method, implemented by comparing the titles of the videos. This will be used as part of our sorting logic.

The VideoAdapter has a setVideos() method, taking a Cursor that we loaded from the MediaStore, as before. However, now VideoAdapter does not hold that Cursor in a field. Rather, it holds an ArrayList of Video objects as the videos field, with setVideos() handling the conversion of data from the Cursor into the Video objects:

```
void setVideos(Cursor c) {
    if (c==null) {
        videos=null;
        notifyDataSetChanged();
    }
    else {
        ArrayList<Video> temp=new ArrayList<>();

        while (c.moveToNext()) {
            temp.add(new Video(c));
        }

        if (videos==null) {
            videos=new ArrayList<>();
        }

        sortAndApply(temp);
    }
}

@Override
```

(from [Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

We will see the sortAndApply() method, and understand what the temp local variable is all about, a bit later in this section. For now, take it on faith that:

- If the Cursor is null (e.g., onLoadReset() was called), we null out the

---

## ADVANCED RECYCLERVIEW

---

videos field and call `notifyDataSetChanged()`, to let the `RecyclerView` know that our entire roster of videos changed

- If the `Cursor` is not null, we convert it into an `ArrayList` of `Video` objects, then use `sortAndApply()` to update the `RecyclerView`

### The Menu

The other time we need to sort the videos is if the user chooses to switch from ascending to descending sort (or back again).

The app has a menu resource with a checkable menu `<item>`, named `sort`, that the user will be able to use to toggle the sort order:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/sort"
    android:checkable="true"
    android:checked="true"
    android:enabled="false"
    android:showAsAction="never"
    android:title="@string/sort_ascending" />
</menu>
```

(from [Java8/VideoLambda/app/src/main/res/menu/actions.xml](#))

Note that it is disabled initially. When the app starts up, we do not yet have our videos, since they need to be loaded from the `MediaStore`. Hence, we keep the item disabled until the videos are ready.

In the activity's `onCreateOptionsMenu()` method, we inflate the resource, get the `sort MenuItem`, hold onto it in a field (also named `sort`), and enable it if the `VideoAdapter` happens to already have some videos:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
    sort=menu.findItem(R.id.sort);
    sort.setEnabled(adapter.getItemCount()>0);

    return(super.onCreateOptionsMenu(menu));
}
```

(from [Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videlist/MainActivity.java](#))

## ADVANCED RECYCLERVIEW

---

Then, in `onOptionsItemSelected()`, if the user taps on this action bar item, we toggle its checked state, then tell the `VideoAdapter` to `sort()` based upon that state:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.sort) {
        item.setChecked(!item.isChecked());
        adapter.sort(item.isChecked());

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

`sort()`, in turn, keeps track of the current sort order, then calls the same `sortAndApply()` that we did in `setVideos()`:

```
        sortAscending=checked;
        sortAndApply(new ArrayList<>(videos));
    }
}
}
```

(from [Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

## The Diff-ing

The job of `sortAndApply()` is to do what the name suggests: sort the videos and apply the sorted list to the `RecyclerView`. In principle, there are two possible scenarios:

1. We are showing the videos for the very first time
2. We are showing the videos again, after a re-sort, or perhaps after a new video was scanned by the `MediaStore`, triggering the `Loader` framework to hand us a fresh `Cursor`

Fortunately, we can handle both the same way:

```
        Collections.sort(newVideos,
            (one, two) -> one.compareTo(two));
    }
```

```
else {
    Collections.sort(newVideos,
        (one, two) -> two.compareTo(one));
}

DiffUtil.Callback cb=new SimpleCallback<>(videos, newVideos);
DiffUtil.DiffResult result=DiffUtil.calculateDiff(cb, true);

videos=newVideos;
result.dispatchUpdatesTo(this);
}

private void sort(boolean checked) {
```

(from [Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videlist/MainActivity.java](#))

The new list of videos is the `newVideos` parameter to `sortAndApply()`. Based on the `sortAscending` value, we use `Collections.sort()` to sort the `newVideos` list... using a Java 8 lambda expression. Lambda expressions are covered [elsewhere in the book](#). However, we could just sort using an anonymous inner class implementation of `Comparator`, such as this for sorting in ascending order:

```
Collections.sort(temp, new Comparator<Video>() {
    @Override
    public int compare(Video one, Video two) {
        return(one.compareTo(two));
    }
});
```

Given the newly-sorted list, we create an instance of a `DiffUtil.Callback` object, called `SimpleCallback`. We will see its implementation shortly. Its role is to help `DiffUtil` calculate the nature of the changes to list of videos, comparing what is in the `RecyclerView` now (`videos`) with what we want the `RecyclerView` to show (`newVideos`).

That `DiffUtil.Callback` object is passed to the `calculateDiff()` method on `DiffUtil`. The second parameter — `true` — indicates whether or not objects in the list may have moved. Sometimes, we know that the updates do not move objects around in the list, but merely insert new ones or remove existing ones. In such cases, `calculateDiff()` can optimize its tracking algorithm to run more efficiently. In our case, we most definitely are changing the positions of existing objects, and therefore we need to pass `true`.

In principle, `calculateDiff()` should be called on a background thread. For long

lists and complicated comparisons, `calculateDiff()` could take long enough that you might [exhibit some jank](#) by taking up too much time on the main application thread. In this case, the comparisons are cheap, and hopefully you do not have too many videos on your test device.

The result of `calculateDiff()` is a `DiffUtil.DiffResult` object. After updating our video field to be the sorted `newVideos` collection, we call `dispatchUpdatesTo()` on the `DiffResult`, to have it apply the changes to the `VideoAdapter`. We need to update videos first because `dispatchUpdatesTo()` may trigger fresh `onBindViewHolder()` calls, and we need to make sure that we are using the newly-sorted list for those.

### The SimpleCallback

`SimpleCallback`, as the name suggests, is a naive implementation of `DiffUtil.Callback`:

```
package com.commonware.android.recyclerview.videolist;

import android.support.v7.util.DiffUtil;
import java.util.ArrayList;

class SimpleCallback<T extends Comparable> extends DiffUtil.Callback {
    private final ArrayList<T> oldItems;
    private final ArrayList<T> newItems;

    public SimpleCallback(ArrayList<T> oldItems,
                          ArrayList<T> newItems) {
        this.oldItems=oldItems;
        this.newItems=newItems;
    }

    @Override
    public int getOldListSize() {
        return(oldItems.size());
    }

    @Override
    public int getNewListSize() {
        return(newItems.size());
    }

    @Override
    public boolean areItemsTheSame(int oldItemPosition,
                                   int newItemPosition) {
```

## ADVANCED RECYCLERVIEW

---

```
        return(oldItems.get(oldItemPosition)
            .equals(newItems.get(newItemPosition)));
    }

    @Override
    public boolean areContentsTheSame(int oldItemPosition,
        int newItemPosition) {
        return(oldItems.get(oldItemPosition)
            .compareTo(newItems.get(newItemPosition))==0);
    }
}
```

(from [Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerviewvideolist/SimpleCallback.java](https://github.com/AndroidCommons/android-recyclerviewvideolist/blob/master/app/src/main/java/com/commonsware/android/recyclerviewvideolist/SimpleCallback.java))

Any `DiffUtil.Callback` needs to implement four key abstract methods:

- `getOldListSize()` and `getNewListSize()`, which return pretty much what their names would indicate
- `areItemsTheSame()`, where you need to indicate if a particular item from the old list (identified by position) represents the same logical entity as does a particular item from the new list (also identified by position)
- `areContentsTheSame()`, where you need to indicate if objects from the old and new list (identified by positions) are similar enough that the user would not notice a visual difference

Those latter two methods basically fill the same roles as do methods of the same names on a `SortedList.Callback`.

In the case of `SimpleCallback`, `areItemsTheSame()` uses `equals()`. Since `Video` implements `equals()` to compare the `video Uri` values, `areItemsTheSame()` will return `true` if the two `Video` objects point to the same video.

`areContentsTheSame()` leverages `compareTo()`, which compares the titles of the videos. If `compareTo()` return `0`, the titles are the same, and so `areContentsTheSame()` returns `true` to indicate that the visual representation of the videos is the same. This might not actually be the case, as we are showing the video thumbnails in the rows, and so it is possible that we have two videos that have the same title but different thumbnails. In that case, `DiffUtil` might not cause `RecyclerView` to redraw one or the other row. An alternative approach would be to have `areContentsTheSame()` simply return the value of `areItemsTheSame()`. This covers the thumbnails issue, at the expense of possibly doing some unnecessary shuffling of `RecyclerView` items, for cases where we have two videos with identical titles and thumbnails. It will be up to you, in your own app, to determine the best

implementation of `areContentsTheSame()` based on your UI.

## ListAdapter. No, Not *That* ListAdapter.

`android.widget.ListAdapter` is what we use with `ListView`.

`android.support.v7.recyclerview.extensions.ListAdapter` is a `ListAdapter` designed to work with `RecyclerView`. In particular, it integrates the `DiffCallback` behavior, so that as you provide updated lists of content, it calculates the differences and animates the necessary changes.

The [RecyclerView/ListAdapter](#) sample project illustrates the use of `ListAdapter`. It has the same functionality as the `SortedList` sample shown earlier in this chapter: animate the changes as we load 25 Latin words slowly into a `RecyclerView`, keeping the list sorted. The differences are:

- We use `ListAdapter` rather than `SortedList`
- We use `RxJava` instead of an `AsyncTask`
- We have to sort the contents ourselves, since `SortedList` is not doing that for us

## The Callback

`ListAdapter` uses `DiffUtil.ItemCallback`. This is very similar to `DiffUtil.Callback`. In particular, it too uses `areItemsTheSame()` and `areContentsTheSame()` for the same roles:

- `areItemsTheSame()` should return true if the two items represent the same thing (e.g., have the same primary key)
- `areContentsTheSame()` should return true if the visual representation of the two items would be identical

However, `ListAdapter` and `ItemCallback` do not expect you to hold onto the lists in the callback — instead, you are passed actual objects for comparison:

```
class StringDiffCallback extends DiffUtil.ItemCallback<String> {
    @Override
    public boolean areItemsTheSame(String oldItem, String newItem) {
        return oldItem.equals(newItem);
    }
}
```

---

## ADVANCED RECYCLERVIEW

---

```
@Override
public boolean areContentsTheSame(String oldItem, String newItem) {
    return areItemsTheSame(oldItem, newItem);
}
}
```

(from [RecyclerView/ListAdapter/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java](#))

In this case, our “models” are simple strings, so `StringDiffCallback` is handed strings for comparison purposes. Strings are very simple, so `areItemsTheSame()` and `areContentsTheSame()` have an identical implementation: use `equals()`. Having both callback methods use the same logic is a reasonable starting point even for more complex models.

## The Adapter

The revised `IconicAdapter` now extends from `ListAdapter`:

```
class IconicAdapter extends ListAdapter<String, RowController> {
    IconicAdapter() {
        super(new StringDiffCallback());
    }

    @NonNull
    @Override
    public RowController onCreateViewHolder(@NonNull ViewGroup parent, int viewType) {
        return(new RowController(getActivity().getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    @Override
    public void onBindViewHolder(@NonNull RowController holder, int position) {
        holder.bindModel(getItem(position));
    }
}
```

(from [RecyclerView/ListAdapter/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java](#))

This works similar to a regular `RecyclerView.Adapter`, with a few differences:

- We need to provide an instance of a suitable `DiffUtil.ItemCallback` in the constructor, so we pass a `StringDiffCallback`
- We do not need to keep track of the actual list of model objects ourselves, as `ListAdapter` does that for us
- In `onBindViewHolder()`, we can call `getItem()` to return the model object for a given position, for use in binding our `RecyclerView.ViewHolder`

To give a `ListAdapter` the models to show, call `submitList()`. If this is the first list

---

## ADVANCED RECYCLERVIEW

---

that the `ListAdapter` has seen, the items just get displayed in the associated `RecyclerView`. If, however, the `ListAdapter` already has a list, the `ListAdapter` uses the `DiffUtil.ItemCallback` to determine what changes are needed in the `RecyclerView` to switch from the old list to the new one. Then, it makes the appropriate calls to make those incremental changes, triggering animated effects along the way.

### The Rx Stuff

This particular sample happens to use [RxJava](#) and [Java 8 lambda expressions](#) for feeding our list of words, 400 milliseconds at a time, to the `RecyclerView`. That is handled in the `onViewCreated()` method of our `SortedFragment`:

```
@Override
public void onViewCreated(@NonNull View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    IconicAdapter adapter=new IconicAdapter();

    setAdapter(adapter);
    setLayoutManager(new LinearLayoutManager(getActivity()));

    ArrayList<String> wordsSoFar=new ArrayList<>();

    sub=Observable.fromArray(ITEMS)
        .zipWith(Observable.interval(400, TimeUnit.MILLISECONDS), (item, interval) -> item)
        .subscribeOn(Schedulers.newThread())
        .observeOn(AndroidSchedulers.mainThread())
        .map(word -> {
            wordsSoFar.add(word);

            Collections.sort(wordsSoFar);

            return new ArrayList<>(wordsSoFar);
        })
        .doOnComplete(() ->
            Toast.makeText(getActivity(), R.string.done, Toast.LENGTH_SHORT)
                .show())
        .subscribe(adapter::submitList);
}
```

(from [RecyclerView/ListAdapter/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java](#))

We start an `Observable` chain with `fromArray()`, which points to our static array of 25 Latin words.

Next, we attach a `zipWith()` operator. For every item emitted from our array, `zipWith()` will wait for an item to be emitted from some other `Observable`, then let us combine those two objects as we see fit. The other `Observable` that we use is created from `interval()`, which simply emits an object every so often, based on a

supplied period. The net effect of this line is that we introduce a 400 millisecond delay for each of the items in the array.

Right now, our `Observable` chain is emitting individual words. What we want to give the `ListAdapter` is the list of words that we have so far, in the order that we want them to appear in the `RecyclerView`. So, we attach a `map()` operator to the chain. For each word that comes in, we:

- Add it to a master copy of the words that we have received so far
- Sort that master copy
- Emit a *copy* of the master copy, as `ListAdapter` needs a fresh `ArrayList` in `submitList()`, not a modified edition of the list that it already has (otherwise, it loses track of what the old list was, since you changed it)

Then, after setting up the threads, we use `doOnComplete()` to find out when our array is finished so we can show a `Toast` to let the user know that all the words were added.

Finally, we `subscribe()` and pass each edition of the sorted list over to the `ListAdapter` by means of `submitList()`.

The net effect is the same as the earlier `SortedList` example: each item appears in the list, with animated effects to handle the inserted values.

## Expandable Rows

A common pattern in vertically-scrolling lists is to have the rows expand and contract when clicked. This allows you to have more information inline in the list, without always taking up all of the vertical space that the information might require.

This might not sound very hard: just toggle the visibility of some widgets, perhaps using an animation.

However, what we really want is that when a row is expanded, that the entirety of the expanded row is visible, assuming that there is sufficient screen space for it. Otherwise, if the user happens to expand some row at the bottom of the list, the user might not realize that more information is available off the bottom of the screen.

Making this work requires knowing where the row is in the list, how much space will

be required when it is expanded, whether the expanded row will fit given the RecyclerView size, and how to scroll the RecyclerView to make the row fit if needed.

That sounds complicated.

And so, we turn to a library: the `ExpandableLayout` provided by [com.github.SilenceDut:ExpandableLayout](https://github.com/SilenceDut/ExpandableLayout). This library is demonstrated in the [RecyclerView/ExpandableRow](#) sample project. However, this sample project makes extensive use of [the data binding framework](#), so you may wish to read that chapter before continuing with this section.

This app is another “list the recent questions on Stack Overflow” apps that have been profiled elsewhere in the book, starting with [the chapter on Internet access](#). In this case, we are using a RecyclerView for the list, with the data binding framework populating the rows.

A Stack Overflow question has [lots of possible pieces of data](#), far more than we would want to display in a RecyclerView row. Even showing a subset of this information would make for a really long list, as each row would be fairly large. So, instead, we will use `ExpandableLayout` to show the title, owner’s avatar, and question score all the time and show the tags, view count, and answer count after the user taps on a row. Since we are “stealing” the click event to expand and collapse the row, we cannot use it for anything else, so we also want a “View” button in the expanded area, to allow the user to view the Stack Overflow question on the Stack Overflow Web site.

Our `build.gradle` file pulls in libraries for accessing the Stack Exchange API (Retrofit and Picasso), libraries for displaying the results (`recyclerview-v7` and `cardview-v7`), plus `ExpandableLayout`:

```
apply plugin: 'com.android.application'

repositories {
    maven { url "https://jitpack.io" }
}

dependencies {
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit:retrofit:1.9.0'
    implementation 'com.android.support:recyclerview-v7:27.1.0'
    implementation 'com.android.support:cardview-v7:27.1.0'
    implementation("com.android.support:support-v4:27.1.0") {
```

## ADVANCED RECYCLERVIEW

---

```
        exclude group: 'com.android.support', module: 'support-media-compat'
    } // for https://issuetracker.google.com/issues/64909326
    implementation 'com.github.SilenceDut:ExpandableLayout:1.2.0'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
        versionCode 1
        versionName "1.0"
        applicationId "com.commonware.android.databind.expandable"
    }

    dataBinding {
        enabled = true
    }
}
```

(from [RecyclerView/ExpandableRow/app/build.gradle](#))

An `ExpandableLayout` contains two children. The first child will be shown all the time, while the second child represents the additional content to be shown when the `ExpandableLayout` is expanded. So, our `res/layout/row.xml` resource contains an `ExpandableLayout`, wrapping around the desired UI. The `ExpandableLayout` itself is wrapped in a `CardView` for formatting, and the whole thing is inside a `<layout>` for the data binding framework:

```
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">

    <data>

        <import type="android.text.Html" />

        <import type="android.text.TextUtils" />

        <variable
            name="question"
            type="com.commonware.android.databind.basic.Question" />

        <variable
            name="controller"
            type="com.commonware.android.databind.basic.QuestionController" />
    </data>
```

## ADVANCED RECYCLERVIEW

---

```
<android.support.v7.widget.CardView
    xmlns:cardview="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    cardview:cardCornerRadius="4dp">

    <com.silencedut.expandablelayout.ExpandableLayout
        android:id="@+id/row_content"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:background="?android:attr/selectableItemBackground"
        android:onTouch="@{controller::onTouch}"
        app:expWithParentScroll="true">

        <LinearLayout
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:orientation="horizontal">

            <ImageView
                android:id="@+id/icon"
                android:layout_width="@dimen/icon"
                android:layout_height="@dimen/icon"
                android:layout_gravity="center_vertical"
                android:contentDescription="@string/icon"
                android:padding="8dp"
                app:error="@{drawable/owner_error}"
                app:imageUrl="@{question.owner.profileImage}"
                app:placeholder="@{drawable/owner_placeholder}" />

            <TextView
                android:id="@+id/title"
                android:layout_width="0dp"
                android:layout_height="wrap_content"
                android:layout_gravity="left|center_vertical"
                android:layout_weight="1"
                android:text="@{Html.fromHtml(question.title)}"
                android:textSize="20sp" />

            <TextView
                android:id="@+id/score"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:layout_gravity="center_vertical"
                android:layout_marginLeft="8dp"
                android:layout_marginRight="8dp"
                android:text="@{Integer.toString(question.score)}"
                android:textSize="40sp"
                android:textStyle="bold" />

        </LinearLayout>

    </ExpandableLayout>

</CardView>

<LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    android:padding="8dp">

    <LinearLayout
```

## ADVANCED RECYCLERVIEW

---

```
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="1"
    android:orientation="vertical">

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:ellipsize="end"
        android:maxLines="1"
        android:text="@{string/tags+" "+TextUtils.join(", ", question.tags)}" />

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@{string/views+" "+question.viewCount}" />

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@{string/answers+" "+question.answerCount}" />

</LinearLayout>

<Button
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:onClick="@{()->controller.showQuestion(context, question)}"
    android:text="@string/btn_view" />
</LinearLayout>
</com.silencedut.expandablelayout.ExpandableLayout>
</android.support.v7.widget.CardView>
</layout>
```

(from [RecyclerView/ExpandableRow/app/src/main/res/layout/row.xml](#))

We do not need to do anything to teach `ExpandableLayout` to expand and collapse based upon click events, as that is built into the class. However, we do opt into one optional feature, via `app:expWithParentScroll="true"`. This indicates that we want to scroll the parent (here, referring to the `RecyclerView`) to allow the expanded `ExpandableLayout` to be fully visible where possible.

## ADVANCED RECYCLERVIEW

When the activity is launched, the rows are collapsed:

## ADVANCED RECYCLERVIEW

Tapping on one expands it to show the rest of the content, including scrolling the RecyclerView so it is visible:

## RecyclerView as Pager

ViewPager has been used for horizontally-swiped page-at-a-time user interfaces since its debut in 2011.

However, ViewPager is not that flexible:

- You can only swipe horizontally. It has no `setSwipeDirection()` or similar method to switch to vertical swiping.
- It was designed to work with fragments as pages. While `PagerAdapter` itself can work with views as pages, even the minimum required API is difficult to understand. And using fragments as pages means that you may wind up in cases with nested fragments, which adds to the complexity.
- While `PagerAdapter` has enough hooks to allow you to add and remove pages on the fly, neither `FragmentPagerAdapter` nor `FragmentStatePagerAdapter` support this use case, requiring you to roll your own `PagerAdapter` implementation.

And so on.

However, as it turns out, RecyclerView can be readily adapted to serve as a ViewPager replacement. Instead of a PagerAdapter, you use an ordinary RecyclerView.Adapter, where your pages are simple views. RecyclerView itself is far more flexible than is ViewPager, giving you a stronger foundation for more advanced paging scenarios.

### Using RecyclerViewPager

The original solution for using RecyclerView as a ViewPager replacement came in the form of a third-party library, `com.github.lsjwzh.RecyclerViewPager`. This library offers a `RecyclerViewPager` subclass of `RecyclerView` that offers the page-at-a-time swiping metaphor.

The [RecyclerViewPager/PlainRVP](#) sample project illustrates its use. This is another rendition of the `io-EditText-widgets` pager that was used in [the chapter on ViewPager](#), swapping in `RecyclerViewPager` for the `ViewPager`.

### Adding the Dependency

The `com.github.lsjwzh.RecyclerViewPager` library is not on JCenter or Maven Central. Instead, it is on `jitpack.io`, an artifact repository that builds artifacts directly from GitHub source repositories. So, to use this library, we need to add `jitpack.io` as a repository, in addition to adding the `RecyclerViewPager` library itself:

```
apply plugin: 'com.android.application'

repositories {
    maven { url "https://jitpack.io" }
}

dependencies {
    implementation 'com.android.support:recyclerview-v7:25.1.0'
    implementation 'com.github.lsjwzh.RecyclerViewPager:lib:v1.1.2'
}

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'

    defaultConfig {
```

---

## ADVANCED RECYCLERVIEW

---

```
    minSdkVersion 15
    targetSdkVersion 25
}
}
```

(from [RecyclerViewPager/PlainRVP/app/build.gradle](#))

### Using the Widget

In the equivalent ViewPager sample app, the main.xml layout resource held the ViewPager. In this sample, it holds the RecyclerViewPager (or, more accurately, the `com.lsjwzh.widget.recyclerviewpager.RecyclerViewPager`, since the class name needs to be fully-qualified since it is coming from a library):

```
<?xml version="1.0" encoding="utf-8"?>
<com.lsjwzh.widget.recyclerviewpager.RecyclerViewPager android:id="@+id/pager"
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:clipToPadding="false"
    android:layout_margin="@dimen/pager_padding"
    app:rvp_singlePageFling="true"
    app:rvp_triggerOffset="0.1" />
```

(from [RecyclerViewPager/PlainRVP/app/src/main/res/layout/main.xml](#))

The `app:rvp_singlePageFling` indicates that we want to limit the user to switch one page at a time, rather than a long fling gesture resulting in moving through many pages at once. The `app:rvp_triggerOffset` attribute is undocumented but appears to control how much of a swipe gesture is necessary to trigger a page change.

### Populating the Pages

With ViewPager, you supply the pages via a PagerAdapter, typically a FragmentPagerAdapter or a FragmentStatePagerAdapter. With RecyclerViewPager, you supply the pages via a RecyclerView.Adapter, just as you would with any other RecyclerView.

So, in `onCreate()` of the MainActivity, we get the RecyclerViewPager, hand it a horizontal LinearLayoutManager, create a PageAdapter, and attach that PageAdapter to the RecyclerViewPager:

## ADVANCED RECYCLERVIEW

---

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    RecyclerViewPager pager=(RecyclerViewPager)findViewById(R.id.pager);

    pager.setLayoutManager(new LinearLayoutManager(this,
        LinearLayoutManager.HORIZONTAL, false));
    adapter=new PageAdapter(pager, getLayoutInflater());
    pager.setAdapter(adapter);
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

By using a horizontal `LinearLayoutManager`, the `RecyclerViewPager` will behave akin to a regular `ViewPager`, with navigation occurring via horizontal swipes. Want a vertical `ViewPager`? Replace the horizontal `LinearLayoutManager` with a vertical one, and you are set.

Our `PageAdapter` is a `RecyclerView.Adapter`, for a `RecyclerView.ViewHolder` named `PageController`. The basic setup for `PageAdapter` is not that different than any other `RecyclerView.Adapter`:

- We create a `PageController` in `onCreateViewHolder()`
- We populate that `PageController` with model data in `onBindViewHolder()`
- We indicate how many items there are in `getItemCount()`

```
class PageAdapter extends RecyclerView.Adapter<PageController> {
    private static final String STATE_BUFFERS="buffers";
    private static final int PAGE_COUNT=10;
    private final RecyclerViewPager pager;
    private final LayoutInflater inflater;
    private ArrayList<String> buffers=new ArrayList<>();

    PageAdapter(RecyclerViewPager pager, LayoutInflater inflater) {
        this.pager=pager;
        this.inflater=inflater;

        for (int i=0;i<10;i++) {
            buffers.add("");
        }
    }

    @Override
    public PageController onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new PageController(inflater.inflate(R.layout.editor, parent, false)));
    }

    @Override
    public void onBindViewHolder(PageController holder, int position) {
```

## ADVANCED RECYCLERVIEW

---

```
holder.setText(bufers.get(position));
}

@Override
public int getItemCount() {
    return(PAGE_COUNT);
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

In this case, our model data is an `ArrayList` of `String` objects, representing the text that the user enters into each page's `EditText`. `PAGE_COUNT` caps the number of editors (and pages) at 10, and so we initialize 10 buffers in the `PageAdapter` constructor.

The layout used for the pages — inflated by `onCreateViewHolder()` — is just a full-page multi-line `EditText` widget:

```
<EditText xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/editor"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:inputType="textMultiLine"
    android:gravity="left|top"
/>
```

(from [RecyclerViewPager/PlainRVP/app/src/main/res/layout/editor.xml](#))

`PageController` is a fairly basic `RecyclerView.ViewHolder`, wrapping our `EditText` and offering a getter and setter for manipulating the text in the editor:

```
package com.commonsware.android.rvp;

import android.support.v7.widget.RecyclerView;
import android.view.View;
import android.widget.EditText;

class PageController extends RecyclerView.ViewHolder {
    private final EditText editor;

    PageController(View itemView) {
        super(itemView);

        editor=(EditText)itemView.findViewById(R.id.editor);
    }

    void setText(String text) {
```

---

## ADVANCED RECYCLERVIEW

---

```
editor.setText(text);
editor.setHint(editor.getContext().getString(R.string.hint,
    getAdapterPosition()+1));
}

String getText() {
    return(editor.getText().toString());
}
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/PageController.java](#))

In case the buffer is empty (as it is at the outset), we also set the hint of the `EditText` to be the current page's index, adding one to adjust the range to start at 1 rather than 0. The hint text itself is in a string resource, with a `%d` placeholder for the page number:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <string name="app_name">RVP Demo</string>
    <string name="hint">Editor #d</string>
</resources>
```

(from [RecyclerViewPager/PlainRVP/app/src/main/res/values/strings.xml](#))

We use the `N`-parameter `getString()` method to not only retrieve the hint string resource but run it through `String.format()` to populate the placeholders, in this case using `getAdapterPosition()` to determine our page number.

### Dealing with Recycling

`RecyclerView` wants to recycle its items. That is in contrast to how the stock `PagerAdapter` implementation works:

- `FragmentPagerAdapter` holds onto every fragment created due to the user's navigation
- `FragmentStatePagerAdapter` holds onto some fragments, but lets others get garbage-collected, to minimize memory consumption

If our pages were read-only, we would not have to worry about recycling. This is how many `RecyclerView` implementations work — they just focus on binding the right data into the right `RecyclerView.ViewHolder` at the right time, based on calls to `onBindViewHolder` in the `RecyclerView.Adapter`.

---

## ADVANCED RECYCLERVIEW

---

However, when the RecyclerView items are interactive, we need to make sure that we hold onto the changed data, rather than having it be overwritten when we bind fresh data into the recycled item's views.

In PageAdapter, we handle this by overriding `onViewDetachedFromWindow()`, which is called when the views of a PageController are no longer part of our activity's window. Typically, this will occur as part of scrolling. In our case, we use this opportunity to grab the current contents of that EditText widget and update our buffers data model to match:

```
@Override
public void onViewDetachedFromWindow(PageController holder) {
    super.onViewDetachedFromWindow(holder);

    buffers.set(holder.getAdapterPosition(), holder.getText());
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

Alternatively, you could aim to deal with this more in “real time”, such as by using a TextWatcher to update the model as the user types. That adds a fair bit of overhead, though.

### Dealing with Configuration Changes

We need to make sure that we do not lose what the user types into the pages when we undergo a configuration change. Since our model is a simple ArrayList of String objects, we can use the saved instance state Bundle to hold onto the in-flight information.

A RecyclerView.Adapter does not have its own `onSaveInstanceState()` method, but we can add one, then call it from MainActivity:

```
@Override
protected void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);

    Bundle adapterState=new Bundle();

    adapter.onSaveInstanceState(adapterState);
    state.putBundle(STATE_ADAPTER, adapterState);
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

## ADVANCED RECYCLERVIEW

---

Here, MainActivity provides a fresh Bundle to the adapter. This way, values that the adapter wishes to save in the instance state will not collide with anything else the activity would want to save in the instance state, due to accidental key collisions. In this case, this may well be superfluous, but it is a worthwhile practice.

The challenge in our PageAdapter is that buffers only has text from those PageController objects that have been recycled. That will not include the currently-visible page or possibly some adjacent pages.

So, we iterate over all pages and call `findViewByIdForAdapterPosition()` on the RecyclerView itself. This will return null for any positions for which no PageController is presently allocated, or the PageController for the position for those positions that are actively being used. For those latter ones, we update the buffers to reflect whatever is in the EditText widgets, saving that into the instance state Bundle:

```
void onSaveInstanceState(Bundle state) {
    for (int i=0;i<PAGE_COUNT;i++) {
        PageController holder=
            (PageController)pager.findViewByIdForAdapterPosition(i);

        if (holder!=null) {
            buffers.set(i, holder.getText());
        }
    }

    state.putStringArrayList(STATE_BUFFERS, buffers);
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

MainActivity has a corresponding `onRestoreInstanceState()` method:

```
@Override
protected void onRestoreInstanceState(Bundle state) {
    super.onRestoreInstanceState(state);

    adapter.onRestoreInstanceState(state.getBundle(STATE_ADAPTER));
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

That delegates the work to the `onRestoreInstanceState()` method on the PageAdapter:

---

## ADVANCED RECYCLERVIEW

---

```
void onRestoreInstanceState(Bundle state) {  
    buffers=state.getStringArrayList(STATE_BUFFERS);  
}
```

(from [RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

This sets up our buffers for use in populating pages again.

### Using SnapHelper

RecyclerViewPager was first released in 2014. Since then, RecyclerView and its supporting classes have evolved. Now, you can get much of the functionality of RecyclerViewPager with an ordinary RecyclerView, with the assistance of SnapHelper. As Lisa Wray profiled in [a droidcon NYC 2016 presentation](#), SnapHelper is a utility class that forces swipe gestures to “snap” to certain locations or boundaries. And, there is a PagerSnapHelper that, in conjunction with properly-configured RecyclerView and items, gives you ViewPager-like behavior.

The [RecyclerViewPager/PlainSnap](#) sample project is a clone of the PlainRVP sample, except that the RecyclerViewPager is replaced by a RecyclerView and a PagerSnapHelper.

There are three requirements of PagerSnapHelper. Two are tied to the layouts: both the RecyclerView and its items need to have match\_parent for android:layout\_width and android:layout\_height. That was how PlainRVP was set up already, though PlainSnap swaps in a RecyclerView for the RecyclerViewPager in main.xml:

```
<?xml version="1.0" encoding="utf-8"?>  
<android.support.v7.widget.RecyclerView android:id="@+id/pager"  
    xmlns:android="http://schemas.android.com/apk/res/android"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent"  
    android:layout_margin="@dimen/pager_padding"  
    android:clipToPadding="false" />
```

(from [RecyclerViewPager/PlainSnap/app/src/main/res/layout/main.xml](#))

The other requirement is that we create an instance of PagerSnapHelper and call attachToRecyclerView() on it, supplying our RecyclerView. This is handled in an updated MainActivity:

```
package com.commonsware.android.rvp;
```

## ADVANCED RECYCLERVIEW

---

```
import android.app.Activity;
import android.os.Bundle;
import android.support.v7.widget.LinearLayoutManager;
import android.support.v7.widget.PagerSnapHelper;
import android.support.v7.widget.RecyclerView;
import android.support.v7.widget.SnapHelper;

public class MainActivity extends Activity {
    private static final String STATE_ADAPTER="adapter";
    private final SnapHelper snapperCarr=new PagerSnapHelper();
    private PageAdapter adapter;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        RecyclerView pager=(RecyclerView)findViewById(R.id.pager);

        pager.setLayoutManager(new LinearLayoutManager(this,
            LinearLayoutManager.HORIZONTAL, false));
        snapperCarr.attachToRecyclerView(pager);

        adapter=new PageAdapter(pager, getLayoutInflater());
        pager.setAdapter(adapter);
    }

    @Override
    protected void onSaveInstanceState(Bundle state) {
        super.onSaveInstanceState(state);

        Bundle adapterState=new Bundle();

        adapter.onSaveInstanceState(adapterState);
        state.putBundle(STATE_ADAPTER, adapterState);
    }

    @Override
    protected void onRestoreInstanceState(Bundle state) {
        super.onRestoreInstanceState(state);

        adapter.onRestoreInstanceState(state.getBundle(STATE_ADAPTER));
    }
}
```

(from [RecyclerViewPager/PlainSnap/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

We hold onto the PagerSnapHelper in a field, to ensure that it will not be garbage-

collected unexpectedly. *Probably* the PagerSnapHelper has sufficient connections to the RecyclerView to ensure that it will stay around as long as its associated RecyclerView does, but that is not apparent from the API or the documentation.

Beyond that, we configure the RecyclerView much as we had configured the RecyclerViewPager, and our PageAdapter and PageController are largely unaffected by the UI switch. In the end, we wind up once again with page-at-a-time horizontal swiping, though this time we can skip the third-party library.

### Adding Tabs

Many times, with a pager-style interface, we want an indicator to help the user understand where they are within the range of pages offered by the pager. One of the more popular indicator styles is tabs, as those also provide an alternative navigation option, with the user tapping on tabs to switch to particular pages.

For adding tabs to a RecyclerView-powered pager, you need a tab implementation that is not tied inextricably to ViewPager, the way PagerTabStrip is. At the same time, you need one that is not tied inextricably to some other particular UI setup, the way that FragmentTabHost is. Instead, you need tabs that “stick to their knitting” and focus solely on handling the tab UI, giving you the hooks necessary to update your UI based on tab changes, and to update the tabs based on other UI changes.

TabLayout, from [the Design Support library](#), is one such tab implementation. While it offers hooks into ViewPager, those are optional. You have two main options for using TabLayout:

1. Literally use the version from the Design Support library, which will require you to use appcompat-v7. This works back to API Level 7, as does RecyclerView itself.
2. Use the TabLayout from [the CWAC-CrossPort library](#), which is the official TabLayout code, with all references to appcompat-v7 replaced by references to Theme.Material and related native items. However, this limits this cross-ported TabLayout to API Level 21 and higher (Android 5.0).

The [RecyclerViewPager/TabSnap](#) sample project is a clone of the PlainSnap sample, with tabs added, via the TabLayout from CWAC-CrossPort. As a result, we need the CWAC-CrossPort dependency and need to raise our minSdkVersion to 21:

```
apply plugin: 'com.android.application'
```

## ADVANCED RECYCLERVIEW

---

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    implementation 'com.android.support:recyclerview-v7:25.1.0'
    implementation 'com.commonsware.cwac:crossport:0.0.2'
}

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 21
        targetSdkVersion 25
        applicationId 'com.commonsware.cwac.rvp.tabsnap'
    }
}
```

(from [RecyclerViewPager/TabSnap/app/build.gradle](#))

The tabs themselves can then go above the RecyclerView, in a vertical LinearLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:orientation="vertical">

    <com.commonsware.cwac.crossport.design.widget.TabLayout
        android:id="@+id/tabs"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        app:tabMode="scrollable"/>

    <android.support.v7.widget.RecyclerView
        android:id="@+id/pager"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_margin="@dimen/pager_padding"
        android:clipToPadding="false" />
</LinearLayout>
```

## ADVANCED RECYCLERVIEW

---

(from [RecyclerViewPager/TabSnap/app/src/main/res/layout/main.xml](#))

Next, we need to set up the tab contents in `onCreate()` of `MainActivity`. To do that, we get our hands on the `TabLayout` using `findViewById()`, then iterate through the items in the `PagerAdapter` to set up tabs for each:

```
final TabLayout tabs=(TabLayout)findViewById(R.id.tabs);

for (int i=0;i<adapter.getItemCount();i++) {
    tabs.addTab(tabs.newTab().setText(adapter.getTabText(this, i)));
}
```

(from [RecyclerViewPager/TabSnap/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

We ask the `PagerAdapter` for the text to show in the tab, via a `getTabText()` method:

```
String getTabText(Context ctxt, int position) {
    return(PageController.getTitle(ctxt, position));
}
```

(from [RecyclerViewPager/TabSnap/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java](#))

That, in turn, delegates to a static version of the `getTitle()` method on `PageController`, to fill in the string resource template with the proper page number:

```
static String getTitle(Context ctxt, int position) {
    return(ctxt.getString(R.string.hint, position+1));
}
```

(from [RecyclerViewPager/TabSnap/app/src/main/java/com/commonsware/android/rvp/PageController.java](#))

We now need to add code in `onCreate()` of `MainActivity` to tie the navigation together:

- When the user taps a tab, we need to update the pager
- When the user swipes the pager, we need to update the tabs to show the new selection

This is handled by event listeners:

```
tabs.addTabSelectedListener(new TabLayout.OnTabSelectedListener() {
    @Override
    public void onTabSelected(TabLayout.Tab tab) {
        pager.smoothScrollToPosition(tab.getPosition());
    }
})
```

## ADVANCED RECYCLERVIEW

---

```
@Override
public void onTabUnselected(TabLayout.Tab tab) {
    // unused
}

@Override
public void onTabReselected(TabLayout.Tab tab) {
    // unused
}
});

pager.setOnScrollListener(new RecyclerView.OnScrollListener() {
    @Override
    public void onScrolled(RecyclerView recyclerView, int dx, int dy) {
        int tab=layoutManager.findFirstCompletelyVisibleItemPosition();

        if (tab>=0 && tab<tabs.getTabCount()) {
            tabs.getTabAt(tab).select();
        }
    }
});
```

(from [RecyclerViewPager/TabSnap/app/src/main/java/com/commonsware/android/rvp/MainActivity.java](#))

When a tab is selected, our anonymous `TabLayout.OnTabSelectedListener` implementation will get control in `onTabSelected()`. There, we tell the `RecyclerView` to scroll to show a particular position, tied to the position of the selected tab.

Similarly, when the user scrolls the pager, we need to update the tabs to show the new selection. To do that, we take advantage of the `findFirstCompletelyVisibleItemPosition()` method on `LinearLayoutManager`. As the (lengthy) method name suggests, this returns the position of the first item that is completely visible within the pager. This might return `-1`, if we are in the middle of a swipe, as no item may be *completely* visible at that point. But, once we get a plausible value, we tell the `TabLayout` to select that tab.

`RecyclerViewPager` has a more sophisticated algorithm for integrating with the official Design Support library implementation of `TabLayout`. `RecyclerViewPager` calculates the position of the tab highlight, based upon the current swipe position, and updates that. This provides visual feedback within the tabs while the swipe is going on. The approach shown in the sample app has the effect of only updating the tabs once the swipe is completed.

## Declaring a LayoutManager in the Layout

The typical way of setting up a `LayoutManager` is to call `setLayoutManager()` on the `RecyclerView`. There may be no choice in some cases, if the `LayoutManager` that you wish to use has a custom constructor that you need.

However, in some cases, where the `LayoutManager` has adequate setters to configure it beyond the constructor, you can set up the `LayoutManager` in your layout resource file. Just add the `app:layoutManager` attribute to the `RecyclerView` element, with the value being:

- the bare class name of a standard `LayoutManager`, such as `LinearLayoutManager`, or
- the fully-qualified class name of some custom `LayoutManager`, one that you wrote or are using from a library

The app XML namespace (`xmlns:app="http://schemas.android.com/apk/res-auto"`) can be added to the layout resource file by an Android Studio quick-fix.

## Transcript Mode

“Transcript mode” with `ListView` means that the `ListView` automatically scrolls to keep the bottom entries in view. This is useful for things like chat transcripts, where you want to append new messages and show those new messages to the user, and the new messages (traditionally) go below older messages. This approach — using `setTranscriptMode()` — has been used a couple of times in this book, such as in [the chapter profiling various event bus implementations](#).

`RecyclerView` also supports this approach, though it is set up somewhat differently.

The [RecyclerView/Transcript](#) sample project is a clone of the [EventBus/GreenRobot3](#) sample project, where the `ListView` is replaced by a `RecyclerView`.

In a layout resource, we declare our `RecyclerView`, with a few interesting attributes:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.RecyclerView android:id="@+id/transcript"
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
```

## ADVANCED RECYCLERVIEW

---

```
app:layoutManager="LinearLayoutManager"  
app:reverseLayout="true"  
app:stackFromEnd="true" />
```

(from [RecyclerView/Transcript/app/src/main/res/layout/main.xml](#))

Specifically, we have:

- `app:layoutManager` defines the layout manager that we want to use, in this case a `LinearLayoutManager`
- `app:reverseLayout="true"` and `app:stackFromEnd="true"`, which combine to give us a transcript-style effect

Note that those latter two attributes are actually documented on `LinearLayoutManager`, not on `RecyclerView` (and, even then, they are largely undocumented). Those attributes may not work with other layout managers (e.g., `GridLayoutManager`).

Beyond that, the rest of the code works pretty much as the original sample app did, except that we need to substitute in `RecyclerView` equivalents for the `ListView` functionality. So, for example, rather than inheriting from `ListViewFragment`, the `EventLogFragment` is now a regular `Fragment`, where we inflate our layout in `onCreateView()` and attach its `EventLogAdapter` in `onViewCreated()`:

```
@Nullable  
@Override  
public View onCreateView(LayoutInflater inflater, ViewGroup container,  
                          Bundle savedInstanceState) {  
    return(inflater.inflate(R.layout.main, container, false));  
}  
  
@Override  
public void onViewCreated(View view, Bundle savedInstanceState) {  
    super.onViewCreated(view, savedInstanceState);  
  
    if (adapter==null) {  
        adapter=new EventLogAdapter();  
    }  
  
    RecyclerView transcript=(RecyclerView)view.findViewById(R.id.transcript);  
  
    transcript.setAdapter(adapter);  
}
```

(from [RecyclerView/Transcript/app/src/main/java/com/commonsware/android/rv/transcript/EventLogFragment.java](#))

## ADVANCED RECYCLERVIEW

---

The old ArrayAdapter is gone, so EventLogAdapter is now a RecyclerView.Adapter, managing a series of ViewHolder objects for our rows:

```
class EventLogAdapter extends RecyclerView.Adapter<ViewHolder> {
    private final ArrayList<RandomEvent> events=new ArrayList<>();

    @Override
    public ViewHolder onCreateViewHolder(ViewGroup parent,
                                       int viewType) {
        View row=
            getActivity()
                .getLayoutInflater()
                .inflate(android.R.layout.simple_list_item_1, parent, false);

        return(new ViewHolder(row));
    }

    @Override
    public void onBindViewHolder(ViewHolder holder,
                                int position) {
        holder.bind(events.get(position));
    }

    @Override
    public int getItemCount() {
        return(events.size());
    }

    void add(RandomEvent event) {
        events.add(event);
        notifyItemInserted(getItemCount());
    }
}

static class ViewHolder extends RecyclerView.ViewHolder {
    private static final DateFormat fmt=
        new SimpleDateFormat("HH:mm:ss", Locale.US);
    private final TextView tv;

    ViewHolder(View itemView) {
        super(itemView);

        tv=(TextView)itemView.findViewById(android.R.id.text1);
    }

    void bind(RandomEvent event) {
        tv.setText(String.format("%s = %x", fmt.format(event.when),

```

## ADVANCED RECYCLERVIEW

---

```
        event.value));  
    }  
}
```

(from [RecyclerView/Transcript/app/src/main/java/com/commonsware/android/rv/transcript/EventLogFragment.java](#))

And, when we get a `RandomEvent`, we `add()` that to our `EventLogAdapter`, which adds it to its array of events and updates the `RecyclerView` to match:

```
@Subscribe(threadMode = ThreadMode.MAIN)  
public void onRandomEvent(final RandomEvent event) {  
    adapter.add(event);  
}
```

(from [RecyclerView/Transcript/app/src/main/java/com/commonsware/android/rv/transcript/EventLogFragment.java](#))

# Advanced Uses of WebView

---

Android uses the WebKit browser engine as the foundation for both its Browser application and the WebView embeddable browsing widget. The Browser application, of course, is something Android users can interact with directly; the WebView widget is something you can integrate into your own applications for places where an HTML interface might be useful.

[Earlier in this book](#), we saw a simple integration of a WebView into an Android activity, with the activity dictating what the browsing widget displayed and how it responded to links.

Here, we will expand on this theme, and show how to more tightly integrate the Java environment of an Android application with the JavaScript environment of WebKit.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one [covering WebView](#). Some of the samples [use LocationManager](#) for obtaining a GPS fix.

## Friends with Benefits

When you integrate a WebView into your activity, you can control what Web pages are displayed, whether they are from a local provider or come from over the Internet, what should happen when a link is clicked, and so forth. And between WebView, WebViewClient, and WebSettings, you can control a fair bit about how the embedded browser behaves. Yet, by default, the browser itself is just a browser, capable of showing Web pages and interacting with Web sites, but otherwise gaining

nothing from being hosted by an Android application.

However, WebView offers a few options for more tightly integrating the Java and JavaScript realms, so Web content can call into your app to get data to display, and your app can push data into the Web page for JavaScript to render.

Unfortunately, the techniques for doing this have changed over the years. Partially that is due to changes in WebView, particularly starting with Android 4.4. But, some of the changes are due to security issues, particularly when you are loading arbitrary content, such as Web-based ads from an ad network, into your WebView.

The following sections will go over four separate sample apps. All do the same thing: provide data about the ambient light level, using the [sensor](#) on the phone or tablet, to the Web page for rendering. The differences are whether we are pushing data from Java into JavaScript (e.g., as the light level changes), or whether we are pulling data from Java using JavaScript (e.g., in response to a user tapping on something in the Web page). Also, we will see two approaches to push and two approaches to pull.

### JavaScript Calling Java: `addJavascriptInterface()`

The `addJavascriptInterface()` method on `WebView` allows you to inject a Java object into the `WebView`, exposing its methods, so they can be called by JavaScript loaded by the Web content in the `WebView` itself.

Now you have the power to provide access to a wide range of Android features and capabilities to your `WebView`-hosted content. If you can access it from your activity, and if you can wrap it in something convenient for use by JavaScript, your Web pages can access it as well.

The [WebKit/SensorPull](#) sample project demonstrates using `addJavascriptInterface()` to pull light sensor data into a Web page to display to the user.

For all four of these sample apps, the UI is just a `WebView`:

```
<?xml version="1.0" encoding="utf-8"?>
<WebView android:id="@+id/webkit"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">
</WebView>
```

## ADVANCED USES OF WEBVIEW

---

(from [WebKit/SensorPull/app/src/main/res/layout/main.xml](#))

In onCreate(), we set things up:

```
@SuppressWarnings({"AddJavascriptInterface", "SetJavaScriptEnabled"})
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    mgr=(SensorManager) getSystemService(Context.SENSOR_SERVICE);
    light=mgr.getDefaultSensor(Sensor.TYPE_LIGHT);

    ww=(WebView) findViewById(R.id.webkit);
    ww.getSettings().setJavaScriptEnabled(true);
    ww.addJavascriptInterface(jsInterface, "LIGHT_SENSOR");
    ww.loadUrl("file:///android_asset/index.html");
}
```

(from [WebKit/SensorPull/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

Specifically, we:

- Get a SensorManager and the appropriate Sensor for measuring ambient light levels, saving those in fields
- Get our WebView via findViewById()
- Enable JavaScript (which comes disabled by default), using getSettings() and setJavaScriptEnabled(true)
- Call addJavascriptInterface(), and
- Load a Web page from assets (which we will examine shortly)

Because we are enabling JavaScript, Lint will complain that this poses security risks, so onCreate() has a @SuppressWarnings annotation for SetJavaScriptEnabled to indicate that we are aware of the risks. Similarly, because we are calling addJavascriptInterface(), Lint will complain that this poses even more security risks. So, @SuppressWarnings suppresses both the SetJavaScriptEnabled warning and the AddJavascriptInterface warning.

Also, you may notice that there is a significant debate within the Android SDK as to whether the “s” in “JavaScript” gets capitalized or not. In general, it does, but addJavascriptInterface() shipped in API Level 1 with a lowercase “s” in its name, and so that method, and variations of it (e.g., the AddJavascriptInterface annotation) will use a lowercase “s”. Eventually, you just get used to this.

---

## ADVANCED USES OF WEBVIEW

---

`addJavascriptInterface()` takes two parameters: a Java object to inject into the JavaScript of the Web page, and a String that is the name by which JavaScript can reference that object. So, we have a `jsInterface` object that JavaScript can reference via `LIGHT_SENSOR`.

`jsInterface` is an instance of `JSInterface`, a static nested class inside `MainActivity`:

```
private static class JSInterface {
    float lux=0.0f;

    private void updateLux(float lux) {
        this.lux=lux;
    }

    @JavascriptInterface
    public String getLux() {
        return(String.format(Locale.US, "{\"lux\": %f}", lux));
    }
}
```

(from [WebKit/SensorPull/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

It just has a getter and setter around the current light level, which is a float named `lux` (referring to the unit of brightness used for the values coming from the ambient light sensor). The getter, however, has two interesting traits:

- It returns a `String`, representing a JSON object wrapped around the `lux` value
- It is annotated with `@JavascriptInterface`

This annotation is required of apps with `android:targetSdkVersion` set to 17 or higher, though it is a good idea to start using it anyway. With such an `android:targetSdkVersion`, in an app running on an Android 4.2 or higher device, *only* public methods with the `@JavascriptInterface` annotation will be accessible by JavaScript code. On earlier devices, or with an earlier `android:targetSdkVersion`, *all* public methods on the `JSInterface` object would be accessible by JavaScript, including those inherited from superclasses like `Object`. Note that your build target (i.e., `compileSdkVersion` in Android Studio) will need to be Android 4.2 or higher in order to reference the `@JavascriptInterface` annotation.

The reason for returning a JSON object (in string form), rather than just the float, is for two reasons:

## ADVANCED USES OF WEBVIEW

---

1. For more complex APIs, you cannot pass into JavaScript an arbitrary Java object. All return types from @JavascriptInterface objects need to be something that JavaScript can use, and a simple way to do that is to create data structures in JSON.
2. float did not seem to work well as a return type, as it always seemed to turn into 0.0 on the JavaScript side, for unknown reasons

We register with the SensorManager to find out when the light level changes, via registerListener() (in onStart()) and unregisterListener() (in onStop()):

```
@Override
protected void onStart() {
    super.onStart();

    mgr.registerListener(this, light, SensorManager.SENSOR_DELAY_UI);
}

@Override
protected void onStop() {
    mgr.unregisterListener(this);

    super.onStop();
}
```

(from [WebKit/SensorPull/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

That, in turn, will trigger a call to onSensorChanged() when the light level changes. There, we pass the light level (the first float out of the values array from the SensorEvent) to the JsInterface instance, ready to be retrieved by the JavaScript code in our Web page:

```
@Override
public void onSensorChanged(SensorEvent sensorEvent) {
    jsInterface.updateLux(sensorEvent.values[0]);
}

@Override
public void onAccuracyChanged(Sensor sensor, int i) {
    // unused
}
```

(from [WebKit/SensorPull/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

In the Web page, we set it up to show the current light level, starting with a value of 0.0. When the user taps on the Light Level caption, we call a pull() JavaScript

## ADVANCED USES OF WEBVIEW

---

function, which:

- Calls our `getLux()` method on the `LIGHT_SENSOR` global object
- Parses our JSON into a JavaScript object
- Calls an `update_lux()` function to update the lux span with the new light level

```
<html>
<head>
<title>Android Light Sensor Demo</title>
<script language="javascript">
  function update_lux(lux) {
    document.getElementById("lux").innerHTML=lux;
  }

  function pull() {
    var result=JSON.parse(LIGHT_SENSOR.getLux());

    update_lux(result.lux);
  }
</script>
</head>
<body>
<p><b><a onClick="pull()">Light Level</a>: </b><span id="lux">0.0</span> lux</p>
</body>
</html>
```

(from [WebKit/SensorPull/app/src/main/assets/index.html](http://WebKit/SensorPull/app/src/main/assets/index.html))

## ADVANCED USES OF WEBVIEW

---

If you run the app, you get our trivial Web page in the webView:

*Figure 517: SensorPull Demo, As Initially Launched*

Tapping on the words “Light Level” will cause JavaScript to request the light level, updating the page to match:

*Figure 518: SensorPull Demo, Showing Light Level*

Note that this sample app will only work on devices with an ambient light sensor. It is rather likely that the app will crash spectacularly on devices lacking such a sensor.

Unfortunately, `addJavascriptInterface()` opens up a number of security issues, outlined [later in this chapter](#). Where possible, avoid the use of this API.

### **Java Calling JavaScript: `loadUrl()` and `evaluateJavascript()`**

Now that we have seen how JavaScript can call into Java, it would be nice if Java could somehow call out to JavaScript. Well, as luck would have it, we can do that too. This is a good thing, otherwise, this would be a really weak section of the book.

What is unusual is how you call out to JavaScript. One might imagine there would be an `evaluateJavaScript()` counterpart to `addJavascriptInterface()`, where you could supply some JavaScript source and have it executed within the context of the currently-loaded Web page.

Actually, there *is* such a method on Android 4.4. However, earlier versions of

## ADVANCED USES OF WEBVIEW

---

Android lacked that method. Instead, on older versions of Android, given your snippet of JavaScript source to execute, you call `loadUrl()` on your `WebView`, as if you were going to load a Web page, but you put `javascript:` in front of your code and use that as the “address” to load.

If you have ever created a “bookmarklet” for a desktop Web browser, you will recognize this technique as being the Android analogue – the `javascript:` prefix tells the browser to treat the rest of the address as JavaScript source, injected into the currently-viewed Web page.

The [WebKit/SensorPush](#) sample project expands upon the `SensorPull` app. This time, though, in addition to pulling via `addJavascriptInterface()`, we support pushing light levels as sensor readings come in.

That comes courtesy of a revised `onSensorChanged()` method:

```
@Override
public void onSensorChanged(SensorEvent sensorEvent) {
    float lux=sensorEvent.values[0];

    jsInterface.updateLux(lux);

    String js=String.format(Locale.US, "update_lux(%f)", lux);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.KITKAT) {
        ww.evaluateJavascript(js, null);
    }
    else {
        ww.loadUrl("javascript:"+js);
    }
}
```

(from [WebKit/SensorPush/app/src/main/java/com/commonware/android/webkit/bridge/MainActivity.java](#))

Before, we just updated the `JsInterface` object with the new light level. Now, we also format a JavaScript call to `update_lux()`, supplying our light level. Then, based on Android OS version (`Build.VERSION.SDK_INT`), we either call `evaluateJavascript()` or `loadUrl()`, the latter also employing the `javascript:` scheme.

Because we had pulled out `update_lux()` as a separate function before, our HTML and JavaScript does not need to change at all:

```
<html>
```

---

## ADVANCED USES OF WEBVIEW

---

```
<head>
<title>Android Light Sensor Demo</title>
<script language="javascript">
  function update_lux(lux) {
    document.getElementById("lux").innerHTML=lux;
  }

  function pull() {
    var result=JSON.parse(LIGHT_SENSOR.getLux());

    update_lux(result.lux);
  }
</script>
</head>
<body>
<p><b><a onClick="pull()">Light Level</a>: </b><span id="lux">0.0</span> lux</p>
</body>
</html>
```

(from [WebKit/SensorPush/app/src/main/assets/index.html](#))

If you run this sample app, you will find that the Web page updates in real time as you wave your hand in front of the light sensor, shine a light on that sensor, etc.

### Java Calling JavaScript: WebMessage

Both of those techniques have worked since API Level 1. But, as mentioned, `addJavascriptInterface()` has security issues. Also, `evaluateJavascript()` (or its `loadUrl()` equivalent) requires the Java code to know what functions are available in the Web page. That may tie the Java and JavaScript more tightly than you might like.

Android 6.0 introduced another pair of options for communicating between Java and JavaScript — `WebMessage` and `WebMessagePort` — that try to eliminate these issues.

The simpler of the two approaches is `WebMessage`. Instead of calling `evaluateJavascript()` or `loadUrl()`, you create a `WebMessage` object and call `postWebMessage()` to deliver it to the JavaScript in your Web page. So, in the [WebKit/SensorMessage](#) sample project, we have an updated `onSensorChanged()` method that does this:

```
@Override
public void onSensorChanged(SensorEvent sensorEvent) {
    float lux=sensorEvent.values[0];

    jsInterface.updateLux(lux);

    String js=String.format(Locale.US, "update_lux(%f)", lux);
```

## ADVANCED USES OF WEBVIEW

---

```
if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.M) {
    ww.postMessage(new WebMessage(jsInterface.getLux()),
        Uri.EMPTY);
}
else if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
    ww.evaluateJavascript(js, null);
}
else {
    ww.loadUrl("javascript:"+js);
}
}
```

(from [WebKit/SensorMessage/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

The `WebMessage` constructor that we are using here takes a simple string that is the content of the message. In this case, it is the JSON object wrapping our light level in lux, using the same `getLux()` method that JavaScript can call on our `JsInterface` instance that we registered via `addJavascriptInterface()`.

`postWebMessage()` takes two parameters. The first is the `WebMessage` to deliver to the page. The other is supposed to be the `Uri` of the Web page. This is supposed to be used to confirm that you are sending the message to the page that you think you are sending it to.

Unfortunately, this is not behaving especially well.

It only works as advertised for `http/https` URLs, or for data that you load using `loadDataWithBaseURL()` and supply some `http` or `https` URL. If you load from a file URL, as we are doing here, you cannot use the actual URL. Instead, you have to use `Uri.EMPTY`, which is a “wildcard” that skips over this test, which is what we use here. Apparently, this is all [working as intended](#).

To receive these messages, our JavaScript needs to define an `onmessage()` global function:

```
<html>
<head>
<title>Android Light Sensor Demo</title>
<script language="javascript">
    function update_lux(lux) {
        document.getElementById("lux").innerHTML=lux;
    }

    function parse(json) {
        var result=JSON.parse(json);
```

## ADVANCED USES OF WEBVIEW

---

```
update_lux(result.lux);
}

function pull() {
    parse(LIGHT_SENSOR.getLux());
}

onmessage = function (e) {
    parse(e.data);
}
</script>
</head>
<body>
<p><b><a onClick="pull()">Light Level</a>: </b><span id="lux">0.0</span> lux</p>
</body>
</html>
```

(from [WebKit/SensorMessage/app/src/main/assets/index.html](#))

This receives the HTML Web message equivalent of the `WebMessage` that we posted. The data field on the supplied event object (`e` in the sample) contains our string. So, we turn around and `parse()` it, just as we would `parse()` the JSON we got from calling `getLux()` on our `LIGHT_SENSOR`.

If you run this sample app on an Android 6.0+ device, you should get the same results as with `SensorPush`, where the light level changes automatically. However, in this case, we will be using code that relies upon `WebMessage` and `postWebMessage()`, instead of `evaluateJavascript()` or `loadUrl()`. In particular, our Java code does not need to know anything about the internal workings of the JavaScript (e.g., function names) — it just passes over the message and relies on the JavaScript to have registered itself appropriately to receive the message.

### JavaScript Calling Java: `WebMessagePort`

What would be nice is to use this `WebMessage` system to be able to replace `addJavascriptInterface()` and allow JavaScript to call back into Java. This is possible, but it is fairly complex.

For our Java code to receive messages sent to it from JavaScript, we need to do three things:

1. Call `createWebMessageChannel()` on the `WebView`. This creates a private communications channel between us and our target Web page. It returns a two-element `WebMessagePort` array. Index 0 of that array is our end of the channel; index 1 is the JavaScript end of the channel.
2. Call `setWebMessageCallback()` on our `WebMessagePort`, supplying a

## ADVANCED USES OF WEBVIEW

---

- WebMessageCallback that will be called with onMessage() when a message arrives on the port from JavaScript.
3. Send the other WebMessagePort to JavaScript using a WebMessage.

In the [WebKit/SensorPort](#) sample project, this is handled by an initPort() method:

```
@TargetApi(Build.VERSION_CODES.M)
private void initPort() {
    final WebMessagePort[] channel=ww.createWebMessageChannel();

    port=channel[0];
    port.setWebMessageCallback(new WebMessagePort.WebMessageCallback() {
        @Override
        public void onMessage(WebMessagePort port, WebMessage message) {
            postLux();
        }
    });

    ww.postMessage(new WebMessage("", new WebMessagePort[]{channel[1]}),
        Uri.EMPTY);
}
```

(from [WebKit/SensorPort/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

The WebMessage constructor that we use this time takes two parameters: an arbitrary string (here, just set to "", as we are not using it) and a one-element WebMessagePort array containing the JavaScript end of the communications channel.

However, we cannot do any of this work until the Web page is ready to be used. Otherwise, the JavaScript code will not receive our WebMessage, since it is not yet ready.

So, we have to postpone calling initPort() until a WebViewClient is called with onPageFinished(), as we do in onCreate():

```
@SuppressWarnings({"AddJavascriptInterface", "SetJavaScriptEnabled"})
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    mgr=(SensorManager) getSystemService(Context.SENSOR_SERVICE);
    light=mgr.getDefaultSensor(Sensor.TYPE_LIGHT);

    ww=(WebView)findViewById(R.id.webkit);
}
```

## ADVANCED USES OF WEBVIEW

---

```
wv.getSettings().setJavaScriptEnabled(true);
wv.addJavascriptInterface(jsInterface, "LIGHT_SENSOR");

if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.M) {
    wv.setWebViewClient(new WebViewClient() {
        @Override
        public void onPageFinished(WebView view, String url) {
            initPort();
        }
    });
}

wv.loadUrl(URL);
}
```

(from [WebKit/SensorPort/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

Our `WebMessageCallback`, upon receipt of a `WebMessage` from the JavaScript, calls a `postLux()` method. We are just using the existence of the message as a “ping” from the JavaScript to Java, asking for us to send it the ambient light level. So, in `postLux()`, we create a `WebMessage` and send it to JavaScript... but not via the `postWebMessage()` method on `WebView`. Instead, we use *our* end of the `WebMessagePort` communications channel, calling `postMessage()` on it, in a `postLux()` method:

```
@TargetApi(Build.VERSION_CODES.M)
private void postLux() {
    port.postMessage(new WebMessage(jsInterface.getLux()));
}
```

(from [WebKit/SensorPort/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java](#))

So, when the JavaScript sends a `WebMessage` to Java, Java sends a `WebMessage` right back, supplying the light level JSON.

To prove that this is working, this sample comments out the automated push of the light level in `onSensorChanged()` — ordinarily, we would call `postLux()` to push over the light level when we get it:

```
@Override
public void onSensorChanged(SensorEvent sensorEvent) {
    float lux = sensorEvent.values[0];

    jsInterface.updateLux(lux);

    String js = String.format(Locale.US, "update_lux(%f)", lux);
}
```

## ADVANCED USES OF WEBVIEW

---

```
if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.M) {
    // postLux();
}
else if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.KITKAT) {
    ww.evaluateJavascript(js, null);
}
else {
    ww.loadUrl("javascript:"+js);
}
}
```

(from [WebKit/SensorPort/app/src/main/java/com/commonware/android/webkit/bridge/MainActivity.java](#))

In JavaScript, our onmessage global function is now a bit more complex as well. We get our end of the communications channel by retrieving our port from ports on the event delivered to onmessage(). Then, we register an onmessage function *on that port*, which is how we receive the light levels that Java delivers via postMessage() on its WebMessagePort. When the user taps the label, we call a pull() function in JavaScript, that calls postMessage() on the port, supplying some string as a message (here, hardcoded as "ping" and ignored by our Java code):

```
<html>
<head>
<title>Android Light Sensor Demo</title>
<script language="javascript">
    function update_lux(lux) {
        document.getElementById("lux").innerHTML=lux;
    }

    function parse(json) {
        var result=JSON.parse(json);

        update_lux(result.lux);
    }

    var port;

    function pull() {
        port.postMessage("ping");
    }

    onmessage = function (e) {
        port = e.ports[0];

        port.onmessage = function (f) {
            parse(f.data);
        }
    }
</script>
</head>
<body>
<p><b><a onClick="pull()">Light Level</a>: </b><span id="lux">0.0</span> lux</p>
```

```
</body>  
</html>
```

(from [WebKit/SensorPort/app/src/main/assets/index.html](#))

If you run this sample on Android 6.0+, and you tap the “Light Level” label, you will get the light level, delivered by means of our `WebMessagePort`-based communications channel.

(NOTE: the author would like to thank Diego Torres Milano for his assistance in [finding out how this stuff works](#)).

## Navigating the Waters

There is no navigation toolbar with the `WebView` widget. This allows you to use it in places where such a toolbar would be pointless and a waste of screen real estate. That being said, if you want to offer navigational capabilities, you can, but you have to supply the UI. `WebView` offers ways to perform garden-variety browser navigation, including:

- `reload()` to refresh the currently-viewed Web page
- `goBack()` to go back one step in the browser history, and `canGoBack()` to determine if there is any history to go back to
- `goForward()` to go forward one step in the browser history, and `canGoForward()` to determine if there is any history to go forward to
- `goBackOrForward()` to go backwards or forwards in the browser history, where negative numbers represent a count of steps to go backwards, and positive numbers represent how many steps to go forwards
- `canGoBackOrForward()` to see if the browser can go backwards or forwards the stated number of steps (following the same positive/negative convention as `goBackOrForward()`)
- `clearCache()` to clear the browser resource cache and `clearHistory()` to clear the browsing history

## Settings, Preferences, and Options (Oh, My!)

With your favorite desktop Web browser, you have some sort of “settings” or “preferences” or “options” window. Between that and the toolbar controls, you can tweak and twiddle the behavior of your browser, from preferred fonts to the behavior of JavaScript.

Similarly, you can adjust the settings of your `WebView` widget as you see fit, via the `WebSettings` instance returned from calling the widget's `getSettings()` method.

There are lots of options on `WebSettings` to play with. Most appear fairly esoteric (e.g., `setFontFamily()`). However, here are some that you may find more useful:

- Control the font sizing via `setDefaultFontSize()` (to use a point size) or `setTextSize()` (to use constants indicating relative sizes like `LARGER` and `SMALLEST`)
- Control Web site rendering via `setUserAgent()`, so you can supply your own user agent string to make the Web server think you are a desktop browser, another mobile device (e.g., iPhone), or whatever. The settings you change are not persistent, so you should store them somewhere (such as via the Android preferences engine) if you are allowing your users to determine the settings, versus hard-wiring the settings in your application.

## Security and Your WebView

More so than normal widgets, `WebView` opens up potential security issues, just as a Web browser could. If all you are doing is displaying your own content, the risks are minimal. If, on the other hand, you are displaying content from third parties, it is possible that their content is malicious in a way that can compromise your app's security, to your users' detriment.

### Rogue JavaScript Risks

If you call `setJavaScriptEnabled(true)` on your `WebSettings`, you are allowing JavaScript code to be loaded and executed by `WebView`. In many cases, this is essential to get your content to render properly (e.g., the JavaScript is issuing AJAX calls). However, if you did not write the scripts, you do not know what they might be doing. If there are flaws in `WebView` — such as those discussed in the next sections — then your users may be at risk.

Even in the absence of such bugs, JavaScript can always:

- Consume so much CPU that it represents an attempt at a denial-of-service attack on the user's device
- Access anything the user enters into the Web page
- Access anything *you* enter into the Web page, using approaches as

javascript: URLs or `evaluateJavaScript()`

### The `addJavaScriptInterface()` Bugs

Another way that rogue JavaScript can attack users is if you use `addJavaScriptInterface()` to allow JavaScript code to call out to a Java object that you supply.

As was noted [earlier in this chapter](#), when `addJavaScriptInterface()` was introduced, there is this `@JavaScriptInterface` annotation that we should apply to the methods we want JavaScript to be able to call on the object we supply via `addJavaScriptInterface()`. This is because of a bug in the `addJavaScriptInterface()` implementation, whereby on 4.1 and below *any* method on the Java object could be called by JavaScript. This includes methods like `getClass()`... which in turn would allow JavaScript to use `Class.forName()` to get at arbitrary stuff. This was used by various bits of malware.

Hence, using `addJavaScriptInterface()` on Android 4.1 and below is rather risky, if you are loading arbitrary third-party JavaScript. If you have the means of examining that JavaScript (e.g., you are loading the scripts yourself), you might perform some simple scans of it to see if they appear to be doing anything unfortunate with your Java object that you injected into JavaScript via `addJavaScriptInterface()`.

Worse, Android sometimes also injects its *own* objects, without our requesting them.

In particular, [this security bug](#) points out that, through Android 4.3, if users have enabled an accessibility service, Android automatically injects objects into `WebView`, using `addJavaScriptInterface()`, named `accessibility` and `accessibilityTraversal`. So, even if you do not inject any objects yourself via `addJavaScriptInterface()`, your `WebView` may be at risk. The security researchers who uncovered this attack vector suggest using `removeJavaScriptInterface()` to specifically get rid of those objects.

### The Same-Origin Policy Bug

Due to a bizarre bug in the parsing of URLs, it is possible for JavaScript code to violate the “same-origin policy” of a `WebView` on Android 4.3 and earlier.

Quoting [Wikipedia](#) from September 2014:

## ADVANCED USES OF WEBVIEW

---

the same-origin policy is an important concept in the web application security model. The policy permits scripts running on pages originating from the same site — a combination of scheme, hostname, and port number — to access each other's DOM with no specific restrictions, but prevents access to DOM on different sites... This mechanism bears a particular significance for modern web applications that extensively depend on HTTP cookies to maintain authenticated user sessions, as servers act based on the HTTP cookie information to reveal sensitive information or take state-changing actions. A strict separation between content provided by unrelated sites must be maintained on the client side to prevent the loss of data confidentiality or integrity.

All modern Web browsers implement the same-origin policy (SOP)... but there can be bugs. A security researcher disclosed that the original AOSP Browser application [failed to implement the SOP properly](#), when a `javascript: URL` has a null byte before the `j` in `javascript`. And while the report was focused on the AOSP Browser app, the problem really lies with `WebView`.

To see this in action, load `https://commonsware.com/misc/sop-demo.html` in the AOSP Browser app on Android 4.3 or lower. This Web page consists of:

```
<html>
<head>
<title>WebView SOP Test</title>
</head>
<body>
<h1>WebView SOP Test</h1>
<iframe name="test" src="http://developer.android.com"></iframe>
<input type="button" value="test"
onclick="window.open('\u0000javascript:alert(document.domain)','test')">
</body>
</html>
```

It is derived from a similar example found in [the blog post outlining the security flaw](#).

In an SOP-compliant browser, clicking the button will have no effect. In the AOSP Browser app, clicking the button shows the domain name of the document in the `iframe`. And, loading this HTML into a `WebView` has the same effect.

Part of the `WebView` overhaul in Android 4.4 — replacing the original implementation with a new one backed by Chromium — had the effect of fixing this bug, whether intentionally or inadvertently.

There is no obvious mitigation approach for this bug, insofar as for the attack shown above, none of the callbacks on `WebViewClient` or `WebChromeClient` seem to allow us to intercept this URL before its JavaScript is executed. If you are loading HTML yourself from a third party, you might consider scanning that HTML for obvious signs of the attack (e.g., regular expression check for `\u0000javascript`), but that will be limited at best. Beyond that, try to limit the content in a `WebView` to be from only one origin, so that there is nothing for attackers to obtain via this bug.

Also note that the security researcher who found this bug has also found [another SOP violation](#), suggesting that mitigation strategies may be impractical.

## Android 8.0 WebView Changes

`WebView`, as Android developers use it, is really a facade API, as of Android 5.0. Previously, the `WebView` implementation was part of the Android framework. Nowadays, the implementation is delegated to the Android System `WebView`, which allows Google to update the `WebView` implementation without relying upon manufacturers to distribute firmware updates.

Hence, to some extent, `WebView` continuously changes, as the Android System `WebView` app gets updated a few times per year.

However, it is only in a new version of Android that Google changes the API or the general approach taken by a `WebView` implementation. In Android 8.0, two significant changes arrived: multi-process mode and support for banning of cleartext traffic.

### Multi-Process Mode

Historically, `WebView` code ran in your app's regular process. Because we often load JavaScript into a `WebView`, having the `WebView` in our process would raise the risks of `WebView` bugs. If JavaScript could cause arbitrary code to execute in our own process, it would have whatever rights our own application code does, including everything for which we have runtime permissions.

Android 7.0 added a developer option for moving the `WebView` execution to a separate process, and that is now standard on Android 8.0. As the documentation describes it, "Web content is handled in a separate, isolated process from the containing app's process for enhanced security."

In principle, this should not require code changes. However, this is a significant architectural change, and so it is worthwhile to fully test your WebView usage on Android 8.0+, to make sure nothing breaks compared with that same code running on Android 7.1 or older devices.

### Honors Cleartext Traffic Setting

If your app has a `targetSdkVersion` over 25, and in your [network security configuration](#) you banned cleartext traffic, WebView will honor that setting on Android 8.0+. On older devices, WebView ignores the network security configuration, and it appears that it still ignores the rest of the configuration (e.g., certificate pinning).

However, this allows you to block the accidental transmission of data over unencrypted channels. Most apps doing network I/O should ban cleartext traffic, at least for debug builds, to identify where they are accidentally using a plain http URL. Apps for which security is a priority might also ban cleartext traffic for release builds.

The [WebKit/BrowserSecure](#) sample project demonstrates this. It has a network security configuration XML file that bans cleartext traffic:

```
<?xml version="1.0" encoding="utf-8"?>
<network-security-config>
  <base-config cleartextTrafficPermitted="false">
    <trust-anchors>
      <certificates src="system" />
    </trust-anchors>
  </base-config>
</network-security-config>
```

(from [WebKit/BrowserSecure/app/src/main/res/xml/net\\_security\\_config.xml](#))

It applies that configuration in the manifest via the `android:networkSecurityConfig` attribute on the `<application>` element:

```
<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:networkSecurityConfig="@xml/net_security_config">
  <activity android:name=".BrowserDemo1">
    <intent-filter>
      <action android:name="android.intent.action.MAIN" />
```

## ADVANCED USES OF WEBVIEW

---

```
        <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
</activity>
</application>
```

(from [WebKit/BrowserSecure/app/src/main/AndroidManifest.xml](#))

The activity just loads up a plain HTTP-served Web page:

```
package com.commonware.android.browser1;

import android.app.Activity;
import android.os.Bundle;
import android.webkit.WebView;

public class BrowserDemo1 extends Activity {
    WebView browser;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        browser=(WebView)findViewById(R.id.webkit);
        browser.loadUrl("http://www.andglobe.com");
    }
}
```

(from [WebKit/BrowserSecure/app/src/main/java/com/commonware/android/browser1/BrowserDemo1.java](#))

The project is set up to target 26:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 25
        targetSdkVersion 26
        applicationId 'com.commonware.android.browser.secure'
    }
}
```

(from [WebKit/BrowserSecure/app/build.gradle](#))

If you change that to have it target 25, the app will run “normally” on Android 8.0, showing the designated Web page. But, with a `targetSdkVersion` set at 26, the `WebView` will not show that page, as it would be loaded over a cleartext (HTTP) connection:

*Figure 519: BrowserSecure Sample, Showing Banned Cleartext Traffic*

## Chrome Custom Tabs

Chrome custom tabs serve as middle ground between using a `WebView` in your own app and launching a URL into a separate Web browser.

With a `WebView`, you have complete control over the overall user experience within your app. However, your `WebView` is decoupled from any other browser the user may be using on the device. Conversely, launching URLs into the user’s chosen browser gives the user their normal browsing experience, but you have no control over the user experience, as the user is now in the browser app, not your app.

With Chrome custom tabs, while Chrome is handling the URL, it will allow you limited control over the action bar (color and custom actions). It also simplifies some things that you might otherwise have had to handle yourself, such as pre-

## ADVANCED USES OF WEBVIEW

---

fetching a Web page to be able to quickly switch to it. Basic integration is also fairly easy, coming in the form of extras on the same sort of ACTION\_VIEW Intent that you might have used for launching the URL in a standalone browser.

At the same time, there are some concerns:

- [The documentation](#) states that there is a “Shared Cookie Jar and permissions model so users don’t have to log in to sites they are already connected to, or re-grant permissions they have already granted”, which would require significant testing to ensure that you are not leaking information into Chrome that might be somehow delivered to other sites (including Google).
- While it uses an ACTION\_VIEW Intent, and so the user can choose to view the URL in a different browser, you will not get the custom integration in that case. This may be fine, but you will need to make sure that from a marketing and documentation standpoint you handle both the case where the user chooses Chrome (and you get the “custom tab”) and the case where the user chooses something else.
- Since any app could handle the ACTION\_VIEW Intent, you need to take into account that any information in the custom extras, like the PendingIntent to use for a custom action bar item, is stuff that you are willing for *arbitrary* apps to get their hands on. Do not assume that your communications will solely be with Chrome.

# The Input Method Framework

---

We think of Android devices as having “soft keyboards”. The official term for this is that Android devices offer one or more “input method editors” (or “input methods” for short). These input methods allow for text entry on a touchscreen, avoiding the need for a physical keyboard. This chapter is focused on how ordinary app developers are affected by input methods, and how an app can help steer the behavior of the input method to benefit the user.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the [section covering the EditText widget](#).

## Keyboards, Hard and Soft

Some Android devices have a hardware keyboard that is visible some of the time (when it is slid out). A few Android devices have a hardware keyboard that is always visible (so-called “bar” or “slab” phones). Most Android devices, though, have no hardware keyboard at all.

The IMF handles all of these scenarios. In short, if there is no hardware keyboard, an input method editor (IME) will be available to the user when they tap on an enabled `EditText`.

This requires no code changes to your application... if the default functionality of the IME is what you want. Fortunately, Android is fairly smart about guessing what you want, so it may be you can just test with the IME but otherwise make no specific code changes.

Of course, the keyboard may not quite behave how you would like. For example, in the Basic/Field sample project, the `FieldDemo` activity has the IME overlaying the multiple-line `EditText`:

*Figure 520: The input method editor, as seen in the FieldDemo sample application*

It would be nice to have more control over how this appears, and for other behavior of the IME. Fortunately, the framework as a whole gives you many options for this, as is described over the bulk of this chapter.

## Tailored To Your Needs

Android 1.1 and earlier offered many attributes on `EditText` widgets to control their style of input, such as `android:password` to indicate a field should be for password entry (shrouding the password keystrokes from prying eyes). Starting in Android 1.5, with the IMF, many of these have been combined into a single `android:inputType` attribute.

The `android:inputType` attribute takes a class plus modifiers, in a pipe-delimited list (where `|` is the pipe character). The class generally describes what the user is allowed to input, and this determines the basic set of keys available on the soft

keyboard. The available classes are:

1. text (the default)
2. number
3. phone
4. datetime
5. date
6. time

Many of these classes offer one or more modifiers, to further refine what the user will be entering. To help explain those, take a look at the `res/layout/main.xml` file from the [InputMethod/IMEDemo1](#) project:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1"
    >
    <TableRow>
        <TextView
            android:text="No special rules:"
            />
        <EditText
            />
    </TableRow>
    <TableRow>
        <TextView
            android:text="Email address:"
            />
        <EditText
            android:inputType="text|textEmailAddress"
            />
    </TableRow>
    <TableRow>
        <TextView
            android:text="Signed decimal number:"
            />
        <EditText
            android:inputType="number|numberSigned|numberDecimal"
            />
    </TableRow>
    <TableRow>
        <TextView
            android:text="Date:"
            />
    </TableRow>
</TableLayout>
```

## THE INPUT METHOD FRAMEWORK

---

```
<EditText
    android:inputType="date"
/>
</TableRow>
<TableRow>
    <TextView
        android:text="Multi-line text:"
    />
    <EditText
        android:inputType="text|textMultiLine|textAutoCorrect"
        android:minLines="3"
        android:gravity="top"
    />
</TableRow>
</TableLayout>
```

(from [InputMethod/IMEDemo/app/src/main/res/layout/main.xml](#))

Here, you will see a `TableLayout` containing five rows, each demonstrating a slightly different flavor of `EditText`:

- One has no attributes at all on the `EditText`, meaning you get a plain text entry field
- One has `android:inputType = "text|textEmailAddress"`, meaning it is text entry, but specifically seeks an email address
- One allows for signed decimal numeric input, via `android:inputType = "number|numberSigned|numberDecimal"`
- One is set up to allow for data entry of a date (`android:inputType = "date"`)
- The last allows for multi-line input with auto-correction of probable spelling errors (`android:inputType = "text|textMultiLine|textAutoCorrect"`)

## THE INPUT METHOD FRAMEWORK

---

The class and modifiers tailor the keyboard. So, a plain text entry field results in a plain soft keyboard:

*Figure 521: A standard input method editor (a.k.a., soft keyboard)*

## THE INPUT METHOD FRAMEWORK

---

An email address field might put the @ symbol on the soft keyboard, perhaps at the cost of a smaller spacebar, depending on the keyboard implementation:

*Figure 522: The input method editor for email addresses*

Note, though, that this behavior is specific to the input method editor. Some editors might put an @ sign on the primary keyboard for an email field. Some might put a “.com” button on the primary keyboard. Some might not react at all. It is up to the implementation of the input method editor — all you can do is supply the hint.

Numbers and dates restrict the keys to numeric keys, plus a set of symbols that may or may not be valid on a given field:

And so on.

By choosing the appropriate `android:inputType`, you can give the user a soft keyboard that best suits what it is they should be entering.

## Tell Android Where It Can Go

You may have noticed a subtle difference between the first and second input method editors, beyond the addition of the @ key. If you look in the lower-right corner of the soft keyboard, the second field's editor has a "Next" button, while the first field's editor has a newline button.

This points out two things:

- `EditText` widgets are multi-line by default if you do not specify `android:inputType`

## THE INPUT METHOD FRAMEWORK

---

- You can control what goes on with that lower-right-hand button, called the action key

By default, on an `EditText` where you have specified `android:inputType`, the action key will be “Next”, moving you to the next `EditText` in sequence, or “Done”, if you are on the last `EditText` on the screen. You can manually stipulate what the action key will be labeled via the `android:imeOptions` attribute. For example, in the `res/layout/main.xml` from the [InputMethod/IMEDemo2](#) sample project, you will see an augmented version of the previous example, where two input fields specify what their action key should look like:

```
<?xml version="1.0" encoding="utf-8"?>
<ScrollView xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
>
    <TableLayout
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:stretchColumns="1"
    >
        <TableRow>
            <TextView
                android:text="No special rules:"
            />
            <EditText
            />
        </TableRow>
        <TableRow>
            <TextView
                android:text="Email address:"
            />
            <EditText
                android:inputType="text|textEmailAddress"
                android:imeOptions="actionSend"
            />
        </TableRow>
        <TableRow>
            <TextView
                android:text="Signed decimal number:"
            />
            <EditText
                android:inputType="number|numberSigned|numberDecimal"
                android:imeOptions="actionDone"
            />
        </TableRow>
    </TableLayout>
</ScrollView>
```

## THE INPUT METHOD FRAMEWORK

---

```
<TableRow>
  <TextView
    android:text="Date:"
  />
  <EditText
    android:inputType="date"
  />
</TableRow>
<TableRow>
  <TextView
    android:text="Multi-line text:"
  />
  <EditText
    android:inputType="text|textMultiLine|textAutoCorrect"
    android:minLines="3"
    android:gravity="top"
  />
</TableRow>
</TableLayout>
</ScrollView>
```

(from [InputMethod/IMEDemo2/app/src/main/res/layout/main.xml](#))

Here, we attach a “Send” action to the action key for the email address (`android:imeOptions = "actionSend"`), and the “Done” action on the middle field (`android:imeOptions = "actionDone"`).

By default, “Next” will move the focus to the next `EditText` and “Done” will close up the input method editor. However, for those, or for any other ones like “Send”, you can use `setOnEditorActionListener()` on `EditText` (technically, on the `TextView` superclass) to get control when the action key is clicked or the user presses the `<Enter>` key. You are provided with a flag indicating the desired action (e.g., `IME_ACTION_SEND`), and you can then do something to handle that request (e.g., send an email to the supplied email address).

If you need more control over the action button, you can set:

- `android:imeActionId`, which provides a custom value for the `actionId` that is passed to `onEditorAction()` of your `OnEditorActionListener`
- `android:imeActionLabel`, where you provide your own caption for the button (bearing in mind that your desired caption may or may not fit)

## Fitting In

You will notice that the IMEDemo2 layout shown above has another difference from its IMEDemo1 predecessor: the use of a `ScrollView` container wrapping the `TableLayout`. This ties into another level of control you have over the input method editors: what happens to your activity's own layout when the input method editor appears?

There are three possibilities, depending on circumstances:

1. Android can “pan” your activity, effectively sliding the whole layout up to accommodate the input method editor, or overlaying your layout, depending on whether the `EditText` being edited is at the top or bottom. This has the effect of hiding some portion of your UI.
2. Android can resize your activity, effectively causing it to shrink to a smaller screen dimension, allowing the input method editor to sit below the activity itself. This is great when the layout can readily be shrunk (e.g., it is dominated by a list or multi-line input field that does not need the whole screen to be functional).
3. In landscape mode, Android may display the input method editor full-screen, obscuring your entire activity. This allows for a bigger keyboard and generally easier data entry.

Android controls the full-screen option purely on its own. And, by default, Android will choose between pan and resize modes depending on what your layout looks like. If you want to specifically choose between pan and resize, you can do so via an `android:windowSoftInputMode` attribute on the `<activity>` element in your `AndroidManifest.xml` file. For example, here is the manifest from IMEDemo2:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.imf.two"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="7"
```

## THE INPUT METHOD FRAMEWORK

---

```
    android:targetSdkVersion="11"/>

<application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
        android:name=".IMEDemo2"
        android:label="@string/app_name"
        android:windowSoftInputMode="adjustResize">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>

</manifest>
```

(from [InputMethod/IMEDemo2/app/src/main/AndroidManifest.xml](#))

---

## THE INPUT METHOD FRAMEWORK

---

Because we specified `resize`, Android will shrink our layout to accommodate the input method editor. With the `ScrollView` in place, this means the scrollbar will appear as needed when the user is scrolling:

*Figure 524: The shrunken, scrollable layout*

## Jane, Stop This Crazy Thing!

Sometimes, you need the input method editor to just go away. For example, if you make the action button be “Search”, the user tapping that button will not automatically hide the editor.

To hide the editor, you will need to make a call to the `InputMethodManager`, a system service that controls these input method editors:

```
InputMethodManager
mgr=(InputMethodManager) getSystemService(INPUT_METHOD_SERVICE);

mgr.hideSoftInputFromWindow(fld.getWindowToken(), 0);
```

(where `fld` is the `EditText` whose input method editor you want to hide)

# Fonts and Text

---

Inevitably, you'll get the question "hey, can we change this font?" when doing application development. The answer depends on what fonts come with the platform, whether you can add other fonts, and how to apply them to the widget or whatever needs the font change.

Android is no different. It comes with some fonts plus a means for adding new fonts. Though, as with any new environment, there are a few idiosyncrasies to deal with.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on [files](#).

## Love The One You're With

Android natively knows three fonts, by the shorthand names of "sans", "serif", and "monospace". For Android 1.x, 2.x, and 3.x, these fonts are actually the Droid series of fonts, created for the Open Handset Alliance by [Ascender](#). A new font set, Roboto, is used in Android 4.x and beyond, though the look of the font changed somewhat in Android 5.0.

For those fonts, you can just reference them in your layout XML, if you choose, such as the following layout from the [Fonts/FontSampler](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
```

## FONTS AND TEXT

---

```
android:stretchColumns="1">

<TableRow>

  <TextView
    android:layout_marginRight="4dip"
    android:text="@string/label_sans"
    android:textSize="20sp" />

  <TextView
    android:id="@+id/sans"
    android:text="@string/hello_world"
    android:textSize="20sp"
    android:typeface="sans" />
</TableRow>

<TableRow>

  <TextView
    android:layout_marginRight="4dip"
    android:text="@string/label_serif"
    android:textSize="20sp" />

  <TextView
    android:id="@+id/serif"
    android:text="@string/hello_world"
    android:textSize="20sp"
    android:typeface="serif" />
</TableRow>

<TableRow>

  <TextView
    android:layout_marginRight="4dip"
    android:text="@string/label_monospace"
    android:textSize="20sp" />

  <TextView
    android:id="@+id/monospace"
    android:text="@string/hello_world"
    android:textSize="20sp"
    android:typeface="monospace" />
</TableRow>

<TableRow>

  <TextView
    android:layout_marginRight="4dip"
```

## FONTS AND TEXT

---

```
        android:text="@string/label_custom"
        android:textSize="20sp" />

<TextView
    android:id="@+id/custom"
    android:text="@string/hello_world"
    android:textSize="20sp" />
</TableRow>

<TableRow android:id="@+id/filerow">

    <TextView
        android:layout_marginRight="4dip"
        android:text="@string/label_custom_from_file"
        android:textSize="20sp" />

    <TextView
        android:id="@+id/file"
        android:text="@string/hello_world"
        android:textSize="20sp" />
</TableRow>
</TableLayout>
```

(from [Fonts/FontSampler/app/src/main/res/layout/main.xml](#))

This layout builds a table showing short samples of five fonts. Notice how the first three have the `android:typeface` attribute, whose value is one of the three built-in font faces (e.g., “sans”).

The three built-in fonts are very nice. However, it may be that a designer, or a manager, or a customer wants a different font than one of those three. Or perhaps you want to use a font for specialized purposes, such as an image font instead of a series of PNG graphics.

The easiest way to accomplish this is to package the desired font(s) with your application. To do this, simply create an `assets/` folder in the project root, and put your TrueType (TTF) fonts in the assets. You might, for example, create `assets/fonts/` and put your TTF files in there. Note that Android has some support for OpenType (OTF) fonts, as well.

Then, you need to tell your widgets to use that font. Unfortunately, you can no longer use layout XML for this, since the XML does not know about any fonts you may have tucked away as an application asset. Instead, you need to make the change in Java code:

## FONTS AND TEXT

---

```
package com.commonware.android.fonts;

import android.app.Activity;
import android.graphics.Typeface;
import android.os.Bundle;
import android.os.Environment;
import android.view.View;
import android.widget.TextView;
import java.io.File;

public class FontSampler extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        TextView tv=(TextView)findViewById(R.id.custom);
        Typeface face=
            Typeface.createFromAsset(getAssets(), "fonts/HandmadeTypewriter.ttf");

        tv.setTypeface(face);

        File font=
            new File(Environment.getExternalStorageDirectory(), "MgOpenCosmeticaBold.ttf");

        if (font.exists()) {
            tv=(TextView)findViewById(R.id.file);
            face=Typeface.createFromFile(font);

            tv.setTypeface(face);
        }
        else {
            findViewById(R.id.filerow).setVisibility(View.GONE);
        }
    }
}
```

(from [Fonts/FontSampler/app/src/main/java/com/commonware/android/fonts/FontSampler.java](#))

Here we grab the `TextView` for our “custom” sample, then create a `Typeface` object via the static `createFromAsset()` builder method. This takes the application’s `AssetManager` (from `getAssets()`) and a path within your `assets/` directory to the font you want.

Then, it is just a matter of telling the `TextView` to `setTypeface()`, providing the `Typeface` you just created. In this case, we are using the [Handmade Typewriter](#) font.

You can also load a font out of a local file and use it. The benefit is that you can customize your fonts after your application has been distributed. On the other hand, you have to somehow arrange to get the font onto the device. But just as you can get a `Typeface` via `createFromAsset()`, you can get a `Typeface` via `createFromFile()`. In our `FontSampler`, we look in the root of “external storage” (typically the SD card) for the `MgOpenCosmeticaBold` TrueType font file, and if it is found, we use it for the

fifth row of the table. Otherwise, we hide that row.

The results?

*Figure 525: The FontSampler application*

Note that Android does not seem to like all TrueType fonts. When Android dislikes a custom font, rather than raise an `Exception`, it seems to substitute Droid Sans (“sans”) quietly. So, if you try to use a different font and it does not seem to be working, it may be that the font in question is incompatible with Android, for whatever reason.

## Yeah, But Do We Really Have To Do This in Java?

One common complaint with font handling in Android is that you have to apply a custom font on a per-widget basis in Java code.

This gets old quickly.

It is not too bad with just a single `TextView`. But for a whole activity, or a whole application, changing all of the relevant `TextView` widgets (and descendents, like

Button) gets to be a bit tedious.

While there are “traverse the widget hierarchy and fix up the fonts” code snippets available, you are probably better served using a third-party library, like Christopher Jenkins’ [Calligraphy](#), which lets you define custom fonts in layout XML files or style resources.

## Here a Glyph, There a Glyph

TrueType fonts can be rather pudgy, particularly if they support an extensive subset of the available Unicode characters. The Handmade Typewriter font used above runs over 70KB; the DejaVu free fonts can run upwards of 500KB apiece. Even compressed, these add bulk to your application, so be careful not to go overboard with custom fonts, lest your application take up too much room on your users’ phones.

Conversely, bear in mind that fonts may not have all of the glyphs that you need. As an example, let us talk about the ellipsis.

Android’s `TextView` class has the built-in ability to “ellipsize” text, truncating it and adding an ellipsis if the text is longer than the available space. You can use this via the `android:ellipsize` attribute, for example. This works fairly well, at least for single-line text.

The ellipsis that Android uses is not three periods. Rather it uses an actual ellipsis character, where the three dots are contained in a single glyph. Hence, any font that you use in a `TextView` where you also use the “ellipsizing” feature will need the ellipsis glyph.

Beyond that, though, Android pads out the string that gets rendered on-screen, such that the length (in characters) is the same before and after “ellipsizing”. To make this work, Android replaces one character with the ellipsis, and replaces all other removed characters with the Unicode character ‘ZERO WIDTH NO-BREAK SPACE’ (U+FEFF). This means the “extra” characters after the ellipsis do not take up any visible space on screen, yet they can be part of the string.

However, this means any custom fonts you use for `TextView` widgets that you use with `android:ellipsize` must also support this special Unicode character. Not all fonts do, and you will get artifacts in the on-screen representation of your shortened strings if your font lacks this character (e.g., rogue X’s appear at the end of the line).

And, of course, Android's international deployment means your font must handle any language your users might be looking to enter, perhaps through a language-specific input method editor.

Hence, while using custom fonts in Android is very possible, there are many potential problems, and so you must weigh carefully the benefits of the custom fonts versus their potential costs.

## Auto-Sizing TextView

Text comes in all lengths.

Sometimes, when showing text in a `TextView`, we can allow that text to word-wrap and extend vertically. Other times, though, that proves to be impractical, such as when using a `TextView` as a label for another widget. However, even in those times, the text to be shown may vary in length by a significant amount. Translations of the label's text might range from a couple of kanji in Japanese to a 20-letter word in German or Icelandic.

One long-standing solution to that problem has been to use an auto-sizing `TextView`. Here, what is being "auto-sized" is the size of the font used for the text, to keep the `TextView` at a fixed dimension regardless of translation. It is up to the developer to ensure that for a given screen size and translation that the font does not wind up being too small to be read.

However, Android itself never had a widget for this, so developers would rely instead upon third-party or home-grown implementations.

Android 8.0 adds this sort of auto-sizing capability to `TextView` itself (and, by extension, subclasses like `Button`). You have two main approaches for implementing this:

- Set `android:autoSizeTextType="uniform"` on the `TextView` to engage auto-size capability. Then, use `android:autoSizeMinTextSize` and `android:autoSizeMaxTextSize` to set the lower and upper bounds for the text size, where Android can choose any size in between those. If you also add `android:autoSizeStepGranularity`, you can choose the increments in which Android will move between the ends of the text size range (the default is 1px).
- Set `android:autoSizeTextType="uniform"` on the `TextView`, as in the above

## FONTS AND TEXT

---

option. Then, instead of providing the starting and ending values of a range, use an `<array>` resource to define specific sizes that you want to support, then use `android:autoSizePresetSizes` to point to that resource. This is a bit more difficult to set up, as you need to define the array resource, but it may simplify testing, as you are in complete control over the possible sizes.

To make this work, you need to constrain the size of the `TextView`, so that it does not expand to fill all available space. That might be through having both axes set to `wrap_content`, but have the container holding the `TextView` limit how big the `TextView` can get. It might be through `TextView`-specific configuration, such as `android:maxLines`. Or, it might be through setting the size of the axes to be some specific dimension or `match_parent`.

The [Basic/AutoSize](#) sample project illustrates the use of both forms of `android:autoSizeTextType`.

The activity's layout consists of an `EditText`, a pair of `TextView` widgets, and a pair of divider lines (horizontal `View` widgets with background and margin), all inside of a vertical `LinearLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    tools:context="com.commonware.android.autosize.MainActivity">

    <EditText
        android:id="@+id/input"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_margin="4dp"
        android:hint="@string/hint_input" />

    <View
        android:layout_width="match_parent"
        android:layout_height="2dp"
        android:layout_margin="4dp"
        android:background="@android:color/black" />

    <TextView
        android:id="@+id/granular"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
```

## FONTS AND TEXT

---

```
    android:layout_margin="4dp"
    android:autoSizeMaxTextSize="40sp"
    android:autoSizeMinTextSize="5sp"
    android:autoSizeStepGranularity="5sp"
    android:autoSizeTextType="uniform"
    android:maxLines="1" />

<View
    android:layout_width="match_parent"
    android:layout_height="2dp"
    android:layout_margin="4dp"
    android:background="@android:color/black" />

<TextView
    android:id="@+id/steps"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    android:autoSizePresetSizes="@array/autosize_sizes"
    android:autoSizeTextType="uniform"
    android:maxLines="1" />

</LinearLayout>
```

(from [Basic/AutoSize/app/src/main/res/layout/activity\\_main.xml](#))

Both TextView widgets have `android:autoSizeTextType` set to `uniform`. The top one uses `android:autoSizeMinTextSize`, `android:autoSizeMaxTextSize`, and `android:autoSizeStepGranularity` to allow the text size to float between 5sp and 40sp in 5sp increments. The bottom one uses `android:autoSizePresetSizes` to tie in an array resource for the valid sizes to use:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <array name="autosize_sizes">
        <item>10sp</item>
        <item>12sp</item>
        <item>14sp</item>
        <item>16sp</item>
        <item>18sp</item>
        <item>20sp</item>
    </array>
</resources>
```

(from [Basic/AutoSize/app/src/main/res/values/arrays.xml](#))

Here, the size can float between 10sp and 20sp in 2sp increments. However, there is

## FONTS AND TEXT

---

no requirement that the sizes increment in a uniform fashion when using the array approach.

The MainActivity that uses the layout sets up a TextWatcher on the EditText and copies what you enter into the two TextView widgets, to allow you to experiment in real time with changes in the text size:

```
EditText input=(EditText)findViewById(R.id.input);
final TextView granular=(TextView)findViewById(R.id.granular);
final TextView steps=(TextView)findViewById(R.id.steps);

input.addTextChangedListener(new TextWatcher() {
    @Override
    public void beforeTextChanged(CharSequence charSequence, int i, int i1,
        int i2) {
        // unused
    }

    @Override
    public void onTextChanged(CharSequence charSequence, int i, int i1,
        int i2) {
        // unused
    }

    @Override
    public void afterTextChanged(Editable editable) {
        granular.setText(editable.toString());
        steps.setText(editable.toString());
    }
});
}
```

(from [Basic/AutoSize/app/src/main/java/com/commonsware/android/autosize/MainActivity.java](#))

## FONTS AND TEXT

---

When you run the app, initially the `EditText` and corresponding `TextView` widgets have no text. If you start typing, you will see your text appear in the `TextView` widgets:

*Figure 526: Auto-Sizing TextViews, with Some Text*

As you continue typing, the text size decreases:

If you are using `appcompat-v7`, there are equivalent capabilities added to its wrapper backport of `TextView`.

## Justified Text

If you are reading the PDF edition of this book, its paragraphs do not use justified text. If you are reading the Kindle edition of this book — at least when using the Amazon Kindle app for Android — its paragraphs do use justified text.

Justified text is when text (e.g., in the middle of a paragraph) fills the entire line, usually with bits of extra space added between the words to get them to neatly fill the available horizontal space.

For years, `TextView` never supported justified text, though you could get it through [third-party libraries](#).

In Android 8.0+, you can now enable justified text on a `TextView` via

## FONTS AND TEXT

---

`setJustificationMode()`. Android 9.0 adds `android:justificationMode` to be able to configure this from a layout resource or theme.

Plain text is so, well, plain.

Fortunately, Android has fairly extensive support for formatted text, before you need to break out something as heavy-weight as `WebView`. However, some of this rich text support has been shrouded in mystery, particularly how you would allow users to edit formatted text.

This chapter will explain how the rich text support in Android works and how you can take advantage of it, with particular emphasis on some open source projects to help you do just that.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on [basic widgets](#) and the [input method framework](#).

## The Span Concept

You may have noticed that many methods in Android accept or return a `CharSequence`. The `CharSequence` interface is little used in traditional Java, if for no other reason than there are relatively few implementations of it outside of `String`. However, in Android, `CharSequence` becomes much more important, because of a sub-interface named `Spanned`.

`Spanned` defines sequences of characters (`CharSequence`) that contain *inline markup rules*. These rules — mostly instances of `CharacterStyle` and `ParagraphStyle` subclasses — indicate whether the “spanned” portion of the characters should be

rendered in an alternate font, or be turned into a hyperlink, or have other effects applied to them.

Methods that take a `CharSequence` as a parameter, therefore, can work equally well with `String` objects as well as objects that implement `Spanned`.

### Implementations

The base interface for rich-text `CharSequence` objects is `Spanned`. This is used for any `CharSequence` that has inline markup rules, and it defines methods for retrieving markup rules applied to portions of the underlying text.

The primary concrete implementation of `Spanned` is `SpannedString`. `SpannedString`, like `String`, is immutable — you cannot change either the text or the formatting of a `SpannedString`.

There is also the `Spannable` sub-interface of `Spanned`. `Spannable` is used for any `CharSequence` with inline markup rules that can be modified, and it defines the methods for modifying the formatting. There is a corresponding `SpannableString` implementation.

Finally, there is a related `Editable` interface, which is for a `CharSequence` that can have its *text* modified in-place. `SpannableStringBuilder` implements both `Editable` and `Spannable`, for modifying text and formatting at the same time.

### TextView and Spanned

One of the most important uses of `Spanned` objects is with `TextView`. `TextView` is capable of rendering a `Spanned`, complete with all of the specified formatting. So, if you have a `Spanned` that indicates that the third word should be rendered in italics, `TextView` will faithfully italicize that word.

`TextView`, of course, is an ancestor of many other widgets, from `EditText` to `Button` to `CheckBox`. Each of those, therefore, can use and render `Spannable` objects. The fact that `EditText` has the ability to render `Spanned` objects — and even allow them to be edited — is key for allowing users to enter rich text themselves as part of your UI.

### Available Spans

As noted above, the markup rules come in the form of instances of base classes

known as `CharacterStyle` and `ParagraphStyle`. Despite those names, most of the SDK-supplied subclasses of `CharacterStyle` and `ParagraphStyle` end in `Span` (not `Style`), and so you will likely see references to these as “spans” as often as “styles”. That also helps minimize confusion between character styles and style resources.

There are well over a dozen supplied `CharacterStyle` subclasses, including:

1. `ForegroundColorSpan` and `BackgroundColorSpan` for coloring text
2. `StyleSpan`, `TextAppearanceSpan`, `TypefaceSpan`, `UnderlineSpan`, and `StrikethroughSpan` for affecting the true “style” of text
3. `AbsoluteSizeSpan`, `RelativeSizeSpan`, `SuperscriptSpan`, and `SubscriptSpan` for affecting the size (and, in some cases, vertical position) of the text

And so on. Similarly, `ParagraphStyle` has subclasses like `BulletSpan` for bulleted lists.

You can implement your own custom subclasses of `CharacterStyle` and `ParagraphStyle`, though the book does not cover this subject at this time.

## Loading Rich Text

Spanned objects do not appear by magic. Plenty of things in Java will give you ordinary strings, from XML and JSON parsers to loading data out of a database to simply hard-coding string constants. However, there are only a few ways that you as a developer will get a `Spanned` complete with formatting, and that includes you creating such a `Spanned` yourself by hand.

### String Resource

The primary way most developers get a `Spanned` object into their application is via a string resource. String resources support inline markup in the form of HTML tags. Bold (`<b>`), italics (`<i>`), and underline (`<u>`) are officially supported, such as:

```
<string name="welcome">Welcome to <b>Android</b>!</string>
```

When you retrieve the string resource via `getText()`, you get back a `CharSequence` that represents a `Spanned` object with the markup rules in place.

## HTML

The next-most common way to get a Spanned object is to use `Html.fromHtml()`. This parses an HTML string and returns a Spanned object, with all recognized tags converted into corresponding spans. You might use this for text loaded from a database, retrieved from a Web service call, extracted from an RSS feed, etc.

Unfortunately, the list of tags that `fromHtml()` understands is undocumented. Based upon the source code to `fromHtml()`, the following seem safe:

- `[a href="..."]`
- `<b>`
- `<big>`
- `<blockquote>`
- `<br>`
- `<cite>`
- `<dfn>`
- `[div align="..."]`
- `<em>`
- `[font size="..." color="..." face="..."]`
- `<h1>`
- `<h2>`
- `<h3>`
- `<h4>`
- `<h5>`
- `<h6>`
- `<i>`
- `[img src="..."]`
- `<p>`
- `<small>`
- `<strong>`
- `<sub>`
- `<sup>`
- `<tt>`
- `<u>`

However, do bear in mind that these are undocumented and therefore are subject to change. Also note that `fromHtml()` is perhaps slower than you might think, particularly for longer strings.

You might also wind up using some other support code to get your HTML. For

example, some data sources might publish text formatted as [Markdown](#) — Stack Overflow, GitHub, etc. use this extensively. Markdown can be converted to HTML, through any number of available Java libraries or via [CWAC-AndDown](#), which wraps the native [hoedown](#) Markdown-to-HTML converter for maximum speed. CWAC-AndDown will be explored in a bit more detail in [the chapter on the NDK](#).

### From EditText

The reason why so much sample code calls `getText()` followed by `toString()` on an `EditText` widget is because `EditText` is going to return an `Editable` object from `getText()`, not a simple string. That's because, in theory, `EditText` could be returning something with formatting applied. The call to `toString()` simply strips out any potential formatting as part of giving you back a `String`.

However, you could elect to use the `Editable` object (presumably a `SpannableStringBuilder`) if you wanted, such as for pouring the entered text into a `TextView`, complete with any formatting that might have wound up on the entered text.

### Manually

You are welcome to create a `SpannableString` via its constructor, supplying the text that you wish to display, then calling various methods on `SpannableString` to format it.

Or, you are welcome to create a `SpannableStringBuilder` via its constructor. In some respects, `SpannableStringBuilder` works like the classic `StringBuilder` — you call `append()` to add more text. However, `SpannableStringBuilder` also offers `delete()`, `insert()`, and `replace()` methods to modify portions of the existing content. It also supports the same methods that `SpannableString` does, via the `Spannable` interface, for applying formatting rules to portions of text.

### Editing Rich Text

If the `Spannable` you wound up with is a `SpannedString`, it is what it is — you cannot change it. If, however, you have a `SpannableString`, that can be modified by you, or by the user. Of course, allowing the user to modify a `Spannable` gets a wee bit tricky, and is why the `RichEditText` project was born.

`Spannable` offers two methods for modifying its formatting: `setSpan()` to apply

## RICH TEXT

---

formatting, and `removeSpan()` to get rid of an existing span. And, since `Spannable` extends `Spanned`, a `Spannable` also has `getSpans()`, to return existing spans of a current type within a certain range of characters in the text. These methods, along with others on `Spanned`, allow you to get and set whatever formatting you wish to apply on a `Spannable` object, such as a `SpannableString`.

For example, let's take a look at the [RichText/Search](#) sample project. Here, we are going to load some text into a `TextView`, then allow the user to enter a search string in an `EditText`, and we will use the `Spannable` methods to highlight the search string occurrences inside the text in the `TextView`.

Our layout is simply an `EditText` atop a `TextView` (wrapped in a `ScrollView`):

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <EditText
        android:id="@+id/search"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:singleLine="true">

        <requestFocus/>
    </EditText>

    <ScrollView
        android:id="@+id/scroll"
        android:layout_width="match_parent"
        android:layout_height="match_parent">

        <TextView
            android:id="@+id/prose"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:text="@string/address"
            android:textAppearance="?android:attr/textAppearanceMedium"/>
    </ScrollView>
</LinearLayout>
```

(from [RichText/Search/app/src/main/res/layout/main.xml](#))

We pre-fill the `TextView` with a string resource (`@string/address`), which in this

## RICH TEXT

---

project is the text of Lincoln's Gettysburg Address, with a bit of inline markup (e.g., "Four score and seven years ago" italicized). So, when we fire up the project at the outset, we see the formatted prose from the string resource:

Figure 528: The RichTextSearch sample, as initially launched

In `onCreate()` of our activity, we find the `EditText` widget and designate the activity itself as being an `OnEditorActionListener` for the `EditText`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    search=(EditText)findViewById(R.id.search);
    search.setOnEditorActionListener(this);
}
```

(from [RichText/Search/app/src/main/java/com/commonsware/android/rich/search/RichTextSearchActivity.java](#))

That means when the user presses <Enter>, we will get control in an `onEditorAction()` method. There, we pass the search text to a private `searchFor()` method, plus ensure that the input method editor is hidden (if one was used to fill in the search text):

## RICH TEXT

---

```
@Override
public boolean onEditorAction(TextView v, int actionId, KeyEvent event) {
    if (event == null || event.getAction() == KeyEvent.ACTION_UP) {
        searchFor(search.getText().toString());

        InputMethodManager imm=
            (InputMethodManager) getSystemService(INPUT_METHOD_SERVICE);

        imm.hideSoftInputFromWindow(v.getWindowToken(), 0);
    }

    return(true);
}
```

(from [RichText/Search/app/src/main/java/com/commonsware/android/rich/search/RichTextSearchActivity.java](#))

The `searchFor()` method is where the formatting is applied to our search text:

```
private void searchFor(String text) {
    TextView prose=(TextView)findViewById(R.id.prose);
    Spannable raw=new SpannableString(prose.getText());
    BackgroundColorSpan[] spans=raw.getSpans(0,
                                           raw.length(),
                                           BackgroundColorSpan.class);

    for (BackgroundColorSpan span : spans) {
        raw.removeSpan(span);
    }

    int index=TextUtils.indexOf(raw, text);

    while (index >= 0) {
        raw.setSpan(new BackgroundColorSpan(0xFF8B008B), index, index
            + text.length(), Spanned.SPAN_EXCLUSIVE_EXCLUSIVE);
        index=TextUtils.indexOf(raw, text, index + text.length());
    }

    prose.setText(raw);
}
```

(from [RichText/Search/app/src/main/java/com/commonsware/android/rich/search/RichTextSearchActivity.java](#))

First, we get a `Spannable` object out of the `TextView`. While an `EditText` returns an `Editable` from `getText()`, `getText()` on a `TextView` returns a `CharSequence`. In particular, the first time we execute `searchFor()`, `getText()` will return a `SpannedString`, as that is what a string resource turns into. However, that is not modifiable, so we convert it into a `SpannableString` so we can apply formatting to it.

## RICH TEXT

---

An optimization would be to see if `getText()` returns something implementing `Spannable` and then just using it directly.

We want to highlight the search terms using a `BackgroundColorSpan`. However, that means we first need to get rid of any existing `BackgroundColorSpan` objects applied to the prose from a previous search — otherwise, we would keep highlighting more and more of the prose. So, we use `getSpans()` to find all `BackgroundColorSpan` objects anywhere in the prose (from index 0 through the length of the text). For each that we find, we call `removeSpan()` to get rid of it from our `Spannable`.

Then, we use `indexOf()` on `TextUtils` to find the first occurrence of whatever the user typed into the `EditText`. If we find it, we create a new `BackgroundColorSpan` and apply it to the matching portion of the prose using `setSpan()`. The last parameter to `setSpan()` is a flag, indicating what should happen if text is inserted at either the starting or ending point. In our case, the text itself is remaining constant, so the flag does not matter much – here, we use `SPAN_EXCLUSIVE_EXCLUSIVE`, which would mean that the span would not cover any text inserted at the starting or ending point of the span.

We then continue using `indexOf()` to find any remaining occurrences of the search text. Once we are done modifying our `Spannable`, we put it into the `TextView` via `setText()`.

## RICH TEXT

---

The result is that all matching substrings are highlighted in a purple/magenta shade:

## Saving Rich Text

SpannableString and SpannedString are not Serializable. There is no built-in way to persist them directly.

However, `Html.toHtml()` will convert a Spanned object into corresponding HTML, for all `CharacterStyle` and `ParagraphStyle` objects that can be readily converted into HTML. You can then persist the resulting HTML any place you would persist a `String` (e.g., database column).

In principle, you could create other similar conversion code, such as something to take a `Spanned` and return the corresponding Markdown source.

## Manipulating Rich Text

The `TextUtils` class has many utility methods that manipulate a `CharSequence`, to allow you to do things that you might ordinarily have done just with methods on

## RICH TEXT

---

String. These utility methods will work with any CharSequence, including SpannedString and SpannableString.

Some are specifically aimed at Spanned objects, such as copySpansFrom() (to apply formatting from one CharSequence onto another). Some are clones of String equivalents, such as split(), join(), and substring(). Yet others are designed for developers using the Canvas 2D drawing API, such as ellipsize() and commaEllipsize() for intelligently truncating messages.

# Animators

---

Users like things that move. Or fade, spin, or otherwise offer a dynamic experience.

Much of the time, such animations are handled for us by the framework. We do not have to worry about sliding rows in a `ListView` when the user scrolls, or as the user pans around a `ViewPager`, and so forth.

However, sometimes, we will need to add our own animations, where we want effects that either are not provided by the framework innately or are simply different (e.g., want something to slide off the bottom of the screen, rather than off the left edge).

Android had an [animation framework](#) back in the beginning, one that is still available for you today. However, Android 3.0 introduced a new *animator* framework that is going to be Android's primary focus for animated effects going forward. Many, but not all, of the animator framework capabilities are available to us as developers via a backport.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Also, you should read the chapter on [custom views](#), to be able to make sense of one of the samples.

## ViewPropertyAnimator

Let's say that you want to fade out a widget, instead of simply setting its visibility to `INVISIBLE` or `GONE`.

For a widget whose name is `v`, on API Level 11 or higher, that is as simple as:

```
v.animate().alpha(0);
```

Here, “alpha” refers to the “alpha channel”. An alpha of 1 is normal opacity, while an alpha of 0 is completely transparent, with values in between representing various levels of translucence.

That may seem rather simple. The good news is, it *really* is that easy. Of course, there is a lot more you can do here, and you might have to worry about supporting older Android versions, and we need to think about things other than fading widgets in and out, and so forth.

First, though, let’s consider what is really going on when we call `animate()` on a widget on API Level 11+.

### Native Implementation

The call to `animate()` returns an instance of `ViewPropertyAnimator`. This object allows us to build up a description of an animation to be performed, such as calling `alpha()` to change the alpha channel value. `ViewPropertyAnimator` uses a so-called [fluent interface](#), much like the various builder classes (e.g., `Notification.Builder`) — calling a method on a `ViewPropertyAnimator()` usually returns the `ViewPropertyAnimator` itself. This allows you to build up an animation via a chained series of method calls, starting with that call to `animate()` on the widget.

You will note that we do not end the chain of method calls with something like a `start()` method. `ViewPropertyAnimator` will automatically arrange to start the animation once we return control of the main application thread back to the framework. Hence, we do not have to explicitly start the animation.

You will also notice that we did not indicate any particulars about how the animation should be accomplished, beyond stating the ending alpha channel value of 0. `ViewPropertyAnimator` will use some standard defaults for the animation, such as a default duration, to determine how quickly Android changes the alpha value from its starting point to 0. Most of those particulars can be overridden from their defaults via additional methods called on our `ViewPropertyAnimator`, such as `setDuration()` to provide a duration in milliseconds.

There are four standard animations that `ViewPropertyAnimator` can perform:

## ANIMATORS

---

1. Changes in alpha channel values, for fading widgets in and out
2. Changes in widget position, by altering the X and Y values of the upper-left corner of the widget, from wherever on the screen it used to be to some new value
3. Changes in the widget's rotation, around any of the three axes
4. Changes in the widget's size, where Android can scale the widget by some percentage to expand or shrink it

We will see an example of changing a widget's position, using the `translationXBy()` method, [later in this chapter](#).

You are welcome to use more than one animation effect simultaneously, such as using both `alpha()` and `translationXBy()` to slide a widget horizontally and have it fade in or out.

There are other aspects of the animation that you can control. By default, the animation happens linearly — if we are sliding 500 pixels in 500ms, the widget will move evenly at 1 pixel/ms. However, you can specify a different “interpolator” to override that default linear behavior (e.g., start slow and accelerate as the animation proceeds). You can attach a listener object to find out about when the animation starts and ends. And, you can specify `withLayer()` to indicate that Android should try to more aggressively use hardware acceleration for an animation, a concept that we will get into in greater detail [later in this chapter](#).

To see this in action, take a look at the [Animation/AnimatorFade](#) sample app.

The app consists of a single activity (MainActivity). It uses a layout that is dominated by a single `TextView` widget, whose ID is `fadee`:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TextView
        android:id="@+id/fadee"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerHorizontal="true"
        android:layout_centerVertical="true"
        android:text="@string/fading_out"
        android:textAppearance="?android:attr/textAppearanceLarge"
        tools:context=".MainActivity"/>
```

## ANIMATORS

---

```
</RelativeLayout>
```

(from [Animation/AnimatorFade/app/src/main/res/layout/activity\\_main.xml](#))

In `onCreate()`, we load up the layout and get our hands on the `fadee` widget:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    fadee=(TextView)findViewById(R.id.fadee);
}
```

(from [Animation/AnimatorFade/app/src/main/java/com/commonsware/android/animator/fade/MainActivity.java](#))

`MainActivity` itself implements `Runnable`, and our `run()` method will perform some animated effects:

```
@Override
public void run() {
    if (fadingOut) {
        fadee.animate().alpha(0).setDuration(PERIOD);
        fadee.setText(R.string.fading_out);
    }
    else {
        fadee.animate().alpha(1).setDuration(PERIOD);
        fadee.setText(R.string.coming_back);
    }

    fadingOut=!fadingOut;

    fadee.postDelayed(this, PERIOD);
}
```

(from [Animation/AnimatorFade/app/src/main/java/com/commonsware/android/animator/fade/MainActivity.java](#))

Specifically, we use `ViewPropertyAnimator` to fade out the `TextView` over a certain period (`fadee.animate().alpha(0).setDuration(PERIOD);`) and set its caption to a value indicating that we are fading out. If we are to be fading back in, we perform the opposite animation and set the caption to a different value. We then flip the `fadingOut` boolean for the next pass and use `postDelayed()` to reschedule ourselves to run after the period has elapsed.

To complete the process, we run() our code initially in `onStart()` and cancel the

postDelayed() loop in onStop():

```
@Override
public void onStart() {
    super.onStart();

    run();
}

@Override
public void onStop() {
    fadee.removeCallbacks(this);

    super.onStop();
}
```

(from [Animation/AnimatorFade/app/src/main/java/com/commonsware/android/animator/fade/MainActivity.java](#))

The result is that the TextView smoothly fades out and in, alternating captions as it goes.

However, it would be really unpleasant if all this animator goodness worked only on API Level 11+. Fortunately for us, somebody wrote a backport.

### Backport Via NineOldAndroids

Jake Wharton wrote [NineOldAndroids](#). This is, in effect, a backport of ViewPropertyAnimator and its underpinnings. There are some slight changes in how you use it, because NineOldAndroids is simply a library. It cannot add methods to existing classes (like adding animate() to View), nor can it add capabilities that the underlying firmware simply lacks. But, it may cover many of your animator needs, even if the name is somewhat inexplicable, and it works going all the way back to API Level 1, ensuring that it will cover any Android release that you care about.

NineOldAndroids is an Android library project. Android Studio users can add a implementation statement to their dependencies closure in build.gradle to pull in com.nineoldandroids:library:... (for some version indicated by ...).

Since NineOldAndroids cannot add animate() to View, the recommended approach is to use a somewhat obscure feature of Java: imported static methods. An import static statement, referencing a particular static method of a class, makes that method available as if it were a static method on the class that you are writing, or as some sort of global function. NineOldAndroids has an animate() method that you

## ANIMATORS

---

can import this way, so instead of `v.animate()`, you use `animate(v)` to accomplish the same end. Everything else is the same, except perhaps some imports, to reference `NineOldAndroids` instead of the native classes.

You can see this in the [Animation/AnimatorFadeBC](#) sample app.

In addition to having the `NineOldAndroids` JAR in `libs/`, the only difference between this edition and the previous sample is in how the animation is set up. Instead of lines like:

```
fadee.animate().alpha(0).setDuration(PERIOD);
```

we have:

```
animate(fadee).alpha(0).setDuration(PERIOD);
```

This takes advantage of our static import:

```
import static com.nineoldandroids.view.ViewPropertyAnimator.animate;
```

If the static import makes you queasy, you are welcome to simply import the `com.nineoldandroids.view.ViewPropertyAnimator` class, rather than the static method, and call the `animate()` method on `ViewPropertyAnimator`:

```
ViewPropertyAnimator.animate(fadee).alpha(0).setDuration(PERIOD);
```

## The Foundation: Value and Object Animators

`ViewPropertyAnimator` itself is a layer atop of a more primitive set of animators, known as value and object animators.

A `ValueAnimator` handles the core logic of transitioning some value, from an old to a new value, over a period of time. `ValueAnimator` offers replaceable “interpolators”, which will determine how the values change from start to finish over the animation period (e.g., start slowly, accelerate, then end slowly). `ValueAnimator` also handles the concept of a “repeat mode”, to indicate if the animation should simply happen once, a fixed number of times, or should infinitely repeat (and, in the latter cases, whether it does so always transitioning from start to finish or if it reverses direction on alternate passes, going from finish back to start).

What `ValueAnimator` does *not* do is actually change anything. It is merely

## ANIMATORS

---

computing the different values based on time. You can call `getAnimatedValue()` to find out the value at any point in time, or you can call `addUpdateListener()` to register a listener object that will be notified of each change in the value, so that change can be applied somewhere.

Hence, what tends to be a bit more popular is `ObjectAnimator`, a subclass of `ValueAnimator` that automatically applies the new values. `ObjectAnimator` does this by calling a setter method on some object, where you supply the object and the “property name” used to derive the getter and setter method names. For example, if you request a property name of `foo`, `ObjectAnimator` will try to call `getFoo()` and `setFoo()` methods on your supplied object.

As with `ViewPropertyAnimator`, `ValueAnimator` and `ObjectAnimator` are implemented natively in API Level 11 and are available via the `NineOldAndroids` backport as well.

To see what `ObjectAnimator` looks like in practice, let us examine the [Animation/ObjectAnimator](#) sample app.

Once again, our activity’s layout is pretty much just a centered `TextView`, here named `word`:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TextView
        android:id="@+id/word"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerHorizontal="true"
        android:layout_centerVertical="true"
        android:textAppearance="?android:attr/textAppearanceLarge"
        tools:context=".MainActivity"/>

</RelativeLayout>
```

(from [Animation/ObjectAnimator/app/src/main/res/layout/activity\\_main.xml](#))

The objective of our activity is to iterate through 25 words, showing one at a time in the `TextView`:

```
package com.commonware.android animator.obj;
```

## ANIMATORS

---

```
import android.animation.ObjectAnimator;
import android.animation.ValueAnimator;
import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;

public class MainActivity extends Activity {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
    private TextView word=null;
    int position=0;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        word=findViewById(R.id.word);

        ValueAnimator
            positionAnim = ObjectAnimator.ofInt(this, "wordPosition", 0, 25);
        positionAnim.setDuration(12500);
        positionAnim.setRepeatCount(ValueAnimator.INFINITE);
        positionAnim.setRepeatMode(ValueAnimator.RESTART);
        positionAnim.start();
    }

    public void setWordPosition(int position) {
        this.position=position;
        word.setText(items[position]);
    }

    public int getWordPosition() {
        return(position);
    }
}
```

(from [Animation/ObjectAnimator/app/src/main/java/com/commonsware/android/animator/obj/MainActivity.java](#))

To accomplish this, we use NineOldAndroids version of ObjectAnimator, saying that we wish to “animate” the wordPosition property of the activity itself, from 0 to 24. We configure the animation to run for 12.5 seconds (i.e., 500ms per word) and to repeat indefinitely by restarting the animation from the beginning on each pass. We

then call `start()` to kick off the animation.

For this to work, though, we need `getWordPosition()` and `setWordPosition()` accessor methods for the theoretical `wordPosition` property. In our case, the “word position” is simply an integer data member of the activity, which we return in `getWordPosition()` and update in `setWordPosition()`. However, we also update the `TextView` in `setWordPosition()`, to display the word at that position.

The net effect is that words appear in our `TextView`, changing on average every 500ms.

## Animating Custom Types

In the previous section, we animated an `int` property of an `Activity`. That works, because Android knows how to compute `int` values between the start and end position, through simple math.

But, what if we wanted to animate something that is not a simple number? For example, what if we want to animate a `Color`, or a `LatLng` from [Maps V2](#), or a `TastyTreat` class of our own design?

So long as we can perform the calculations, we can animate a type of anything we want, using `TypeEvaluator` and `ofObject()` on `ObjectAnimator`.

A `TypeEvaluator` is a simple interface, containing a single method that we need to override: `evaluate()`. However, `TypeEvaluator` uses generics, and so our implementation will actually be of some concrete class (e.g., a `TypeEvaluator` of `TastyTreat`). Our job in `evaluate()` is to return a value of our designated type (e.g., `TastyTreat`) given three inputs:

1. The initial value for our animation range, in the form of our designated type
2. The end value for our animation range, in the form of our designated type
3. The fraction along that range that represents how much we have moved from the initial value to the end value

Note that the fraction is not limited to being between 0 and 1, as certain interpolators (e.g., an overshoot interpolator) might result in a fraction being negative (e.g., we overshoot past the initial value) or greater than one (e.g., we overshoot past the end value).

For example, to have a `TypeEvaluator` of `Color`, we might have `evaluate()` generate a new `Color` instance based upon applying the fraction to the initial and end red, green, blue, and alpha channels.

To use a `TypeEvaluator`, instead of `ofInt()`, `ofFloat()`, or similar simple factory methods on `ObjectAnimator`, we use `ofObject()`. `ofObject()` takes the object to be animated, the property to be animated, the `TypeEvaluator` to assist in the actual animation, and the final value of the animation (or, optionally, a series of waypoints to be animated along).

A flavor of `ofObject()` that takes the property name — akin to the `wordPosition` of `ofInt()` used in the previous section — has been around since API Level 11. API Level 14 added an `ofObject()` method that takes a `Property` value instead of the name of the property. This version has the added benefit of type-safety, as it can ensure that your object to be animated, `TypeEvaluator`, and final position are all of the same type.

You can see an example of using `TypeEvaluator` this way in [the chapter on Maps V2](#), as we animate the movement of a map marker from a starting point to an ending point.

## Hardware Acceleration

Animated effects operate much more smoothly with hardware acceleration. There are two facets to employing hardware acceleration for animations: enabling it overall and directing its use for the animations themselves.

Hardware acceleration is enabled overall on Android devices running Android 4.0 or higher (API Level 14). On Android 3.x, hardware acceleration is available but is disabled by default — use `android:hardwareAccelerated="true"` in your `<application>` or `<activity>` element in the manifest to enable it on those versions. Hardware acceleration for 2D graphics operations like widget animations is not available on older versions of Android.

While this will provide some benefit across the board, you may also wish to consider rendering animated widgets or containers in an off-screen buffer, or “hardware layer”, that then gets applied to the screen via the GPU. In particular, the GPU can apply certain animated transformations to a hardware layer without forcing software to redraw the widgets or containers (e.g., what happens when you `invalidate()` them). As it turns out, these GPU-enhanced transformations match the ones

---

## ANIMATORS

---

supported by `ViewPropertyAnimator`:

1. Changes in alpha channel values, for fading widgets in and out
2. Changes in widget position, by altering the X and Y values of the upper-left corner of the widget, from wherever on the screen it used to be to some new value
3. Changes in the widget's rotation, around any of the three axes
4. Changes in the widget's size, where Android can scale the widget by some percentage to expand or shrink it

By having the widget be rendered in a hardware layer, these `ViewPropertyAnimator` operations are significantly more efficient than before.

However, since hardware layers take up video memory, generally you do not want to keep a widget or container in a hardware layer indefinitely. Instead, the recommended approach is to have the widget or container be rendered in a hardware layer only while the animation is ongoing, by calling `setLayerType()` for `LAYER_TYPE_HARDWARE` before the animation begins, then calling `setLayerType()` for `LAYER_TYPE_NONE` (i.e., return to default behavior) when the animation completes. Or, for `ViewPropertyAnimator` on API Level 16 and higher, use `withLayer()` in the fluent interface to have it apply the hardware layer automatically just for the animation duration.

We will see examples of using hardware acceleration this way in the next section.

## The Three-Fragment Problem

The original tablet implementation of Gmail organized its landscape main activity into two panes, one on the left taking up ~30% of the screen, and one on the right taking up the remainder:

*Figure 530: Gmail Fragments (image courtesy of Google and AOSP)*

Gmail had a very specific navigation mode in its main activity when viewed in landscape on a tablet, where upon some UI event (e.g., tapping on something in the right-hand area):

- The original left-hand fragment (Fragment A) slid off the screen to the left
- The original right-hand fragment (Fragment B) slid to the left edge of the screen and shrunk to take up the spot vacated by Fragment A
- Another fragment (Fragment C) slid in from the right side of the screen and expanded to take up the spot vacated by Fragment B

And a BACK button press reversed this operation.

This is a bit tricky to set up, leading to the author of this book posting [a question on Stack Overflow to get input](#). Here, we will examine one of the results of that discussion, based in large part on the implementation of the AOSP Email app, which has a similar navigation flow. The other answers on that question may have merit in other scenarios as well.

You can see one approach for implementing the three-pane solution in the [Animation/ThreePane](#) sample app.

### The ThreePaneLayout

The logic to handle the animated effects is encapsulated in a `ThreePaneLayout` class. It is designed to be used in a layout XML resource where you supply the contents of the three panes, sizing the first two as you want, with the third “pane” having zero width at the outset:

```
<com.commonware.android.anim.threepane.ThreePaneLayout xmlns:android="http://schemas.android.com/apk/res/
android"
  xmlns:tools="http://schemas.android.com/tools"
  android:id="@+id/root"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <FrameLayout
    android:id="@+id/left"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="3"/>

  <FrameLayout
    android:id="@+id/middle"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="7"/>
```

## ANIMATORS

---

```
<Button
    android:layout_width="0dp"
    android:layout_height="match_parent"/>

</com.commonware.android.anim.threepane.ThreePaneLayout>
```

(from [Animation/ThreePane/app/src/main/res/layout/activity\\_main.xml](#))

ThreePaneLayout itself is a subclass of LinearLayout, set up to always be horizontal, regardless of what might be set in the layout XML resource.

```
public ThreePaneLayout(Context context, AttributeSet attrs) {
    super(context, attrs);
    initSelf();
}

void initSelf() {
    setOrientation(HORIZONTAL);
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonware/android/anim/threepane/ThreePaneLayout.java](#))

When the layout finishes inflating, we grab the three panes (defined as the first three children of the container) and stash them in data members named left, middle, and right, with matching getter methods:

```
@Override
public void onFinishInflate() {
    super.onFinishInflate();

    left=getChildAt(0);
    middle=getChildAt(1);
    right=getChildAt(2);
}

public View getLeftView() {
    return(left);
}

public View getMiddleView() {
    return(middle);
}

public View getRightView() {
    return(right);
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonware/android/anim/threepane/ThreePaneLayout.java](#))

---

## ANIMATORS

---

The major operational API, from the standpoint of an activity using `ThreePaneLayout`, is `hideLeft()` and `showLeft()`. `hideLeft()` will switch from showing the left and middle widgets in their original size and position to showing the middle and right widgets wherever left and middle had been originally. `showLeft()` reverses the operation.

The problem is that, initially, we do not know where the widgets are or how big they are, as that should be able to be set from the layout XML resource and are not known until the `ThreePaneLayout` is actually applied to the screen. Hence, we lazy-retrieve those values in `hideLeft()`, plus remove any weights that had been originally defined, setting the actual pixel widths on the widgets instead:

```
public void hideLeft() {
    if (leftWidth == -1) {
        leftWidth=left.getWidth();
        middleWidthNormal=middle.getWidth();
        resetWidget(left, leftWidth);
        resetWidget(middle, middleWidthNormal);
        resetWidget(right, middleWidthNormal);
        requestLayout();
    }

    translateWidgets(-1 * leftWidth, left, middle, right);

    ObjectAnimator.ofInt(this, "middleWidth", middleWidthNormal,
        leftWidth).setDuration(ANIM_DURATION).start();
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

The work to change the weights into widths is handled in `resetWidget()`:

```
private void resetWidget(View v, int width) {
    LinearLayout.LayoutParams p=
        (LinearLayout.LayoutParams)v.getLayoutParams();

    p.width=width;
    p.weight=0;
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

After the lazy-initialization and widget cleanup, we perform the two animations. `translateWidgets()` will slide each of our three widgets to the left by the width of the left widget, using a `ViewPropertyAnimator` and a hardware layer:

## ANIMATORS

---

```
private void translateWidgets(int deltaX, View... views) {
    for (final View v : views) {
        v.setLayerType(View.LAYER_TYPE_HARDWARE, null);

        v.animate().translationXBy(deltaX).setDuration(ANIM_DURATION)
            .setListener(new AnimatorListenerAdapter() {
                @Override
                public void onAnimationEnd(Animator animation) {
                    v.setLayerType(View.LAYER_TYPE_NONE, null);
                }
            });
    }
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

The resize animation — to set the middle size to be what left had been — is handled via an `ObjectAnimator`, for a theoretical property of `middleWidth` on `ThreePaneLayout`. That is backed by a `setMiddleWidth()` method that adjusts the width property of the middle widget's `LayoutParams` and triggers a redraw:

```
@SuppressWarnings("unused")
private void setMiddleWidth(int value) {
    middle.getLayoutParams().width=value;
    requestLayout();
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

The `showLeft()` method simply performs those two animations in reverse:

```
public void showLeft() {
    translateWidgets(leftWidth, left, middle, right);

    ObjectAnimator.ofInt(this, "middleWidth", leftWidth,
        middleWidthNormal).setDuration(ANIM_DURATION)
        .start();
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

## Using the ThreePaneLayout

The sample app uses one activity (`MainActivity`) and one fragment (`SimpleListFragment`) to set up and use the `ThreePaneLayout`. The objective is a UI that roughly mirrors that of the AOSP Email app: a list on the left, a list in the

## ANIMATORS

---

```
((MainActivity) getActivity()).onListItemClick(this, position);
}

void setContents(ArrayList<String> contents) {
    setListAdapter(new ArrayAdapter<String>(
        getActivity(),
        R.layout.simple_list_item_1,
        contents));
}
}
```

(from [Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/SimpleListFragment.java](#))

MainActivity populates the left FrameLayout with a SimpleListFragment in onCreate(), if the fragment does not already exist (e.g., from a configuration change). When an item in the left list is clicked, MainActivity populates the middle FrameLayout. When an item in the middle list is clicked, it sets the caption of the right Button and uses hideLeft() to animate that Button onto the screen, hiding the left list. If the user presses BACK, and our left list is not showing, MainActivity calls showLeft() to reverse the animation:

```
package com.commonsware.android.anim.threepane;

import android.app.Activity;
import android.os.Bundle;
import android.widget.Button;
import java.util.ArrayList;

public class MainActivity extends Activity {
    private static final String KEY_MIDDLE_CONTENTS="middleContents";
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
    private boolean isLeftShowing=true;
    private SimpleListFragment middleFragment=null;
    private ArrayList<String> middleContents=null;
    private ThreePanelLayout root=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        root=(ThreePanelLayout)findViewById(R.id.root);
```

## ANIMATORS

---

```
if (getFragmentManager().findFragmentById(R.id.left) == null) {
    getFragmentManager().beginTransaction()
        .add(R.id.left,
            SimpleListFragment.newInstance(items))
        .commit();
}

middleFragment=
    (SimpleListFragment)getFragmentManager().findFragmentById(R.id.middle);
}

@Override
public void onBackPressed() {
    if (!isLeftShowing) {
        root.showLeft();
        isLeftShowing=true;
    }
    else {
        super.onBackPressed();
    }
}

@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putStringArrayList(KEY_MIDDLE_CONTENTS, middleContents);
}

@Override
protected void onRestoreInstanceState(Bundle inState) {
    middleContents=inState.getStringArrayList(KEY_MIDDLE_CONTENTS);
}

void onItemClick(SimpleListFragment fragment, int position) {
    if (fragment == middleFragment) {
        ((Button)root.getRightView()).setText(middleContents.get(position));

        if (isLeftShowing) {
            root.hideLeft();
            isLeftShowing=false;
        }
    }
    else {
        middleContents=new ArrayList<String>();

        for (int i=0; i < 20; i++) {
            middleContents.add(items[position] + " #" + i);
        }
    }
}
```

## ANIMATORS

```
    }

    if (getFragmentManager().findFragmentById(R.id.middle) == null) {
        middleFragment=SimpleListFragment.newInstance(middleContents);
        getFragmentManager().beginTransaction()
            .add(R.id.middle, middleFragment).commit();
    }
    else {
        middleFragment.setContents(middleContents);
    }
}
}
```

## The Results

If you run this app on a landscape tablet running API Level 11 or higher, you start off with a single list of words on the left:

Clicking on a word brings up a second list, taking up the rest of the screen, with

## ANIMATORS

---

numbered entries based upon the clicked-upon word:

---

## ANIMATORS

---

Clicking on an entry in the second list starts the animation, sliding the first list off to the left, sliding the second list into the space vacated by the first list, and sliding in a “detail view” into the right portion of the screen:

Pressing BACK once will reverse the animation, restoring you to the two-list perspective.

### The Backport

The ThreePane sample described above uses the native API Level 11 version of the animator framework and the native implementation of fragments. However, the same approach can work using the Android Support package’s version of fragments and NineOldAndroids. You can see this in the [Animation/ThreePaneBC](#) sample app.

Besides changing the import statements and adding the NineOldAndroids JAR file, the only other changes of substance were:

- Using `ViewPropertyAnimator.animate(v)` instead of `v.animate()` in `translateWidgets()`
- Conditionally setting the hardware acceleration layers via `setLayerType()` in

`translateWidgets()` based upon API level, as that method was only added in API Level 11

The smoothness of animations, though, will vary by hardware capabilities. For example, on a first-generation Kindle Fire, running Android 2.3, the backport works but is not especially smooth, while the animations are very smooth on more modern hardware where hardware acceleration can be applied.

### The Problems

As we will see in [the chapter on “jank”](#), there is some stutter in the rendering of this app. Fixing it requires removing the animated change in the width of the middle pane, which in turn makes the animation itself look worse. More details on the analysis can be found in [the “jank” chapter](#).

# Legacy Animations

---

Before `ViewPropertyAnimator` and the rest of [the animator framework](#) were added in API Level 11, we had the original `Animation` base class and specialized animations based upon it, like `TranslateAnimation` for movement and `AlphaAnimation` for fades. On the whole, you will want to try to use the animator framework where possible, as the new system is more powerful and efficient than the legacy `Animation` approach. However, particularly for apps where the `NineOldAndroids` backport is insufficient, you may wish to use the legacy framework.

After an overview of the role of the [animation](#) framework, we go in-depth to animate the [movement](#) of a widget across the screen. We then look at [alpha animations](#), for fading widgets in and out. We then see how you can get control during the [lifecycle](#) of an animation, how to control the [acceleration](#) of animations, and how to [group](#) animations together for parallel execution. Finally, we see how the same framework can now be used to control the animation for the switching of [activities](#).

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on [basic resources](#) and [basic widgets](#). Also, you should read the chapter on [custom views](#).

## It's Not Just For Toons Anymore

Android has a package of classes (`android.view.animation`) dedicated to animating the movement and behavior of widgets.

They center around an `Animation` base class that describes what is to be done. Built-

in animations exist to move a widget (`TranslateAnimation`), change the transparency of a widget (`AlphaAnimation`), revolve a widget (`RotateAnimation`), and resize a widget (`ScaleAnimation`). There is even a way to aggregate animations together into a composite `Animation` called an `AnimationSet`. Later sections in this chapter will examine the use of several of these animations.

Given that you have an animation, to apply it, you have two main options:

1. You may be using a container that supports animating its contents, such as a `ViewFlipper` or `TextSwitcher`. These are typically subclasses of `ViewAnimator` and let you define the “in” and “out” animations to apply. For example, with a `ViewFlipper`, you can specify how it flips between `Views` in terms of what animation is used to animate “out” the currently-visible `View` and what animation is used to animate “in” the replacement `View`.
2. You can simply tell any `View` to `startAnimation()`, given the `Animation` to apply to itself. This is the technique we will be seeing used in the examples in this chapter.

## A Quirky Translation

Animation takes some getting used to. Frequently, it takes a fair bit of experimentation to get it all working as you wish. This is particularly true of `TranslateAnimation`, as not everything about it is intuitive, even to authors of Android books.

### Mechanics of Translation

The simple constructor for `TranslateAnimation` takes four parameters describing how the widget should move: the before and after `X` offsets from the current position, and the before and after `Y` offsets from the current position. The Android documentation refers to these as `fromXDelta`, `toXDelta`, `fromYDelta`, and `toYDelta`.

In Android’s pixel-space, an  $(X, Y)$  coordinate of  $(0, 0)$  represents the upper-left corner of the screen. Hence, if `toXDelta` is greater than `fromXDelta`, the widget will move to the right, if `toYDelta` is greater than `fromYDelta`, the widget will move down, and so on.

### Imagining a Sliding Panel

Some Android applications employ a sliding panel, one that is off-screen most of the

time but can be called up by the user (e.g., via a menu) when desired. When anchored at the bottom of the screen, you get a container that slides up from the bottom and slides down and out when being removed.

One way to implement such a panel is to have a container (e.g., a `LinearLayout`) whose contents are absent (`INVISIBLE`) when the panel is closed and is present (`VISIBLE`) when the drawer is open. If we simply toggled `setVisibility()` using the aforementioned values, though, the panel would wink open and closed immediately, without any sort of animation. So, instead, we want to:

1. Make the panel visible and animate it up from the bottom of the screen when we open the panel
2. Animate it down to the bottom of the screen and make the panel invisible when we close the panel

### The Aftermath

This brings up a key point with respect to `TranslateAnimation`: the animation temporarily moves the widget, but if you want the widget to stay where it is when the animation is over, you have to handle that yourself. Otherwise, the widget will snap back to its original position when the animation completes.

In the case of the panel opening, we handle that via the transition from `INVISIBLE` to `VISIBLE`. Technically speaking, the panel is always “open”, in that we are not, in the end, changing its position. But when the body of the panel is `INVISIBLE`, it takes up no space on the screen; when we make it `VISIBLE`, it takes up whatever space it is supposed to.

Later in this chapter, we will cover how to use animation listeners to accomplish this end for closing the panel.

### Introducing `SlidingPanel`

With all that said, turn your attention to the [Animation/SlidingPanel](#) sample project and, in particular, the `SlidingPanel` class.

This class implements a layout that works as a panel, anchored to the bottom of the screen. A `toggle()` method can be called by the activity to hide or show the panel. The panel itself is a `LinearLayout`, so you can put whatever contents you want in there.

## LEGACY ANIMATIONS

---

We use two flavors of `TranslateAnimation`, one for opening the panel and one for closing it.

Here is the opening animation:

```
anim=new TranslateAnimation(0.0f, 0.0f,  
                           getHeight(),  
                           0.0f);
```

(from [Animation/SlidingPanel/app/src/main/java/com/commonsware/android/anim/SlidingPanel.java](#))

Our `fromXDelta` and `toXDelta` are both 0, since we are not shifting the panel's position along the horizontal axis. Our `fromYDelta` is the panel's height according to its layout parameters (representing how big we want the panel to be), because we want the panel to start the animation at the bottom of the screen; our `toYDelta` is 0 because we want the panel to be at its "natural" open position at the end of the animation.

Conversely, here is the closing animation:

```
anim=new TranslateAnimation(0.0f, 0.0f, 0.0f,  
                           getHeight());
```

(from [Animation/SlidingPanel/app/src/main/java/com/commonsware/android/anim/SlidingPanel.java](#))

It has the same basic structure, except the Y values are reversed, since we want the panel to start open and animate to a closed position.

The result is a container that can be closed:

*Figure 534: The SlidingPanel sample application, with the panel closed*

... or open, in this case toggled via a menu choice in the `SlidingPanelDemo` activity:

*Figure 535: The SlidingPanel sample application, with the panel open*

### Using the Animation

When setting up an animation, you also need to indicate how long the animation should take. This is done by calling `setDuration()` on the animation, providing the desired length of time in milliseconds.

When we are ready with the animation, we simply call `startAnimation()` on the `SlidingPanel` itself, causing it to move as specified by the `TranslateAnimation` instance.

### Fading To Black. Or Some Other Color.

`AlphaAnimation` allows you to fade a widget in or out by making it less or more transparent. The greater the transparency, the more the widget appears to be “fading”.

## Alpha Numbers

You may be used to alpha channels, when used in #AARRGGBB color notation, or perhaps when working with alpha-capable image formats like PNG.

Similarly, `AlphaAnimation` allows you to change the alpha channel for an entire widget, from fully-solid to fully-transparent.

In Android, a float value of 1.0 indicates a fully-solid widget, while a value of 0.0 indicates a fully-transparent widget. Values in between, of course, represent various amounts of transparency.

Hence, it is common for an `AlphaAnimation` to either start at 1.0 and smoothly change the alpha to 0.0 (a fade) or vice versa.

## Animations in XML

With `TranslateAnimation`, we showed how to construct the animation in Java source code. One can also create animation resources, which define the animations using XML. This is similar to the process for defining layouts, albeit much simpler.

For example, there is a second animation project, [Animation/SlidingPanelEx](#), which demonstrates a panel that fades out as it is closed. In there, you will find a `res/anim/` directory, which is where animation resources should reside. In there, you will find `fade.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<alpha xmlns:android="http://schemas.android.com/apk/res/android"
    android:fromAlpha="1.0"
    android:toAlpha="0.0" />
```

(from [Animation/SlidingPanelEx/app/src/main/res/anim/fade.xml](#))

The name of the root element indicates the type of animation (in this case, alpha for an `AlphaAnimation`). The attributes specify the characteristics of the animation, in this case a fade from 1.0 to 0.0 on the alpha channel.

This XML is the same as calling `new AlphaAnimation(1.0f, 0.0f)` in Java.

## Using XML Animations

To make use of XML-defined animations, you need to inflate them, much as you

---

might inflate a View or Menu resource. This is accomplished by using the `loadAnimation()` static method on the `AnimationUtils` class, seen here in our `SlidingPanel` constructor:

```
public SlidingPanel(final Context ctxt, AttributeSet attrs) {
    super(ctxt, attrs);

    TypedArray a=ctxt.obtainStyledAttributes(attrs,
                                             R.styleable.SlidingPanel,
                                             0, 0);

    speed=a.getInt(R.styleable.SlidingPanel_speed, 300);

    a.recycle();

    fadeOut=AnimationUtils.loadAnimation(ctxt, R.anim.fade);
}
```

(from [Animation/SlidingPanelEx/app/src/main/java/com/commonsware/android/anim2/SlidingPanel.java](#))

Here, we are loading our fade animation, given a `Context`. This is being put into an `Animation` variable, so we neither know nor care that this particular XML that we are loading defines an `AlphaAnimation` instead of, say, a `RotateAnimation`.

## When It's All Said And Done

Sometimes, you need to take action when an animation completes.

For example, when we close the panel, we want to use a `TranslationAnimation` to slide it down from the open position to closed... then *keep* it closed. With the system used in `SlidingPanel`, keeping the panel closed is a matter of calling `setVisibility()` on the contents with `INVISIBLE`.

However, you cannot do that when the animation begins; otherwise, the panel is gone by the time you try to animate its motion.

Instead, you need to arrange to have it become invisible when the animation ends. To do that, you use an animation listener.

An animation listener is simply an instance of the `AnimationListener` interface, provided to an animation via `setAnimationListener()`. The listener will be invoked when the animation starts, ends, or repeats (the latter courtesy of `CycleInterpolator`, discussed later in this chapter). You can put logic in the

---

## LEGACY ANIMATIONS

---

`onAnimationEnd()` callback in the listener to take action when the animation finishes.

For example, here is the `AnimationListener` for `SlidingPanel`:

```
Animation.AnimationListener collapseListener=new Animation.AnimationListener() {
    public void onAnimationEnd(Animation animation) {
        setVisibility(View.INVISIBLE);
    }

    public void onAnimationRepeat(Animation animation) {
        // not needed
    }

    public void onAnimationStart(Animation animation) {
        // not needed
    }
};
```

(from [Animation/SlidingPanel/app/src/main/java/com/commonsware/android/anim/SlidingPanel.java](#))

All we do is set our content's visibility to be `INVISIBLE`, thereby closing the panel.

## Loose Fill

You will see attributes, available on `Animation`, named `android:fillEnabled` and `android:fillAfter`. Reading those, you may think that you can dispense with the `AnimationListener` and just use those to arrange to have your widget wind up being “permanently” in the state represented by the end of the animation. All you would have to do is set each of those to true in your animation XML (or the equivalent in Java), and you would be set.

At least for `TranslateAnimation`, you would be mistaken.

It actually will look like it works — the animated widgets will be drawn in their new location. However, if those widgets are clickable, they will not be clicked in their new location, but rather in their old one. This, of course, is not terribly useful.

Hence, even though it is annoying, you will want to use the `AnimationListener` techniques described in this chapter.

## Hit The Accelerator

In addition to the `Animation` classes themselves, Android also provides a set of `Interpolator` classes. These provide instructions for how an animation is supposed

to behave during its operating period.

For example, the `AccelerateInterpolator` indicates that, during the duration of an animation, the rate of change of the animation should begin slowly and accelerate until the end. When applied to a `TranslateAnimation`, for example, the sliding movement will start out slowly and pick up speed until the movement is complete.

There are several implementations of the `Interpolator` interface besides `AccelerateInterpolator`, including:

1. `AccelerateDecelerateInterpolator`, which starts slowly, picks up speed in the middle, and slows down again at the end
2. `DecelerateInterpolator`, which starts quickly and slows down towards the end
3. `LinearInterpolator`, the default, which indicates the animation should proceed smoothly from start to finish
4. `CycleInterpolator`, which repeats an animation for a number of cycles, following the `AccelerateDecelerateInterpolator` pattern (slow, then fast, then slow)

To apply an interpolator to an animation, simply call `setInterpolator()` on the animation with the `Interpolator` instance, such as the following line from `SlidingPanel`:

```
anim.setInterpolator(new AccelerateInterpolator(1.0f));
```

(from [Animation/SlidingPanel/app/src/main/java/com/commonsware/android/anim/SlidingPanel.java](#))

You can also specify one of the stock interpolators via the `android:interpolator` attribute in your animation XML file.

## Animate. Set. Match.

For the `Animation/SlidingPanelEx` project, though, we want the panel to slide open, but also fade when it slides closed. This implies two animations working at the same time (a fade and a slide). Android supports this via the `AnimationSet` class.

An `AnimationSet` is itself an `Animation` implementation. Following the composite design pattern, it simply cascades the major `Animation` events to each of the animations in the set.

## LEGACY ANIMATIONS

---

To create a set, just create an `AnimationSet` instance, add the animations, and configure the set. For example, here is the logic from the `SlidingPanel` implementation in `Animation/SlidingPanelEx`:

```
public void toggle() {
    TranslateAnimation anim=null;
    AnimationSet set=new AnimationSet(true);

    isOpen=!isOpen;

    if (isOpen) {
        set.setVisibility(View.VISIBLE);
        anim=new TranslateAnimation(0.0f, 0.0f,
                                   getHeight(),
                                   0.0f);
    }
    else {
        anim=new TranslateAnimation(0.0f, 0.0f, 0.0f,
                                   getHeight());
        anim.setAnimationListener(collapseListener);
        set.addAnimation(fadeOut);
    }

    set.addAnimation(anim);
    set.setDuration(speed);
    set.setInterpolator(new AccelerateInterpolator(1.0f));
    startAnimation(set);
}
```

(from [Animation/SlidingPanelEx/app/src/main/java/com/commonsware/android/anim2/SlidingPanel.java](#))

If the panel is to be opened, we make the contents visible (so we can animate the motion upwards), and create a `TranslateAnimation` for the upward movement. If the panel is to be closed, we create a `TranslateAnimation` for the downward movement, but also add a pre-defined `AlphaAnimation` (`fadeOut`) to an `AnimationSet`. In either case, we add the `TranslateAnimation` to the set, give the set a duration and interpolator, and run the animation.

## Active Animations

Starting with Android 1.5, users could indicate if they wanted to have inter-activity animations: a slide-in/slide-out effect as they switched from activity to activity. However, at that time, they could merely toggle this setting on or off, and applications had no control over these animations whatsoever.

## LEGACY ANIMATIONS

---

Starting in Android 2.0, though, developers have a bit more control. Specifically:

1. Developers can call `overridePendingTransition()` on an Activity, typically after calling `startActivity()` to launch another activity or `finish()` to close up the current activity. The `overridePendingTransition()` indicates an in/out animation pair that should be applied as control passes from this activity to the next one, whether that one is being started (`startActivity()`) or is the one previous on the stack (`finish()`).
2. Developers can start an activity via an Intent containing the `FLAG_ACTIVITY_NO_ANIMATION` flag. As the name suggests, this flag requests that animations on the transitions involving this activity be suppressed.

These are prioritized as follows:

- Any call to `overridePendingTransition()` is always taken into account
- Lacking that, `FLAG_ACTIVITY_NO_ANIMATION` will be taken into account
- In the normal case, where neither of the two are used, whatever the user's preference, via the Settings application, is applied

# Custom Drawables

---

Many times, our artwork can simply be some PNG or JPEG files, perhaps with different variations in different resource directories by density.

Sometimes, though, we need something more.

In addition to supporting standard PNG and JPEG files, Android has a number of custom drawable resource formats — mostly written in XML — that handle specific scenarios.

For example, you may wish to customize “the background” of a `Button`, but a `Button` really has several different background images for different circumstances (normal, pressed, focused, disabled, etc.). Android has a certain type of drawable resource that aggregates other drawable resources, indicating which of those other resources should be used in different circumstances (e.g., for a normal button use X, for a disabled button use Y).

In this chapter, we will explore these non-traditional types of “drawables” and how you can use them within your apps.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on [basic resources](#), [basic widgets](#), and [vector drawables](#).

Having read the chapters on [animators](#) and [legacy animations](#) would be useful.

## Where Do These Things Go?

All of the drawables described in this chapter, unless otherwise noted, are density-independent. Hence, they do not normally go in a density-dependent directories like `res/drawable-hdpi/`. However, that still leaves three possible candidates: `res/drawable-nodpi/`, `res/drawable-anydpi/`, and the unadorned `res/drawable/`.

### **nodpi: Fallback**

A drawable in `res/drawable-nodpi/` is valid for any screen density. However, if there is another drawable with the same base name in a density-specific directory, and the device running your app happens to have that screen density, the density-specific resource will be used. As a result, `-nodpi` becomes a fallback, to be used in cases where you do not have something specific for a density.

For example, suppose that we have `res/drawable-nodpi/foo.xml` and `res/drawable-xxhdpi/foo.png`. An `-xxhdpi` device would use the PNG; all other devices would use the XML.

### **anydpi: Takeover**

A drawable in `res/drawable-anydpi/` also is valid for any screen density. However, in this case, the `-anydpi` variant trumps any density-specific variant.

For example, suppose that we have `res/drawable-anydpi/foo.xml` and `res/drawable-xxhdpi/foo.png`. **All devices** would use the XML, even `-xxhdpi` devices.

For this reason, often you will see `-anydpi` used in conjunction with other qualifiers. A popular one will be `-v21`, to restrict the resources to be used on API Level 21+ devices.

### **No Qualifier: Just Say “WTF?”**

`res/drawable/` is a synonym for `res/drawable-mdpi/`, for backwards compatibility with *really* old Android apps, written before we had density-specific resources. Hence, `res/drawable/` is not really an appropriate choice for density-independent drawables.

Alas, Android Studio may put some drawables here, for uncertain reasons.

So long as there are no other resources with the same basename, the choice made by Android Studio's developers is unlikely to cause any harm.

## ColorDrawable

The simplest XML drawable format, by far, is for `ColorDrawable`. Not surprisingly, this defines a `Drawable` that is a solid color.

So, you can have a `res/drawable/thing.xml` file, containing something like this:

```
<color xmlns:android="http://schemas.android.com/apk/res/android"
    android:color="#80FF00FF"/>
```

From there, you can use `@drawable/thing` or `R.drawable.thing` in the same places that you would use any other drawable resource.

Note that a `ColorDrawable` is different than a color resource. A color resource (e.g., `res/values/colors.xml`) specifies a color. A `ColorDrawable` resource defines a `Drawable` of a color. A `ColorDrawable` resource is welcome to reference a color defined by a color resource, though:

```
<color xmlns:android="http://schemas.android.com/apk/res/android"
    android:color="@color/primary_dark"/>
```

## AnimationDrawable

The original way of doing animation on the Web was via the animated GIF. An individual GIF file could contain many frames, and the browser would switch between those frames to display a basic animated effect. This was used by Web designers for things both good (animated progress “spinners”) and bad (“hit the monkey” ad banners).

Android, on the whole, does not support animated GIF files, certainly not as regular images for use with widgets like `ImageView`.

However, there are times where having this sort of frame-by-frame animation would be useful. For example, in [another chapter](#), we will look at `ProgressBar`, which is Android's primary way of demonstrating progress of background work. You may wish to customize the “spinning wheel” image that Android uses by default, to match your app's color scheme, or to spin your company logo, or whatever. On the

## CUSTOM DRAWABLES

---

Web, particularly on older browsers, you might use an animated GIF for that. On Android, you still could, though it would require a [third-party library](#) or some fairly heavyweight solutions (e.g., WebView, Movie).

Another possibility is to use an AnimationDrawable. AnimationDrawable has the net effect of an animated GIF:

- You define a series of images that serve as the frames of the animation
- You define how long each of those images should be on the screen
- You define whether the animation should loop back to the beginning after it reaches the end or not

However, rather than encoding all of this in an animated GIF, you instead encode this information in an XML file, stored as a drawable resource.

XML-encoded drawable resources are typically stored in a drawable directory that does *not* contain density information, such as `res/drawable/`. That is because the XML-encoded drawable resources are density-invariant: they behave the same regardless of density. Those, like the AnimationDrawable, that refer to other images might well refer to other images that are stored in density-dependent resource directories, but the XML-encoded drawable itself is independent of density.

An AnimationDrawable is defined as in XML with a root `<animation-list>` element, containing a series of `<item>` elements for each frame:

```
<animation-list xmlns:android="http://schemas.android.com/apk/res/android"
    android:oneshot="true">
    <item android:drawable="@drawable/frame1" android:duration="250" />
    <item android:drawable="@drawable/frame2" android:duration="250" />
    <item android:drawable="@drawable/frame3" android:duration="250" />
    <item android:drawable="@drawable/frame4" android:duration="250" />
</animation-list>
```

The root `<animation-list>` element can have an `android:oneshot` attribute, indicating whether the animation should repeat after displaying the last frame (false) or stop (true).

The `<item>` elements have `android:drawable` attributes pointing to the individual images for the individual frames. Usually these frames are PNG or JPEG files, but you refer to them as drawable resources, using `@drawable` syntax, so Android can find the right image based upon the density (or other characteristics) of the current device. The `<item>` elements also need an `android:duration` attribute, specifying

## CUSTOM DRAWABLES

---

the time in milliseconds that this frame should be on the screen. While the above example has all durations the same, that is not required.

For example, the Android OS uses AnimationDrawable resources in a few places. One is for the download icon used in a Notification for use with DownloadManager and similar situations. That drawable resource – `stat_sys_download.xml` — looks like this:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
/* //device/apps/common/res/drawable/status_icon_background.xml
**
** Copyright 2008, The Android Open Source Project
**
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
**
**     http://www.apache.org/licenses/LICENSE-2.0
**
** Unless required by applicable law or agreed to in writing, software
** distributed under the License is distributed on an "AS IS" BASIS,
** WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
** See the License for the specific language governing permissions and
** limitations under the License.
*/
-->
<animation-list
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:oneshot="false">
    <item android:drawable="@drawable/stat_sys_download_anim0" android:duration="200"
    />
    <item android:drawable="@drawable/stat_sys_download_anim1" android:duration="200"
    />
    <item android:drawable="@drawable/stat_sys_download_anim2" android:duration="200"
    />
    <item android:drawable="@drawable/stat_sys_download_anim3" android:duration="200"
    />
    <item android:drawable="@drawable/stat_sys_download_anim4" android:duration="200"
    />
    <item android:drawable="@drawable/stat_sys_download_anim5" android:duration="200"
    />
</animation-list>
```

Here, we have a repeating animation (`android:oneshot="false"`), consisting of six frames, each on the screen for 200 milliseconds.

By specifying an `AnimationDrawable` in your `Notification` for its icon, you too can have this sort of animated effect. Of course, the animation is “fire and forget”: other than by removing or replacing the `Notification`, you cannot affect the animation in any other way.

### Animated GIF Conversion

It may be that you have an animated GIF that you would like to use as the basis for your `AnimationDrawable`. If you have passing familiarity with Ruby, the author of this book has published [a Ruby script, named `gif2animdraw`](#), that automates the conversion.

To use `gif2animdraw`, in addition to the script itself and a Ruby interpreter, you will need the `RMagick`, `slop`, and `builder` gems. Note that `RMagick`, in turn, will require `ImageMagick` libraries and therefore is a bit more complicated to install than is your ordinary gem.

On Linux environments, you can also `chmod` the script to run it directly; otherwise, you would run it via the `ruby` command.

The script takes four command-line switches:

- `-i` should point to the GIF file to be converted
- `-o` should point to the root output directory, which typically would be a project's `res/` directory
- `-d` should have, as a value, one of the Android density bucket names (e.g., `hdpi`); this will be used as the density for the frames of the GIF
- Optionally, include `--oneshot` to indicate that this should be a one-shot animation, not a repeating one

The results will be:

- A `drawable/` directory underneath your supplied root, containing a file with the same name as the GIF file, but with a `.xml` extension, representing the `AnimationDrawable` itself
- A `drawable-XXXX/` directory, where `XXXX` is your stated density, containing each frame of the animated GIF, as a PNG file, with a sequentially numbered filename based on the GIF's filename

## StateListDrawable

Another XML-defined drawable resource, the `StateListDrawable`, is key if you want to have different images when widgets are in different states.

As outlined in the introduction to this chapter, what makes a `Button` visually be a `Button` is its background. To handle different looks for the `Button` background for different states (normal, pressed, disabled, etc.), the standard `Button` background is a `StateListDrawable`, one that looks something like this:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at

    http://www.apache.org/licenses/LICENSE-2.0

Unless required by applicable law or agreed to in writing, software
distributed under the License is distributed on an "AS IS" BASIS,
WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
See the License for the specific language governing permissions and
limitations under the License.
-->
<selector xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:state_window_focused="false" android:state_enabled="true"
        android:drawable="@drawable/btn_default_normal" />
    <item android:state_window_focused="false" android:state_enabled="false"
        android:drawable="@drawable/btn_default_normal_disable" />
    <item android:state_pressed="true"
        android:drawable="@drawable/btn_default_pressed" />
    <item android:state_focused="true" android:state_enabled="true"
        android:drawable="@drawable/btn_default_selected" />
    <item android:state_enabled="true"
        android:drawable="@drawable/btn_default_normal" />
    <item android:state_focused="true"
        android:drawable="@drawable/btn_default_normal_disable_focused" />
    <item
        android:drawable="@drawable/btn_default_normal_disable" />
</selector>
```

The XML has a `<selector>` root element, indicating this is a `StateListDrawable`. The `<item>` elements inside the root describe what `Drawable` resource should be

---

used if the `StateListDrawable` is being used in some state. For example, if the “window” (think activity or dialog) does not have the focus (`android:state_window_focused="false"`) and the Button is enabled (`android:state_enabled="true"`), then we use the `@drawable/btn_default_normal` Drawable resource. That resource, as it turns out, is a nine-patch PNG file, described [later in this chapter](#).

Android applies each rule in turn, top-down, to find the Drawable to use for a given state of the `StateListDrawable`. The last rule has no `android:state_*` attributes, meaning it is the overall default image to use if none of the other rules match.

So, if you want to change the background of a Button, you need to:

- Copy the above resource, found in your Android SDK as `res/drawable/btn_default.xml` inside any of the `platforms/` directories, into your project
- Copy each of the Button state nine-patch images into your project
- Modify whichever of those nine-patch images you want, to affect the visual change you seek
- If need be, tweak the states and images defined in the `StateListDrawable` XML you copied
- Reference the local `StateListDrawable` as the background for your Button

The backgrounds of most widgets that have backgrounds by default will use a `StateListDrawable`. Searching a platform version’s `res/drawable/` directory for XML files containing `<selector>` elements comes up with a rather long list.

## ColorStateList

A `ColorStateList` is analogous to a `StateListDrawable`, in that it defines states and identifies what should be used for a given state. Whereas `StateListDrawable` ties states to drawables, `ColorStateList` ties states to colors. This allows you to, say, change the color of some text based upon whether that text is drawn in a widget that is being pressed, or has the focus, or is disabled. If you tailor the background of a text-based widget using a `StateListDrawable`, you may well wind up tailoring the foreground text using a `ColorStateList`.

While this chapter mentions `ColorStateList`, technically a `ColorStateList` is not a Drawable. You do not use it in methods that take drawables or in widget XML attributes that take drawables. Rather, there are other methods and other attributes that take a `ColorStateList`, such as `android:textColor`.

## CUSTOM DRAWABLES

---

Similarly, while you can define a `ColorStateList` in XML, you do not do so in a `res/drawable/` resource directory, but rather a `res/color/` resource directory. Beyond that, though, a `ColorStateList` XML resource looks a lot like a `StateListDrawable` XML resource, such as this definition of `@android:color/primary_text_dark` from Android 4.4:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at

    http://www.apache.org/licenses/LICENSE-2.0

Unless required by applicable law or agreed to in writing, software
distributed under the License is distributed on an "AS IS" BASIS,
WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
See the License for the specific language governing permissions and
limitations under the License.
-->

<selector xmlns:android="http://schemas.android.com/apk/res/android">
  <item android:state_enabled="false" android:color="@android:color/
bright_foreground_dark_disabled"/>
  <item android:state_window_focused="false" android:color="@android:color/
bright_foreground_dark"/>
  <item android:state_pressed="true" android:color="@android:color/
bright_foreground_dark_inverse"/>
  <item android:state_selected="true" android:color="@android:color/
bright_foreground_dark_inverse"/>
  <item android:state_activated="true" android:color="@android:color/
bright_foreground_dark_inverse"/>
  <item android:color="@android:color/bright_foreground_dark"/> <!-- not selected -->
</selector>
```

Based upon the state, the `ColorStateList` pulls in a separate resource to define the actual color. Those colors, in turn, are defined via `<color>` elements in `res/values/colors.xml` as color resources, or are pulled in from system-defined colors (`@android:color/...` syntax):

```
<color name="background_dark">#ff000000</color>
<color name="background_light">#ffffffff</color>
<color name="bright_foreground_dark">@android:color/background_light</color>
<color name="bright_foreground_light">@android:color/background_dark</color>
```

```
<color name="bright_foreground_dark_disabled">#80ffffff</color>
<color name="bright_foreground_light_disabled">#80000000</color>
<color name="bright_foreground_dark_inverse">@android:color/
bright_foreground_light</color>
<color name="bright_foreground_light_inverse">@android:color/
bright_foreground_dark</color>
```

## LayerDrawable

A LayerDrawable basically stacks a bunch of other drawables on top of each other. Later drawables are drawn on top of earlier drawables, much as later children of a RelativeLayout are drawn on top of earlier children.

Typically, you will create a LayerDrawable via a <layer-list> XML drawable resource.

For example, a ToggleButton widget has a LayerDrawable as its background:

```
?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at

    http://www.apache.org/licenses/LICENSE-2.0

Unless required by applicable law or agreed to in writing, software
distributed under the License is distributed on an "AS IS" BASIS,
WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
See the License for the specific language governing permissions and
limitations under the License.
-->

<layer-list xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:id="@+android:id/background" android:drawable="@android:drawable/
btn_default_small" />
    <item android:id="@+android:id/toggle" android:drawable="@android:drawable/
btn_toggle" />
</layer-list>
```

This LayerDrawable draws two images on top of each other. One is a standard small button background (@android:drawable/btn\_default\_small). The other is the actual face of the toggle itself — a StateListDrawable that uses different images for

checked and unchecked states.

In the `<layer-list>`, you can have several `<item>` elements. Each `<item>` element usually will need an `android:drawable` attribute, pointing to the drawable that should be drawn. Optionally, you can assign ID values to the items via `android:id` attributes, much like you would do for widgets in a layout XML resource. Later on, you can call `findDrawableByLayerId()` on the `LayerDrawable` to retrieve an individual `Drawable` representing the layer, given its `android:id` value.

There are also `android:left`, `android:right`, `android:top`, and `android:bottom` attributes, which you can use to provide dimension values to offset an image within the layered set. For example, you could use `android:left` to inset one of the layers by a certain number of pixels (or dp or whatever).

By default, the layers in the `LayerDrawable` are scaled to fit the size of whatever `View` is holding them (e.g., the size of the `ToggleButton` using the `LayerDrawable` as a background). To prevent this, you can skip the `android:drawable` attribute, and instead nest a `<bitmap>` element inside the `<item>`, where you can provide an `android:gravity` attribute to control how the image should be handled relative to its containing `View`. We will get more into nested `<bitmap>` elements [later in this chapter](#).

## TransitionDrawable

A `TransitionDrawable` is a `LayerDrawable` with one added feature: for a two-layer drawable, it can smoothly transition from showing one layer to another on top.

For example, you may have noticed that when you tap-and-hold on a row in a `ListView` that the selector highlight has an animated effect, slowly shifting colors from the color used for a simple click to one signifying that you have long-clicked the row. Android accomplishes this via a `TransitionDrawable`, set up as a `<transition>` XML drawable resource:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at

http://www.apache.org/licenses/LICENSE-2.0
```

## CUSTOM DRAWABLES

---

```
    Unless required by applicable law or agreed to in writing, software
    distributed under the License is distributed on an "AS IS" BASIS,
    WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
    See the License for the specific language governing permissions and
    limitations under the License.
-->

<transition xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:drawable="@android:drawable/list_selector_background_pressed" />
    <item android:drawable="@android:drawable/list_selector_background_longpress" />
</transition>
```

The `TransitionDrawable` object has a `startTransition()` method that you can use, that will have Android smoothly switch from the first drawable to the second. You specify the duration of the transition as a number of milliseconds passed to `startTransition()`. There are also options to reverse the transition, set up more of a cross-fade effect, and the like.

## LevelListDrawable

A `LevelListDrawable` is similar in some respects to a `StateListDrawable`, insofar as one specific item from the “list drawable” will be displayed based upon certain conditions. In the case of `StateListDrawable`, the conditions are based upon the state of the widget using the drawable (e.g., checked, pressed, disabled). In the case of `LevelListDrawable`, it is merely an integer level.

For example, the status or system bar of your average Android device has an icon indicating the battery charge level. That is actually implemented as a `LevelListDrawable`, via an XML resource containing a root `<level-list>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
/* //device/apps/common/res/drawable/stat_sys_battery.xml
**
** Copyright 2007, The Android Open Source Project
**
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
**
**     http://www.apache.org/licenses/LICENSE-2.0
**
** Unless required by applicable law or agreed to in writing, software
** distributed under the License is distributed on an "AS IS" BASIS,
```

---

## CUSTOM DRAWABLES

---

```
** WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
** See the License for the specific language governing permissions and
** limitations under the License.
*/
-->

<level-list xmlns:android="http://schemas.android.com/apk/res/android">
  <item android:maxLevel="4" android:drawable="@android:drawable/
stat_sys_battery_0" />
  <item android:maxLevel="15" android:drawable="@android:drawable/
stat_sys_battery_15" />
  <item android:maxLevel="35" android:drawable="@android:drawable/
stat_sys_battery_28" />
  <item android:maxLevel="49" android:drawable="@android:drawable/
stat_sys_battery_43" />
  <item android:maxLevel="60" android:drawable="@android:drawable/
stat_sys_battery_57" />
  <item android:maxLevel="75" android:drawable="@android:drawable/
stat_sys_battery_71" />
  <item android:maxLevel="90" android:drawable="@android:drawable/
stat_sys_battery_85" />
  <item android:maxLevel="100" android:drawable="@android:drawable/
stat_sys_battery_100" />
</level-list>
```

This `LevelListDrawable` has eight items, whose `android:drawable` attributes point to specific other drawable resources (in this case, standard PNG files with different implementations for different densities). Each `<item>` has an `android:maxLevel` value. When someone calls `setLevel()` on the `Drawable` or `setImageLevel()` on the `ImageView`, Android will choose the item with the lowest `maxLevel` that meets or exceeds the requested level, and show that. In the case of the battery icon, when the battery level changes, the status bar picks up that change and calls `setImageLevel()` with the battery charge percentage (expressed as an integer from 0-100) — that, in turn, triggers the right PNG file to be displayed.

Another use of `LevelListDrawable` is with a `RemoteViews`, such as for an [app widget](#). The `setImageLevel()` method is “remotable”, despite not being directly part of the `RemoteViews` API. Hence, given that you use a `LevelListDrawable` in your app widget’s layout, you should be able to use `setInt()` with a method name of “`setImageLevel`” to have the app widget update to display the proper image.

## ScaleDrawable and ClipDrawable

A `ScaleDrawable` does pretty much what its name suggests: it scales another

---

drawable. A `ClipDrawable` does pretty much what *its* name suggests: it clips another drawable.

How they do this, and how you control it, requires a bit more explanation.

Like `LevelListDrawable`, `ScaleDrawable` and `ClipDrawable` leverage the `setLevel()` method on `Drawable` (or the `setImageLevel()` method on `ImageView`). Whereas `LevelListDrawable` uses this to choose an individual image out of a set of possible images, `ScaleDrawable` and `ClipDrawable` use the level to control how much an image should be scaled or clipped. For this, they support a range of levels from 0 to 10000.

### Scaling

For a level of 0, `ScaleDrawable` will not draw anything. For a level from 1 to 10000, `ScaleDrawable` will scale an image from a configurable minimum size to the bounds of the `View` to which the drawable is applied.

The amount of scaling is determined by `android:scaleHeight` and `android:scaleWidth` attributes:

```
<?xml version="1.0" encoding="utf-8"?>
<scale xmlns:android="http://schemas.android.com/apk/res/android"
    android:drawable="@android:drawable/btn_default"
    android:scaleGravity="left|top"
    android:scaleHeight="50%"
    android:scaleWidth="50%"/>
```

(from [Drawable/ScaleClip/app/src/main/res/drawable/scale.xml](#))

The above `ScaleDrawable` (denoted by the `<scale>` root element) says that we should scale both height and width of the underlying drawable to 50% of the available space for the drawable, when the level is at its maximum (10000).

Note that you do not have to scale along both dimensions. If, for example, you kept `android:scaleWidth` but deleted `android:scaleHeight`, `setImageLevel()` would control the scaled width of the underlying image (provided via `android:drawable`) but not the height.

The `android:scaleGravity` attribute indicates where the scaled image should reside within the available space (the 10000 level, determined by the bounds of the `View` to which the drawable is applied). The value shown above, `center`, keeps the image

centered within the available space, and shrinks or expands it around the center. A value of `left|top` would keep the image in the upper-left corner of the space, having the visual effect of moving the lower-right corner based upon the supplied level.

### Clipping

Scaling proportionally reduces the height and/or width of an image. Clipping, on the other hand, chops off part of the height or width of the image.

```
<clip xmlns:android="http://schemas.android.com/apk/res/android"
    android:clipOrientation="horizontal"
    android:drawable="@drawable/btn_default_normal"
    android:gravity="left"/>
```

(from [Drawable/ScaleClip/app/src/main/res/drawable/clip.xml](#))

In this sample `ClipDrawable` (indicated by the `<clip>` root element), we are going to allow the level to chop off part of the image indicated by the `android:drawable` attribute. Our `android:clipOrientation`, set to `horizontal`, means we are going to chop off part of the width (`vertical` would have us chop off part of the height). The amount that is going to be chopped off is the level you supply (e.g., `setImageLevel()`) divided by 10000. Hence, a level of 5000 will chop off 0.5 (a.k.a., 50%) of the image.

Where in the image the clipping occurs is determined by the `android:gravity` attribute. An `android:clipOrientation` of `horizontal` and an `android:gravity` of `left`, as in the sample drawable above, means that the left side of the image is retained, and the image will be clipped on the right. Specifying `right` instead of `left` would reverse that, clipping the image from the right, while `center` would clip equally from both sides. There are other gravity values as well, such as `top` and `bottom` values to be used with a vertical orientation.

### Seeing It In Action

To see these effects, take a look at the [Drawable/ScaleClip](#) sample project. This is derived from [an earlier example](#) showing how to use `ViewPager` with `PagerTabStrip`. In that example, we had 10 tabs, each being a large `EditText` widget. In this example, we have 2 tabs, “Scale” and “Clip”, both using the same layout:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
```

## CUSTOM DRAWABLES

---

```
<ImageView
    android:id="@+id/image"
    android:layout_width="150dp"
    android:layout_height="150dp"
    android:layout_centerHorizontal="true"
    android:layout_marginTop="20dp"
    android:scaleType="fitXY"/>

<SeekBar
    android:id="@+id/level"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentBottom="true"
    android:layout_marginBottom="20dp"
    android:layout_marginLeft="20dp"
    android:layout_marginRight="20dp"
    android:max="10000"
    android:progress="10000"/>

</RelativeLayout>
```

(from [Drawable/ScaleClip/app/src/main/res/layout/scaleclip.xml](#))

This is simply a 150dp square `ImageView` towards the top of the screen and a `SeekBar` towards the bottom of the screen. The `SeekBar` will be used to control the level applied to a `ScaleDrawable` and `ClipDrawable`, which is why we have `android:max` set to 10000. We also have our “progress” (original `SeekBar` value) set to 10000, so the bar’s thumb will be fully slid over to the right at the outset.

The fragments that we will use for the tabs both inherit from a common abstract `FragmentBase` class:

```
package com.commonware.android.scaleclip;

import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import android.widget.SeekBar;

abstract public class FragmentBase extends Fragment implements
    SeekBar.OnSeekBarChangeListener {
    abstract void setBackgroundImage(ImageView image);
```

## CUSTOM DRAWABLES

---

```
private ImageView image=null;

@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    setRetainInstance(true);

    View result=inflater.inflate(R.layout.scaleclip, container, false);
    SeekBar bar=((SeekBar)result.findViewById(R.id.level));

    bar.setOnSeekBarChangeListener(this);
    image=(ImageView)result.findViewById(R.id.image);
    setImageBackground(image);
    image.setImageLevel(bar.getProgress());

    return(result);
}

@Override
public void onProgressChanged(SeekBar seekBar, int progress,
                             boolean fromUser) {
    image.setImageLevel(progress);
}

@Override
public void onStartTrackingTouch(SeekBar seekBar) {
    // no-op
}

@Override
public void onStopTrackingTouch(SeekBar seekBar) {
    // no-op
}
}
```

(from [Drawable/ScaleClip/app/src/main/java/com/commonsware/android/scaleclip/FragmentBase.java](#))

In `onCreateView()`, we inflate the above layout file, hook up the fragment itself to be the listener for `SeekBar` change events, call the subclass' `setImageBackground()` method to populate the `ImageView` with an image, and set the `ImageView`'s level to be the initial value of the `SeekBar`. When the `SeekBar` value changes, our `onProgressChanged()` method will adjust the level.

The concrete subclasses — `ScaleFragment` and `ClipFragment` — simply populate the `ImageView` with the `ScaleDrawable` and `ClipDrawable` resources shown earlier in

## CUSTOM DRAWABLES

---

this section:

```
package com.commonware.android.scaleclip;

import android.widget.ImageView;

public class ScaleFragment extends FragmentBase {
    @Override
    void setBackgroundImage(ImageView image) {
        image.setImageResource(R.drawable.scale);
    }
}
```

(from [Drawable/ScaleClip/app/src/main/java/com/commonware/android/scaleclip/ScaleFragment.java](#))

```
package com.commonware.android.scaleclip;

import android.widget.ImageView;

public class ClipFragment extends FragmentBase {
    @Override
    void setBackgroundImage(ImageView image) {
        image.setImageResource(R.drawable.clip);
    }
}
```

(from [Drawable/ScaleClip/app/src/main/java/com/commonware/android/scaleclip/ClipFragment.java](#))

Those two drawables based their scaling and clipping on `res/drawable-xdpi/btn_default_normal.9.png`. This is a slightly-modified copy of the default button background, and is a nine-patch PNG file. We will discuss nine-patch PNG files [later in this chapter](#) — suffice it to say for now that it is a PNG file with rules about how it should be stretched.

## CUSTOM DRAWABLES

---

Our scale tab starts off showing the full image:

*Figure 536: ScaleDrawable, Level of 10000*

## CUSTOM DRAWABLES

---

As we start sliding the SeekBar thumb to the left, the image shrinks progressively:

*Figure 537: ScaleDrawable, Level of Approximately 5000*

## CUSTOM DRAWABLES

---

It eventually tends towards the 50% level specified in our `android:scaleHeight` and `android:scaleWidth` values:

*Figure 538: ScaleDrawable, Level of Approximately 100*

Sliding it all the way to the left, though, causes the image to vanish.

## CUSTOM DRAWABLES

---

The ClipDrawable starts off looking much like the ScaleDrawable:

*Figure 539: ClipDrawable, Level of 10000*

As we slide the SeekBar to the left, the right side of the image gets clipped:

## InsetDrawable

An InsetDrawable allows you to apply insets on any side (or all sides) of some other drawable resource. The use case cited in [the documentation](#) is “This is used when a View needs a background that is smaller than the View’s actual bounds”. However, at the present time, nothing in the Android open source code uses this particular type of resource, or even the Java class.

In principle, though, you could have an XML drawable resource that looked like this:

```
<?xml version="1.0" encoding="utf-8"?>
<inset xmlns:android="http://schemas.android.com/apk/res/android"
    android:drawable="@drawable/something_or_another"
    android:insetLeft="20dp"
    android:insetTop="10dp" />
```

When used as the background for some View, for example, Android would pull in the something\_or\_another resource and effectively add 20dp of left margin and 10dp

of top margin on the background when calculating its size and drawing it on the screen.

## ShapeDrawable

ShapeDrawable is the original approach to implementing limited vector art on Android. It gives you what amounts to a very tiny subset of SVG, for creating simple vector art shapes.

The root element of a ShapeDrawable resource is <shape>, which may have child elements, along with attributes, to configure what gets rendered on the screen when the drawable is applied.

This section will review the elements and attributes available to you, with sample drawables (and screenshots) culled from the [Drawable/Shape](#) sample project.

This is a “sampler” project, designed to depict a number of ShapeDrawables. To accomplish this, we will use action bar tabs. Our activity (MainActivity) has a pair of static int arrays, one pointing at string resources to use for tab captions, the other pointing at corresponding drawable resources:

```
package com.commonware.android.shape;

import android.app.ActionBar;
import android.app.ActionBar.Tab;
import android.app.ActionBar.TabListener;
import android.app.Activity;
import android.app.FragmentTransaction;
import android.os.Bundle;
import android.widget.ImageView;

public class MainActivity extends Activity implements TabListener {
    private static final int TABS[] = { R.string.solid, R.string.gradient,
        R.string.border, R.string.rounded, R.string.ring,
        R.string.layered };
    private static final int DRAWABLES[] = { R.drawable.rectangle,
        R.drawable.gradient, R.drawable.border, R.drawable.rounded,
        R.drawable.ring, R.drawable.layered };
    private ImageView image=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);
    }
}
```

## CUSTOM DRAWABLES

---

```
image=(ImageView)findViewById(R.id.image);

ActionBar bar=getActionBar();
bar.setNavigationMode(ActionBar.NAVIGATION_MODE_TABS);

for (int i=0; i < TABS.length; i++) {
    bar.addTab(bar.newTab().setText(getString(TABS[i]))
        .setTabListener(this));
}

@Override
public void onTabSelected(Tab tab, FragmentTransaction ft) {
    image.setImageResource(DRAWABLES[tab.getPosition()]);
}

@Override
public void onTabUnselected(Tab tab, FragmentTransaction ft) {
    // no-op
}

@Override
public void onTabReselected(Tab tab, FragmentTransaction ft) {
    // no-op
}
}
```

(from [Drawable/Shape/app/src/main/java/com/commonsware/android/shape/MainActivity.java](http://Drawable/Shape/app/src/main/java/com/commonsware/android/shape/MainActivity.java))

In `onCreate()`, we toggle the `ActionBar` into tab-navigation mode, then iterate over the arrays and add one tab per element.

Our layout is an `ImageView`, named `image`, centered on the screen, taking up 80% of the horizontal space, plus has 20dp of top and bottom margin:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/LinearLayout1"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal"
    android:gravity="center"
    android:weightSum="10">

    <ImageView
        android:id="@+id/image"
```

## CUSTOM DRAWABLES

---

```
android:src="@drawable/rectangle"
android:layout_width="0dp"
android:layout_height="match_parent"
android:layout_marginTop="20dp"
android:layout_marginBottom="20dp"
android:layout_gravity="center"
android:layout_weight="8"/>
```

```
</LinearLayout>
```

(from [Drawable/Shape/app/src/main/res/layout/activity\\_main.xml](#))

In our activity's `onTabSelected()` — implemented because the activity is the `TabListener` for our tabs — we get the position of our tab and fill in the appropriate drawable into the `ImageView`.

Given that, let's take a look at how to construct a `ShapeDrawable`, along with some sample drawables.

### **<shape>**

Your root element, not surprisingly, is `<shape>`.

The primary thing that you will define on the `<shape>` element is the redundantly-named `android:shape` attribute, to define what sort of shape you want:

- `line` (a shape with no interior)
- `oval` (also for ellipses)
- `rectangle` (including rounded rectangles)
- `ring` (for partially-filled circles)

There are some other attributes available on `<shape>` for a ring, which we will examine [later in this chapter](#).

### **<solid>**

Your shape will usually require some sort of fill, to say what color goes in the shape. There are two types of fills: solid and gradient.

For a solid fill, add a `<solid>` child element to the `<shape>`, with an `android:color` attribute indicating what color to use. As with most places in Android, this can either be a literal color or a reference to a color resource.

## CUSTOM DRAWABLES

---

So, for example, we can specify a solid red rectangle as:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">
    <solid android:color="#FFAA0000"/>
</shape>
```

(from [Drawable/Shape/app/src/main/res/drawable/rectangle.xml](#))

This gives us the following visual result:

*Figure 541: ShapeDrawable, Solid Red Rectangle*

### **<gradient>**

Your alternative fill is a gradient. The nice thing about gradients with ShapeDrawable is that they are generated at runtime from the specifications in the ShapeDrawable, and therefore will be smooth. Gradients that appear in PNG files and the like, if stretched, will tend to have a banding effect.

Gradient fills are defined via a <gradient> child element of the <shape> element.

## CUSTOM DRAWABLES

---

The simplest way to set up a gradient is to use three attributes:

- `android:startColor` and `android:endColor`, to specify the starting and ending colors of the gradient, respectively, and
- `android:angle`, to specify what direction the gradient “flows” in

The angle must be a multiple of 45 degrees. 0 degrees is left-to-right, 90 degrees is bottom-to-top, 180 degrees is right-to-left, and 270 degrees is top-to-bottom.

So, for example, we could change our rectangle to have a gradient fill, from red to blue, with red at the top, via:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <gradient
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFF0000" />

</shape>
```

(from [Drawable/Shape/app/src/main/res/drawable/gradient.xml](#))

That gives us:

*Figure 542: ShapeDrawable, Gradient Fill Rectangle*

We will examine some other gradient options in the section on rings, [later in this chapter](#).

### **<stroke>**

If you want a separate color for a border around your shape, you can use the `<stroke>` element, as a child of the `<shape>` element, to configure one.

There are four attributes that you can declare. The two that you will probably always use are `android:color` (to indicate the color of the border) and `android:width` (to indicate the thickness of the border). By default, using just those two will give you a solid line around the edge of your shape.

If you would prefer a dashed border, you can add in `android:dashWidth` (to indicate how long each dash segment should be) and `android:dashGap` (to indicate how long the gaps between dash segments should be).

So, for example, we can add a dashed border to our gradient rectangle via a suitable

## CUSTOM DRAWABLES

---

<stroke> element:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <gradient
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFF0000" />

    <stroke
        android:width="2dp"
        android:dashGap="4dp"
        android:dashWidth="20dp"
        android:color="#FF000000" />

</shape>
```

(from [Drawable/Shape/app/src/main/res/drawable/border.xml](#))

This gives us:

*Figure 543: ShapeDrawable, Gradient Fill Rectangle with Dashed Border*

### <corners>

If we are implementing a rectangle shape, but we really want it to be a rounded rectangle, we can add a <corners> element as a child of the <shape> element. You can specify the radius to apply to the corners, either for all corners (e.g., `android:radius`), or for individual corners (e.g., `android:topLeftRadius`). Here, “radius” basically means the size of the circle that should implement the corner, where a radius of `0dp` would indicate the default square corner.

So, if we wanted to add rounded corners to our gradient-filled, dash-outlined rectangle, we could use this:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <gradient
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFF0000" />

    <stroke
        android:dashGap="4dp"
        android:dashWidth="20dp"
        android:width="2dp"
        android:color="#FF000000" />

    <corners android:radius="8dp" />

</shape>
```

(from [Drawable/Shape/app/src/main/res/drawable/rounded.xml](#))

This gives us the following:

*Figure 544: ShapeDrawable, Gradient Fill Rounded Rectangle with Dashed Border*

### **<padding> and <size>**

There are also `<padding>` and `<size>` elements that you can add, that specify padding to put on the various sides and the overall size of the drawable. More often than not, you would actually handle this on the `ImageView` or other widget that is using your drawable, but if you would prefer to define those things in the drawable itself, you are welcome to do so.

### **Put a Ring On It**

Rings are a bit more complicated, in large part because they are not completely filled. With a ring, the “fill” is filling what goes in the ring itself, not the “hole” in the center of the ring. This means that we need to teach Android more about how that “hole” is supposed to be set up.

To do that, we need to provide two pieces of information:

1. How big the inner radius should be, where by “inner radius” Android means

- “the radius of the hole”
2. How thick the ring should be

The ring will then be drawn based upon that inner radius and thickness.

You might wonder, “well, where does the size of the actual drawable come into play?” After all, if we specify an inner radius of 20dp and a thickness of 10dp, that would give us an outer radius of 30dp, for a total width of 60dp... regardless of how big the actual drawable is.

And that is completely correct.

However, for both the inner radius and the thickness, you have two choices of how to specify their values:

1. As actual sizes (dimensions or references to dimension resources)
2. As ratios to the overall drawable width (defined by `<size>` or the widget that is using the drawable)

This gives us four total attributes to choose from, to be placed on the `<shape>` element for ring drawables:

1. `android:innerRadius`
2. `android:innerRadiusRatio`
3. `android:thickness`
4. `android:thicknessRatio`

Therefore, if you want the ring’s size to be based on the size of the drawable, you would use `innerRadiusRatio`, `thicknessRatio`, or both.

The other thing about rings is that they are round. Hence, a default linear gradient fill — going from one side of the drawable to another — may not be what you really want. You can control the type of gradient fill to use via the `android:type` attribute on the `<gradient>` element. There are three possible values:

1. `linear` (the default behavior)
2. `radial`, where the gradient starts from the center (or another point that you define) and changes color from that center to the edges
3. `sweep`, where the gradient revolves clockwise in a circle, starting from whatever `android:angle` you specify (or 0, meaning “east”, as the default)

## CUSTOM DRAWABLES

---

So, for example, take a look at the following ShapeDrawable:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:innerRadiusRatio="3"
    android:shape="ring"
    android:thickness="15dp"
    android:useLevel="false">

    <gradient
        android:centerColor="#4c737373"
        android:endColor="#ff9933cc"
        android:startColor="#4c737373"
        android:type="sweep" />

</shape>
```

(from [Drawable/Shape/app/src/main/res/drawable/ring.xml](#))

Here, we:

- Declare that our shape is a ring
- Indicate that the distance between the inner radius and the outer radius of the ring should be 15dp
- Indicate that there is a 3:1 ratio between the width of the image and the radius of the “hole” in the ring
- Indicate that the fill should be a gradient that sweeps clockwise from the default angle of 0
- Indicate that the first half of the gradient (start to center) should remain a constant color
- Indicate that the second half of the gradient (center to end) should change color from gray to purple

We also have `android:useLevel="false"` in the `<shape>` element. For unknown reasons, this is required for rings but not for other types of shapes.

This gives us:

*Figure 545: ShapeDrawable, Ring with Gradient Fill*

## BitmapDrawable

Having an XML drawable format named `BitmapDrawable` may seem like a contradiction in terms. However, `BitmapDrawable` is not an XML representation of a bitmap, but rather an XML representation of operations to perform on an actual bitmap.

The big thing that `BitmapDrawable` offers is `android:tiledMode`, which turns a single bitmap into a repeating bitmap. The bitmap is tiled, horizontally and vertically, using a tiling mode that you specify.

This is demonstrated in the [Drawable/TileMode](#) sample project.

Our activity's layout is just a `LinearLayout`, set to fill the screen:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/widget"
```

## CUSTOM DRAWABLES

---

```
android:layout_width="match_parent"  
android:layout_height="match_parent"  
android:orientation="horizontal">
```

```
</LinearLayout>
```

(from [Drawable/TileMode/app/src/main/res/layout/activity\\_main.xml](#))

Our activity populates action bar tabs, where it applies a particular background image to the `LinearLayout` (known as `R.id.widget`) based on the selected tab:

```
package com.commonware.android.tilemode;  
  
import android.app.ActionBar;  
import android.app.ActionBar.Tab;  
import android.app.ActionBar.TabListener;  
import android.app.Activity;  
import android.app.FragmentTransaction;  
import android.os.Bundle;  
import android.view.View;  
  
public class MainActivity extends Activity implements TabListener {  
    private static final int TABS[] = { R.string._default, R.string.clamp,  
        R.string.repeat, R.string.mirror };  
    private static final int DRAWABLES[] = { R.drawable._default,  
        R.drawable.clamp, R.drawable.repeat, R.drawable.mirror };  
    private View widget=null;  
  
    @Override  
    public void onCreate(Bundle savedInstanceState) {  
        super.onCreate(savedInstanceState);  
        setContentView(R.layout.activity_main);  
  
        widget=findViewById(R.id.widget);  
  
        ActionBar bar=getActionBar();  
        bar.setNavigationMode(ActionBar.NAVIGATION_MODE_TABS);  
  
        for (int i=0; i < TABS.length; i++) {  
            bar.addTab(bar.newTab().setText(getString(TABS[i]))  
                .setTabListener(this));  
        }  
    }  
  
    @Override  
    public void onTabSelected(Tab tab, FragmentTransaction ft) {  
        widget.setBackgroundResource(DRAWABLES[tab.getPosition()]);  
    }  
}
```

## CUSTOM DRAWABLES

---

```
@Override
public void onTabUnselected(Tab tab, FragmentTransaction ft) {
    // no-op
}

@Override
public void onTabReselected(Tab tab, FragmentTransaction ft) {
    // no-op
}
}
```

(from [Drawable/TileMode/app/src/main/java/com/commonsware/android/tilemode/MainActivity.java](#))

The `res/drawable/_default.xml` resource, used on the first tab, is an unadorned `BitmapDrawable` resource, where our `<bitmap>` element simply has an `android:src` attribute pointing to a bitmap to be used for this `BitmapDrawable`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
    android:src="@drawable/hatch"/>
```

(from [Drawable/TileMode/app/src/main/res/drawable/\\_default.xml](#))

## CUSTOM DRAWABLES

---

Since we have not specified a tile mode, the image is stretched to fill the size of our `LinearLayout` when serving as its background:

*Figure 546: `BitmapDrawable`, Without `android:tileMode`*

The `res/drawable/clamp.xml` resource, used on the second tab, adds `android:tileMode="clamp"`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/hatch"
  android:tileMode="clamp"/>
```

(from [Drawable/TileMode/app/src/main/res/drawable/clamp.xml](#))

## CUSTOM DRAWABLES

---

This causes the right-most column of pixels and the bottom-most row of pixels to be repeated to fill the available space:

*Figure 547: BitmapDrawable, Clamped*

Zooming in on the upper-left portion of our LinearLayout demonstrates this:

*Figure 548: Portion of BitmapDrawable, Clamped*

The `res/drawable/repeat.xml` resource, used on the third tab, employs `android:tileMode="repeat"`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/hatch"
  android:tileMode="repeat"/>
```

(from [Drawable/TileMode/app/src/main/res/drawable/repeat.xml](#))

## CUSTOM DRAWABLES

---

Here, the image is simply repeated *in toto* to fill the available space, rather than only its lower-right edges:

Figure 549: *BitmapDrawable, Repeated*

Zooming in on an arbitrary chunk of the LinearLayout shows this effect:

*Figure 550: Portion of BitmapDrawable, Repeated*

The `res/drawable/mirror.xml` resource, used on the fourth tab, uses `android:tileMode="mirror"`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/hatch"
  android:tileMode="mirror"/>
```

(from [Drawable/TileMode/app/src/main/res/drawable/mirror.xml](#))

## CUSTOM DRAWABLES

---

Here, the image is repeated, but alternately mirrored along the repeating axis. So, it is flipped horizontally for each repeat along the horizontal axis, and it is flipped vertically for each repeat along the vertical axis:

*Figure 551: BitmapDrawable, Mirrored*

Zooming in on an arbitrary chunk of the LinearLayout shows this effect:

*Figure 552: Portion of BitmapDrawable, Mirrored*

## Composite Drawables

Let's say that we wanted to have a pair of ShapeDrawable images, one superimposed on another. Since a single ShapeDrawable defines only one shape, we would need something else to assist with stacking the images.

One possibility would be to use a LayerDrawable, creating three total resources:

1. The first ShapeDrawable, in its own resource file
2. The second ShapeDrawable, in its own resource file
3. The LayerDrawable, holding references to the two ShapeDrawable resources

And this will certainly work. But you have an alternative: put all of it into a single drawable resource.

An android:drawable attribute in an <item> element can be replaced by child elements representing another drawable structure. Hence, rather than having a LayerDrawable with two <item> elements pointing to other drawable resources, we could have those same <item> elements *contain* the other drawable XML structures, and thereby cut our number of files from 3 to 1.

For example, we could have something like this:

```
<?xml version="1.0" encoding="utf-8"?>
<layer-list xmlns:android="http://schemas.android.com/apk/res/android">

  <item>
    <shape android:shape="rectangle">
      <gradient
        android:angle="270"
        android:endColor="#FF000FF"
        android:startColor="#FFFF000" />

      <stroke
        android:dashGap="4dp"
        android:dashWidth="20dp"
        android:width="2dp"
        android:color="#FF00000" />

      <corners android:radius="8dp" />
    </shape>
  </item>
  <item>
    <shape
```

## CUSTOM DRAWABLES

---

```
    android:innerRadiusRatio="3"
    android:shape="ring"
    android:thickness="15dp"
    android:useLevel="false">
    <gradient
        android:endColor="#FFFFFFF"
        android:startColor="#ff000000"
        android:type="sweep" />
    </shape>
</item>

</layer-list>
```

(from [Drawable/Shape/app/src/main/res/drawable/layered.xml](#))

This is a LayerDrawable, layering two ShapeDrawable structures. The first ShapeDrawable is our dash-bordered, gradient-filled, rounded rectangle from before. The second ShapeDrawable is a ring with a simple gradient sweep fill, from black to white.

This gives us:

*Figure 553: Composite Drawable*

## CUSTOM DRAWABLES

---

Hence, any of the drawable XML structures other than ShapeDrawable can, in their `<item>` elements, hold any drawable XML structure, instead of pointing to another separate resource.

Android uses this trick as well. For example, the stock ProgressBar image is based off of a LayerDrawable wrapped around three ShapeDrawable structures:

```
<?xml version="1.0" encoding="utf-8"?>

limitations under the License.
-->

<layer-list xmlns:android="http://schemas.android.com/apk/res/android">

    <item android:id="@android:id/background">
        <shape>
            <corners android:radius="5dip" />
            <gradient
                android:startColor="#ff9d9e9d"
                android:centerColor="#ff5a5d5a"
                android:centerY="0.75"
                android:endColor="#ff747674"
                android:angle="270"
            />
        </shape>
    </item>

    <item android:id="@android:id/secondaryProgress">
        <clip>
            <shape>
                <corners android:radius="5dip" />
                <gradient
                    android:startColor="#80ffd300"
                    android:centerColor="#80ffb600"
                    android:centerY="0.75"
                    android:endColor="#a0ffc000"
                />
            </shape>
        </clip>
    </item>
</layer-list>
```

```
                android:angle="270"
            />
        </shape>
    </clip>
</item>

<item android:id="@android:id/progress">
    <clip>
        <shape>
            <corners android:radius="5dip" />
            <gradient
                android:startColor="#ffffd300"
                android:centerColor="#ffffb600"
                android:centerY="0.75"
                android:endColor="#ffffcb00"
                android:angle="270"
            />
        </shape>
    </clip>
</item>
</layer-list>
```

We will get into how this works with a ProgressBar in [a separate chapter](#).

## A Stitch In Time Saves Nine

Most of the types of non-traditional drawable resources you can create in Android are described in XML... but not all.

As you read through the Android documentation, you no doubt ran into references to “nine-patch” or “9-patch” and wondered what Android had to do with [quilting](#). Rest assured, you will not need to take up needlework to be an effective Android developer.

If, however, you are looking to create backgrounds for resizable widgets, like a Button, you may wish to work with nine-patch images.

As the Android documentation states, a nine-patch is “a PNG image in which you define stretchable sections that Android will resize to fit the object at display time to accommodate variable sized sections, such as text strings”. By using a specially-created PNG file, Android can avoid trying to use vector-based formats (e.g., ShapeDrawable) and their associated overhead when trying to create a background

at runtime. Yet, at the same time, Android can still resize the background to handle whatever you want to put inside of it, such as the text of a Button.

In this section, we will cover some of the basics of nine-patch graphics, including how to customize and apply them to your own Android layouts.

Note that nine-patch PNG files, while they provide stretching rules, are still somewhat dependent upon density. You may wish to have different versions of your nine-patch PNG files for different densities, and therefore these images should be put in density-specific resource directories (e.g., `res/drawable-hdpi/`).

### The Name and the Border

Nine-patch graphics are PNG files whose names end in `.9.png`. This means they can be edited using normal graphics tools, but Android knows to apply nine-patch rules to their use.

What makes a nine-patch graphic different than an ordinary PNG is a one-pixel-wide border surrounding the image. When drawn, Android will remove that border, showing only the stretched rendition of what lies inside the border. The border is used as a control channel, providing instructions to Android for how to deal with stretching the image to fit its contents.

### Padding and the Box

Along the right and bottom sides, you can draw one-pixel-wide black lines to indicate the “padding box”. Android will stretch the image such that the contents of the widget will fit inside that padding box.

## CUSTOM DRAWABLES

---

For example, suppose we are using a nine-patch as the background of a Button. When you set the text to appear in the button (e.g., “Hello, world!”), Android will compute the size of that text, in terms of width and height in pixels. Then, it will stretch the nine-patch image such that the text will reside inside the padding box. What lies outside the padding box forms the border of the button, typically a rounded rectangle of some form.

*Figure 554: The padding box, as shown by a set of control lines to the right and bottom of the stretchable image*

### Stretch Zones

To tell Android where on the image to actually do the stretching, draw one-pixel-wide black lines on the top and left sides of the image. Android will scale the graphic only in those areas — areas outside the stretch zones are not stretched.

## CUSTOM DRAWABLES

---

Perhaps the most common pattern is the center-stretch, where the middle portions of the image on both axes are considered stretchable, but the edges are not:

*Figure 555: The stretch zones, as shown by a set of control lines to the left and top of the stretchable image*

Here, the stretch zones will be stretched just enough for the contents to fit in the padding box. The edges of the graphic are left unstretched.

Some additional rules to bear in mind:

1. If you have multiple discrete stretch zones along an axis (e.g., two zones separated by whitespace), Android will stretch both of them but keep them in their current proportions. So, if the first zone is twice as wide as the second zone in the original graphic, the first zone will be twice as wide as the second zone in the stretched graphic.
2. If you leave out the control lines for the padding box, it is assumed that the padding box and the stretch zones are one and the same.

## Tooling

Android Studio has a nine-patch PNG editor, based on the now-discontinued

## CUSTOM DRAWABLES

---

draw9patch utility used previously by Android app developers. To work with this tool:

- If you have a regular PNG that you want to convert into a nine-patch PNG, right-click over it and choose “Create 9-patch file” from the context menu
- If you already have a nine-patch PNG (with the `.9.png` extension), or you created one using “Create 9-patch file”, just double-click on the image to bring it up in a nine-patch editor

*Figure 556: Android Studio, Editing a Nine-Patch PNG*

While a regular graphics editor would allow you to draw any color on any pixel, the nine-patch editor limits you to drawing or erasing pixels in the control area:

- Set a pixel (making it black) by clicking on it
- Clear a pixel by shift-clicking on it

If you attempt to draw inside the main image area itself, you will be blocked.

On the right, you will see samples of the image in various stretched sizes, so you can see the impact as you change the stretchable zones and padding box.

While this is convenient for working with the nine-patch nature of the image, you will still need some other graphics editor to create or modify the body of the image itself. For example, the image shown above, from the [Drawable/NinePatch](#) project, is a modified version of a nine-patch graphic from the SDK's [ApiDemos](#), where the GIMP was used to add the neon green stripe across the bottom portion of the image.

### Using Nine-Patch Images

Nine-patch images are most commonly used as backgrounds, as illustrated by the following layout from the [Drawable/NinePatch](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <TableLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:stretchColumns="1"
    >
        <TableRow
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
        >
            <TextView
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:layout_gravity="center_vertical"
                android:text="Horizontal:"
            />
            <SeekBar android:id="@+id/horizontal"
                android:layout_width="match_parent"
                android:layout_height="wrap_content"
            />
        </TableRow>
        <TableRow
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
        >
            <TextView
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:layout_gravity="center_vertical"
                android:text="Vertical:"
            />
        </TableRow>
    </TableLayout>
</LinearLayout>
```

## CUSTOM DRAWABLES

---

```
    />
    <SeekBar android:id="@+id/vertical"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
    />
</TableRow>
</TableLayout>
<LinearLayout
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <Button android:id="@+id/resize"
        android:layout_width="96px"
        android:layout_height="96px"
        android:text="Hi!"
        android:textSize="10sp"
        android:background="@drawable/button"
    />
</LinearLayout>
</LinearLayout>
```

(from [Drawable/NinePatch/app/src/main/res/layout/main.xml](#))

Here, we have two SeekBar widgets, labeled for the horizontal and vertical axes, plus a Button set up with our nine-patch graphic as its background (`android:background = "@drawable/button"`).

The NinePatchDemo activity then uses the two SeekBar widgets to let the user control how large the button should be drawn on-screen, starting from an initial size of 64px square:

```
package com.commonware.android.ninepatch;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.LinearLayout;
import android.widget.SeekBar;

public class NinePatchDemo extends Activity {
    SeekBar horizontal=null;
    SeekBar vertical=null;
    View thingToResize=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }
}
```

## CUSTOM DRAWABLES

---

```
thingToResize=findViewById(R.id.resize);

horizontal=(SeekBar)findViewById(R.id.horizontal);
vertical=(SeekBar)findViewById(R.id.vertical);

horizontal.setMax(144); // 240 less 96 starting size
vertical.setMax(144); // keep it square @ max

horizontal.setOnSeekBarChangeListener(h);
vertical.setOnSeekBarChangeListener(v);
}

SeekBar.OnSeekBarChangeListener h=new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar,
        int progress,
        boolean fromTouch) {
        ViewGroup.LayoutParams old=thingToResize.getLayoutParams();
        ViewGroup.LayoutParams current=new LinearLayout.LayoutParams(64+progress,
            old.height);

        thingToResize.setLayoutParams(current);
    }

    public void onStartTrackingTouch(SeekBar seekBar) {
        // unused
    }

    public void onStopTrackingTouch(SeekBar seekBar) {
        // unused
    }
};

SeekBar.OnSeekBarChangeListener v=new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar,
        int progress,
        boolean fromTouch) {
        ViewGroup.LayoutParams old=thingToResize.getLayoutParams();
        ViewGroup.LayoutParams current=new LinearLayout.LayoutParams(old.width,
            64+progress);

        thingToResize.setLayoutParams(current);
    }

    public void onStartTrackingTouch(SeekBar seekBar) {
        // unused
    }

    public void onStopTrackingTouch(SeekBar seekBar) {
        // unused
    }
};
}
```

(from [Drawable/NinePatch/app/src/main/java/com/commonsware/android/ninepatch/NinePatchDemo.java](#))

## CUSTOM DRAWABLES

---

The result is an application that can be used much like the right pane of `draw9patch`, to see how the nine-patch graphic looks on an actual device or emulator in various sizes:

*Figure 557: The NinePatch sample project, in its initial state*

## CUSTOM DRAWABLES

---

*Figure 558: The NinePatch sample project, after making it bigger horizontally*

## CUSTOM DRAWABLES

---

*Figure 559: The NinePatch sample application, after making it bigger in both dimensions*

# Mapping with Maps V2

---

One of Google's most popular services — after search, of course — is Google Maps, where you can find everything from the nearest pizza parlor to directions from New York City to San Francisco (only 2,905 miles!) to street views and satellite imagery.

Android has had mapping capability from the beginning, with an API available to us as developers to bake maps into our apps. However, as we will [see shortly](#), that original API was getting a bit stale.

In December 2012, Google released a long-awaited update to the mapping capabilities available to Android app developers. The original mapping solution, now known as the Maps V1, worked but had serious limitations. The new mapping solution, known as Maps V2, offers greater power and greater ease of handling common situations, though it too has its rough edges.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, along with [the chapter on drawables](#). Also, one of the samples involves [location tracking](#), and another of the samples involves the use of [the animator framework](#).

One section involves the use of Picasso, covered in [the chapter on Internet access](#).

This chapter also makes the occasional reference back to Maps V1 for comparisons, mostly for the benefit of developers already familiar with Maps V1 and looking to migrate to Maps V2. However, prior experience with Maps V1 is not necessary to understand this chapter.

## A Brief History of Mapping on Android

Back in the dawn of Android, we were given the Maps SDK add-on. This would allow us to load a firmware-hosted mapping library into our applications, then embed maps into our activities, by means of a MapView widget.

And it worked.

More importantly, from the standpoint of users, the results from our apps were visually indistinguishable from the built-in Maps application available on devices that had the Maps SDK add-on.

This was the case through most of 2009. Eventually, though, the Google Maps team wanted to update the Maps application... but, for whatever reason, the decision was made to *not* update the Maps SDK add-on as well. At this point, the Google Maps team effectively forked the Maps SDK add-on, causing the Maps application to diverge from what other Android app developers could deliver. Over time, this feature gap became quite pronounced.

The release of Android 3.0 in early 2011 compounded the problems. Now, we needed to consider using fragments to help manage our code and deliver solutions to all screen sizes. Alas, while we could add maps to our fragments, we could only do so on API Level 11 or higher — the fragments backport from the Android Support package did not work with the Maps SDK add-on.

The release of Maps V2 helped all of this significantly. Now we have proper map support for native and backported versions of the fragment framework. We also have a look and feel that is closer to what the Maps application itself supports. While we still cannot reach feature parity with the Maps application, our SDK apps can at least look like they belong on the same device as the Maps application.

More importantly, as of the time of this writing, Maps V1 is no longer an option for new developers. Those who already have Maps V1 API keys can use Maps V1, but no new Maps V1 API keys are being offered. That leaves you with either using Maps V2 or [some alternative mapping solution](#).

## Where You Can Use Maps V2

Many devices will be able to use Maps V2... but not all. Notably:

- Devices need to support OpenGL ES 2.0+, to handle the new vector-based tiles that Maps V2 uses. [Over 99% of Android devices](#) in use today that support the Play Store (or its “Android Market” predecessor) also support OpenGL ES 2.0+.
- Devices will need an update to the Play Services Framework that accompanies the Play Store. Devices that do not have the Play Store — either because they are forever stuck on the old Android Market or, like the Kindle Fire, never had Play Store support in the first place — will be unable to use Maps V2.

[Later in this chapter](#), we will look at other mapping libraries that you could use instead of either of Google’s mapping solutions.

## Licensing Terms for Maps V2

As with the original Maps SDK add-on, to use Maps V2, you must agree to [a terms of service agreement](#) to be authorized to embed Google Maps within your application. If you intend to use Maps V2, you should review these terms closely, as they place many restrictions on developers. The most notorious of these is that you cannot use Maps V2 to create an application that offers “real time navigation or route guidance, including but not limited to turn-by-turn route guidance that is synchronized to the position of a user’s sensor-enabled device.”

If you find these terms to be an issue for your application, you may need to consider [alternative mapping solutions](#).

## What You Need to Start

If you wish to use Maps V2 in one or more of your Android applications, this section will outline what you need to get started.

### Your Signing Key Fingerprint(s)

As with the legacy Maps SDK add-on, you will need fingerprints of your app signing keys, to tie your apps to your Google account and the API keys you will be generating. However, unlike the legacy Maps SDK add-on, the fingerprints you will be using will be created using the SHA-1 hash algorithm, rather than MD5.

First, you will need to know where the keystore is for your signing key. For a

## MAPPING WITH MAPS V2

---

production keystore that you created yourself for your production apps, you should know where it is located already. For the debug keystore, used by default during development, the location is dependent upon operating system:

- macOS and Linux: `~/ .android/debug.keystore`
- Windows XP: `C:\Documents and Settings\%USER\.android\debug.keystore`
- Windows Vista and Windows 7: `C:\Users\%USER\.android\debug.keystore`

(where `%USER` is your Windows user name)

You will then need to run the `keytool` command, to dump information related to this keystore. The `keytool` command is in your Java SDK, not the Android SDK. You will need to run this from a command line (e.g., Command Prompt in Windows). The specific command to run is:

```
keytool -list -v -keystore ... -alias androiddebugkey -storepass android -keypass android
```

where the `...` is replaced by the path to your debug keystore, enclosed in quotation marks if the path contains spaces. For your production keystore, you would supply your own alias and passwords.

This should emit output akin to:

```
Alias name: androiddebugkey
Creation date: Aug 7, 2011
Entry type: PrivateKeyEntry
Certificate chain length: 1
Certificate<1>:
Owner: CN=Android Debug, O=Android, C=US
Issuer: CN=Android Debug, O=Android, C=US
Serial number: 4e3f2684
Valid from: Sun Aug 07 19:57:56 EDT 2011 until: Tue Jul 30 19:57:56 EDT 2041
Certificate fingerprints:
  MD5:  98:84:0E:36:F0:B3:48:9C:CD:13:EB:C6:D8:7F:F3:B1
  SHA1: E6:C5:81:EB:8A:F4:35:B0:04:84:3E:6E:C3:88:BD:B2:66:52:E7:09
Signature algorithm name: SHA1withRSA
Version: 3
```

You will need to make note of the SHA1 entry (see third line from the bottom of the above sample).

### Your Google Account

To sign up for an API key, you need a Google account. Ideally, this account would be the same one you intend to use for submitting apps to the Play Store (if, indeed, you intend to do so).

### Your API Key

Given that you are logged into the aforementioned Google account, you can visit [the Google Cloud Console](#) to request access to the Maps V2 API. They have a tendency to keep changing this set of pages, but these instructions were good as of late February 2014:

- Create a project via the “Create project” option, if you have not done so already for something else (e.g., [GCM](#))
- Open your project, then select “APIs & auth” from the left navigation bar, and in there select “APIs”
- Sift through the various APIs until you find “Google Maps Android API v2”, then toggle that on
- Agree to the Terms of Service that appears when you try to toggle on Maps V2 access
- Click “Credentials” in the left navigation bar
- Click the “CREATE NEW KEY” button
- In the popup dialog, choose “Android key”
- In the fields that appear once you chose “Android key”, fill in your app’s package name and your SHA1 fingerprint, then click the “Create” button

This will give you an “API key” that you will need for your application.

If you wish to have more than one app use Maps V2, you can click “Edit allowed Android applications” for a key, to return to the dialog where you can paste in another SHA1 fingerprint and package name, separated by a semicolon. Or, if you prefer, you can create new keys for each application.

For apps that are in (or going to) production, you will need to supply both the debug and production SHA1 fingerprints with your package name. By doing this on the same key, you will use the same API key string for both debug and production builds, which simplifies things a fair bit over the separate API keys you would have used with the legacy Maps SDK add-on.

Also note that a single API key seems to only support a few fingerprint/package

pairs. If you try adding a new pair, and the form ignores you, you will need to set up a separate API key for additional pairs.

### The Play Services Library

You also need to set up the Google Play Services library for use with your app.

While this used to be published via a separate “Google Repository” that you had to download to your development machine, nowadays, it is part of Google’s overall public Maven repository, the one that `google()` points to in your `build.gradle` files. Most likely, your project is already set up to use this repository.

If so, all you need to do is add a dependency on `com.google.android.gms:play-services-maps` for some likely version (e.g., `com.google.android.gms:play-services-maps:15.0.1`) to your dependencies closure.

Note, though, that starting with version `10.x`, the `minSdkVersion` imposed by the Play Services libraries is `14`. If your desired `minSdkVersion` is lower than that, you will need to remain on older versions of the Play Services libraries.

### The Book Samples... And You!

If you wish to try to run the book samples outlined in this chapter, you will need to replace the Maps V2 API key in the manifest with your own.

### Setting Up a Basic Map

With that preparation work completed, now you can start working on projects that use the Maps V2 API. In this section, we will review the [MapsV2/Basic](#) sample project, which simply brings up a Maps V2 map of the world.

### The Dependency

Android Studio users need an entry in their top-level dependencies closure to pull in the Play Services SDK artifact:

```
dependencies {  
    implementation 'com.android.support:support-v4:27.1.1'  
    implementation 'com.google.android.gms:play-services-maps:15.0.1'  
}
```

### The Project Setup and the Manifest

This project uses Maps V2, and so it has a reference to that library project.

Our manifest file is fairly traditional, though there are a number of elements in it that are required by Maps V2:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonware.android.mapsv2.basic"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission
    android:name="android.permission.WRITE_EXTERNAL_STORAGE"
    android:maxSdkVersion="22" />

  <uses-feature
    android:glEsVersion="0x00020000"
    android:required="false" />

  <application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name="MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>

    <meta-data
      android:name="com.google.android.maps.v2.API_KEY"
      android:value="AIzaSyC4iyT46cB00IdKGcy5EmAxK5uCOQX20y8" />

    <meta-data
      android:name="com.google.android.gms.version"
      android:value="@integer/google_play_services_version" />

  </application>
```

## MAPPING WITH MAPS V2

---

```
</manifest>
```

(from [MapsV2/Basic/app/src/main/AndroidManifest.xml](#))

Specifically:

- We need the `WRITE_EXTERNAL_STORAGE` permissions, but only on Android 5.1 and below, so we can use `android:maxSdkVersion="22"` to only request that permission on older devices
- We need a `<meta-data>` element, with a name of `com.google.android.maps.v2.API_KEY`, whose value is the API key we got from the Google APIs Console for use with this particular package name.
- We can have a second `<meta-data>` element, with a name of `com.google.android.gms.version`, with a value of the `@integer/google_play_services_version` (an integer resource supplied by the Play Services SDK library project). Starting with version 8.1.0 of the Maps V2 library, this element is not essential, as it will be added automatically to our manifest via [the manifest merger process](#). However, code written for older versions of Maps V2 than 8.1.0 will need the element, and there is no particular harm in having it.

We also should include a `<uses-feature>` element for OpenGL ES 2.0. If your app absolutely must be able to run Maps V2, have `android:required="true"` (or drop the `android:required` attribute entirely, as `true` is the default), which will force devices to have OpenGL ES 2.0 to run your app. If your app will gracefully degrade for devices incapable of running Maps V2, use `android:required="false"`, as is shown in the sample.

Beyond those items, everything else in this project is based on what the app needs, more so than what Maps V2 needs. Note, though, that the Play Services SDK library project will add additional items to our manifest, notably requests for a few other permissions, like `INTERNET`. Also note that we used to need to define and use a custom permission, based upon our app's package name and ending in `MAPS_RECEIVE`. This is not required as of Play Services 3.1.59 and the "rev 8" release of the Play Services SDK.

### The Play Services Detection

In the fullness of time, all devices that are capable of using Maps V2 will already have the on-device portion of this logic, known as the "Google Play services" app.

## MAPPING WITH MAPS V2

---

However, it is entirely possible, in the short term, that you will encounter devices that are capable of using Maps V2 (e.g., they have OpenGL ES 2.0 or higher), but do not have the “Google Play services” app from the Play Store, and therefore you cannot actually *use* Maps V2 in your app.

This is a departure from the Maps V1 approach, where either the device shipped with maps capability, or it did not, and nothing (legally) could be done to change that state.

To determine whether or not the Maps V2 API is available to you, the best option is to call the `isGooglePlayServicesAvailable()` static method on the `GooglePlayServicesUtil` utility class supplied by the Play Services library. This will return an `int`, with a value of `ConnectionResult.SUCCESS` if Maps V2 can be used right away.

Actually assisting the user to get Maps V2 set up all the way is conceivable but is also bug-riddled and annoying. The `MapsV2/Basic` sample app has an `AbstractMapActivity` base class that is designed to hide most of this annoyance from you. If you wish to know the details of how this works, we will cover it [later in this chapter](#).

### The Fragment and Activity

Our main activity — `MainActivity` — extends from the aforementioned `AbstractMapActivity` and simply overrides `onCreate()`, as most activities do:

```
package com.commonware.android.mapsv2.basic;

import android.os.Bundle;

public class MainActivity extends AbstractMapActivity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (readyToGo()) {
            setContentView(R.layout.activity_main);
        }
    }
}
```

(from [MapsV2/Basic/app/src/main/java/com/commonware/android/mapsv2/basic/MainActivity.java](#))

## MAPPING WITH MAPS V2

---

We call `setContentView()` to load up the `activity_main` layout resource:

```
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/map"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    class="com.google.android.gms.maps.SupportMapFragment"/>
```

(from [MapsV2/Basic/app/src/main/res/layout/activity\\_main.xml](#))

That resource, in turn, has a `<fragment>` element pointing to a `com.google.android.gms.maps.SupportMapFragment` class supplied by the Play Services library. This is a fragment that knows how to display a Maps V2 map. There is a corresponding `com.google.android.gms.maps.MapFragment` class based on the native `Fragment` class.

You will notice, though, that we only call `setContentView()` if a `readyToGo()` method returns `true`. The `readyToGo()` method is supplied by the `AbstractMapActivity` class and returns `true` if we are safe to go ahead and use Maps V2, `false` otherwise. In the `false` case, `AbstractMapActivity` will be taking care of trying to get Maps V2 going, and we need do nothing further.

### The Result

When you run the app, assuming that Maps V2 is ready for use, you will get a basic map showing a good-sized chunk of the planet:

*Figure 560: Maps V2 Map, as Initially Viewed*

If your Maps V2 API key is incorrect, or you do not have this app's package name set up for that key in the Google APIs Console, you will get an "Authorization failure" error message in Logcat, and you will get a blank map, akin to the behavior seen in Maps V1 when you had an invalid `android:apiKey` attribute on the `MapView`.

### Playing with the Map

Showing a map of a good-sized chunk of the planet is nice, and it is entirely possible that is precisely what you wanted to show the user. If, on the other hand, you wanted to show the user something else — another location, a closer look, etc. — you will need to further configure your map, via a `GoogleMap` object.

To see how this is done, take a look at the [MapsV2/NooYawk](#) sample application. This is a clone of `MapsV2/Basic` that adds in logic to center and zoom the map over a

## MAPPING WITH MAPS V2

---

portion of New York City.

The `onCreate()` method of the revised `MapActivity` is now a bit more involved:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (readyToGo()) {
        setContentView(R.layout.activity_main);

        SupportMapFragment mapFrag=
            (SupportMapFragment)getSupportFragmentManager().findFragmentById(R.id.map);

        if (savedInstanceState == null) {
            mapFrag.getMapAsync(this);
        }
    }
}
```

(from [MapsV2/NooYawk/app/src/main/java/com/commonsware/android/mapsv2/nooyawk/MainActivity.java](#))

After calling `setContentView()`, we can retrieve our `SupportMapFragment` via `findFragmentById()`, no different than any other static fragment.

Then, if `savedInstanceState` is `null` — meaning that the activity is not being recreated, but instead is being created from scratch — we call `getMapAsync()` on the `SupportMapFragment`. This triggers some asynchronous work to set up a `GoogleMap` object. `getMapAsync()` takes an implementation of `OnMapReadyCallback` as a parameter. In this case, `OnMapReadyCallback` is implemented on the activity itself.

That `GoogleMap` object will then be delivered to us in `onMapReady()`. Most of our work in configuring the map will be accomplished by calling methods on this `GoogleMap` object:

```
@Override
public void onMapReady(GoogleMap map) {
    CameraUpdate center=
        CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
            -73.98180484771729));
    CameraUpdate zoom=CameraUpdateFactory.zoomTo(15);

    map.moveCamera(center);
    map.animateCamera(zoom);
}
```

(from [MapsV2/NooYawk/app/src/main/java/com/commonsware/android/mapsv2/nooyawk/MainActivity.java](#))

To change where the map is centered, we can create a `CameraUpdate` object from the

## MAPPING WITH MAPS V2

---

CameraUpdateFactory (“camera” in this case referring to the position of the user’s virtual eyes with respect to the surface of the Earth). The `newLatLng()` factory method on CameraUpdateFactory will give us a CameraUpdate object that can re-center the map over a supplied latitude and longitude. Those coordinates are encapsulated in a LatLng object and are maintained as decimal degrees as Java `float` or `double` values (as opposed to the Maps V1 `GeoPoint`, which used integer microdegrees).

To change the zoom level of the map, we need another CameraUpdate object, this time from the `zoomTo()` factory method on CameraUpdateFactory. As with Maps V1, the zoom levels start at 1 and zoom in by powers of two. As you will see, a value of 15 gives you a nice block-level view of a city like New York City.

To actually apply these changes to the map, we have two methods on `GoogleMap`:

1. `moveCamera()` will perform a “smash cut” and immediately change the map based upon the supplied CameraUpdate
2. `animateCamera()` will smoothly animate the map from its original state to the new state supplied by the CameraUpdate

## MAPPING WITH MAPS V2

In our case, we immediately shift to the proper position, but then zoom in from the default zoom level to 15, giving us a map centered over Columbus Circle, in the southwest corner of Central Park in Manhattan:

Figure 561: Maps V2 Centered Over Columbus Circle, New York City

Note that you might want to do both actions simultaneously, rather than have one be animated and one not as in this sample. In that case, you can manually create a `CameraPosition` object that describes the desired center, zoom, etc., then use the `newCameraPosition()` method on `CameraUpdateFactory` to get a `CameraUpdate` instance that will apply all of those changes.

## Map Tiles

The map, by default, shows the normal tile set. `setMapType()` on the `GoogleMap` allows you to switch to satellite, hybrid (satellite view plus place labels), or terrain tile sets.

## Placing Simple Markers

For markers — push-pins and the like — you simply hand markers to the `GoogleMap`

## MAPPING WITH MAPS V2

---

for display, as is illustrated in the [MapsV2/Markers](#) sample application. This is a clone of MapsV2/NooYawk, with four markers for four landmarks within Manhattan.

Our `onCreate()` method on `MainActivity` now always invokes `getMapAsync()`, not just when the activity is first created. However, we still check `savedInstanceState` and set a new `needsInit` boolean data member to `true` if `savedInstanceState` is `null`:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (readyToGo()) {
        setContentView(R.layout.activity_main);

        SupportMapFragment mapFrag=
            (SupportMapFragment) getSupportFragmentManager().findFragmentById(R.id.map);

        if (savedInstanceState == null) {
            needsInit=true;
        }

        mapFrag.getMapAsync(this);
    }
}
```

(from [MapsV2/Markers/app/src/main/java/com/commonsware/android/mapsv2/markers/MainActivity.java](#))

Our `onMapReady()` method performs the camera adjustments if `needsInit` is `true`. It also has four additional statements – calls to a private `addMarker()` method to define the four landmarks:

```
@Override
public void onMapReady(GoogleMap map) {
    if (needsInit) {
        CameraUpdate center=
            CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
                -73.98180484771729));

        CameraUpdate zoom=CameraUpdateFactory.zoomTo(15);

        map.moveCamera(center);
        map.animateCamera(zoom);
    }

    addMarker(map, 40.748963847316034, -73.96807193756104,
        R.string.un, R.string.united_nations);
    addMarker(map, 40.76866299974387, -73.98268461227417,
        R.string.lincoln_center,
        R.string.lincoln_center_snippet);
    addMarker(map, 40.765136435316755, -73.97989511489868,
```

## MAPPING WITH MAPS V2

---

```
R.string.carnegie_hall, R.string.practice_x3);
addMarker(map, 40.70686417491799, -74.01572942733765,
R.string.downtown_club, R.string.heisman_trophy);
}
```

(from [MapsV2/Markers/app/src/main/java/com/commonsware/android/mapsv2/markers/MainActivity.java](#))

The `addMarker()` method on our `MainActivity` adds markers by creating a `MarkerOptions` object and passing it to the `addMarker()` on `GoogleMap`. `MarkerOptions` offers a so-called “fluent” interface, with a series of methods to affect one aspect of the `MarkerOptions`, each of which returns the `MarkerOptions` object itself. That way, configuring a `MarkerOptions` is a chained series of method calls:

```
private void addMarker(GoogleMap map, double lat, double lon,
    int title, int snippet) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
        .title(getString(title))
        .snippet(getString(snippet)));
}
```

(from [MapsV2/Markers/app/src/main/java/com/commonsware/android/mapsv2/markers/MainActivity.java](#))

Here, we:

- Set the `position()` of the marker, in the form of another `LatLng` object
- Set the `title()` and `snippet()` of the marker to be a pair of strings loaded from string resources

We will see other methods available on `MarkerOptions` in upcoming sections of this chapter.

`addMarker()` on `GoogleMap` returns an actual `Marker` object, which we could hold onto to change certain aspects of it later on (e.g., its title). In the case of this sample, we ignore this.

Now, you may be wondering why we set up the markers on every `onMapReady()` invocation, not just in the `needsInit` block. That is because while a `SupportMapFragment` retains its camera information (center, zoom, etc.) on a configuration change, it does *not* retain its markers. Hence, we need to re-establish the markers in all calls to `onCreate()`, not just the very first one.

## MAPPING WITH MAPS V2

---

With no other changes, we get a version of the map that shows markers at our designated locations:

## MAPPING WITH MAPS V2

---

Initially, we only see two markers, as the other two are outside the current center position and zoom level of the map. If the user changes the center or zoom, markers will come and go as needed:

We do not need to worry about managing the markers ourselves, so long as the GoogleMap performance is adequate. It is likely that dumping 10,000 markers into a GoogleMap will still result in sluggish responses, though, so you may need to add and remove markers yourself based upon what portion of the world the user happens to be examining in the map at the moment.

### Seeing All the Markers

When you add markers to a map, there is no guarantee that the markers will be visible given the map's current center position and zoom level. In fact, it is entirely possible that you add a bunch of markers and *none* are visible, so the user may not realize that the markers were added.

There is a way that you can center and zoom the map to show some set of markers, based on their positions. You get to choose the markers: all of them, the four nearest

## MAPPING WITH MAPS V2

---

markers, etc.

We can see how this works in the [MapsV2/Bounds](#) sample application. This is a clone of MapsV2/Markers from the previous section, with reworked code to show all four markers when the map is first displayed.

The key to making this work is a `LatLngBounds` object. This represents a bounding box that contains all `LatLng` locations handed to the `LatLngBounds`. To build up a `LatLngBounds`, you can use the `LatLngBounds.Builder` class. So, our revised `MainActivity` has a `LatLngBounds.Builder` private data member:

```
private LatLngBounds.Builder builder=new LatLngBounds.Builder();
```

(from [MapsV2/Bounds/app/src/main/java/com/commonsware/android/mapsv2/markers/MainActivity.java](#))

Our revised `addMarker()` method adds the `LatLng` values from our markers as they are added to the map:

```
private void addMarker(GoogleMap map, double lat, double lon,
                      int title, int snippet) {
    Marker marker=
        map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                    .title(getString(title))
                    .snippet(getString(snippet)));

    builder.include(marker.getPosition());
}
```

(from [MapsV2/Bounds/app/src/main/java/com/commonsware/android/mapsv2/markers/MainActivity.java](#))

Finally, the revised `onMapReady()` moves the `CameraUpdateFactory` work until after all four of the `addMarker()` calls and changes it a bit:

```
@Override
public void onMapReady(final GoogleMap map) {
    addMarker(map, 40.748963847316034, -73.96807193756104,
              R.string.un, R.string.united_nations);
    addMarker(map, 40.76866299974387, -73.98268461227417,
              R.string.lincoln_center,
              R.string.lincoln_center_snippet);
    addMarker(map, 40.765136435316755, -73.97989511489868,
              R.string.carnegie_hall, R.string.practice_x3);
    addMarker(map, 40.70686417491799, -74.01572942733765,
              R.string.downtown_club, R.string.heisman_trophy);

    if (needsInit) {
```

## MAPPING WITH MAPS V2

---

```
findViewById(android.R.id.content).post(new Runnable() {
    @Override
    public void run() {
        CameraUpdate allTheThings=
            CameraUpdateFactory.newLatLngBounds(builder.build(), 32);

        map.moveCamera(allTheThings);
    }
});
}
```

(from [MapsV2/Bounds/app/src/main/java/com/commonsware/android/mapsv2/markers/MainActivity.java](#))

Specifically, we:

- Ask the `LatLngBounds.Builder` to `build()` the `LatLngBounds`
- Pass that to the `newLatLngBounds()` method on `CameraUpdateFactory`, along with an inset value in pixels (all `LatLng` locations will be that many pixels in from the edges, or more)
- Use `moveCamera()` to center and zoom the map based upon the resulting `CameraUpdate`

All of this is done in a `Runnable` which we `post()` to a `View` (here, the `FrameLayout` of our activity supplied by Android as `android.R.id.content`). `GoogleMap` cannot ensure that all of our markers are visible until it knows how big the map is, and that is not known until the map is rendered to the screen. `post()` will add our work to the end of the main application thread's work queue. The `Runnable` will not be run until after the map is on the screen, at which time the `CameraUpdate` can work.

## Flattening and Rotating Markers

Markers, by default, appear to be “push pins” pressed into the surface of the map. This is not necessarily obvious with the default top-down perspective of the map camera. But, if you use a two-finger vertical swiping gesture, you can change the camera tilt, and that will illustrate the “push pin” effect a bit better:

*Figure 564: Maps V2 with Markers, Viewed on a Tilt*

However, you have options for flat markers and rotated markers.

## MAPPING WITH MAPS V2

---

A flat marker is one that is flat on the map. In other words, rather than theoretically rising out of the Z axis of the map, the marker is kept on the X-Y plane:

*Figure 565: Maps V2 with Markers, One Normal, One Flat*

## MAPPING WITH MAPS V2

It is also possible to rotate a marker. The flat marker in the previous screenshot is rotated 90 degrees from its normal “bulb on the north side” orientation. The following screenshot shows another flat marker, rotated 270 degrees from normal:

Figure 566: Maps V2 with Markers, Flat and Rotated

These features can be handy for providing pointers in a particular direction, such as indicating not only the location to make a turn, but what direction to turn at that location.

These capabilities are courtesy of `flat()` and `rotation()` methods on `MarkerOptions`, plus corresponding getters and setters on `Marker` itself. To see how this works, let's examine the [MapsV2/FlatMarkers](#) sample application. This is a clone of `MapsV2/Markers`, with markers applied using different values for `flat()` and `rotation()`.

Specifically, our own `addMarker()` helper method now takes and applies a boolean parameter for `flat` (`true` means it is flat, `false` means normal behavior), as well as a float parameter for `rotation` (a value between 0 and 360 for the rotation off the default in degrees):

```
private void addMarker(GoogleMap map, double lat, double lon,
    int title, int snippet, boolean flat,
    float rotation) {
```

## MAPPING WITH MAPS V2

---

```
map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
    .title(getString(title))
    .snippet(getString(snippet))
    .flat(flat).rotation(rotation));
}
```

(from [MapsV2/FlatMarkers/app/src/main/java/com/commonsware/android/mapsv2/flatmarkers/MainActivity.java](#))

When we call `addMarker()`, we supply corresponding values:

```
addMarker(map, 40.748963847316034, -73.96807193756104,
    R.string.un, R.string.united_nations, false, 180);
addMarker(map, 40.76866299974387, -73.98268461227417,
    R.string.lincoln_center,
    R.string.lincoln_center_snippet, false, 0);
addMarker(map, 40.765136435316755, -73.97989511489868,
    R.string.carnegie_hall, R.string.practice_x3, true, 90);
addMarker(map, 40.70686417491799, -74.01572942733765,
    R.string.downtown_club, R.string.heisman_trophy, true,
    270);
```

(from [MapsV2/FlatMarkers/app/src/main/java/com/commonsware/android/mapsv2/flatmarkers/MainActivity.java](#))

## MAPPING WITH MAPS V2

---

```
<ImageView
    android:id="@+id/icon"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:padding="2dip"
    android:src="@drawable/ic_launcher"
    android:contentDescription="@string/icon"/>

<LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <TextView
        android:id="@+id/title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="25sp"
        android:textStyle="bold"/>

    <TextView
        android:id="@+id/snippet"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="15sp"/>
</LinearLayout>
</LinearLayout>
```

(from [MapsV2/Popups/app/src/main/res/layout/popup.xml](#))

Here, we will show the title and snippet in our own chosen font size and weight, plus show the launcher icon on the left.

To use this layout, we must create an `InfoWindowAdapter` implementation — in the case of this sample project, that is found in the `PopupAdapter` class:

```
package com.commonware.android.mapsv2.popups;

import android.annotation.SuppressLint;
import android.view.LayoutInflater;
import android.view.View;
import android.widget.TextView;
import com.google.android.gms.maps.GoogleMap.InfoWindowAdapter;
import com.google.android.gms.maps.model.Marker;
```

## MAPPING WITH MAPS V2

---

```
class PopupAdapter implements InfoWindowAdapter {
    private View popup=null;
    private LayoutInflater inflater=null;

    PopupAdapter(LayoutInflater inflater) {
        this.inflater=inflater;
    }

    @Override
    public View getInfoWindow(Marker marker) {
        return(null);
    }

    @SuppressWarnings("InflateParams")
    @Override
    public View getInfoContents(Marker marker) {
        if (popup == null) {
            popup=inflater.inflate(R.layout.popup, null);
        }

        TextView tv=(TextView)popup.findViewById(R.id.title);

        tv.setText(marker.getTitle());
        tv=(TextView)popup.findViewById(R.id.snippet);
        tv.setText(marker.getSnippet());

        return(popup);
    }
}
```

(from [MapsV2/Popups/app/src/main/java/com/commonsware/android/mapsv2/popups/PopupAdapter.java](#))

When an info window is to be displayed, Android will first call `getInfoWindow()` on our `InfoWindowAdapter`, passing in the `Marker` whose info window is needed. If we return a `View` here, that will be used for the entire info window. If, instead, we return `null`, Android will call `getInfoContents()`, passing in the same `Marker` object. If we return a `View` here, Android will use that as the “body” of the info window, with Android supplying the border. If we return `null`, the default info window is displayed. This way, we can conditionally do any of the three possibilities (replace the window, replace the contents, or accept the default).

In our case, `getInfoContents()` will inflate the `popup.xml` layout and populate the two `TextView` widgets with the title and snippet from the `Marker`. However, we cache the inflated layout and reuse it on the second and subsequent calls to `getInfoContents()`. Despite the “adapter” name conjuring up visions of

## MAPPING WITH MAPS V2

---

ListAdapter and having multiple outstanding views, InfoWindowAdapter will only ever use one View at a time. Hence, rather than inflate our layout each time we need to show the info window, we can safely reuse the previously-used View.

Then, we just need to tell the GoogleMap to use our InfoWindowAdapter, via a call to `setInfoWindowAdapter()`, such as this statement from `onMapReady()` of our new edition of MainActivity:

```
map.setInfoWindowAdapter(new PopupAdapter(getLayoutInflater()));
```

(from [MapsV2/Popups/app/src/main/java/com/commonsware/android/mapsv2/popups/MainActivity.java](#))

Now, when the user taps on a marker, they will get our customized info window:

We can also call `setOnInfoWindowClickListener()` on our GoogleMap, passing in an implementation of the `OnInfoWindowClickListener` interface, to find out when the user taps on the info window. In the case of MainActivity, we set up the activity itself to implement that interface and be the listener:

```
map.setOnInfoWindowClickListener(this);
```

(from [MapsV2/Popups/app/src/main/java/com/commonsware/android/mapsv2/popups/MainActivity.java](#))

This requires us to implement an `onInfoWindowClick()` method, where we are passed the Marker representing the tapped-upon info window:

## MAPPING WITH MAPS V2

```
@Override
public void onInfoWindowClick(Marker marker) {
    Toast.makeText(this, marker.getTitle(), Toast.LENGTH_LONG).show();
}
```

(from [MapsV2/Popups/app/src/main/java/com/commonsware/android/mapsv2/popups/MainActivity.java](#))

Here, we just display a Toast with the title of the Marker when the user taps an info window:

*Figure 569: Maps V2 with Toast Triggered by Tap on Info Window*

Note that, according to the documentation, you can only find out about taps on the entire info window. Indeed, if you try setting up click listeners on the widgets in your custom layout, you will find that they are not called. This is because the View you return for the info window is converted into a Bitmap, which is then displayed. Presumably, this is to steer developers in the direction of making larger tap targets, rather than expecting users to tap tiny elements within an info window. On the other hand, if your design calls for a large info window containing several navigation options, you will need to either re-think your design or avoid the info window system. We will see how to find out about taps on markers more directly [later in this chapter](#).

## Images and Your Info Window

The `Bitmap` approach that Maps V2 uses for the info window introduces an additional challenge: updating the info window itself. Normally, we would just update the individual widgets in the info window, the way we might update widgets in an already-visible row in a `ListView`. However, that is not an option here, as our widgets are discarded almost immediately.

One particular occurrence of this problem comes when you want to show an image in the info window. If the image is a resource, or is already in memory, showing it is not a big problem, as you can just populate your `ImageView` in your info window with it. However, if the image is a file (or, worse, needs to be downloaded), you want to load the image asynchronously. However, if you kick off some background thread, like an `AsyncTask`, to retrieve the image, you will return from your `InfoWindowAdapter` method long before the task is complete. Your info window will show whatever placeholder image you used; the image you loaded will never be seen, even if you update your original `ImageView`.

There are two solutions to this problem.

The best solution, by far, is to have the images before you need them, wherever possible. For example, if you are showing a map with 25 markers, for which you need 25 thumbnail images, start downloading those images while you are showing the map. With luck, at the point in time when the user taps on a marker to show the info window, you will have your image already.

However, this approach will not work well if:

- You need a ridiculous number of images, or
- You need images, but they need to be downloaded full-sized and turned into thumbnails locally, as that might consume quite a bit of bandwidth, or
- Your last name is Murphy, and therefore the user taps on an info window before you have had a chance to prepare its image

The workaround is to make note of the `Marker` the user tapped upon to open its info window, then call `showInfoWindow()` on that `Marker` to cause the info window to be redisplayed once you have your image, triggering calls to your `InfoWindowAdapter`. There, you can see that your image cache includes the image that you need, and you can apply it to the info window.

---

## MAPPING WITH MAPS V2

---

The problem *here* is that it is possible that the user tapped on another marker, after the first one, while you were busily fetching and loading the image. Hence, rather than blindly calling `showInfoWindow()` on the Marker, you should call `isInfoWindowShown()` first, and only call `showInfoWindow()` to force the refresh if `isInfoWindowShown()` returns true. Otherwise, some other marker's info window is shown. The user is not expecting this earlier info window to somehow magically reappear.

All of this is a pain. It can be made a bit less of a pain by use of an image fetching-and-caching library like [Picasso](#). We can see how this can be applied by looking at the [MapsV2/ImagePopups](#) sample application. This is a clone of MapsV2/Popups, with some additions to handle lazy-populating an info window based upon a downloaded image.

First, since we are going to be generating some thumbnails based on downloaded imagery, it helps to establish a fixed-size `ImageView` for our icon. So, this project has a pair of dimension resources, for the image height and width:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="icon_width">96dp</dimen>
  <dimen name="icon_height">64dp</dimen>
</resources>
```

(from [MapsV2/ImagePopups/app/src/main/res/values/dimens.xml](#))

Those are then used in a revised version of the popup layout resource:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="horizontal">

  <ImageView
    android:id="@+id/icon"
    android:layout_width="@dimen/icon_width"
    android:layout_height="@dimen/icon_height"
    android:padding="2dip"
    android:src="@drawable/ic_launcher"
    android:contentDescription="@string/icon"/>

  <LinearLayout
    android:layout_width="match_parent"
```

## MAPPING WITH MAPS V2

---

```
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:orientation="vertical">

        <TextView
            android:id="@+id/title"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:textSize="25sp"
            android:textStyle="bold"/>

        <TextView
            android:id="@+id/snippet"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:textSize="15sp"/>
    </LinearLayout>
</LinearLayout>
```

(from [MapsV2/ImagePopups/app/src/main/res/layout/popup.xml](#))

We need some way of keeping track of what images should be used for each marker. This is somewhat annoying to implement, as we cannot subclass `Marker`, since it is marked as `final` and cannot be extended. However, we can use `getId()` on a `Marker` to obtain a unique ID, and we can use that as the key to additional model data. We will examine variations on this technique [later in this chapter](#). For now, this sample gets away with a simple `HashMap`, mapping the string ID of a `Marker` to a `Uri` representing an image to be shown for that `Marker`'s info window:

```
private HashMap<String, Uri> images=new HashMap<String, Uri>();
```

(from [MapsV2/ImagePopups/app/src/main/java/com/commonsware/android/mapsv2/imagepopups/MainActivity.java](#))

Our private `addMarker()` method now takes a `String` name of an image, and it adds a `Uri` pointing to that image to the `HashMap`, keyed by the ID of the generated `Marker`:

```
private void addMarker(GoogleMap map, double lat, double lon,
                      int title, int snippet, String image) {
    Marker marker=
        map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                      .title(getString(title))
                      .snippet(getString(snippet)));

    if (image != null) {
```

## MAPPING WITH MAPS V2

---

```
images.put(marker.getId(),
            Uri.parse("http://misc.commonsware.com/mapsv2/"
                    + image));
    }
}
```

(from [MapsV2/ImagePopups/app/src/main/java/com/commonsware/android/mapsv2/imagepopups/MainActivity.java](#))

For three of our markers, we pass in actual filenames; for a fourth, null is used, indicating that there is no suitable image for use:

```
addMarker(map, 40.748963847316034, -73.96807193756104,
            R.string.un, R.string.united_nations, "UN_HQ.jpg");
addMarker(map, 40.76866299974387, -73.98268461227417,
            R.string.lincoln_center,
            R.string.lincoln_center_snippet,
            "Avery_Fisher_Hall.jpg");
addMarker(map, 40.765136435316755, -73.97989511489868,
            R.string.carnegie_hall, R.string.practice_x3,
            "Carnegie_Hall.jpg");
addMarker(map, 40.70686417491799, -74.01572942733765,
            R.string.downtown_club, R.string.heisman_trophy, null);
```

(from [MapsV2/ImagePopups/app/src/main/java/com/commonsware/android/mapsv2/imagepopups/MainActivity.java](#))

Note that the three images being used in this chapter come from Wikipedia. One is public domain, the others are licensed under the Creative Commons Attribution 1.0 license. Those two are a picture of [Avery Fisher Hall](#), part of the Lincoln Center for the Performing Arts (courtesy of [Geographer](#)) and the other is a picture of [the United Nations building](#) (courtesy of [WorldIslandInfo](#)).

The PopupAdapter needs access to these images. It will also need access to a Context, for use with Picasso. So, PopupAdapter now has data members for these, which are passed into a revised version of its constructor by MainActivity. That constructor not only holds onto the new objects, but it retrieves the values of the dimension resources for our images, converted by Android into pixels for the screen density of the device that we are running on:

```
PopupAdapter(Context ctxt, LayoutInflater inflater,
              HashMap<String, Uri> images) {
    this.ctxt=ctxt;
    this.inflater=inflater;
    this.images=images;

    iconWidth=
        ctxt.getResources().getDimensionPixelSize(R.dimen.icon_width);
```

## MAPPING WITH MAPS V2

---

```
    iconHeight=
        ctxt.getResources().getDimensionPixelSize(R.dimen.icon_height);
}
```

(from [MapsV2/ImagePopups/app/src/main/java/com/commonsware/android/mapsv2/imagepopups/PopupAdapter.java](#))

The revised `getInfoContents()` method is significantly more complicated than was its predecessor:

```
@SuppressWarnings("InflateParams")
@Override
public View getInfoContents(Marker marker) {
    if (popup == null) {
        popup=inflater.inflate(R.layout.popup, null);
    }

    if (lastMarker == null
        || !lastMarker.getId().equals(marker.getId())) {
        lastMarker=marker;

        TextView tv=(TextView)popup.findViewById(R.id.title);

        tv.setText(marker.getTitle());
        tv=(TextView)popup.findViewById(R.id.snippet);
        tv.setText(marker.getSnippet());

        Uri image=images.get(marker.getId());
        ImageView icon=(ImageView)popup.findViewById(R.id.icon);

        if (image == null) {
            icon.setVisibility(View.GONE);
        }
        else {
            icon.setVisibility(View.VISIBLE);
            Picasso.with(ctxt).load(image).resize(iconWidth, iconHeight)
                .centerCrop().noFade()
                .placeholder(R.drawable.placeholder)
                .into(icon, new MarkerCallback(marker));
        }
    }

    return(popup);
}
```

(from [MapsV2/ImagePopups/app/src/main/java/com/commonsware/android/mapsv2/imagepopups/PopupAdapter.java](#))

We track the last Marker that we have processed in a `lastMarker` data member.

## MAPPING WITH MAPS V2

---

Initially, of course, that will be null. If it is, or if the Marker passed into `getInfoContents()` is a different one (based on the `getId()` value), then we populate the popup View. This includes fetching the Uri from the HashMap of Uri values (given the Marker ID). If there is no Uri, `getInfoContents()` marks the `ImageView` as GONE, so it will not take up space in the popup. If, however, there is an image Uri, `getInfoContents()` asks Picasso to “do its thing”:

- Load the image from the Uri
- Resize the image to be the desired dimensions for the `ImageView`, center-cropping to keep the right aspect ratio
- Skip the fade-in animation that is normally applied when Picasso populates an `ImageView` (as the Maps V2 `Bitmap` is generated before the animation completes, resulting in a washed-out image)
- Use a particular placeholder drawable resource while the image is loading
- Populate the `ImageView` with the results, specifying a `MarkerCallback` to be notified of the results

`MarkerCallback`, as an implementation of Picasso’s `Callback` interface, needs `onError()` and `onSuccess()` methods. `onError()` just dumps a message to Logcat, while `onSuccess()` refreshes the info window, via a call to `showInfoWindow()` on the Marker, if that info window is still showing:

```
static class MarkerCallback implements Callback {
    Marker marker=null;

    MarkerCallback(Marker marker) {
        this.marker=marker;
    }

    @Override
    public void onError() {
        Log.e(getClass().getSimpleName(), "Error loading thumbnail!");
    }

    @Override
    public void onSuccess() {
        if (marker != null && marker.isInfoWindowShown()) {
            marker.showInfoWindow();
        }
    }
}
```

(from [MapsV2/ImagePopups/app/src/main/java/com/commonsware/android/mapsv2/imagepopups/PopupAdapter.java](#))

If you run this sample app, you will see the popup with a placeholder image at first, quickly being replaced by the thumbnail supplied by Picasso:

Figure 570: Maps V2 with Popup and Thumbnail

## Setting the Marker Icon

Maps V2 includes a stock marker icon that looks a lot like the standard Google Maps marker. You have three major choices for what to use for your own markers:

1. Stick with the stock icon, which is the default behavior
2. Change the stock icon to a different hue
3. Replace the stock icon with your own from an asset, resource, file, or in-memory Bitmap

To indicate that you want a different icon than the stock one, use the `icon()` method on the `MarkerOptions` fluent interface. This takes a `BitmapDescriptor`, which you get from one of a series of static methods on the `BitmapDescriptorFactory` class.

For example, you might have a revised version of the `addMarker()` method of

## MAPPING WITH MAPS V2

---

MainActivity that took a hue — a value from 0 to 360 representing different colors along a color wheel. 0 represents red, 120 represents green, and 240 represents blue, with different shades in between. There is a series of HUE\_ constants defined on BitmapDescriptorFactory, plus a defaultMarker() method that takes a hue as a parameter and returns a BitmapDescriptor that will use the stock icon, colored to the specified hue:

```
private void addMarker(GoogleMap map, double lat, double lon,
    int title, int snippet, int hue) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
        .title(getString(title))
        .snippet(getString(snippet))
        .icon(BitmapDescriptorFactory.defaultMarker(hue)));
}
```

(from [MapsV2/Taps/app/src/main/java/com/commonsware/android/mapsv2/taps/MainActivity.java](#))

This could then be used to give you different colors per marker, or by category of marker, etc.:

Figure 571: Maps V2 with Alternate Marker Hues

Note that you can modify the icon at runtime via the setIcon() method on the Marker returned by addMarker() method on GoogleMap.

However, you cannot draw the marker directly yourself, the way you might have with Maps V1. What you *can* do is draw to a Bitmap-backed Canvas object, then use the resulting Bitmap with `BitmapFactoryDescriptor` and its `fromBitmap()` factory method.

## Responding to Taps

Perhaps we would like to find out when a user taps on one of our markers, instead of displaying an info window. Maybe we want to have some other UI response to that tap in our app.

To do that, simply create an implementation of the `OnMarkerClickListener` interface and attach it to the `GoogleMap` via `setOnMarkerClickListener()`. You will then be called with `onMarkerClick()` when the user taps on a marker, and you are passed the `Marker` object in question. If you return `true`, you are indicating that you are handling the event; returning `false` means that default handling (the info window) should be done.

You can see this, plus the multi-colored markers, in the [MapsV2/Taps](#) sample application. This takes `MapsV2/Popups` and adds a `Toast` when the user taps a marker, in addition to displaying the info window:

```
@Override
public boolean onMarkerClick(Marker marker) {
    Toast.makeText(this, marker.getTitle(), Toast.LENGTH_LONG).show();

    return(false);
}
```

---

## MAPPING WITH MAPS V2

---

(from [MapsV2/Taps/app/src/main/java/com/commonsware/android/mapsv2/taps/MainActivity.java](#))

Figure 572: Maps V2 with Toast and Info Window

Our call to `setOnMarkerClickListener()` is up in the `onMapReady()` method of `MainActivity`:

```
map.setOnMarkerClickListener(this);
```

(from [MapsV2/Taps/app/src/main/java/com/commonsware/android/mapsv2/taps/MainActivity.java](#))

## Dragging Markers

By default, markers are not draggable. But, if you call `draggable(true)` on your `MarkerOptions` when creating the marker — or call `setDraggable(true)` on the `Marker` later on — Android will automatically support drag-and-drop. The user can tap-and-hold on the marker to enable drag mode, then slide the marker around the map.

Note that at the present time, this functionality is a little odd. When you tap-and-hold the marker, with drag mode enabled, the marker initially jumps away from its original position. The user can reposition the marker to any desired location, and

## MAPPING WITH MAPS V2

---

the marker will seem to “drop” where the user requests. Why the marker makes the sudden shift at the outset, using the default marker settings, is unclear.

Of course, your code may need to know about drag-and-drop events, such as to update your own data model to reflect the newly-chosen location. You can register an `OnMarkerDragListener` that will be notified of the start of the drag, where the marker slides during the drag, and where the marker is dropped at the end of the drag.

You can see all of this in the [MapsV2/Drag](#) sample application, which is a clone of `MapsV2/Popup` with drag-and-drop enabled.

To enable drag-and-drop, we just chain `draggable(true)` onto the series of calls on our `MarkerOptions` when creating the markers:

```
private void addMarker(GoogleMap map, double lat, double lon,
                      int title, int snippet) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                 .title(getString(title))
                 .snippet(getString(snippet))
                 .draggable(true));
}
```

(from [MapsV2/Drag/app/src/main/java/com/commonsware/android/mapsv2/drag/MainActivity.java](#))

We also register `MainActivity` as being the drag listener, up in `onMapReady()`:

```
map.setOnMarkerDragListener(this);
```

(from [MapsV2/Drag/app/src/main/java/com/commonsware/android/mapsv2/drag/MainActivity.java](#))

That requires `MainActivity` to implement `OnMarkerDragListener`, which in turn requires three methods to be defined: `onMarkerDragStart()`, `onMarkerDrag()`, and `onMarkerDragEnd()`:

```
@Override
public void onMarkerDragStart(Marker marker) {
    LatLng position=marker.getPosition();

    Log.d(getClass().getSimpleName(), String.format("Drag from %f:%f",
                                                    position.latitude,
                                                    position.longitude));
}

@Override
```

## MAPPING WITH MAPS V2

---

```
public void onMarkerDrag(Marker marker) {
    LatLng position=marker.getPosition();

    Log.d(getClass().getSimpleName(),
        String.format("Dragging to %f:%f", position.latitude,
            position.longitude));
}

@Override
public void onMarkerDragEnd(Marker marker) {
    LatLng position=marker.getPosition();

    Log.d(getClass().getSimpleName(), String.format("Dragged to %f:%f",
        position.latitude,
        position.longitude));
}
```

(from [MapsV2/Drag/app/src/main/java/com/commonsware/android/mapsv2/drag/MainActivity.java](#))

Here, we just dump the information about the new marker position in Logcat.

So, if you run this app and drag-and-drop a marker, you will see output in Logcat akin to:

```
12-19 13:10:36.442: D/MainActivity(22510): Drag from 40.770876:-73.982499
12-19 13:10:36.892: D/MainActivity(22510): Dragging to 40.770876:-73.981593
12-19 13:10:36.912: D/MainActivity(22510): Dragging to 40.770795:-73.981352
12-19 13:10:36.932: D/MainActivity(22510): Dragging to 40.770754:-73.981141
.
.
.
12-19 13:10:38.292: D/MainActivity(22510): Dragging to 40.769596:-73.983615
12-19 13:10:38.372: D/MainActivity(22510): Dragged to 40.769596:-73.983615
```

The actual list of events was much longer, as `onMarkerDrag()` is called a *lot*, so the ... in the Logcat entries above reflect another 50 or so lines for a drag-and-drop that took a couple of seconds.

Also, up in `onCreate()`, we retain our `SupportMapFragment` across configuration changes via `setRetainInstance(true)`:

```
mapFrag.setRetainInstance(true);
```

(from [MapsV2/Drag/app/src/main/java/com/commonsware/android/mapsv2/drag/MainActivity.java](#))

Retaining the fragment instance causes the fragment to keep our markers in their

---

moved positions, rather than resetting them to their original positions.

## The “Final” Limitations

In Maps V2, not only do you not create Marker objects directly yourself, but Marker is marked as final and cannot be extended. Hence, you cannot use a Marker directly to hold model data.

However, Marker does have getId(), an immutable identifier for the Marker. We can use that as a key for a HashMap that allows us to get at additional model data associated with the Marker.

You can see this approach in the [MapsV2/Models](#) sample application, which is a clone of MapsV2/Popup where we use the ID in just this fashion.

Our simplified model is merely the data we poured into our Marker objects in the original MapsV2/Popup project:

```
package com.commonware.android.mapsv2.model;

import android.content.Context;

public class Model {
    String title;
    String snippet;
    double lat;
    double lon;

    Model(Context ctxt, double lat, double lon, int title,
          int snippet) {
        this.title=ctxt.getString(title);
        this.snippet=ctxt.getString(snippet);
        this.lat=lat;
        this.lon=lon;
    }

    String getTitle() {
        return(title);
    }

    String getSnippet() {
        return(snippet);
    }
}
```

## MAPPING WITH MAPS V2

---

```
double getLatitude() {
    return(lat);
}

double getLongitude() {
    return(lon);
}
}
```

(from [MapsV2/Models/app/src/main/java/com/commonsware/android/mapsv2/model/Model.java](#))

Our activity holds onto a `HashMap` of these `Model` objects, with the map keyed by the Marker ID (a `String`):

```
private HashMap<String, Model> models=new HashMap<String, Model>();
```

(from [MapsV2/Models/app/src/main/java/com/commonsware/android/mapsv2/model/MainActivity.java](#))

Of course, a real application would have a much more elaborate setup than this.

We then arrange to populate our map with Marker objects created from our `Model` objects, moving the add-the-markers-to-the-map logic to an `addMarkers()` method:

```
private void addMarkers(GoogleMap map) {
    Model model=
        new Model(this, 40.748963847316034, -73.96807193756104,
            R.string.un, R.string.united_nations);

    models.put(addMarkerForModel(map, model).getId(), model);

    model=
        new Model(this, 40.76866299974387, -73.98268461227417,
            R.string.lincoln_center,
            R.string.lincoln_center_snippet);
    models.put(addMarkerForModel(map, model).getId(), model);

    model=
        new Model(this, 40.765136435316755, -73.97989511489868,
            R.string.carnegie_hall, R.string.practice_x3);
    models.put(addMarkerForModel(map, model).getId(), model);

    model=
        new Model(this, 40.70686417491799, -74.01572942733765,
            R.string.downtown_club, R.string.heisman_trophy);
    models.put(addMarkerForModel(map, model).getId(), model);
}
```

## MAPPING WITH MAPS V2

---

```
private Marker addMarkerForModel(GoogleMap map, Model model) {
    LatLng position=
        new LatLng(model.getLatitude(), model.getLongitude());

    return(map.addMarker(new MarkerOptions().position(position)
        .title(model.getTitle())
        .snippet(model.getSnippet())));
}
```

(from [MapsV2/Models/app/src/main/java/com/commonsware/android/mapsv2/model/MainActivity.java](#))

Notice that `addMarkerForModel()` returns the `Marker`, and we use `getId()` on that `Marker` as the key when adding a `Model` to the `HashMap`.

Our `PopupAdapter` gets the data for the info window from the `Model` (though, in truth, in this case, it could have gotten the data from the `Marker` itself, since we did not add more information to the info window):

```
package com.commonsware.android.mapsv2.model;

import android.view.LayoutInflater;
import android.view.View;
import android.widget.TextView;
import java.util.HashMap;
import com.google.android.gms.maps.GoogleMap.InfoWindowAdapter;
import com.google.android.gms.maps.model.Marker;

class PopupAdapter implements InfoWindowAdapter {
    LayoutInflater inflater=null;
    HashMap<String, Model> models=null;

    PopupAdapter(LayoutInflater inflater, HashMap<String, Model> models) {
        this.inflater=inflater;
        this.models=models;
    }

    @Override
    public View getInfoWindow(Marker marker) {
        return(null);
    }

    @Override
    public View getInfoContents(Marker marker) {
        View popup=inflater.inflate(R.layout.popup, null);

        TextView tv=(TextView)popup.findViewById(R.id.title);
    }
}
```

```
tv.setText(models.get(marker.getId()).getTitle());
tv=(TextView)popup.findViewById(R.id.snippet);
tv.setText(models.get(marker.getId()).getSnippet());

return(popup);
}
```

(from [MapsV2/Models/app/src/main/java/com/commonsware/android/mapsv2/model/PopupAdapter.java](#))

Visually, this is indistinguishable from the original MapsV2/Popups project. Of course, a real app would have more complex models, perhaps containing more discrete information for a more complex info window.

## A Bit More About IPC

IPC is not only a problem in terms of disappearing Marker objects.

If you run a Maps V2 app under [Traceview](#), to see what methods get called and how much time everything takes, you will see that many, many operations with GoogleMap do little in your process, but instead make synchronous calls to a Play Services process to do the real work. You need to avoid manipulating your GoogleMap in time-sensitive portions of your code.

## Finding the User

It is often useful to help point out to the user their current location. That is a matter of adding a suitable location permission (e.g., ACCESS\_FINE\_LOCATION) and calling `setMyLocationEnabled(true)` on your GoogleMap. This activates a layer that will highlight their location, with the user having an option of having the “camera” (i.e., their perspective on the map) reposition itself to their location and move as they move. This latter capability is activated by a small icon in the upper right of the map.

There does not appear to be a way to *force* camera tracking of the user’s position — you are reliant upon the user tapping that icon. You also have no control over the nature of the location provider that is used.

However, there is a workaround for this, proposed in [a Stack Overflow answer](#) — provide your own location data and update the camera yourself, by means of `setLocationSource()`. `setLocationSource()` lets you push locations to the

---

## MAPPING WITH MAPS V2

---

GoogleMap, making other adjustments (e.g., camera position) along the way.

You can see this in operation in the [MapsV2/Location](#) sample application, which is based on MapsV2/Popup but with a variety of changes to deal with location tracking. A lot of that has to do with [the runtime permissions system](#) on Android 6.0+, as we need permission from the user to be able to work with the device location.

### Dealing with the Runtime Permission

onCreate() of MainActivity now looks radically different:

```
@Override
protected void onCreate(Bundle state) {
    super.onCreate(state);

    if (state==null) {
        needsInit=true;
    }
    else {
        isInPermission=state.getBoolean(STATE_IN_PERMISSION, false);
        autoFollow=state.getBoolean(STATE_AUTO_FOLLOW, true);
    }

    onCreateForRealz(canGetLocation());
}
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

Most of the original business logic from onCreate() has been moved into onCreateForRealz(). That method takes a boolean parameter, indicating whether or not we have permission to access the user's location. Here, we get that from a canGetLocation() method that, in turn, uses ContextCompat.checkSelfPermission() to see if we hold ACCESS\_FINE\_LOCATION:

```
private boolean canGetLocation() {
    return(ContextCompat.checkSelfPermission(this,
        Manifest.permission.ACCESS_FINE_LOCATION)==
        PackageManager.PERMISSION_GRANTED);
}
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

If we can work with locations, onCreateForRealz() will do what onCreate() used to do: call readyToGo() and, if we are ready to go, bring up the map:

## MAPPING WITH MAPS V2

---

```
private void onCreateForRealz(boolean canGetLocation) {
    if (canGetLocation) {
        if (readyToGo()) {
            setContentView(R.layout.activity_main);

            SupportMapFragment mapFrag=
                (SupportMapFragment)getSupportFragmentManager().findFragmentById(R.id.map);

            mapFrag.getMapAsync(this);
        }
    }
    else if (!isInPermission) {
        isInPermission=true;

        ActivityCompat.requestPermissions(this,
            new String[] {Manifest.permission.ACCESS_FINE_LOCATION},
            REQUEST_PERMS);
    }
}
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

If we do not have access to the user's location, this particular sample app is not that interesting, so we will ask the user for permission, via a call to `ActivityCompat.requestPermissions()`. This will eventually trigger a call to `onRequestPermissionsResult()`:

```
@Override
public void onRequestPermissionsResult(int requestCode,
    String[] permissions,
    int[] grantResults) {

    isInPermission=false;

    if (requestCode==REQUEST_PERMS) {
        if (canGetLocation()) {
            onCreateForRealz(true);
        }
        else {
            finish(); // denied permission, so we're done
        }
    }
}
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

Here, if we can now get the location, we go ahead and run through `onCreateForRealz()` again, to initialize the map. If, however, the user denied us the right to access the location, we `finish()` and exit the activity outright.

Throughout this code, you have seen references to an `isInPermission` field. This

## MAPPING WITH MAPS V2

---

tracks whether or not we are in the middle of requesting a permission:

- It is initialized to false in the activity
- It is set to true just before calling `requestPermissions()`
- It is set back to false in `onRequestPermissionsResult()`
- It is saved across configuration changes via `onSaveInstanceState()` and is retrieved from that state in `onCreate()`:

```
@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putBoolean(STATE_IN_PERMISSION, isInPermission);
    outState.putBoolean(STATE_AUTO_FOLLOW, autoFollow );
}
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

(where `STATE_IN_PERMISSION` is a static final String to use as a key for the Bundle value)

This allows us to check whether or not we are in the middle of requesting permissions already in `onCreateForRealz()` and avoid popping up the permission-request dialog twice if the user rotates the screen while the first dialog is up, then denies the permission.

### Tracking If We Should Follow the User

The UI has a checkable overflow item in the action bar, named `follow`. When checked, we will use `LocationManager` to move the map camera ourselves to the user's location. When unchecked, we will show the `my-location` layer, and the user can manually jump to their current location via the button supplied by that layer.

So, we need to keep track of whether we should be automatically following the user or not.

To that end, we have an `autoFollow` field, initially set to true, as the action item checkbox initially is checked. We toggle that field as the user checks and unchecks the item:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
```

## MAPPING WITH MAPS V2

---

```
menu.findItem(R.id.follow).setChecked(autoFollow);

return super.onCreateOptionsMenu(menu);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.follow) {
        item.setChecked(!item.isChecked());
        autoFollow=item.isChecked();
        follow();

        return true;
    }

    return super.onOptionsItemSelected(item);
}
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

We also call a `follow()` method to update the UI based on the user's choice — we will see that method shortly.

We also hold onto that `autoFollow` value in the saved instance state `Bundle` and restore it when the activity is recreated.

### Showing the My-Location Layer

Part of what we do in `onMapReady()` is call `setMyLocationEnabled(true)` on the map, which puts a blue dot at the user's location:

```
@Override
public void onMapReady(final GoogleMap map) {
    this.map=map;

    if (needsInit) {
        CameraUpdate center=
            CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
                -73.98180484771729));

        CameraUpdate zoom=CameraUpdateFactory.zoomTo(15);

        map.moveCamera(center);
        map.animateCamera(zoom);
    }

    addMarker(map, 40.748963847316034, -73.96807193756104,
```

## MAPPING WITH MAPS V2

---

```
        R.string.un, R.string.united_nations);
addMarker(map, 40.76866299974387, -73.98268461227417,
        R.string.lincoln_center,
        R.string.lincoln_center_snippet);
addMarker(map, 40.765136435316755, -73.97989511489868,
        R.string.carnegie_hall, R.string.practice_x3);
addMarker(map, 40.70686417491799, -74.01572942733765,
        R.string.downtown_club, R.string.heisman_trophy);

map.setInfoWindowAdapter(new PopupAdapter(getLayoutInflater()));
map.setOnInfoWindowClickListener(this);

map.setMyLocationEnabled(true);
locMgr=(LocationManager) getSystemService(LOCATION_SERVICE);
crit.setAccuracy(Criteria.ACCURACY_FINE);
follow();
}
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

Part of what `follow()` does is call `setMyLocationButtonEnabled()`, with a suitable boolean value, to toggle whether the “jump to my location” button is shown:

```
private void follow() {
    if (map!=null && locMgr!=null) {
        if (autoFollow) {
            locMgr.requestLocationUpdates(0L, 0.0f, crit, this, null);
            map.setLocationSource(this);
            map.getUiSettings().setMyLocationButtonEnabled(false);
        }
        else {
            map.getUiSettings().setMyLocationButtonEnabled(true);
            map.setLocationSource(null);
            locMgr.removeUpdates(this);
        }
    }
}
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

## Supplying Location Data

The rest of `follow()` either starts up or stops our request for location data using `LocationManager`, plus setting up our activity as being the source of location data, using `setLocationSource()`.

## MAPPING WITH MAPS V2

---

`setLocationSource()` takes a `LocationSource` implementation, and we implement that interface on the activity itself. It therefore needs `activate()` and `deactivate()` methods, where we can track a supplied `OnLocationChangeListener` for us to use:

```
@Override
public void activate(OnLocationChangeListener listener) {
    this.mapLocationListener=listener;
}

@Override
public void deactivate() {
    this.mapLocationListener=null;
}
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

`LocationManager` will supply our location data to `onLocationChanged()`. There, we do two things:

1. Forward the location along to the `OnLocationChangeListener` supplied to our `LocationSource`, and
2. Update the camera to point at the user's location

```
@Override
public void onLocationChanged(Location location) {
    if (mapLocationListener != null) {
        mapLocationListener.onLocationChanged(location);

        LatLng latLng=
            new LatLng(location.getLatitude(), location.getLongitude());
        CameraUpdate cu=CameraUpdateFactory.newLatLng(latLng);

        map.animateCamera(cu);
    }
}
```

(from [MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java](#))

The result is that while `autoFollow` is true, we will find the user's location and use that to update the map. When `autoFollow` is false, we let the map itself handle that role, including showing that “jump to my location” button.

## Drawing Lines and Areas

If you wanted to draw on a map in the Maps V1 framework, you created an `Overlay`

---

## MAPPING WITH MAPS V2

---

and drew upon it. This forced you to handle low-level drawing work yourself, as you were handed a Canvas object and had to handle all the lines, fills, and so forth yourself.

Maps V2 offers a different approach. Free-form drawing is still conceivable, though it appears to have to be handled in the form of tile overlays instead of map overlays. However, for the simpler cases of drawing lines and areas, Maps V2 has built-in polyline, polygon, and circle support. You tell the GoogleMap what needs to be drawn, and it handles drawing it, both initially and as the map is zoomed or panned. A polyline is a line connecting a series of points; a polygon is a region defined by a series of corners. A circle, from the standpoint of Maps V2, is defined by a center coordinate and a radius.

We can see polylines and polygons on a GoogleMap in the [MapsV2/Polylines](#) sample application, which is a clone of MapsV2/Popup with two additions:

- A polyline connecting the locations of our four markers
- A polygon enclosing the area of Manhattan known as the Garment District (bounded by 34th Street, 42nd Street, Fifth Avenue, and Ninth Avenue)

To draw those, we simply add a few lines to `onMapReady()` of `MainActivity`:

```
PolylineOptions line=
    new PolylineOptions().add(new LatLng(40.70686417491799,
        -74.01572942733765),
        new LatLng(40.76866299974387,
        -73.98268461227417),
        new LatLng(40.765136435316755,
        -73.97989511489868),
        new LatLng(40.748963847316034,
        -73.96807193756104))
        .width(5).color(Color.RED);

map.addPolyline(line);

PolygonOptions area=
    new PolygonOptions().add(new LatLng(40.748429, -73.984573),
        new LatLng(40.753393, -73.996311),
        new LatLng(40.758393, -73.992705),
        new LatLng(40.753484, -73.980882))
        .strokeColor(Color.BLUE);

map.addPolygon(area);
```

(from [MapsV2/Polylines/app/src/main/java/com/commonsware/android/mapsv2/poly/MainActivity.java](#))

## MAPPING WITH MAPS V2

---

The API for adding polylines and polygons is reminiscent of the API for adding markers: define an `Options` object with the characteristics of the item to be drawn, then call an `add...()` method on `GoogleMap` to add the item.

So, to add a polyline, we create a `PolylineOptions` object. Using its fluent interface, we `add()` a series of `LatLng` objects, representing the points to be connected by the line. We also specify the line width in *pixels* via `width()` and the color of the line via `color()`. If we had several lines that might overlap, we could specify the `zIndex()`, where higher indexes indicate lines to be drawn over the top of lines with lower indexes. We add the polyline to the map by passing our `PolylineOptions` to `addPolyline()` on `GoogleMap`.

This gives us a line connecting the four markers, with `GoogleMap` handling the details of where the line should be drawn on the screen given the current map center and zoom levels:

Note that the polyline is drawn using a flat Mercator projection by default. For most maps, that is perfectly fine. If your map will be showing countries and continents, rather than city blocks, you might want to call `geodesic(true)` on the `PolylineOptions`, to have the line drawn on a geodesic curve, reflecting the

---

## MAPPING WITH MAPS V2

---

spherical nature of the Earth ([dissenting opinions on that](#) notwithstanding).

Similarly, we create a `PolygonOptions` object, configure it, and pass it to `addPolygon` for our Garment District box. The `add()` method on `PolygonOptions` will take the corners of our polygon, automatically enclosing that region. We also specify the `strokeColor()`. We could have specified a `fillColor()` (default is transparent), `strokeWidth()` (default is 10 pixels), `zIndex()`, and `geodesic()`.

If we run the app and pan the map down to the south a bit, we see our polygon:

*Figure 574: Maps V2 with Polyline and Polygon*

As with the polyline, Android automatically handles drawing what is needed based on map center and zoom levels.

Note that, as with markers, we need to re-add the polylines and polygons after a configuration change, as the `GoogleMap` does not retain that information.

## Gestures and Controls

By default, standard gestures and controls are enabled on your map:

- The user can change zoom level either by + and - buttons or via “pinch-to-zoom” gestures
- The user can change the center of the map via simple swipe gestures
- The user can change the camera tilt via two-finger vertical swipes, so instead of a traditional top-down perspective, the user can see things on an angle
- The user can change the orientation of the map via a two-finger rotating swipe, to change the typical “north is to the top of the map” to some other orientation

You can obtain a `UiSettings` object from your `GoogleMap` via `getUiSettings()` to disable these features, if desired:

- `setRotateGesturesEnabled()`
- `setScrollGesturesEnabled()` (for panning the map)
- `setTiltGesturesEnabled()`
- `setZoomControlsEnabled()` (for the + and - buttons)
- `setZoomGesturesEnabled()` (for pinch-to-zoom)

There is also `setAllGesturesEnabled()` to toggle on or off all gesture-based map control. This is roughly analogous to the `android:clickable` attribute on the Maps V1 edition of `MapView`.

There is also `setCompassEnabled()`, to indicate if a compass should be shown if the user changes the map orientation via a rotate gesture.

## Tracking Camera Changes

If you have gestures enabled, the user can change the perspective of the map, referred to as changing the camera position. You may need to know about these changes, to perform various operations in your app based upon what is presently visible on the screen.

Originally, to find out when the camera position changes, you could call `setOnCameraChangeListener()` on the `GoogleMap`, supplying an implementation of `OnCameraChangeListener`, which would be called with `onCameraChange()` as the user pans, zooms, or tilts the map. This approach was deprecated and replaced with a series of listeners:

- `OnCameraMoveStartedListener`, invoked when the user starts moving the map

## MAPPING WITH MAPS V2

---

- `OnCameraMoveListener`, invoked when the user continues moving the map after having originally started moving it, all in one gesture
- `OnCameraIdleListener`, invoked when the user stops moving the map (e.g., lifts up their finger or stylus)
- `OnCameraMoveCanceledListener`, invoked if you do something programmatically to interrupt the camera movement

To see how this works, we can take a quick peek at the [MapsV2/Camera](#) sample application, which is a clone of `MapsV2/Popup` with camera position tracking enabled.

Late in `onMapReady()` of `MainActivity`, we call a series of setter methods on the `GoogleMap` to associate `MainActivity` itself as the listener for these events:

```
map.setOnCameraMoveStartedListener(this);
map.setOnCameraMoveListener(this);
map.setOnCameraMoveCanceledListener(this);
map.setOnCameraIdleListener(this);
```

(from [MapsV2/Camera/app/src/main/java/com/commonsware/android/mapsv2/camera/MainActivity.java](#))

This requires `MainActivity` to implement all four of those listener interfaces:

```
public class MainActivity extends AbstractMapActivity implements
    OnMapReadyCallback, OnInfoWindowClickListener,
    OnCameraMoveStartedListener,
    OnCameraMoveListener,
    OnCameraMoveCanceledListener,
    OnCameraIdleListener {
```

(from [MapsV2/Camera/app/src/main/java/com/commonsware/android/mapsv2/camera/MainActivity.java](#))

And, this requires `MainActivity` to implement the callback method for each of those listeners:

## MAPPING WITH MAPS V2

---

Listener Interface	Event Method
OnCameraMoveStartedListener	onCameraMoveStarted(int i)
OnCameraMoveListener	onCameraMove()
OnCameraIdleListener	onCameraIdle()
OnCameraMoveCanceledListener	onCameraMoveCanceled()

```
@Override
public void onCameraIdle() {
    CameraPosition position=map.getCameraPosition();

    Log.d("onCameraIdle",
        String.format("lat: %f, lon: %f, zoom: %f, tilt: %f",
            position.target.latitude,
            position.target.longitude, position.zoom,
            position.tilt));
}

@Override
public void onCameraMoveCanceled() {
    CameraPosition position=map.getCameraPosition();

    Log.d("onCameraMoveCanceled",
        String.format("lat: %f, lon: %f, zoom: %f, tilt: %f",
            position.target.latitude,
            position.target.longitude, position.zoom,
            position.tilt));
}

@Override
public void onCameraMove() {
    CameraPosition position=map.getCameraPosition();

    Log.d("onCameraMove",
        String.format("lat: %f, lon: %f, zoom: %f, tilt: %f",
            position.target.latitude,
            position.target.longitude, position.zoom,
            position.tilt));
}

@Override
public void onCameraMoveStarted(int i) {
```

## MAPPING WITH MAPS V2

---

```
CameraPosition position=map.getCameraPosition();

Log.d("onCameraMoveStarted",
    String.format("lat: %f, lon: %f, zoom: %f, tilt: %f",
        position.target.latitude,
        position.target.longitude, position.zoom,
        position.tilt));
}
```

(from [MapsV2/Camera/app/src/main/java/com/commonsware/android/mapsv2/camera/MainActivity.java](#))

Here, we just log a message to Logcat on each camera position change, logging:

- the latitude and longitude of the map center, obtained from the target `LatLng` data member of the `CameraPosition` object supplied to `onCameraChange()`,
- the zoom level of the map, from the `zoom` data member of `CameraPosition`, and
- the tilt of the map, in degrees, from the `tilt` data member of `CameraPosition`

As a result, if you run this app and play around with the various gestures, you get a series of Logcat messages with the results:

```
10-08 12:13:54.449 28718-28718/com.commonsware.android.mapsv2.camera D/
onCameraMoveStarted: lat: 40.771664, lon: -73.986067, zoom: 15.000000, tilt: 0.000000
10-08 12:13:54.453 28718-28718/com.commonsware.android.mapsv2.camera D/onCameraMove:
lat: 40.771773, lon: -73.985717, zoom: 15.000000, tilt: 0.000000
10-08 12:13:54.483 28718-28718/com.commonsware.android.mapsv2.camera D/onCameraMove:
lat: 40.771805, lon: -73.985701, zoom: 15.000000, tilt: 0.000000
10-08 12:13:54.500 28718-28718/com.commonsware.android.mapsv2.camera D/onCameraMove:
lat: 40.771843, lon: -73.985669, zoom: 15.000000, tilt: 0.000000
.
.
.
10-08 12:13:57.001 28718-28718/com.commonsware.android.mapsv2.camera D/onCameraIdle:
lat: 40.774540, lon: -73.985632, zoom: 15.000000, tilt: 0.000000
```

Note that `onCameraMoveStarted()` will be invoked for three reasons:

1. The user started panning, tilting, or rotating the map, or used a pinch-to-zoom gesture
2. The user did something else that triggered a camera change, such as tapping the “my location” button to move the camera to their current location
3. You did something programmatically to change the camera position

The parameter passed into `onCameraMoveStarted()` will contain a reason code (e.g., `REASON_GESTURE`) to help you distinguish these cases, if that level of detail is needed by your app.

## Maps in Fragments and Pagers

One key limitation of Maps V1 was that you could only have one `MapView` instance per *process*. Presumably, the proprietary code at the heart of the Maps SDK add-on used static data members for some state management, ones that would get messed up if there were two or more `MapView` widgets in active use.

Fortunately, Maps V2 gets rid of this restriction. You are welcome to have multiple `SupportMapFragment` objects if that makes sense. Maps are relatively memory-intensive, so you should not be planning on having dozens or hundreds of them in use at a time, but you can have more than one.

To showcase this, the [MapsV2/Pager](#) sample application hosts 10 `SupportMapFragment` instances as pages in a `ViewPager`. The bulk of the application is a clone of one of the `ViewPager` samples from [the chapter on ViewPager](#).

Having maps in a `ViewPager` presents a bit of a problem, in terms of interpreting horizontal swipe events. Normally, `ViewPager` handles those itself. However, that would mean that the user cannot pan the map horizontally, which makes using the map somewhat challenging. In this sample, we will augment the `ViewPager` with logic to allow horizontal swiping on the maps and on the tab strip.

Our activity inflates a layout that contains our `ViewPager` along with a `PagerTabStrip`:

```
<?xml version="1.0" encoding="utf-8"?>
<com.commonware.android.mapsv2.pager.MapAwarePager xmlns:android="http://schemas.android.com/apk/res/
android"
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <android.support.v4.view.PagerTabStrip
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_gravity="top"/>

</com.commonware.android.mapsv2.pager.MapAwarePager>
```

(from [MapsV2/Pager/app/src/main/res/layout/activity\\_main.xml](#))

## MAPPING WITH MAPS V2

---

However, you will note that this is not `ViewPager`, but rather `MapAwarePager`, a custom subclass of `ViewPager` that we will examine shortly.

`MainActivity` then populates the `MapAwarePager` with an instance of a `MapPagerAdapter`:

```
package com.commonware.android.mapsv2.pager;

import android.os.Bundle;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;

public class MainActivity extends AbstractMapActivity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (readyToGo()) {
            setContentView(R.layout.activity_main);

            ViewPager pager=findViewById(R.id.pager);

            pager.setAdapter(buildAdapter());
        }
    }

    private PagerAdapter buildAdapter() {
        return(new MapPagerAdapter(this, getSupportFragmentManager()));
    }
}
```

(from [MapsV2/Pager/app/src/main/java/com/commonware/android/mapsv2/pager/MainActivity.java](#))

`MapPagerAdapter` is a `FragmentStatePagerAdapter`, not a `FragmentPagerAdapter`. This means that as the user swipes through our `ViewPager`, the adapter has the right to discard old fragments when it creates new ones. This helps reduce the overall memory footprint of our activity.

```
package com.commonware.android.mapsv2.pager;

import android.content.Context;
import android.support.v4.app.Fragment;
import android.support.v4.app.FragmentManager;
import android.support.v4.app.FragmentStatePagerAdapter;

public class MapPagerAdapter extends FragmentStatePagerAdapter {
    Context ctxt=null;
}
```

## MAPPING WITH MAPS V2

---

```
public MapPageAdapter(Context ctxt, FragmentManager mgr) {
    super(mgr);
    this.ctxt=ctxt;
}

@Override
public int getCount() {
    return(10);
}

@Override
public Fragment getItem(int position) {
    return(new PageMapFragment());
}

@Override
public String getPageTitle(int position) {
    return(ctxt.getString(R.string.map_page_title) + String.valueOf(position + 1));
}
}
```

(from [MapsV2/Pager/app/src/main/java/com/commonsware/android/mapsv2/pager/MapPageAdapter.java](#))

MapPageAdapter declares that there should be ten pages (in `getCount()`) and returns an instance of `PageMapFragment` for each page. `PageMapFragment` is a subclass of `SupportMapFragment`, and so is responsible for displaying our map:

```
package com.commonsware.android.mapsv2.pager;

import android.os.Bundle;
import android.view.View;
import com.google.android.gms.maps.CameraUpdate;
import com.google.android.gms.maps.CameraUpdateFactory;
import com.google.android.gms.maps.GoogleMap;
import com.google.android.gms.maps.OnMapReadyCallback;
import com.google.android.gms.maps.SupportMapFragment;
import com.google.android.gms.maps.model.LatLng;
import com.google.android.gms.maps.model.MarkerOptions;

public class PageMapFragment extends SupportMapFragment implements OnMapReadyCallback {
    private boolean needsInit=false;

    @Override
    public void onViewCreated(View view, Bundle savedInstanceState) {
        super.onViewCreated(view, savedInstanceState);

        if (savedInstanceState == null) {
            needsInit=true;
        }

        getMapAsync(this);
    }

    @Override
    public void onMapReady(final GoogleMap map) {
        if (needsInit) {
            CameraUpdate center=
                CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
```

## MAPPING WITH MAPS V2

---

```
        -73.98180484771729));  
    CameraUpdate zoom=CameraUpdateFactory.zoomTo(15);  
  
    map.moveCamera(center);  
    map.animateCamera(zoom);  
}  
  
addMarker(map, 40.748963847316034, -73.96807193756104, R.string.un,  
    R.string.united_nations);  
addMarker(map, 40.76866299974387, -73.98268461227417,  
    R.string.lincoln_center, R.string.lincoln_center_snippet);  
addMarker(map, 40.765136435316755, -73.97989511489868,  
    R.string.carnegie_hall, R.string.practice_x3);  
addMarker(map, 40.70686417491799, -74.01572942733765,  
    R.string.downtown_club, R.string.heisman_trophy);  
}  
  
private void addMarker(GoogleMap map, double lat, double lon,  
    int title, int snippet) {  
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))  
        .title(getString(title))  
        .snippet(getString(snippet)));  
}  
}
```

(from [MapsV2/Pager/app/src/main/java/com/commonsware/android/mapsv2/pager/PageMapFragment.java](#))

If we simply wanted to display an unconfigured map, we could just have `MapPageAdapter` create and return instances of `SupportMapFragment` directly. If we want to configure our map, though, we need to get control when the `GoogleMap` object is ready for use. One way to do that is to extend `SupportMapFragment` and override `onViewCreated()` and call `getMapAsync()` there to begin the whole get-the-`GoogleMap`-loaded process. In `onMapReady()`, we can then go ahead and configure the map much as we have done in previous examples, just from within the fragment itself rather than from the hosting activity.

`MapAwarePager` overrides one key method of `ViewPager`: `canScroll()`:

```
package com.commonsware.android.mapsv2.pager;  
  
import android.content.Context;  
import android.support.v4.view.PagerTabStrip;  
import android.support.v4.view.ViewPager;  
import android.util.AttributeSet;  
import android.view.SurfaceView;  
import android.view.View;  
  
public class MapAwarePager extends ViewPager {  
    public MapAwarePager(Context context, AttributeSet attrs) {  
        super(context, attrs);  
    }  
}
```

## MAPPING WITH MAPS V2

---

```
@Override
protected boolean canScroll(View v, boolean checkV, int dx, int x,
                             int y) {
    if (v instanceof SurfaceView || v instanceof PagerTabStrip) {
        return(true);
    }

    return(super.canScroll(v, checkV, dx, x, y));
}
}
```

(from [MapsV2/Pager/app/src/main/java/com/commonsware/android/mapsv2/pager/MapAwarePager.java](#))

`canScroll()` should return `true` if the `View` (and specifically the supplied X and Y coordinates within that `View`) can be scrolled horizontally, `false` otherwise. In our case, we want to say that the map and the tab strip are each scrollable horizontally. As it turns out, the passed-in `View` for our `SupportMapFragment` will be the map if it is a subclass of `SurfaceView` (determined by trial and error on the author's part, with hopes for a more authoritative solution in a future edition of the Maps V2 API). So, if the passed-in `View` is either a `SurfaceView` or a `PagerTabStrip`, we return `true`, otherwise we default to normal logic.

## MAPPING WITH MAPS V2

The result is a series of independent maps, one per page:

Figure 575: Multiple Maps V2 Maps in a ViewPager

Each map is independent: if the user pans or zooms one map, that has no impact on any of the other pages. Panning the maps horizontally works; to move between pages, use the tab strip.

## Animating Marker Movement

Markers, by default, are static, unless you make them be draggable, and then only the user can drag them.

However, you are welcome to update the position of a Marker at any point, by calling `setPosition()` and supplying a new `LatLng`. The Marker then will jump to that position.

But what if you want to animate the movement of a Marker from its current position to a new one? Maps V2 does not offer anything “out of the box” for implementing this, but Google demonstrated approaches for this in [a “DevBytes” video](#) and related [bit of code in a GitHub Gist](#). This section will cover the technique appropriate for API Level 14+, including a full working sample (the Gist shows code but not its usage).

### Problem #1: Animating a LatLng

The position of a Marker is a LatLng, as we have seen previously. LatLng is not a simple number, and so the animator framework needs our assistance to animate them. Specifically, we need a TypeEvaluator for LatLng, with our evaluate() method taking the initial and end positions and computing another LatLng representing the fraction position between those other positions. This concept was introduced back in [the chapter on the animator framework](#).

A simple approach to computing the fractional LatLng would be to apply the fraction to the latitude and the longitude as Java double values:

```
LatLng interpolate(float fraction, LatLng initial, LatLng end) {  
    double lat = (end.latitude - initial.latitude) * fraction + initial.latitude;  
    double lng = (end.longitude - initial.longitude) * fraction + initial.longitude;  
  
    return(new LatLng(lat, lng));  
}
```

That would work reasonably well for fairly close points, such as animating a marker within a city. However, animating markers across longer distances means that we have to take into account some geographic realities that a simple calculation will miss.

### Problem #2: The Earth Is Not Flat (Really!)

One bit of reality is that the Earth is round. The above calculation assumes that the Earth is flat. Calculating “great circle” positions requires a fair bit of spherical trigonometry, known to cause loss of hair in software developers.

Hence, ideally, we will use somebody’s existing debugged algorithm for that.

### Problem #3: 180 Equals -180, At Least For Longitude

The other problem is that longitudes wrap around, as 180 degrees longitude is equivalent to -180 degrees longitude, and longitudinal values are considered to be between 180 and -180. In cases where we would not cross 180 degrees longitude, this is not an issue. However, a simple calculation might miss this and wind up having our animation “take the long way” (e.g., animating from -175 degrees longitude to 175 degrees longitude by going 350 degrees around the Earth, rather than just 10 degrees and crossing the International Date Line).

### Introducing Some Googly Assistance

Google themselves have released a [utility library for Maps V2](#). It offers polyline and polygon decoding, primarily for interoperability with other location-related Google services like the Google Directions API. The `SphericalUtil` class handles all of the nasty math for computing distances along the surface of the Earth and related calculations. It also offers `BubbleIconFactory`, which makes it easy to create marker icons that look a bit like info windows (complete with border and caret) wrapping around a bit of text or an icon.

In our case, we can use `SphericalUtil` to handle Problem #2 and Problem #3, interpolating the location between two `LatLng` values, taking the curvature of the Earth and longitude idiosyncrasies into account.

### Seeing This in Action

The [MapsV2/Animator](#) sample project is a modified version of the `MapsV2/Markers` project, adding in the notion of animating a marker from its original position (Lincoln Center) to a new position (Penn Station) within Manhattan.

Since we want to use the Google map utility library, we need to add it as a dependency. Android Studio users can simply add implementation `'com.google.maps.android:android-maps-utils:0.3.4'` (or a higher version) to the dependencies closure.

We need to know where our starting and ending position for the animation will be, in terms of `LatLng` objects. Since those have no dependencies upon a `Context` or anything, we can simply declare them as `static final` values:

```
private static final LatLng PENN_STATION=new LatLng(40.749972,  
                                                    -73.992319);  
private static final LatLng LINCOLN_CENTER=  
    new LatLng(40.76866299974387, -73.98268461227417);
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

We will also need the actual `Marker` object created when we add our starting position (`LINCOLN_CENTER`) to the map. So far, we have ignored the `Marker` returned by `addMarker()` on `GoogleMap`, but now we need that. So, our own `addMarker()` method now returns this value:

```
private Marker addMarker(GoogleMap map, double lat, double lon,
```

## MAPPING WITH MAPS V2

---

```
        int title, int snippet) {
    return(map.addMarker(new MarkerOptions().position(new LatLng(lat,
                                                                lon))
                        .title(getString(title))
                        .snippet(getString(snippet))));
}
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

We also now have a `markerToAnimate` data member of the activity, for our Marker, which we populate from our modified `addMarker()` method:

```
addMarker(map, 40.748963847316034, -73.96807193756104,
          R.string.un, R.string.united_nations);
markerToAnimate=
    addMarker(map, LINCOLN_CENTER.latitude,
              LINCOLN_CENTER.longitude, R.string.lincoln_center,
              R.string.lincoln_center_snippet);
addMarker(map, 40.765136435316755, -73.97989511489868,
          R.string.carnegie_hall, R.string.practice_x3);
addMarker(map, 40.70686417491799, -74.01572942733765,
          R.string.downtown_club, R.string.heisman_trophy);
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

To make the sample work repeatedly, it would be nice to support bi-directional animation, starting with animating from Lincoln Center to Penn Station, then reversing the animation to go back to Lincoln Center. That means that we need to know, for any particular animation, where the end position should be. So, we track a `LatLng` for the next end position, surprisingly named `nextAnimationEnd`, initializing it to be `PENN_STATION` (since we are starting at the outset at `LINCOLN_CENTER`):

```
private LatLng nextAnimationEnd=PENN_STATION;
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

Next, we need to give the user a means of actually requesting the animation to run. To do that, we define a new menu XML resource for an animate menu item (using the directions icon for lack of a better handy icon):

```
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/animate"
        android:icon="@android:drawable/ic_menu_directions"
        android:showAsAction="ifRoom">
```

## MAPPING WITH MAPS V2

---

```
    android:title="@string/animate"/>
</menu>
```

(from [MapsV2/Animator/app/src/main/res/menu/animate.xml](#))

We then load that menu resource in an overridden `onCreateOptionsMenu()` and direct the click event to an `animateMarker()` method in `onOptionsItemSelected()`:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.animate, menu);

    return(super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.animate) {
        animateMarker();

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [MapsV2/Animator/app/src/main/java/com/commonware/android/mapsv2/animator/MainActivity.java](#))

In `animateMarker()`, we need to do two things:

1. Actually run the animation
2. Ensure that the camera position is such that the animation will actually be visible, as it is pointless to animate a marker between two points if the currently-viewed portion of the map does not show those points

To handle the camera position, we need to use `moveCamera()` with a `CameraUpdate` from `CameraUpdateFactory`, as we used to set the initial camera position and zoom level. To handle the case where we want one or more points to be visible, we can use the `newLatLngBounds()` method on `CameraUpdateFactory`. This takes a `LatLngBounds` describing the area that needs to be visible, plus a padding amount in pixels for where that area should be inset within the map.

Of course, this implies that we have a `LatLngBounds`.

## MAPPING WITH MAPS V2

---

Since `LatLngBounds` also does not depend upon a `Context` or much of anything, we can define one of those as a static `final` data member, using a `LatLngBounds.Builder` instance:

```
private static final LatLngBounds bounds=  
    new LatLngBounds.Builder().include(LINCOLN_CENTER)  
        .include(PENN_STATION).build();
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

A `LatLngBounds.Builder` takes one or more `LatLng` objects — passed in via `include()` — then constructs a `LatLngBounds` that encompasses all of those points via `build()`.

Our `animateMarker()` method then starts off by using `moveCamera()` to reset the camera to show that defined region:

```
private void animateMarker() {  
    map.moveCamera(CameraUpdateFactory.newLatLngBounds(bounds, 48));  
  
    Property<Marker, LatLng> property=  
        Property.of(Marker.class, LatLng.class, "position");  
    ObjectAnimator animator=  
        ObjectAnimator.ofObject(markerToAnimate, property,  
            new LatLngEvaluator(), nextAnimationEnd);  
    animator.setDuration(2000);  
    animator.start();  
  
    if (nextAnimationEnd == LINCOLN_CENTER) {  
        nextAnimationEnd=PENN_STATION;  
    }  
    else {  
        nextAnimationEnd=LINCOLN_CENTER;  
    }  
}
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

Then, we need to set up the animation. To do this, we will use the object animator framework, specifically an `ObjectAnimator`. We know the `Marker` that we want to animate (`markerToAnimate`) and we know where we want to animate it to (`nextAnimationEnd`). What we need is to indicate the property to animate on this object, plus provide help to actually animate a `LatLng`.

To specify the property, we could just pass in the name of the property ("position").

---

## MAPPING WITH MAPS V2

---

However, in `animateMarker()`, we set up a `Property` object via the `static of()` factory method. This makes our use of `ofObject()` more type-safe, as `Property` will help enforce that we are animating a `Marker` using `LatLng` values.

To animate `LatLng` values, we need a `TypeEvaluator` for `LatLng`, here defined as a static inner class named `LatLngEvaluator`:

```
private static class LatLngEvaluator implements TypeEvaluator<LatLng> {
    @Override
    public LatLng evaluate(float fraction, LatLng startValue,
                          LatLng endValue) {
        return(SphericalUtil.interpolate(startValue, endValue, fraction));
    }
}
```

(from [MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java](#))

Our `evaluate()` method turns around and calls the static `interpolate()` method on `SphericalUtil`, supplied by Google's map utility library. `interpolate()` handles all the nasty spherical trigonometry and stuff, so we do not have to.

We then set the duration of the animation to be two seconds, and start the animation.

Finally, to reverse the animation for the next request, `animateMarker()` resets the value of `nextAnimationEnd` to be `PENN_STATION` or `LINCOLN_CENTER`, wherever we will animate to next.

### Honoring Traffic Rules, Like “Drive Only On Streets”

You will notice that our animation ignores other aspects of reality, such as buildings that might be in the way. Sometimes, that is appropriate, such as animating the movement of:

- a bird
- a plane
- [a costumed superhero with independent flight capability](#)

Sometimes, though, we need to take into account those obstacles, such as animating the movement of:

- a pedestrian
- a car

- [a costumed superhero “flying” by means of swinging between buildings using dynamically-generated cables of either natural or synthetic origin](#)

However, to do this implies that we know where the obstacles are. Or, more accurately, we would need to animate the marker along known good waypoints, such as streets.

The animation would not be especially difficult, as `ofObject()` can take a series of waypoints. However, we would need to find those waypoints, and there is nothing in Maps V2 itself that supplies this data.

## Maps, of the Indoor Variety

The good news is that Maps V2 supports Google’s indoor maps, for those venues for which Google has indoor map data.

The bad news is that for some reason, only one map at a time supports indoor maps. The default will be that the first map you create will support indoor maps, and others will not.

To see if a given map offers indoor map capability, you can call `isIndoorEnabled()` on `GoogleMap`. To toggle this capability, call `setIndoorEnabled()`.

## Taking a Snapshot of a Map

Once a map is drawn, you can take a snapshot of it, converting the viewed map into a `Bitmap` object. This is designed to take an image of the map and use it in places where a `SupportMapFragment`, or even a `MapView`, cannot go, such as:

- Things tied to a `RemoteViews`, such as a custom `Notification`
- Thumbnails of maps, for an app that allows users to manipulate several maps at once

The `GoogleMap` object has two flavors of a `snapshot()` method. Both take a `SnapshotReadyCallback` object. You will need to supply an instance of something implementing the `SnapshotReadyCallback` interface, overriding `onSnapshotReady()`, where you will receive your `Bitmap`.

One flavor of `snapshot()` takes just the `SnapshotReadyCallback`; the other also takes a `Bitmap` of the proper dimensions, such as a previous snapshot `Bitmap` that you

want to recycle. Using the latter `snapshot()` is recommended where possible, so you do not need to allocate new `Bitmap` objects on each `snapshot()` call.

Note that `snapshot()` will only work once the map is actually rendered. So, for example, calling `snapshot()` from `onCreate()` of your activity will fail, because the map has not been rendered yet. `snapshot()` is designed to be called based upon user input, either to manually capture a snapshot or based on navigation (e.g., tapping on a `ListView` item triggers saving a snapshot of the current map as a thumbnail before changing the map contents).

Also, the documentation for `snapshot()` contains the following:

**Note:** Images of the map must not be transmitted to your servers, or otherwise used outside of the application. If you need to send a map to another application or user, send data that allows them to reconstruct the map for the new user instead of a snapshot.

As this statement may be tied to the terms and conditions of your use of Maps V2, you should talk with qualified legal counsel before:

- Saving a snapshot to external storage
- Sharing a snapshot via `ACTION_SEND`
- Sending a snapshot to your server

or similar operations.

## SupportMapFragment vs. MapView

So far, all the examples shown in this chapter use `SupportMapFragment`. In most cases, this is the right thing to use.

However, there may be places where you really want to use a `View`, rather than a `Fragment`, for your maps.

The good news is that Maps V2 does have a `MapView`. `SupportMapFragment` usually handles creating and managing the `MapView` for you, but you can, if you wish, avoid `SupportMapFragment` and manage the `MapView` yourself.

The biggest limitation is that you need to forward the lifecycle methods from your activity or fragment on to the `MapView`, calling `onCreate()`, `onResume()`, `onPause()`, `onDestroy()`, and `onSaveInstanceState()` on the `MapView`. Normally,

SupportMapFragment would do that for you, saving you the trouble.

Also note that while MapView is a ViewGroup, you are not allowed to add child widgets to it.

## About That AbstractMapActivity Class...

Early on, we hand-waved our way past the AbstractMapActivity that all of our MainActivity classes inherit from, and we skirted past the readyToGo() method that we were calling. Also, you may have noticed that our app has an action bar overflow item, that we do not seem to be creating in MainActivity.

Now, it is time to dive into what is going on in our AbstractMapActivity implementations.

The readyToGo() method in AbstractMapActivity is designed to help us determine if Maps V2 is “ready to go” and, if not, to help the user perhaps fix their device such that Maps V2 will work in the future:

```
protected boolean readyToGo() {
    GoogleApiAvailability checker=
        GoogleApiAvailability.getInstance();

    int status=checker.isGooglePlayServicesAvailable(this);

    if (status == ConnectionResult.SUCCESS) {
        if (getVersionFromPackageManager(this)>=2) {
            return(true);
        }
        else {
            Toast.makeText(this, R.string.no_maps, Toast.LENGTH_LONG).show();
            finish();
        }
    }
    else if (checker.isUserResolvableError(status)) {
        AlertDialogFragment.newInstance(status)
            .show(getFragmentManager(),
                TAG_ERROR_DIALOG_FRAGMENT);
    }
    else {
        Toast.makeText(this, R.string.no_maps, Toast.LENGTH_LONG).show();
        finish();
    }
}
```

## MAPPING WITH MAPS V2

---

```
return(false);  
}
```

(from [MapsV2/Basic/app/src/main/java/com/commonsware/android/mapsv2/basic/AbstractMapActivity.java](https://android.googlesource.com/platform/cts/+master/tests/tests/graphics/src/android/opengl/cts/OpenGlEsVersionTest.java))

Determining the availability of Maps V2 — or anything in the Play Services SDK — is handled through an instance of `GoogleApiAvailability`. You get a singleton instance of this class via its static `getInstance()` method.

First, we call `isGooglePlayServicesAvailable()` method on the `GoogleApiAvailability` singleton. This will return an integer indicating whether Maps V2 is available for our use or not.

If the return value is `ConnectionResult.SUCCESS` — meaning Maps V2 is indeed available to us — we check to see if OpenGL ES is version 2.0 or higher, as we did not require that in the manifest. There are a few ways in Android to check the OpenGL ES version. This sample uses some code from the Compatibility Test Suite (CTS), examining `PackageManager` to determine the major level:

```
// following from  
// https://android.googlesource.com/platform/cts/+master/tests/tests/graphics/src/android/opengl/cts/  
OpenGlEsVersionTest.java  
  
/*

 */  
  
private static int getVersionFromPackageManager(Context context) {  
    PackageManager packageManager=context.getPackageManager();  
    FeatureInfo[] featureInfos=  
        packageManager.getSystemAvailableFeatures();  
    if (featureInfos != null && featureInfos.length > 0) {  
        for (FeatureInfo featureInfo : featureInfos) {  
            // Null feature name means this feature is the open  
            // gl es version feature.  
            if (featureInfo.name == null) {  
                if (featureInfo.reqGlEsVersion != FeatureInfo.GL_ES_VERSION_UNDEFINED) {  
                    return getMajorVersion(featureInfo.reqGlEsVersion);  
                }  
            }  
        }  
    }  
}
```

## MAPPING WITH MAPS V2

---

```
        else {
            return 1; // Lack of property means OpenGL ES
                    // version 1
        }
    }
}
return 1;
}

/** @see FeatureInfo#getGLesVersion() */
private static int getMajorVersion(int glEsVersion) {
    return((glEsVersion & 0xffff0000) >> 16);
}
```

(from [MapsV2/Basic/app/src/main/java/com/commonware/android/mapsv2/basic/AbstractMapActivity.java](#))

If the major version is 2 or higher, we return true from `readyToGo()`, so `MainActivity` knows to continue on setting up the map. If the major version is 1, we display a `Toast` — a production-grade app would do something else to let the user know of the problem, most likely.

But, what if `isGooglePlayServicesAvailable()` returns something else?

There are two major possibilities here:

1. The error is something that the user might be able to rectify, such as by downloading the Google Play Services app from the Play Store
2. The error is something that the user cannot recover from

We can distinguish these two cases by calling `isUserResolvableError()` on the `GoogleApiAvailability` singleton, passing in the value we received from `isGooglePlayServicesAvailable()`. This will return true if the user might be able to fix the problem, false otherwise.

In the false case, the user is just out of luck, so we display a `Toast` to alert them of this fact, then `finish()` the activity and return false, so `MainActivity` skips over the rest of its work.

In the true case, we can display something to the user to prompt them to fix the problem. One way to do that is to use a dialog obtained from Google code, by calling the static `getErrorDialog()` method on a `GoogleApiAvailability` singleton. In our case, we wrap that in a `DialogFragment` named `ErrorDialogFragment`, implemented as a static inner class of `AbstractMapActivity`:

```
public static class ErrorDialogFragment extends DialogFragment {
    static final String ARG_ERROR_CODE="errorCode";
}
```

## MAPPING WITH MAPS V2

---

```
static AlertDialogFragment newInstance(int errorCode) {
    Bundle args=new Bundle();
    AlertDialogFragment result=new AlertDialogFragment();

    args.putInt(ARG_ERROR_CODE, errorCode);
    result.setArguments(args);

    return(result);
}

@Override
public Dialog onCreateDialog(Bundle savedInstanceState) {
    Bundle args=getArguments();
    GoogleApiAvailability checker=
        GoogleApiAvailability.getInstance();

    return(checker.getErrorDialog(getActivity(),
        args.getInt(ARG_ERROR_CODE), 0));
}

@Override
public void onDismiss(DialogInterface dlg) {
    if (getActivity()!=null) {
        getActivity().finish();
    }
}
}
```

(from [MapsV2/Basic/app/src/main/java/com/commonsware/android/mapsv2/basic/AbstractMapActivity.java](#))

While the code and comments around `getErrorDialog()` suggest that there is some way for us to find out if the user performed actions that fix the problem, this code does not seem to work well in practice. After all, downloading Google Play Services is asynchronous, so even if the user returns to our app, it is entirely likely that Maps V2 is still unavailable. As a result, when the user is done with the dialog, we `finish()` the activity, forcing the user to start it again if and when they are done downloading Google Play Services.

Testing this code requires an older device, one in which the “Google Play services” app can be uninstalled... if it can be installed at all.

As it turns out, not all Android devices support the Play Store, or the Google Play Services by extension. Notably, if the device [lacks the Play Store](#), `isUserRecoverableError()` returns true, even though the user cannot recover from

this situation (except perhaps via a firmware update).

(An earlier problem where `getErrorDialog()` [could return null](#) even for cases where the error is supposedly user-recoverable has been fixed)

## Helper Libraries for Maps V2

Many developers have been busy writing libraries that help in the development of Maps V2 applications, beyond Google's own utility library mentioned in [the section on animating markers](#).

## MAPPING WITH MAPS V2

---

Perhaps the most expansive of these is [the Android Maps Extensions library](#). The big thing that this library offers is marker clustering, where as the user zooms out, individual markers are replaced by a marker representing a cluster, so you avoid flooding a small area with too many individual markers:

*Figure 576: Map with Many Markers (from Android Maps Extensions demo app)*

## MAPPING WITH MAPS V2

---

*Figure 577: Same Map with Cluster Markers (from Android Maps Extensions demo app)*

## MAPPING WITH MAPS V2

---

This library wraps the Maps V2 classes, allowing the library to offer extensions to the standard Maps V2 API, including:

- Associating your own data with Marker, Polygon, Polyline, and other classes, to tie them back to your models
- Getters to retrieve previously-defined markers, etc.
- Etc.

Another library offering marker clustering is [clusterkraf](#), from Two Toasters.

The clusterkraf library can optionally integrate with [Cyril Mottier's Polaris2 library](#). His original Polaris library aimed to provide more features to Maps V1; Polaris2 fills a similar role for Maps V2. At this time, Polaris2 is a smaller library, simply because Maps V2 handles much of what Polaris provided. Polaris2, like Android Maps Extensions, wraps the Maps V2 API with its own classes, in lieu of subclassing (since most Maps V2 classes are marked `final`). Of note, Polaris2 offers `reset()` methods on many of the `Options` classes (e.g., `MarkerOptions`), and offers constants for the minimum and maximum valid latitude and longitude.

## Problems with Maps V2 at Runtime

Portions of the logic that powers your Maps V2 `SupportMapFragment` are supplied by the Google Play Services app. As a result, many operations with Maps V2, such as manipulating markers, require IPC calls between your app and Google Play Services. If those IPC calls are synchronous, they will add a bit of overhead to your app — enough that you will want to avoid them in time-critical pieces of code, tight loops, and the like.

## Problems with Maps V2 Deployment

Of course, the key question is: should you be using Maps V2 at all?

Google thinks so, as they have [turned off access to new API keys for Maps V1](#). That makes ongoing development of Maps V1 solutions a bit risky, as you cannot create new API keys for new signing keys, such as if you need to replace your debug keystore.

However, Maps V2 has some deployment limitations at this time. While 99.8+% of Android devices that have the Play Store have the requisite OpenGL ES 2.0+, some devices that have a suitable OpenGL ES version may not have the Play Store or otherwise be unable to get Google Play Services, required for using Maps V2. The `isGooglePlayServicesAvailable()` approach advocated by Google can help determine this at runtime, though this approach used to have some bugs, and it still cannot always help you recover from this problem.

And, as the next section illustrates, not every Android device supports Maps V2, because not every device supports Google Play Services.

## What Non-Compliant Devices Show

If your app tries to bring up Maps V2 on a device that cannot possibly have the Play Services Framework — such as a Kindle Fire — the user will see an error dialog:

*Figure 579: Maps V2 Error on Kindle Fire*

For those devices, you will need to consider some alternative source of maps.

## Mapping Alternatives

Beyond using Maps V2 or Maps V1, you may need to consider other mapping alternatives. The Google mapping APIs are only available on Android devices that have the Maps SDK add-on (Maps V1) or Google Play Services (Maps V2). Not all devices have those. And, the limitations of Maps V2 deployment and the deprecation of Maps V1 may convince you that relying upon Google for maps is not safe at the present time.

The most common native replacement for Google’s mapping is [OpenStreetMap](#), which to some extent is “the Wikipedia of maps”. [OSMDroid](#) is a library that provides a Maps V1-ish API for embedding OpenStreetMap-based maps into your application.

Another solution is to integrate Web-based Google maps into your app, the same way that you might embed them into your Web site. An activity hosting a WebView can display a Web-based Google Map, for example.

Certain devices may have access to other native mapping solutions. For example, Amazon has published [their own maps API](#) for use with the Kindle Fire.

# Crafting Your Own Views

---

One of the classic forms of code reuse is the GUI widget. Since the advent of Microsoft Windows — and, to some extent, even earlier — developers have been creating their own widgets to extend an existing widget set. These range from 16-bit Windows “custom controls” to 32-bit Windows OCX components to the innumerable widgets available for Java Swing and SWT, and beyond. Android lets you craft your own widgets as well, such as extending an existing widget with a new UI or new behaviors.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## Pick Your Poison

You have five major options for creating a custom `View` class.

First, your “custom `View` class” might really only be custom `Drawable` resources. Many widgets can adopt a radically different look and feel just with replacement graphics. For example, you might think that these toggle buttons from the Android 2.1 Google Maps application are some fancy custom widget:

*Figure 580: Google Maps navigation toggle buttons*

In reality, those are just radio buttons with replacement images.

Second, your custom View class might be a simple subclass of an existing widget, where you override some behaviors or otherwise inject your own logic. Unfortunately, most of the built-in Android widgets are not really designed for this sort of simple subclassing, so you may be disappointed in how well this particular technique works.

Third, your custom View class might be a composite widget — akin to an activity's contents, complete with layout and such, but encapsulated in its own class. This allows you to create something more elaborate than you will just by tweaking resources. We will see this later in the chapter with `ColorMixer`.

Fourth, you might want to implement your own layout manager, if your GUI rules do not fit well with `RelativeLayout`, `TableLayout`, or other built-in containers. For example, you might want to create a layout manager that more closely mirrors the “box model” approach taken by XUL and Flex, or you might want to create one that mirrors Swing's `FlowLayout` (laying widgets out horizontally until there is no more room on the current row, then start a new row).

Finally, you might want to do something totally different, where you need to draw the widget yourself. For example, the `ColorMixer` widget uses `SeekBar` widgets to control the mix of red, blue, and green. But, you might create a `ColorWheel` widget that draws a spectrum gradient, detects touch events, and lets the user pick a color that way.

Some of these techniques are fairly simple; others are fairly complex. All share some common traits, such as widget-defined attributes, that we will see throughout the remainder of this chapter.

## Colors, Mixed How You Like Them

The classic way for a user to pick a color in a GUI is to use a color wheel like this one:

*Figure 581: Color Wheel*

However, a color wheel like that is difficult to manipulate on a touch screen, particularly a capacitive touchscreen designed for finger input. Fingers are great for gross touch events and lousy for selecting a particular color pixel.

Another approach is to use a mixer, with sliders to control the red, green, and blue values:

Figure 582: The ColorMixer widget, inside an activity

That is the custom widget you will see in this section, based on the code in the [Views/ColorMixer](#) sample project.

### The Layout

ColorMixer is a composite widget, meaning that its contents are created from other widgets and containers. Hence, we can use a layout file to describe what the widget should look like.

The layout to be used for the widget is not that much: three SeekBar widgets (to control the colors), three TextView widgets (to label the colors), and one plain View (the “swatch” on the left that shows what the currently selected color is). Here is the file, found in `res/layout/mixer.xml` in the Views/ColorMixer project:

```
<?xml version="1.0" encoding="utf-8"?>
<merge xmlns:android="http://schemas.android.com/apk/res/android">
  <View android:id="@+id/swatch">
```

```
    android:layout_width="40dip"
    android:layout_height="40dip"
    android:layout_alignParentLeft="true"
    android:layout_centerVertical="true"
    android:layout_marginLeft="4dip"
  />
  <TextView android:id="@+id/redLabel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/swatch"
    android:layout_toRightOf="@id/swatch"
    android:layout_marginLeft="4dip"
    android:text="@string/red"
    android:textSize="24sp"
  />
  <SeekBar android:id="@+id/red"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/redLabel"
    android:layout_toRightOf="@id/redLabel"
    android:layout_marginLeft="4dip"
    android:layout_marginRight="8dip"
  />
  <TextView android:id="@+id/greenLabel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_below="@id/redLabel"
    android:layout_toRightOf="@id/swatch"
    android:layout_marginLeft="4dip"
    android:layout_marginTop="4dip"
    android:text="@string/green"
    android:textSize="24sp"
  />
  <SeekBar android:id="@+id/green"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/greenLabel"
    android:layout_toRightOf="@id/greenLabel"
    android:layout_marginLeft="4dip"
    android:layout_marginRight="8dip"
  />
  <TextView android:id="@+id/blueLabel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_below="@id/greenLabel"
    android:layout_toRightOf="@id/swatch"
    android:layout_marginLeft="4dip"
    android:layout_marginTop="4dip"
```

---

## CRAFTING YOUR OWN VIEWS

---

```
    android:text="@string/blue"
    android:textSize="24sp"
  />
  <SeekBar android:id="@+id/blue"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/blueLabel"
    android:layout_toRightOf="@id/blueLabel"
    android:layout_marginLeft="4dip"
    android:layout_marginRight="8dip"
  />
</merge>
```

(from [Views/ColorMixer/app/src/main/res/layout/mixer.xml](#))

One thing that is a bit interesting about this layout, though, is the root element: `<merge>`. A `<merge>` layout is a bag of widgets that can be poured into some other container. The layout rules on the children of `<merge>` are then used in conjunction with whatever container they are added to. As we will see shortly, `ColorMixer` itself inherits from `RelativeLayout`, and the children of the `<merge>` element will become children of `ColorMixer` in Java. Basically, the `<merge>` element is only there because XML files need a single root — otherwise, the `<merge>` element itself is ignored in the layout.

### The Attributes

Widgets usually have attributes that you can set in the XML file, such as the `android:src` attribute you can specify on an `ImageButton` widget. You can create your own custom attributes that can be used in your custom widget, by creating a `res/values/attrs.xml` file containing `declare-styleable` resources to specify them.

For example, here is the attributes file for `ColorMixer`:

```
<resources>
  <declare-styleable name="ColorMixer">
    <attr name="initialColor" format="color" />
  </declare-styleable>
</resources>
```

(from [Views/ColorMixer/app/src/main/res/values/attrs.xml](#))

The `declare-styleable` element describes what attributes are available on the widget class specified in the `name` attribute — in our case, `ColorMixer`. Inside

`declare-styleable` you can have one or more `attr` elements, each indicating the name of an attribute (e.g., `initialColor`) and what data format the attribute has (e.g., `color`). The data type will help with compile-time validation and in getting any supplied values for this attribute parsed into the appropriate type at runtime.

Here, we indicate there is only one attribute: `initialColor`, which will hold the initial color we want the mixer set to when it first appears.

There are many possible values for the `format` attribute in an `attr` element, including:

1. `boolean`
2. `color`
3. `dimension`
4. `float`
5. `fraction`
6. `integer`
7. `reference` (which means a reference to another resource, such as a `Drawable`)
8. `string`

You can even support multiple formats for an attribute, by separating the values with a pipe (e.g., `reference|color`).

### The Class

Our `ColorMixer` class, a subclass of `RelativeLayout`, will take those attributes and provide the actual custom widget implementation, for use in activities.

### Constructor Flavors

A `View` has three possible constructors:

1. One takes just a `Context`, which usually will be an `Activity`
2. One takes a `Context` and an `AttributeSet`, the latter of which represents the attributes supplied via layout XML
3. One takes a `Context`, an `AttributeSet`, and the default style to apply to the attributes

If you are expecting to use your custom widget in layout XML files, you will need to implement the second constructor and chain to the superclass. If you want to use

---

## CRAFTING YOUR OWN VIEWS

---

styles with your custom widget when declared in layout XML files, you will need to implement the third constructor and chain to the superclass. If you want developers to create instances of your View class in Java code directly, you probably should implement the first constructor and, again, chain to the superclass.

In the case of `ColorMixer`, all three constructors are implemented, eventually routing to the three-parameter edition, which initializes our widget. Below, you will see the first two of those constructors, with the third coming up in the next section:

```
public ColorMixer(Context context) {
    this(context, null);
}

public ColorMixer(Context context, AttributeSet attrs) {
    this(context, attrs, 0);
}
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](#))

### Using the Attributes

The `ColorMixer` has a starting color — after all, the `SeekBar` widgets and `swatch View` have to show something. Developers can, if they wish, set that color via a `setColor()` method:

```
public void setColor(int color) {
    red.setProgress(Color.red(color));
    green.setProgress(Color.green(color));
    blue.setProgress(Color.blue(color));
    swatch.setBackgroundColor(color);
}
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](#))

If, however, we want developers to be able to use layout XML, we need to get the value of `initialColor` out of the supplied `AttributeSet`. In `ColorMixer`, this is handled in the three-parameter constructor:

```
public ColorMixer(Context context, AttributeSet attrs, int defStyle) {
    super(context, attrs, defStyle);

    ((Activity)getContext())
        .getLayoutInflater()
        .inflate(R.layout.mixer, this, true);
}
```

## CRAFTING YOUR OWN VIEWS

---

```
swatch=findViewById(R.id.swatch);

red=(SeekBar)findViewById(R.id.red);
red.setMax(0xFF);
red.setOnSeekBarChangeListener(onMix);

green=(SeekBar)findViewById(R.id.green);
green.setMax(0xFF);
green.setOnSeekBarChangeListener(onMix);

blue=(SeekBar)findViewById(R.id.blue);
blue.setMax(0xFF);
blue.setOnSeekBarChangeListener(onMix);

if (attrs!=null) {
    TypedArray a=getContext()
                .obtainStyledAttributes(attrs,
                                        R.styleable.ColorMixer,
                                        0, 0);

    setColor(a.getInt(R.styleable.ColorMixer_initialColor,
                    0xFFA4C639));
    a.recycle();
}
}
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](https://github.com/commonsware/android-colormixer/blob/master/Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java))

There are three steps for getting attribute values:

- Get a TypedArray conversion of the AttributeSet by calling `obtainStyledAttributes()` on our Context, supplying it the AttributeSet and the ID of our styleable resource (in this case, `R.styleable.ColorMixer`, since we set the name of the declare-styleable element to be `ColorMixer`)
- Use the TypedArray to access specific attributes of interest, by calling an appropriate getter (e.g., `getInt()`) with the ID of the specific attribute to fetch (`R.styleable.ColorMixer_initialColor`)
- Recycle the TypedArray when done, via a call to `recycle()`, to make the object available to Android for use with other widgets via an object pool (versus creating new instances every time)

Note that the name of any given attribute, from the standpoint of TypedArray, is the name of the styleable resource (`R.styleable.ColorMixer`) concatenated with an underscore and the name of the attribute itself (`_initialColor`).

---

## CRAFTING YOUR OWN VIEWS

---

In `ColorMixer`, we get the attribute and pass it to `setColor()`. Since `getInt()` on `AttributeSet` takes a default value, we supply some stock color that will be used if the developer declined to supply an `initialColor` attribute.

Also note that our `ColorMixer` constructor inflates the widget's layout. In particular, it supplies `true` as the third parameter to `inflate()`, meaning that the contents of the layout should be added as children to the `ColorMixer` itself. When the layout is inflated, the `<merge>` element is ignored, and the `<merge>` element's children are added as children to the `ColorMixer`.

### Saving the State

Similar to activities, a custom `View` overrides `onSaveInstanceState()` and `onRestoreInstanceState()` to persist data as needed, such as to handle a screen orientation change. The biggest difference is that rather than receive a `Bundle` as a parameter, `onSaveInstanceState()` must return [a Parcelable](#) with its state... including whatever state comes from the parent `View`.

The simplest way to do that is to return a `Bundle`, in which we have filled in our state (the chosen color) and the parent class' state (whatever that may be).

So, for example, here are implementations of `onSaveInstanceState()` and `onRestoreInstanceState()` from `ColorMixer`:

```
@Override
public Parcelable onSaveInstanceState() {
    Bundle state=new Bundle();

    state.putParcelable(SUPERSTATE, super.onSaveInstanceState());
    state.putInt(COLOR, getColor());

    return(state);
}

@Override
public void onRestoreInstanceState(Parcelable ss) {
    Bundle state=(Bundle)ss;

    super.onRestoreInstanceState(state.getParcelable(SUPERSTATE));

    setColor(state.getInt(COLOR));
}
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](#))

### The Rest of the Functionality

ColorMixer defines a callback interface, named `OnColorChangeListener`:

```
public interface OnColorChangeListener {
    public void onColorChange(int argb);
}
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](#))

ColorMixer also provides getters and setters for an `OnColorChangeListener` object:

```
public OnColorChangeListener getOnColorChangeListener() {
    return(listener);
}

public void setOnColorChangeListener(OnColorChangeListener listener) {
    this.listener=listener;
}
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](#))

The rest of the logic is mostly tied up in the `SeekBar` handler, which will adjust the swatch based on the new color and invoke the `OnColorChangeListener` object, if there is one:

```
private SeekBar.OnSeekBarChangeListener onMix=new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar, int progress,
        boolean fromUser) {
        int color=getColor();

        swatch.setBackgroundColor(color);

        if (listener!=null) {
            listener.onColorChange(color);
        }
    }

    public void onStartTrackingTouch(SeekBar seekBar) {
        // unused
    }

    public void onStopTrackingTouch(SeekBar seekBar) {
        // unused
    }
};
```

(from [Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java](#))

### Seeing It In Use

The project contains a sample activity, `ColorMixerDemo`, that shows the use of the `ColorMixer` widget.

The layout for that activity, shown below, can be found in `res/layout/main.xml` of the `Views/ColorMixer` project:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:mixer="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="vertical"
  >
  <TextView android:id="@+id/color"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
  />
  <com.commonsware.android.colormixer.ColorMixer
    android:id="@+id/mixer"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    mixer:initialColor="#FFA4C639"
  />
</LinearLayout>
```

(from [Views/ColorMixer/app/src/main/res/layout/main.xml](#))

Notice that the root `LinearLayout` element defines two namespaces, the standard `android` namespace, and a separate one named `mixer`. The `mixer` namespace is given a URL of `http://schemas.android.com/apk/res-auto`, which indicates to the Android build system to match up `mixer` attributes with their respective widgets that are supplied via Android library projects.

Our `ColorMixer` widget is in the layout, with a fully-qualified class name (`com.commonsware.android.colormixer.ColorMixer`), since `ColorMixer` is not in the `android.widget` package. Notice that we can treat our custom widget like any other, giving it a width and height and so on.

The one attribute of our `ColorMixer` widget that is unusual is `mixer:initialColor`. `initialColor`, you may recall, was the name of the attribute we declared in `res/values/attrs.xml` and retrieve in Java code, to represent the color to start with. The `mixer` namespace is needed to identify where Android should be pulling the rules

---

## CRAFTING YOUR OWN VIEWS

---

for what sort of values an `initialColor` attribute can hold. Since our `<attr>` element indicated that the format of `initialColor` was `color`, Android will expect to see a color value here, rather than a string or dimension.

The `ColorMixerDemo` activity is not very elaborate:

```
package com.commonware.android.colormixer;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;

public class ColorMixerDemo extends Activity {
    private TextView color=null;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        color=findViewById(R.id.color);

        ColorMixer mixer=findViewById(R.id.mixer);

        mixer.setOnColorChangeListener(onColorChange);
    }

    private ColorMixer.OnColorChangeListener onColorChange=
        new ColorMixer.OnColorChangeListener() {
            public void onColorChange(int argb) {
                color.setText(Integer.toHexString(argb));
            }
        };
}
```

(from [Views/ColorMixer/app/src/main/java/com/commonware/android/colormixer/ColorMixerDemo.java](#))

It gets access to both the `ColorMixer` and the `TextView` in the main layout, then registers an `OnColorChangeListener` with the `ColorMixer`. That listener, in turn, puts the value of the color in the `TextView`, so the user can see the hex value of the color along with the shade itself in the swatch.

## ReverseChronometer: Simply a Custom Subclass

Sometimes, what you want to achieve only requires a basic subclass of an existing

## CRAFTING YOUR OWN VIEWS

---

widget (or container), into which you can pour your business logic.

For example, Android has a `Chronometer` widget, which is used for denoting elapsed time of some operation. It works well, but it only counts up from zero. It cannot be used to display a countdown instead.

But, we can roll a `ReverseChronometer` that does, simply by subclassing `TextView`, as seen in the [Views/ReverseChronometer](#) sample project:

```
package com.commonware.android.revchron;

import android.content.Context;
import android.graphics.Color;
import android.os.SystemClock;
import android.util.AttributeSet;
import android.widget.TextView;

public class ReverseChronometer extends TextView implements Runnable {
    long startTime=0L;
    long overallDuration=0L;
    long warningDuration=0L;

    public ReverseChronometer(Context context, AttributeSet attrs) {
        super(context, attrs);

        reset();
    }

    @Override
    public void run() {
        long elapsedSeconds=
            (SystemClock.elapsedRealtime() - startTime) / 1000;

        if (elapsedSeconds < overallDuration) {
            long remainingSeconds=overallDuration - elapsedSeconds;
            long minutes=remainingSeconds / 60;
            long seconds=remainingSeconds - (60 * minutes);

            setText(String.format("%d:%02d", minutes, seconds));

            if (warningDuration > 0 && remainingSeconds < warningDuration) {
                setTextColor(0xFFFF6600); // orange
            }
            else {
                setTextColor(Color.BLACK);
            }
        }
    }
}
```

```
        postDelayed(this, 1000);
    }
    else {
        setText("0:00");
        setTextColor(Color.RED);
    }
}

public void reset() {
    startTime=SystemClock.elapsedRealtime();
    setText("--:--");
    setTextColor(Color.BLACK);
}

public void stop() {
    removeCallbacks(this);
}

public void setOverallDuration(long overallDuration) {
    this.overallDuration=overallDuration;
}

public void setWarningDuration(long warningDuration) {
    this.warningDuration=warningDuration;
}
}
```

(from [Views/ReverseChronometer/app/src/main/java/com/commonsware/android/revchron/ReverseChronometer.java](https://github.com/commonsware/android-revchron/blob/master/ReverseChronometer.java))

ReverseChronometer is designed to show minutes and seconds remaining from some initial time. In the constructor, by means to a call to a `reset()` method, we set the text of the `TextView` to show a generic starting point (“--:--”), set its color to black, and note the current time (`SystemClock.elapsedRealtime()`) in a `startTime` data member.

ReverseChronometer also tracks two durations in seconds, with corresponding setter methods:

- `overallDuration` is how long the countdown should run from beginning to end
- `warningDuration` is how far from the end we should change the color of the `TextView` from black to orange, to hint to the viewer that time is running out

ReverseChronometer implements `Runnable`, and when its `run()` method is called, it

## CRAFTING YOUR OWN VIEWS

---

determines how many seconds have elapsed since that `startTime` value. Depending on the amount of seconds remaining, we either:

- Just update the text to show the minutes and seconds remaining
- Update the text and set the color to black or orange
- Set the text to “0:00” (time has run out) and set the text color to red

In either of the first two cases, we also call `postDelayed()` to schedule ourselves to run again in a second, where we can update the `TextView` contents once more. That continues until somebody calls `stop()`.

As with any custom `View`, we can reference this in a layout XML resource, fully-qualifying the class name used as the name of our XML element for the widget. And, since we inherit from `TextView`, we can set any of the attributes that we want on that `TextView`, in terms of styling the text, positioning it within a parent container, etc.:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    tools:context=".MainActivity">

    <com.commonsware.android.revchron.ReverseChronometer
        android:id="@+id/chrono"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerInParent="true"
        android:textSize="50sp"
        android:textStyle="bold"/>

</RelativeLayout>
```

(from [Views/ReverseChronometer/app/src/main/res/layout/activity\\_main.xml](#))

All our activity needs to do is set the durations, then call `run()` and `stop()` at appropriate times, such as when the activity is resumed and paused:

```
package com.commonsware.android.revchron;

import android.app.Activity;
import android.os.Bundle;

public class MainActivity extends Activity {
    private ReverseChronometer chrono=null;
```

## CRAFTING YOUR OWN VIEWS

---

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    chrono=(ReverseChronometer)findViewById(R.id.chrono);
    chrono.setOverallDuration(90);
    chrono.setWarningDuration(10);
}

@Override
public void onResume() {
    super.onResume();

    chrono.run();
}

@Override
public void onPause() {
    chrono.stop();

    super.onPause();
}
}
```

(from [Views/ReverseChronometer/app/src/main/java/com/commonsware/android/revchron/MainActivity.java](#))

The result is much as you would expect: a countdown of the time remaining:

*Figure 583: ReverseChronometer, Early in Countdown*

...changing to orange when we are within the warning duration:

...and changing to red when time has run out:

*Figure 585: ReverseChronometer, With Complete Time Elapsed*

Of course, much more could be done with this widget, if you chose:

- Support other constructors, beyond the two-argument constructor needed for layout inflation
- Support setting durations and colors via custom XML attributes
- Adding listeners for warning and expired events, so other things can be done at those points in time (e.g., play a sound, vibrate the device)

## AspectRatioLockedFrameLayout: A Custom Container

You can also craft your own custom container classes, whether inheriting straight from `ViewGroup` to implement your own set of layout rules, or by extending an existing `ViewGroup` to merely augment its functionality.

For example, there may be cases where you want to control the aspect ratio of some set of widgets. This is important when working with preview frames off of the Camera to prevent distortion, for example.

## CRAFTING YOUR OWN VIEWS

---

AspectLockedFrameLayout, therefore, is a custom extension of FrameLayout that ensures that its contents are kept within a particular aspect ratio, reducing the height or width of the contents to keep that aspect ratio.

AspectLockedFrameLayout is published as part of the CWAC-Layouts project, with [its own GitHub repo](#). As with many of the CWAC projects, the reusable code is distributed as a JAR and as an Android library project, with a demo/ sub-project illustrating the use of some of the library's contents.

AspectLockedFrameLayout holds onto two data members:

- A double (aspectRatio) that represents a specific aspect ratio to maintain, initialized to 0.0
- A View (aspectRatioSource) that represents some other widget whose aspect ratio should be matched, initialized to null

AspectLockedFrameLayout has corresponding setters for each:

```
        lockedHeight=(int)(lockedWidth / localRatio + .5);
    }

    // Add the padding of the border.
    lockedWidth+=hPadding;
    lockedHeight+=vPadding;

    // Ask children to follow the new preview dimension.
    super.onMeasure(MeasureSpec.makeMeasureSpec(lockedWidth,
                                                MeasureSpec.EXACTLY),
                   MeasureSpec.makeMeasureSpec(lockedHeight,
                                                MeasureSpec.EXACTLY));
    }
}

/**
 * Supplies a View as a source. The AspectLockedFrameLayout will aim to
 * match the aspect ratio of this View. This is a one-time check; if the
 * View changes its aspect ratio later, the AspectLockedFrameLayout will
 * not attempt to match it.
 *
 * @param v some View
 */
```

The “business logic” of maintaining the aspect ratio comes in onMeasure(). onMeasure() is called on a ViewGroup when it is time for it to determine its actual size, based upon things like the requested height and width and the sizes of its

## CRAFTING YOUR OWN VIEWS

---

children. In our case `onMeasure()` needs to be tweaked to maintain the aspect ratio, assuming that we have an aspect ratio to work with:

```
}

/**
 * {@inheritDoc}
 */
public AspectLockedFrameLayout(Context context, AttributeSet attrs) {
    super(context, attrs);
}

// from com.android.camera.PreviewFrameLayout, with slight
// modifications

/**
 * {@inheritDoc}
 */
@Override
protected void onMeasure(int widthSpec, int heightSpec) {
    double localRatio=aspectRatio;

    if (localRatio == 0.0 && aspectRatioSource != null
        && aspectRatioSource.getHeight() > 0) {
        localRatio=
            (double)aspectRatioSource.getWidth()
                / (double)aspectRatioSource.getHeight();
    }

    if (localRatio == 0.0) {
        super.onMeasure(widthSpec, heightSpec);
    }
    else {
        int lockedWidth=MeasureSpec.getSize(widthSpec);
        int lockedHeight=MeasureSpec.getSize(heightSpec);

        if (lockedWidth == 0 && lockedHeight == 0) {
            throw new IllegalArgumentException(
                "Both width and height cannot be zero -- watch out for
scrollable containers");
        }

        // Get the padding of the border background.
        int hPadding=getPaddingLeft() + getPaddingRight();
        int vPadding=getPaddingTop() + getPaddingBottom();

        // Resize the preview frame with correct aspect ratio.
        lockedWidth-=hPadding;
        lockedHeight-=vPadding;

        if (lockedHeight > 0 && (lockedWidth > lockedHeight * localRatio)) {
            lockedWidth=(int)(lockedHeight * localRatio + .5);
        }
    }
}
```

We start by determining what actually is the desired aspect ratio, held onto in a `localRatio` local variable. That will be `aspectRatio` if we do not have an `aspectRatioSource` that already knows its size, otherwise we will calculate the

aspect ratio from the source. And, if `localRatio` turns out to be `0.0`, indicating that we do not have an aspect ratio to maintain, we just chain to the superclass, so `AspectRatioLockedFrameLayout` will behave just like a normal `FrameLayout`.

If we *do* have an aspect ratio to maintain, we start by determining our requested height and width. `onMeasure()` is passed a pair of “specs” that provides details about our requested size, and we can get the height and width from those by means of the `MeasureSpec` helper class. We remove any horizontal padding — padding is considered to be “outside” the locked area and therefore is ignored in aspect ratio calculations. We then adjust the height or the width, as needed, to maintain the aspect ratio. We add back in the padding, then chain to the superclass with revised height and width “specs” via `MeasureSpec`.

Note that much of this logic was derived from `com.android.camera.PreviewFrameLayout` from the AOSP Camera application, which is used to maintain the aspect ratio of the `SurfaceView` used to display preview frames.

To use an `AspectRatioLockedFrameLayout`, just add it to your layout XML file, with an appropriate child widget/container representing the material that needs to maintain a particular aspect ratio. Since the `AspectRatioLockedFrameLayout` is overriding its natural size, you can use `android:layout_gravity` to control its positioning within some parent widget, such as centering it:

```
<FrameLayout
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <com.commonware.cwac.layouts.AspectLockedFrameLayout
        android:id="@+id/source"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_gravity="center">

        <!-- children go here -->
    </com.commonware.cwac.layouts.AspectLockedFrameLayout>
</FrameLayout>
```

## Mirror and MirroringFrameLayout: Draw It Yourself

Another scenario where aspect ratios matter is when you are presenting information on an external display via `Presentation`, as is covered [elsewhere in this book](#).

Ideally, you fill the external display. And normally this will happen for you automatically, as your `Presentation` content view should fill the available screen space... assuming that the content has the right aspect ratio, or can be suitably stretched.

One scenario where this might be a problem is if you want *the same material* shown on both the main display and on the external display. For example, suppose that you are using `Presentation` to deliver... well... a presentation. The external display is probably some form of video projector, and you will want your slides or other materials shown there. However, it is useful for you to be able to see those same slides and such on the tablet, as typically the projector screen is behind, or to the side of, the presenter. If the presenter has to keep turning around to confirm what is shown on “the big screen”, it can detract from the presentation.

Moreover, you might not only want to *show* the same material, but have it stem *from the same source*, on the tablet, for interactivity reasons. Suppose that you want to display a Web page. You might just pop up a `WebView` in the `Presentation`. But... how do you scroll? The `Presentation` offers no touch interface — projector screens do not magically respond to pinch-to-zoom just because we happen to be projecting something onto them from an Android tablet.

In this case, ideally we would like to *mirror* something. Have the actual widgets shown on the tablet, which can then respond to touch events and the like. At the same time, capture what is shown on the tablet and reproduce it, verbatim, on the `Presentation` for the audience to see. Now everybody can see the same material, and the presenter can manipulate that material.

But now aspect ratios come into play. We want to fill the `Presentation` display space, without black bars or stretching or whatever. That only works if our source material — the widgets and containers to be mirrored — have the same aspect ratio as the `Presentation`'s `Display` itself.

With that in mind, the CWAC Layouts project also contains two classes to solve this problem:

- `MirroringFrameLayout` is an `AspectRatioFrameLayout` that also can mirror its content to...
- `Mirror`, a `View` that takes a `Bitmap` representing the `MirroringFrameLayout` contents and displays it

Technically, `MirroringFrameLayout` works with a `MirrorSink`, an interface that can

receive updates to the content to be mirrored when that content changes. Mirror implements MirrorSink, and you could have other classes implement MirrorSink as well if that made sense for your app. The sections that follow focus on MirroringFrameLayout working with a Mirror, as that is the most likely scenario.

### MirroringFrameLayout

MirroringFrameLayout extends AspectLockedFrameLayout, so that we can lock the aspect ratio of the to-be-mirrored contents to match the aspect ratio of the Mirror. The Mirror is designed to be projected by the Presentation, and so if the Mirror fills the Presentation's Display, we want our MirroringFrameLayout to match the aspect ratio so the entire Display can indeed be filled.

Of course, a ViewGroup like FrameLayout normally just has its children draw to the screen. In our case, we need to capture what is drawn ourselves, to supply to the Mirror as needed. This is a bit tricky.

```
package com.commonware.cwac.layouts;

import android.content.Context;
import android.graphics.Bitmap;
import android.graphics.Canvas;
import android.graphics.Rect;
import android.util.AttributeSet;
import android.view.ViewTreeObserver.OnPreDrawListener;
import android.view.ViewTreeObserver.OnScrollChangedListener;

/**
 * A FrameLayout that locks its aspect ratio (courtesy of AspectLockedFrameLayout)
 * and supplies "screenshots" of its contents to an associated MirrorSink,
 * such as a Mirror.
 *
 * Principally, MirroringFrameLayout and Mirror are designed for use with
 * Android's Presentation system. The MirroringFrameLayout would be part of the
 * UI of the activity on the mobile device, allowing for user interaction. The
 * Mirror would be used in the Presentation to show an audience (e.g., via a
 * projector) what is shown inside the MirroringFrameLayout on the mobile
 * device.
 */
public class MirroringFrameLayout extends AspectLockedFrameLayout
    implements OnPreDrawListener, OnScrollChangedListener {
    private MirrorSink mirror=null;
    private Bitmap bmp=null;
    private Canvas bmpBackedCanvas=null;
    private Rect rect=new Rect();

    /**
     * {@inheritDoc}
     */
    public MirroringFrameLayout(Context context) {
        this(context, null);
    }
}
```

## CRAFTING YOUR OWN VIEWS

---

```
/**
 * {@inheritDoc}
 */
public MirroringFrameLayout(Context context, AttributeSet attrs) {
    super(context, attrs);

    setWillNotDraw(false);
}

/**
 * Associate a MirrorSink; this sink will be given bitmaps representing
 * updated contents of the MirroringFrameLayout as those contents change.
 *
 * @param mirror a Mirror or other MirrorSink implementation
 */
public void setMirror(MirrorSink mirror) {
    this.mirror=mirror;

    if (mirror != null) {
        setAspectRatioSource(mirror);
    }
}

/**
 * {@inheritDoc}
 */
@Override
public void onAttachedToWindow() {
    super.onAttachedToWindow();

    getViewTreeObserver().addOnPreDrawListener(this);
    getViewTreeObserver().addOnScrollChangedListener(this);
}

/**
 * {@inheritDoc}
 */
@Override
public void onDetachedFromWindow() {
    getViewTreeObserver().removeOnPreDrawListener(this);
    getViewTreeObserver().removeOnScrollChangedListener(this);

    super.onDetachedFromWindow();
}

/**
 * {@inheritDoc}
 */
@Override
public void draw(Canvas canvas) {
    if (mirror != null) {
        bmp.eraseColor(0);

        super.draw(bmpBackedCanvas);
        getDrawingRect(rect);
        canvas.drawBitmap(bmp, null, rect, null);
        mirror.update(bmp);
    }
    else {
```

```
        super.draw(canvas);
    }
}

/**
 * {@inheritDoc}
 */
@Override
protected void onSizeChanged(int w, int h, int oldw, int oldh) {
    initBitmap(w, h);

    super.onSizeChanged(w, h, oldw, oldh);
}

/**
 * {@inheritDoc}
 */
@Override
public boolean onPreDraw() {
    if (mirror != null) {
        if (bmp == null) {
            requestLayout();
        }
        else {
            invalidate();
        }
    }

    return(true);
}

/**
 * {@inheritDoc}
 */
@Override
public void onScrollChanged() {
    onPreDraw();
}

private void initBitmap(int w, int h) {
    if (mirror != null) {
        if (bmp == null || bmp.getWidth() != w || bmp.getHeight() != h) {
            if (bmp != null) {
                bmp.recycle();
            }

            bmp=Bitmap.createBitmap(w, h, Bitmap.Config.ARGB_8888);
            bmpBackedCanvas=new Canvas(bmp);
        }
    }
}
}
```

Our one-argument constructor uses `this()` to chain to the two-argument constructor. The two-argument constructor calls `setWillNotDraw(false)` indicating to Android that we want this `ViewGroup` to participate in the drawing process like a regular `View` — normally, certain steps in the drawing process are skipped as being

irrelevant to `View` classes that do not draw anything themselves.

We have a `setMirror()` method, where the activity or fragment can supply the `MirrorSink` that is connected to this `MirroringFrameLayout`. In addition to holding onto the `MirrorSink` in a mirror data member, we call `setAspectRatioSource()`, inherited from `AspectRatioLockedFrameLayout`, so our contents will match the aspect ratio from that source.

`MirroringFrameLayout` overrides `onAttachedToWindow()` and `onDetachedFromWindow()`. As one might guess, these callbacks are called when views are attached and detached from some window. Usually, that window represents an activity, though it could represent a `Dialog` or a `Presentation`.

In those callbacks, we connect with the `ViewTreeObserver` of the `MirroringFrameLayout`. A `ViewTreeObserver` is a way to find out about events of a view tree, rooted at some `ViewGroup`. In our case, we want to find out when children are going to be drawn (`addOnPreDrawListener()`) and when they are scrolled (`addOnScrollChangeListener()`).

We override `onSizeChanged()`. This is called on any `View` when its size may have changed, either because it is being sized initially when the UI is being set up, or because something else nearby changed size (e.g., its parent) and therefore the size of the `View` itself may now be different. In our case, we use `onSizeChanged()` to set up a `Bitmap` object, sized to match our size, and a `Canvas` object that wraps around that `Bitmap` object. As you will see, we will use this `Canvas` to capture what is being drawn on the screen, for later use by the `Mirror`.

We also override `draw()`. This is, in effect, the “entry point” into the logic that causes a `View` to render itself on the screen, by drawing to a supplied `Canvas` object. Most `View` classes do not override `draw()`, as the real rendering is done in an `onDraw()` method, as we will see with `Mirror` later in this chapter. However, in our case, we have to override `draw()` for one simple reason: we do not want to draw to the `Canvas` supplied by Android to the `draw()` method. We want to draw to our own `Canvas`, backed by that `Bitmap`.

To that end, if we have a `MirrorSink`, we:

- Make sure the `Bitmap` starts off blank by calling `eraseColor()`
- Chain to the superclass, replacing the `Canvas` given to us in `draw()` by our own `Bitmap`-backed `Canvas`
- Calculate a `Rect` object with our size and position, using `getDrawingRect()`

- Use that Rect and the Bitmap to render the Bitmap to the “real” Canvas supplied to us in draw()
- Call update() on the MirrorSink, to give it the new Bitmap

By rendering our contents to the Bitmap-backed Canvas, instead of the normal one, we capture a copy of the output, in the form of the Bitmap. Since the Bitmap has the same size as the “real” Canvas (courtesy of our onSizeChanged() work), when we draw the Bitmap onto the Canvas, we effectively “color in” the same pixels in the same spots as if we had skipped all of this and left the normal draw() logic alone. But, since we still hold onto our Bitmap, we can use those same pixels elsewhere... such as in our Mirror.

The problem with relying on draw() is that it is not always called when there are changes to widgets within the MirroringFrameLayout. In particular, WebView often does not trigger draw() on the MirroringFrameLayout. That’s where the pre-draw and scroll-changed events from the ViewTreeObserver come into play: they give us more indication that we need to update our Bitmap.

The onPreDraw() method is called when a child of this MirroringFrameLayout is about to be drawn. If we have our MirrorSink, we then either call requestLayout() (if we have no bitmap yet) or invalidate() (if we do), to trigger Android to go through the draw process for the MirroringFrameLayout too, allowing us to update our Bitmap.

The onScrollChanged() method is called when a child of this MirroringFrameLayout has been scrolled. This delegates to onPreDraw(), to run through the same logic to force an update to the Bitmap.

## Mirror

Mirror extends the base View class, and so it is the most “raw” of all the custom widgets and containers shown so far in this chapter. It has an update() method, used to connect the MirroringFrameLayout from which the Mirror can obtain what it is supposed to display:

```
package com.commonware.cwac.layouts;

import android.content.Context;
import android.graphics.Bitmap;
import android.graphics.Canvas;
import android.graphics.Rect;
import android.util.AttributeSet;
```

## CRAFTING YOUR OWN VIEWS

---

```
import android.view.View;

/**
 * A View that implements MirrorSink and renders the supplied bitmaps to its
 * own contents. When connected to a MirroringFrameLayout, Mirror will aim to
 * show the same contents as is in the MirroringFrameLayout, at the same aspect
 * ratio, though possibly at a different size.
 *
 * Principally, MirroringFrameLayout and Mirror are designed for use with
 * Android's Presentation system. The MirroringFrameLayout would be part of the
 * UI of the activity on the mobile device, allowing for user interaction. The
 * Mirror would be used in the Presentation to show an audience (e.g., via a
 * projector) what is shown inside the MirroringFrameLayout on the mobile
 * device.
 */
public class Mirror extends View implements MirrorSink {
    private Rect rect=new Rect();
    private Bitmap bmp=null;

    /**
     * {@inheritDoc}
     */
    public Mirror(Context context) {
        super(context);
    }

    /**
     * {@inheritDoc}
     */
    public Mirror(Context context, AttributeSet attrs) {
        super(context, attrs);
    }

    /**
     * {@inheritDoc}
     */
    public Mirror(Context context, AttributeSet attrs, int defStyle) {
        super(context, attrs, defStyle);
    }

    /**
     * {@inheritDoc}
     */
    @Override
    public void update(Bitmap bmp) {
        this.bmp=bmp;
        invalidate();
    }
}
```

```
/**
 * {@inheritDoc}
 */
@Override
protected void onDraw(Canvas canvas) {
    super.onDraw(canvas);

    if (bmp != null) {
        getDrawingRect(rect);

        calcCenter(rect.width(), rect.height(), bmp.getWidth(),
            bmp.getHeight(), rect);
        canvas.drawBitmap(bmp, null, rect, null);
    }
}

// based upon http://stackoverflow.com/a/14679729/115145

static void calcCenter(int vw, int vh, int iw, int ih, Rect out) {
    double scale=
        Math.min((double)vw / (double)iw, (double)vh / (double)ih);

    int h=(int)(scale * ih);
    int w=(int)(scale * iw);
    int x=((vw - w) >> 1);
    int y=((vh - h) >> 1);

    out.set(x, y, x + w, y + h);
}
}
```

The bulk of the “business logic” lies in `onDraw()`, plus a helper `calcCenter()` static method.

`onDraw()` is called on a `View` when it is time for that widget to actually draw its visual representation onto the supplied `Canvas`. Different widgets will use different drawing primitive methods offered by `Canvas`, to draw lines and text and whatnot. In our case, we:

- Calculate a `Rect` object with our size and position, using `getDrawingRect()`
- Get the `Bitmap` object from the `MirroringFrameLayout`, via a call to `getLastBitmap()` (which simply returns the `Bitmap` that the `MirroringFrameLayout` is using)
- Call `calcCenter` to adjust our `Rect` to take into account the fact that our size

- may be different than the size of the actual Bitmap
- Call `drawBitmap()` on our Canvas, to render the Bitmap into the location specified by the Rect, where `drawBitmap()` will automatically down-sample or up-sample the image as needed to fill the necessary space

### Usage and Results

Normally, you would use the `Mirror` in a layout for a `Presentation` and the `MirroringFrameLayout` in an activity that controls the `Presentation`. However, it is possible to use both in the same layout file, for light testing. However, please do not put the `Mirror` inside of the `MirroringFrameLayout`, as this is likely to cause a rupture in the space-time continuum, and you really do not want to be responsible for that.

So, in the `SimpleMirrorActivity` from the `demo/` sub-project, we use a layout that has both `Mirror` and `MirroringFrameLayout`, with the latter set to mirror a `WebView`:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    tools:context=".SimpleMirrorActivity">

    <FrameLayout
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="1">

        <com.commonsware.cwac.layouts.MirroringFrameLayout
            android:id="@+id/source"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:layout_gravity="center">

            <EditText
                android:id="@+id/editor"
                android:layout_width="match_parent"
                android:layout_height="match_parent"
                android:gravity="left|top"
                android:inputType="textMultiLine"/>
        </com.commonsware.cwac.layouts.MirroringFrameLayout>
    </FrameLayout>

    <View
```

## CRAFTING YOUR OWN VIEWS

---

```
        android:layout_width="match_parent"
        android:layout_height="4dip"
        android:background="#FF000000" />

<com.commonware.cwac.layouts.Mirror
    android:id="@+id/target"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="2" />

</LinearLayout>
```

In this case, we set the background of the `FrameLayout` holding our `MirroringFrameLayout` to green, to show how the `MirroringFrameLayout` size is changed to maintain our aspect ratio.

(or, perhaps we just like green)

Besides configuring the to-be-mirrored widgets, all you need to do is call `setMirror()` on the `MirroringFrameLayout` to enable the mirroring logic:

## CRAFTING YOUR OWN VIEWS

```
package com.commonware.cwac.layouts.demo;

import android.app.Activity;
import android.os.Bundle;
import com.commonware.cwac.layouts.Mirror;
import com.commonware.cwac.layouts.MirroringFrameLayout;

public class SimpleMirrorActivity extends Activity {
    MirroringFrameLayout source=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.simple_mirror);

        source=findViewById(R.id.source);
        Mirror target=findViewById(R.id.target);

        source.setMirror(target);
    }
}
```

*Figure 586: MirroringFrameLayout Above Its Mirror*

While the bottom portion is just the Mirror and therefore is non-interactive, the top

---

## CRAFTING YOUR OWN VIEWS

---

is the real `WebView`, which can be scrolled, with the resulting changes reflected in the `Mirror` in real-time:

Figure 587: `MirroringFrameLayout` and `Mirror`, Showing Scrolled Contents

### Limitations

`MirroringFrameLayout` only works for materials drawn in the Java layer, that therefore can be drawn to the Bitmap-backed Canvas. Content *not* drawn in the Java layer will not work with `MirroringFrameLayout`, notably anything involving a `SurfaceView`. This not only includes your own `SurfaceView` widgets, but anything else that depends upon `SurfaceView`, such as `VideoView` or the Maps V2 `MapView` and `MapFragment`.

Also, the re-sampling done by `Mirror` is not especially sophisticated and will cause jagged effects, particularly when up-sampling. Ideally, the `MirroredFrameLayout` will be the same size or larger than the `Mirror`. This may not always be possible, particularly with a `Mirror` shown on a 1080p external display, but the closer you can get will improve the output.

# Advanced Preferences

---

We saw `SharedPreferences` and `PreferenceFragment` [earlier in the book](#). However, we can have more elaborate preference collection options if we wish, such as a full master-detail implementation like the Settings app sports. There are also many other common attributes on the preference XML elements that we might consider taking advantage of, such as allowing us to automatically enable and disable preferences based upon whether some other preference is checked or unchecked.

In this chapter, we will explore some of these additional capabilities in the world of Android preferences.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on `SharedPreferences`](#).

## Introducing `PreferenceActivity`

If you have a fairly simple set of preferences to collect from the user, using a single `PreferenceFragment` should be sufficient.

On the far other end of the spectrum, Android's Settings app collects a massive amount of preference values from the user. These are spread across a series of groups of preferences, known as preference headers.

While your app may not need to collect as many preferences as does the Settings app, you may need more than what could be collected easily in a single `PreferenceFragment`. In that case, you can consider adopting the same structure of

headers-and-fragments that the Settings app uses, by means of a PreferenceActivity.

To see this in action, take a look at the [Prefs/FragmentsBC](#) sample project. It is very similar to the original SharedPreferences demo app from [before](#). However, this one arranges to collect a fifth preference value, in a separate PreferenceFragment, and uses PreferenceActivity to allow access to both PreferenceFragment UI structures.

### Defining Your Preference Headers

In the master-detail approach offered by PreferenceActivity, the “master” list is a collection of preference headers. Typically, you would define these in another XML resource. In the sample project, that is found in `res/xml/preference_headers.xml`:

```
<preference-headers xmlns:android="http://schemas.android.com/apk/res/android">

  <header
    android:fragment="com.commonware.android.preffragsbc.EditPreferences$First"
    android:summary="@string/header1summary"
    android:title="@string/header1title">
  </header>
  <header
    android:fragment="com.commonware.android.preffragsbc.EditPreferences$Second"
    android:summary="@string/header2summary"
    android:title="@string/header2title">
  </header>

</preference-headers>
```

(from [Prefs/FragmentsBC/app/src/main/res/xml/preference\\_headers.xml](#))

Here, your root element is `<preference-headers>`, containing a series of `<header>` elements. Each `<header>` contains at least three attributes:

1. `android:fragment`, which identifies the Java class implementing the PreferenceFragment to use for this header, as is described in the next section
2. `android:title`, which is a few words identifying this header to the user

Once again, you may wish to also include `android:summary`, which is a short sentence explaining what the user will find inside of this header.

You can, if you wish, include one or more `<extra>` child elements inside the

<header> element. These values will be put into the “arguments” Bundle that the associated PreferenceFragment can retrieve via getArguments().

### Creating Your PreferenceActivity

EditPreferences — which in the original sample app was a regular Activity — is now a PreferenceActivity. It contains little more than the two fragments referenced in the above preference header XML:

```
package com.commonsware.android.preffragsbc;

import android.os.Bundle;
import android.preference.PreferenceActivity;
import android.preference.PreferenceFragment;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
    @Override
    public void onBuildHeaders(List<Header> target) {
        loadHeadersFromResource(R.xml.preference_headers, target);
    }

    @Override
    protected boolean isValidFragment(String fragmentName) {
        if (First.class.getName().equals(fragmentName)
            || Second.class.getName().equals(fragmentName)) {
            return(true);
        }

        return(false);
    }

    public static class First extends PreferenceFragment {
        @Override
        public void onCreate(Bundle savedInstanceState) {
            super.onCreate(savedInstanceState);

            addPreferencesFromResource(R.xml.preferences);
        }
    }

    public static class Second extends PreferenceFragment {
        @Override
        public void onCreate(Bundle savedInstanceState) {
            super.onCreate(savedInstanceState);
        }
    }
}
```

## ADVANCED PREFERENCES

---

```
        addPreferencesFromResource(R.xml.preferences2);
    }
}
}
```

(from [Prefs/FragmentsBC/app/src/main/java/com/commonsware/android/preffragsbc/EditPreferences.java](#))

`onBuildHeaders()` is where we supply the preference headers, via a call to `loadHeadersFromResource()`.

We also need to have an `isValidFragment()` method, that will return true if the supplied fragment name is one we should be showing in this `PreferenceActivity`, false otherwise. This will only be called on Android 4.4+. However, we need to set up the project build target (e.g., `compileSdkVersion` in Android Studio) to API Level 19 or higher. Failing to have this method will cause your app to crash on Android 4.4+ devices, when the user tries to bring up one of your `PreferenceFragments`.

Each `PreferenceFragment` is then responsible for calling `addPreferencesFromResource()` to populate its contents. In this case, we now have two such resources: `res/xml/preferences.xml` (the original, used by `First`) and `res/xml/preferences2.xml` (used by `Second`).

### The Results

On a wide enough screen — like that of a Nexus 9 in landscape — we get a master-detail presentation:

*Figure 588: PreferenceActivity UI, on a Landscape Nexus 9*

Here, we see the first preference fragment already pre-selected, showing its settings. Tapping on the second header will show the other preferences.

---

## ADVANCED PREFERENCES

---

On a smaller screen, the master-detail approach means that we see a list of headers first:

*Figure 589: PreferenceActivity UI, on a Portrait Nexus 5*

Tapping the headers give us access to the individual fragments.

## Intents for Headers or Preferences

If you have the need to collect some preferences that are beyond what the standard preferences can handle, you have some choices.

One is to create a custom Preference. Extending `DialogPreference` to create your own Preference implementation is not especially hard. However, it does constrain you to something that can fit in a dialog.

Another option is to specify an `<intent>` element as a child of a `<header>` element. When the user taps on this header, your specified Intent is used with `startActivity()`, giving you a gateway to your own activity for collecting things that are beyond what the preference UI can handle. For example, you could have the following `<header>`:

```
<header android:icon="@drawable/something"
        android:title="Fancy Stuff"
        android:summary="Click here to transcend your
plane of existence">
    <intent android:action="com.commonware.android.MY_CUSTOM_ACTION" />
</header>
```

Then, so long as you have an activity with an `<intent-filter>` specifying your desired action (`com.commonware.android.MY_CUSTOM_ACTION`), that activity will get control when the user taps on the associated header.

## Conditional Headers

The two-tier, headers-and-preferences approach is fine and helps to organize large rosters of preferences. However, it does tend to steer developers in the direction of displaying headers *all of the time*. For many apps, that is rather pointless, because there are too few preferences to collect to warrant having more than one header.

One alternative approach is to use the headers on larger devices, but skip them on smaller devices. That way, the user does not have to tap past a single-item `ListFragment` just to get to the actual preferences to adjust.

This is a wee bit tricky to implement. However, you have two options for how to accomplish it.

(The author would like to thank Richard Le Mesurier, whose question on this topic spurred the development of this section and its samples)

### Option #1: Do Not Define the Headers

The basic plan in the first approach is to have smarts in `onBuildHeaders()` to handle this. `onBuildHeaders()` is the callback that Android invokes on our `PreferenceActivity` to let us define the headers to use in the master-detail pattern. If we want to have headers, we would supply them here; if we want to skip the headers, we would instead fall back to the classic (and, admittedly, deprecated) `addPreferencesFromResource()` method to load up some preference XML.

There is an `isMultiPane()` method on `PreferenceActivity`, starting with API Level 11, that will tell you if the activity will render with two fragments (master+detail) or not. In principle, this would be ideal to use. Unfortunately, it does not seem to be designed to be called from `onBuildHeaders()`. Similarly,

## ADVANCED PREFERENCES

---

`addPreferencesFromResource()` does not seem to be callable from `onBuildHeaders()`. Both are due to timing: `onBuildHeaders()` is called in the middle of the `PreferenceActivity` `onCreate()` processing.

So, we have to do some fancy footwork.

By examining [the source code to PreferenceActivity](#), you will see that the logic that drives the single-pane vs. dual-pane UI decision boils down to:

```
onIsHidingHeaders() || !onIsMultiPane()
```

If that expression returns true, we are in single-pane mode; otherwise, we are in dual-pane mode. `onIsHidingHeaders()` will normally return false, while `onIsMultiPane()` will return either true or false based upon screen size.

So, we can leverage this information in a `PreferenceActivity` to conditionally load our headers, as seen in the `EditPreferences` class in the [Prefs/SingleHeader](#) sample project:

```
package com.commonware.android.pref1header;

import android.os.Bundle;
import android.preference.PreferenceActivity;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
    private boolean needResource=false;

    @SuppressWarnings("deprecation")
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (needResource) {
            addPreferencesFromResource(R.xml.preferences);
        }
    }

    @Override
    public void onBuildHeaders(List<Header> target) {
        if (onIsHidingHeaders() || !onIsMultiPane()) {
            needResource=true;
        }
        else {
            loadHeadersFromResource(R.xml.preference_headers, target);
        }
    }
}
```

## ADVANCED PREFERENCES

---

```
    }  
    }  
  
    @Override  
    protected boolean isValidFragment(String fragmentName) {  
        return(StockPreferenceFragment.class.getName().equals(fragmentName));  
    }  
}
```

(from [Prefs/SingleHeader/app/src/main/java/com/commonsware/android/prefiheader/EditPreferences.java](#))

Here, if we are in dual-pane mode, `onBuildHeaders()` populates the headers as normal. If, though, we are in single-pane mode, we skip that step and make note that we need to do some more work in `onCreate()`.

Then, in `onCreate()`, if we did not load our headers we use the classic `addPreferencesFromResource()` method.

The net result is that on Android 3.0+ tablets, we get the dual-pane, master-detail look with our one header, but on smaller devices (regardless of version), we roll straight to the preferences themselves.

Note that this sample application uses a single `PreferenceFragment` implementation, named `StockPreferenceFragment`:

```
package com.commonsware.android.pref1header;  
  
import android.os.Bundle;  
import android.preference.PreferenceFragment;  
  
public class StockPreferenceFragment extends PreferenceFragment {  
    @Override  
    public void onCreate(Bundle savedInstanceState) {  
        super.onCreate(savedInstanceState);  
  
        int res=  
            getActivity().getResources()  
                .getIdentifier(getArguments().getString("resource"),  
                    "xml",  
                    getActivity().getPackageName());  
  
        addPreferencesFromResource(res);  
    }  
}
```

(from [Prefs/SingleHeader/app/src/main/java/com/commonsware/android/prefiheader/StockPreferenceFragment.java](#))

## ADVANCED PREFERENCES

---

StockPreferenceFragment does what it is supposed to: call `addPreferencesFromResource()` in `onCreate()` with the resource ID of the preferences to load. However, rather than hard-coding a resource ID, as we normally would, we look it up at runtime.

The `<extra>` elements in our preference header XML supply the name of the preference XML to be loaded:

```
<preference-headers xmlns:android="http://schemas.android.com/apk/res/android">
  <header
    android:fragment="com.commonware.android.pref1header.StockPreferenceFragment"
    android:summary="@string/header1summary"
    android:title="@string/header1title">
    <extra
      android:name="resource"
      android:value="preferences"/>
    </header>
</preference-headers>
```

(from [Prefs/SingleHeader/app/src/main/res/xml/preference\\_headers.xml](#))

We get that name via the arguments Bundle (`getArguments().getString("resource")`).

To look up a resource ID at runtime, we can use the `Resources` object, available from our activity via a call to `getResources()`. `Resources` has a method, `getIdentifier()`, that will return a resource ID given three pieces of information:

1. The base name of the resource (in our case, the value retrieved from the `<extra>` element)
2. The type of the resource (e.g., "xml")
3. The package holding the resource (in our case, our own package, retrieved from our activity via `getPackageName()`)

Note that `getIdentifier()` uses reflection to find this value, and so there is some overhead in the process. Do not use `getIdentifier()` in a long loop – cache the value instead.

The net is that `StockPreferenceFragment` loads the preference XML described in the `<extra>` element, so we do not need to create separate `PreferenceFragment` implementations per preference header.

## Option #2: Go Directly to the Fragment

The advantage of the above approach is that it works with Android’s own logic of whether to display the master-detail fragments or just one at a time. However, that logic — the fact that `onIsHidingHeaders() || !onIsMultiPane()` determines the look of the activity — is not documented, and therefore may change in future Android releases.

Another option is to launch your `PreferenceActivity` in such a way that tells Android to skip showing the headers. This approach is better documented and therefore perhaps more stable. This can also be used in cases where you do want headers sometimes, but at other times you want to route the user to a specific `PreferenceFragment`. The downside is that this technique only works on API Level 11+.

To see how this works, take a look at the [Prefs/SingleHeader2](#) sample project.

Our `EditPreferences` class is the same implementation as in the original sample for this chapter, except that we only load up the single XML resource’s worth of preferences:

```
package com.commonware.android.pref1header;

import android.preference.PreferenceActivity;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
    @Override
    public void onBuildHeaders(List<Header> target) {
        loadHeadersFromResource(R.xml.preference_headers, target);
    }

    @Override
    protected boolean isValidFragment(String fragmentName) {
        return (StockPreferenceFragment.class.getName().equals(fragmentName));
    }
}
```

(from [Prefs/SingleHeader2/app/src/main/java/com/commonware/android/pref1header/EditPreferences.java](#))

However, there is a change in our main activity (`FragmentsDemo`). Before, when the user chose the “Settings” action bar overflow item, we would just call `startActivity()` to bring up `EditPreferences`. Now, we delegate that work to an `editPrefs()` method on `FragmentsDemo`, which will have the smarts to control *how*

## ADVANCED PREFERENCES

---

we bring up the `EditPreferences` activity:

```
private void editPrefs() {
    Intent i=new Intent(this, EditPreferences.class);

    i.putExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT,
        StockPreferenceFragment.class.getName());

    Bundle b=new Bundle();

    b.putString("resource", "preferences");

    i.putExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT_ARGUMENTS, b);

    startActivity(i);
}
```

(from [Prefs/SingleHeader2/app/src/main/java/com/commonsware/android/prefheader/FragmentsDemo.java](#))

Here, we will add two extras to our Intent:

- `EXTRA_SHOW_FRAGMENT`, set to the fully-qualified class name of the `PreferenceFragment` to be displayed, here obtained by calling `getName()` on the `Class` object for `StockPreferenceFragment`
- `EXTRA_SHOW_FRAGMENT_ARGUMENTS`, set to a `Bundle` containing the same values that would ordinarily be loaded from the `<extra>` elements in the preference header XML resource (in our case, the name of the preference XML resource to load)

Those extras will be automatically handled by `PreferenceActivity` (on API Level 11+) and will have the effect of directly taking the user to our one-and-only fragment, bypassing the headers.

## Dependent Preferences

In the Settings app, or in other apps that appear to be using `PreferenceFragment`-based UIs, you may have noticed that there are times when preferences are disabled. They become enabled when you check a `CheckBoxPreference` or toggle on a `SwitchPreference`.

That is handled via the `android:dependency` attribute on the to-be-disabled preferences. The value of `android:dependency` is the key of a `TwoStatePreference` subclass, such as a `CheckBoxPreference` or a `SwitchPreference`. The enabled/

## ADVANCED PREFERENCES

---

disabled state of the preference with the `android:dependency` attribute depends on the checked state of the named dependency.

For example, the [Prefs/Dependency](#) sample project is a clone of [the original SharedPreferences demo app](#) with one slight change: all the preferences other than checkbox are now dependent upon checkbox:

```
<PreferenceScreen xmlns:android="http://schemas.android.com/apk/res/android">

    <CheckBoxPreference
        android:key="checkbox"
        android:summary="@string/pref1summary"
        android:title="@string/pref1title" />

    <RingtonePreference
        android:dependency="checkbox"
        android:key="ringtone"
        android:showDefault="true"
        android:showSilent="true"
        android:summary="@string/pref2summary"
        android:title="@string/pref2title" />

    <EditTextPreference
        android:dependency="checkbox"
        android:dialogTitle="@string/dialogtitle"
        android:key="text"
        android:summary="@string/pref3summary"
        android:title="@string/pref3title" />

    <ListPreference
        android:dependency="checkbox"
        android:dialogTitle="@string/listdialogtitle"
        android:entries="@array/cities"
        android:entryValues="@array/airport_codes"
        android:key="list"
        android:summary="@string/pref4summary"
        android:title="@string/pref4title" />

</PreferenceScreen>
```

(from [Prefs/Dependency/app/src/main/res/xml/preferences.xml](#))

## ADVANCED PREFERENCES

---

When you run the project, the dependent preferences are disabled while the checkbox is unchecked:

*Figure 590: Dependent Preferences, Disabled*

...but become enabled once the user checks the checkbox:

*Figure 591: Dependent Preferences, Enabled*

## Nested Screens

Perhaps you have more preferences than you want to collect on a single screen, but you do not feel that a master-detail presentation is the right structure. Or, perhaps you have *lots* of preferences to collect, and even collecting preferences into groups by header is insufficient.

Another possibility is to nest preference screens. One screen holds another. On the outer preference screen, the user has a “preference” entry that simply displays the nested screen, as opposed to directly collecting any preferences.

A `<PreferenceScreen>` element in your preference XML can hold another `<PreferenceScreen>` element. That inner `<PreferenceScreen>` can come in one of two forms:

1. Inside the inner `<PreferenceScreen>` you have more preference XML elements. This means there is only one `PreferenceFragment` for the whole

## ADVANCED PREFERENCES

---

- structure (outer `<PreferenceScreen>`, including the inner `<PreferenceScreen>`). However, visually, the user will “drill down” from the outer screen into the inner one by tapping on an entry.
2. The inner `<PreferenceScreen>` has an `android:fragment` attribute, just like a preference header might. This points to a `Fragment` — typically a `PreferenceFragment` — that will be responsible for the “inner” content. This is a bit more complex to set up, as it requires a couple of fragments. However, it gives you greater flexibility. Plus, it is fairly easy to then switch from using preference headers and the master-detail approach to using nested preference screens, or back again, as you are simply reusing the same `PreferenceFragment` implementations in either case.

The [Prefs/NestedScreens](#) sample project takes the master-detail approach shown earlier in this chapter and switches it to having a top-level screen and a nested screen. This is accomplished by adding a `<PreferenceScreen>` element to `res/xml/preferences.xml`, pointing to our `Second PreferenceFragment`:

```
<PreferenceScreen
    android:fragment="com.commonware.android.preffragsbc.EditPreferences$Second"
    android:key="unused"
    android:title="@string/nested_title"/>
```

(from [Prefs/NestedScreens/app/src/main/res/xml/preferences.xml](#))

Here, the `android:title` (and optional `android:summary`) will be shown on the *outer* screen, as an entry that the user can tap on to get to this inner screen. While in this sample, we are not using `android:key`, in principle you could use this to get at the `PreferenceScreen` itself to manipulate it at runtime (e.g., disable it).

For this style of `<PreferenceScreen>` to work, the preference XML must be used by a `PreferenceFragment` in a `PreferenceActivity` — you cannot use it with a regular `Activity`. However, just because you use `PreferenceActivity` does not mean that you have to opt into the master-detail structure. We can use the same `onCreate()`, `show-the-PreferenceFragment` approach that we use with a regular `Activity`.

However, there is one big catch: when the user taps on the entry that will launch the inner screen, the Android framework will start *another instance* of our `PreferenceActivity`. It will give us the same `EXTRA_SHOW_FRAGMENT` value as we saw earlier in this chapter. However, `PreferenceActivity` will automatically show that fragment; we do not need to show it ourselves.

But, this means that our `onCreate()` needs to distinguish between the “show the outer screen ourselves” case and the “show the inner screen automatically” case,

---

## ADVANCED PREFERENCES

---

which we can do by seeing if EXTRA\_SHOW\_FRAGMENT exists:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getIntent().getStringExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT)==null) {
        if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new First()).commit();
        }
    }
}
```

(from [Prefs/NestedScreens/app/src/main/java/com/commonsware/android/preffragsbc/EditPreferences.java](#))

The result is that we see the outer screen first, containing our entry for the inner screen:

*Figure 592: Nested Preferences, Outer Screen*

Tapping on that entry brings up the inner, nested, screen:

*Figure 593: Nested Preferences, Inner Screen*

## Listening to Preference Changes

Sometimes, you may need to take steps when the user interacts with a preference in your PreferenceFragment-based UI.

A common scenario for this comes with the summary. In some cases, is it handy to have the summary reflect the current value of the preference. While some preferences naturally show their value inline (e.g., a CheckBoxPreference), those that extend from DialogPreference only show their value when the user taps on the preference to display the dialog. Putting something in the summary that reflects the value can save the user a click.

However, by default, the summary is static, populated by the `android:summary` attribute in your preference XML. If you want it to reflect the current preference value, you not only need to be able to set the summary in Java, but to be able to respond when the user changes the value, so you can update the summary again.

---

## ADVANCED PREFERENCES

---

The [Prefs/CustomSubtitle](#) sample project demonstrates how this works. This is yet another clone of [the original SharedPreferences demo app](#). This time, the preference XML is unchanged from the original. However, we have a slightly more elaborate PreferenceFragment implementation:

```
public static class Prefs extends PreferenceFragment
    implements Preference.OnPreferenceChangeListener {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        addPreferencesFromResource(R.xml.preferences);

        Preference pref=findPreference("text");

        updateSummary(pref,
            pref.getSharedPreferences().getString(pref.getKey(), null));
        pref.setOnPreferenceChangeListener(this);
    }

    @Override
    public boolean onPreferenceChange(Preference pref, Object newValue) {
        updateSummary(pref, newValue.toString());

        return(true);
    }

    private void updateSummary(Preference pref, String value) {
        if (value==null || value.length()==0) {
            pref.setSummary(R.string.msg_missing_text);
        }
        else {
            pref.setSummary(value);
        }
    }
}
```

(from [Prefs/CustomSubtitle/app/src/main/java/com/commonsware/android/preffrag/EditPreferences.java](#))

In `onCreate()`, after `addPreferencesFromResource()`, we call `findPreference()` to retrieve the `Preference` object that manages the snippet of UI for a particular preference. The flow here mimics that of `setContentView()` and `findViewById()`: first you inflate the resource, then you find the Java object corresponding to some XML element out of that resource. `findPreference()` takes the key of the preference that you are looking for; in this case, we are looking for the `EditTextPreference`, whose key is `text`.

## ADVANCED PREFERENCES

---

We then call a private `updateSummary()` method, which takes the Preference and the current value of that preference and updates the summary. To get the current value, `onCreate()` can ask the Preference for its backing `SharedPreferences` (via `getSharedPreferences()`), then retrieve the value using standard getters (e.g., `getString()`). `updateSummary()` then shows the string representation of the current value, or a canned message if there does not appear to be a current value.

We also register the fragment itself as being the `OnPreferenceChangeListener`, and register the fragment with the preference via `setOnPreferenceChangeListener()`. This means that when the user manipulates this preference, we will be called with `onPreferenceChange()`. This is done *before the `SharedPreferences` are updated*. Our options are either to return `true` and have the normal persistence process continue, or return `false` and manage persistence ourselves (e.g., perform some conversion on the raw value before storing it). In our case, we are just using this to call `updateSummary()` again.

If you install the app and run it, you will not have an existing value for the preference, and so the summary shows a stock message:

*Figure 594: Custom Subtitle Demo, Before Editing Text*

After you tap on the `EditTextPreference` and fill in some value in the dialog, the

summary updates to show what you typed in:

## Defaults, and Defaults

When you use `SharedPreferences` to retrieve a value, you can usually provide a default value along with the key for the value that you want. If there is no preference value for that key, you get the default that you supplied.

A preference in preference XML also has an `android:defaultValue` attribute. This is, roughly speaking, the preference UI counterpart to that second parameter to the `SharedPreferences` getters. If the user interacts with the preference, the `android:defaultValue` value will be presented to the user if there was no preference value stored for that key in the underlying `SharedPreferences`.

To synchronize these, you can call `setDefaultValues()` on the `PreferenceManager` class. Given the resource ID of some preference XML, `PreferenceManager` will find all `android:defaultValue` attributes and then persist those default values to the `SharedPreferences` under their respective keys.

## Listening to Preference Value Changes

Sometimes, you will have components that need to know when preference values are changed elsewhere in your app. For example, you may have a Service that is using information from SharedPreferences, and the Service may need to know when those values change.

One approach, used in all the sample apps, is simply to re-read the preference values as needed, rather than caching them in data members or something. After the first time SharedPreferences are accessed, the SharedPreferences themselves are held in heap space, and so accessing them can be fairly cheap. So, the sample apps' launcher activities just re-read the preference values in `onResume()` and update the UI that way.

If, however, that is inappropriate, inconvenient, or otherwise not what you want to do, you can call `registerOnSharedPreferenceChangeListener()` on a SharedPreferences object, supplying an instance of an implementation of the `OnSharedPreferenceChangeListener` interface. That object will be called with `onSharedPreferenceChanged()` every time a preference value changes. You are given the key to the changed value, so you can implement a filter to only pay attention to keys that matter to you. When one of those keys is reported to have changed, you can ask the SharedPreferences for the new value.

## Dynamic ListPreference Contents

Many times, the items that the user can choose from in your ListPreference or MultiSelectListPreference are fixed, allowing you to populate them from `<string-array>` resources. However, sometimes, the items (display names and corresponding values) are dynamic, based upon information held elsewhere: database, server, or something at a system level. For those, we need to be able to define the preference in XML, but configure its contents in Java code.

For example, the [Introspection/SAWMonitor](#) sample project is a monitor for new and upgraded apps that ask for the `SYSTEM_ALERT_WINDOW` permission. Such apps have the right to draw over top of other apps, for anything from Facebook "chatheads" to [tapjacking attacks](#).

However, some apps may request this permission that you are perfectly fine with having it. By default, SAWMonitor will point out this permission on each subsequent update, which can get tiresome after a while. Hence, SAWMonitor

## ADVANCED PREFERENCES

---

allows you to add apps to a “whitelist”; those apps will be ignored, even if they request `SYSTEM_ALERT_WINDOW`.

To that end, we have a `settings.xml` resource describing some preferences to collect from the user:

```
<?xml version="1.0" encoding="utf-8"?>
<PreferenceScreen xmlns:android="http://schemas.android.com/apk/res/android">
  <SwitchPreference
    android:key="enabled"
    android:title="@string/msg_enable"
    android:defaultValue="true"/>
  <MultiSelectListPreference
    android:key="whitelist"
    android:title="@string/msg_whitelist" />
</PreferenceScreen>
```

(from [Intropection/SAWMonitor/app/src/main/res/xml/settings.xml](#))

Here we have two preferences: a `SwitchPreference` for whether we should be monitoring for `SYSTEM_ALERT_WINDOW` at all, and a `MultiSelectListPreference` to allow the user to control the whitelist.

In `onCreate()` of our `SettingsFragment`, we load up those preferences into the UI via `addPreferencesFromResource()`, use `findPreference()` to retrieve both of the `Preference` objects, and use `setOnPreferenceChangeListener()` to be notified about changes to the enabled preference:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    addPreferencesFromResource(R.xml.settings);
    pm=getActivity().getPackageManager();

    enabled=(SwitchPreference)findPreference(MonitorApp.PREF_ENABLED);

    populateWhitelist((MultiSelectListPreference)findPreference("whitelist"));
}
```

(from [Intropection/SAWMonitor/app/src/main/java/com/commonsware/android/sawmonitor/SettingsFragment.java](#))

The `populateWhitelist()` call is where we fill in the details for the `MultiSelectListPreference`. In our case, the possible values are the apps presently installed that have requested the `SYSTEM_ALERT_WINDOW` permission. So, we use `PackageManager` to find those, then use that information to populate the whitelist

## ADVANCED PREFERENCES

---

preference:

```
void populateWhitelist(MultiSelectListPreference whitelist) {
    List<ApplicationInfo> apps=pm.getInstalledApplications(0);

    Collections.sort(apps,
        new ApplicationInfo.DisplayNameComparator(pm));

    ArrayList<CharSequence> displayNames=
        new ArrayList<CharSequence>();
    ArrayList<String> packageNames=new ArrayList<String>();

    for (ApplicationInfo app : apps) {
        try {
            PackageInfo pkgInfo=
                pm.getPackageInfo(app.packageName,
                    PackageManager.GET_PERMISSIONS);

            if (pkgInfo.requestedPermissions!=null) {
                for (String perm : pkgInfo.requestedPermissions) {
                    if (SYSTEM_ALERT_WINDOW.equals(perm)) {
                        displayNames.add(app.loadLabel(pm));
                        packageNames.add(app.packageName);
                        break;
                    }
                }
            }
        }
        catch (PackageManager.NameNotFoundException e) {
            // should not happen, quietly ignore
        }
    }

    whitelist
        .setEntries(displayNames
            .toArray(new CharSequence[displayNames.size()]));
    whitelist
        .setEntryValues(packageNames
            .toArray(new String[packageNames.size()]));
}
```

(from [Introspection/SAWMonitor/app/src/main/java/com/commonsware/android/sawmonitor/SettingsFragment.java](#))

Most of the code is determining which applications have that permission. However, `MultiSelectListPreference` complicates matters, by having two separate setter methods for its contents:

## ADVANCED PREFERENCES

---

- `setEntries()` sets the display names, what the user will see in the multi-select dialog
- `setEntryValues()` sets the corresponding values, what will be stored in the `SharedPreferences` based upon the user's input

These each take arrays of `CharSequence` implementations, like `String`. Hence, we need two parallel arrays of values, rather than a single `ArrayList` of `Pair` objects or something.

With that in mind, `populateWhitelist()`:

- Gets the list of installed applications from the `PackageManager` (`pm` is a field initialized in `onCreate()`)
- Sorts those by display name, so our results will wind up in alphabetical order
- Creates an `ArrayList` for the display names and a separate one for the package names, which will serve as our entry values
- Iterates over the applications, gets the permissions requested by each app, and if any of those is `SYSTEM_ALERT_WINDOW`, add the display name (`loadLabel()`) and the package name to their respective lists
- Converts each of those `ArrayList` objects into a corresponding Java array, and passes them to their appropriate setters

## ADVANCED PREFERENCES

---

The resulting SettingsFragment has the two preferences:

*Figure 596: SAWMonitor SettingsFragment*

Tapping on the “Whitelist” entry brings up the `MultiSelectListPreference`:

*Figure 597: SAWMonitor Whitelist MultiSelectListPreference*

If you run the app on your device or emulator, you will wind up with different possible entries in the `MultiSelectListPreference`, as the mix of apps requesting `SYSTEM_ALERT_WINDOW` will be different for different devices and users.

## Dealing with External Changes to Preferences

What happens if you have a `PreferenceFragment` in the foreground, and the preference changes “behind the scenes” by some other component of your app?

For preferences with dialogs — `ListPreference`, `EditTextPreference`, etc. — the pattern seems to be “transaction by dialog”. Whatever the preference value is at the time the dialog appears is what the user sees, and that does not change (and cannot readily *be* changed) if the preference changes while that dialog is on the screen.

However, for inline preferences — `CheckBoxPreference`, `SwitchPreference`, etc. — while the UI will not automatically update based on the external change, you can handle that yourself.

For example, `SAWMonitor` offers [an optional notification shade tile using a](#)

---

## ADVANCED PREFERENCES

---

[TileService on Android 7.0+ devices](#). The tile allows the user to enable and disable the monitoring, just as the user can from the SwitchPreference. So... what happens if the SettingsFragment is on the screen, the user slides open the notification shade, and taps the tile? By default, the SettingsFragment would be oblivious to this, with the result of the SwitchPreference being out of sync.

But, we can fix this.

In SettingsFragment, in onStart(), we register for preference changes, plus call a syncEnabledStates() method. We unregister from preference changes in onStop():

```
@Override
public void onStart() {
    super.onStart();

    prefs=PreferenceManager.getDefaultSharedPreferences(getActivity());
    prefs.registerOnSharedPreferenceChangeListener(this);
    syncEnabledStates();
}

@Override
public void onStop() {
    super.onStop();

    prefs.unregisterOnSharedPreferenceChangeListener(this);
}
```

(from [Introspection/SAWMonitor/app/src/main/java/com/commonsware/android/sawmonitor/SettingsFragment.java](#))

The onSharedPreferenceChanged() method on our SettingsFragment will be called when any of our preferences changes. If the enabled preference changes, we call syncEnabledStates():

```
@Override
public void onSharedPreferenceChanged(SharedPreferences prefs,
                                     String s) {
    if (MonitorApp.PREF_ENABLED.equals(s)) {
        syncEnabledStates();
    }
}
```

(from [Introspection/SAWMonitor/app/src/main/java/com/commonsware/android/sawmonitor/SettingsFragment.java](#))

syncEnabledStates() simply updates the checked state of enabled based upon the now-current value in SharedPreferences:

---

## ADVANCED PREFERENCES

---

```
void syncEnabledStates() {  
    enabled.setChecked(prefs.getBoolean(MonitorApp.PREF_ENABLED, false));  
}
```

(from [Introspection/SAWMonitor/app/src/main/java/com/commonsware/android/sawmonitor/SettingsFragment.java](#))

Hence, this also handles the case where our `SettingsFragment` was displayed, the user navigated elsewhere, one of our preferences changes, and then the user returns to our running `SettingsFragment`. Normally, the `SettingsFragment` might miss that preference change, but with this implementation, the `SettingsFragment` will be kept in sync with the actual preference value.

## Preferences in Device Settings App

On Android 7.0+, you can have the Settings app show a “gear” icon on your activity that collects preferences. When the user taps that gear, the Settings app will launch your designated activity:

*Figure 598: Settings Activity Gear Icon*

To offer this, you need to add an `<intent-filter>` for your desired activity, with an `<action>` of `android.intent.action.APPLICATION_PREFERENCES`:

## ADVANCED PREFERENCES

---

```
<activity
  android:name="EditPreferences"
  android:label="@string/app_name">
  <intent-filter>
    <action android:name="android.intent.action.APPLICATION_PREFERENCES" />
    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

However, by default, there is a cost to this: *any app* can start your settings activity, whenever another app wants to. Your settings activity is exported once you add the `<intent-filter>`, and it needs to be exported for the Settings app to be able to start the activity.

However, it is fairly likely that this activity was not exported before you added this `<intent-filter>`. And while you may not mind it if the Settings app starts this activity, or if your own application code starts this activity, you may not want arbitrary other apps to start this activity. A general rule of thumb in modern development is to keep your “attack surface” low. Having an activity be exported for little value is an unnecessary increase in your app’s attack surface.

There is no officially-documented solution for this, though [perhaps they will add one someday](#).

There are two candidate approaches. An [unexpected](#) one works: you can mark the activity as being not exported, via `android:exported="false"`. For some reason, the Settings app can still start up that activity, [perhaps due to some system-level privilege](#). However, other apps will be unable to start the activity. This would result in an `<activity>` element like this:

```
<activity
  android:name="EditPreferences"
  android:label="@string/app_name"
  android:exported="false">
  <intent-filter>
    <action android:name="android.intent.action.APPLICATION_PREFERENCES" />
    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

Another approach that should work is to use `android:permission` to limit what other apps can start your activity, choosing a permission that the Settings app is sure to have but that most other apps will lack. `WRITE_SECURE_SETTINGS` is one candidate:

```
<activity
  android:name="EditPreferences"
  android:label="@string/app_name"
  android:permission="android.permission.WRITE_SECURE_SETTINGS">
  <intent-filter>
    <action android:name="android.intent.action.APPLICATION_PREFERENCES" />
    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

Now, the only other apps that can start your activity must hold the `WRITE_SECURE_SETTINGS` permission, which ordinary Android SDK apps cannot hold.

### Custom Preference Storage

SharedPreferences are stored in an app's portion of internal storage as an XML file. This is fine in many cases. However, it is a problem for apps that need to ensure that persisted data is encrypted. While you can create a wrapper around SharedPreferences that encrypts the keys and values, that will not work well with things like the preference screen UI system. Basically, anything that does not know about the wrapper would try working with the actual SharedPreferences data and be broken by the encryption.

This has always been disappointing, considering that SharedPreferences is an interface, and so setting up some sort of decorator approach should have been fairly easy to add.

In Android 8.0+, Google does not do that.

However, they *do* add in another mechanism: PreferenceDataStore.

You can create a PreferenceDataStore and associate it with a PreferenceManager via `setPreferenceDataStore()`. Then, all SharedPreferences loaded from that PreferenceManager will not use the normal XML-based persistence. Instead, the PreferenceDataStore will be used instead. That interface has getter and setter methods for all of the types supported by SharedPreferences, and it is the responsibility of some instance of PreferenceDataStore to handle the persistence as you see fit.

This solution is goofy, but it works, after a fashion, as is illustrated in the [Prefs/DataStore](#) sample project.

## ADVANCED PREFERENCES

---

In that project, we have a SillyDataStore implementation of the PreferenceDataStore interface. It just stuffs all the data into a HashMap:

```
package com.commonware.android.preffrag;

import android.preference.PreferenceDataStore;
import java.util.HashMap;
import java.util.Map;
import java.util.Set;

class SillyDataStore implements PreferenceDataStore {
    static private final SillyDataStore INSTANCE=new SillyDataStore();
    private Map<String, Object> cache=new HashMap<>();

    static SillyDataStore get() {
        return(INSTANCE);
    }

    private SillyDataStore() {
        // just here to prevent accidental creation from outside
    }

    @Override
    public void putString(String key, String value) {
        cache.put(key, value);
    }

    @Override
    public void putStringSet(String key, Set<String> values) {
        cache.put(key, values);
    }

    @Override
    public void putInt(String key, int value) {
        cache.put(key, value);
    }

    @Override
    public void putLong(String key, long value) {
        cache.put(key, value);
    }

    @Override
    public void putFloat(String key, float value) {
        cache.put(key, value);
    }
}
```

## ADVANCED PREFERENCES

---

```
@Override
public void putBoolean(String key, boolean value) {
    cache.put(key, value);
}

@SuppressWarnings("Since15")
@Override
public String getString(String key, String defValue) {
    return((String)cache.getOrDefault(key, defValue));
}

@SuppressWarnings("Since15")
@Override
public Set<String> getStringSet(String key, Set<String> defValues) {
    return((Set<String>)cache.getOrDefault(key, defValues));
}

@SuppressWarnings("Since15")
@Override
public int getInt(String key, int defValue) {
    return((Integer)cache.getOrDefault(key, defValue));
}

@SuppressWarnings("Since15")
@Override
public long getLong(String key, long defValue) {
    return((Long)cache.getOrDefault(key, defValue));
}

@SuppressWarnings("Since15")
@Override
public float getFloat(String key, float defValue) {
    return((Float)cache.getOrDefault(key, defValue));
}

@SuppressWarnings("Since15")
@Override
public boolean getBoolean(String key, boolean defValue) {
    return((Boolean)cache.getOrDefault(key, defValue));
}
}
```

(from [Prefs/DataStore/app/src/main/java/com/commonsware/android/preffrag/SillyDataStore.java](#))

This implementation is truly silly, as it does no type checking and no persistence. It should be considered the bare minimum implementation of a PreferenceDataStore, though one that might be useful, instead of rolling a mock, in

## ADVANCED PREFERENCES

---

unit testing.

(note: the `@SuppressWarnings("Since15")` annotations are because this code uses the `getOrDefault()` method on `HashMap`, which was added in Java 8 and is new to Android 8.0)

There is a singleton instance of `SillyDataStore`. That way we can ensure that the same instance is used wherever we want it.

We apply that singleton in the `PreferenceFragment` subclass:

```
public static class Prefs extends PreferenceFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getPreferenceManager().getPreferenceDataStore()==null) {
            getPreferenceManager().setPreferenceDataStore(SillyDataStore.get());
        }

        addPreferencesFromResource(R.xml.preferences);
    }
}
```

(from [Prefs/DataStore/app/src/main/java/com/commonsware/android/preffrag/EditPreferences.java](#))

Here, we check to see if there is a `PreferenceDataStore` associated with the `PreferenceManager` and, if not, we attach the `SillyDataStore` singleton. This causes the `SharedPreferences` used by this `PreferenceFragment` to use the `SillyDataStore` for storage, instead of the default XML-based persistence.

This works... somewhat. There are some problems.

First, a `PreferenceManager` is not a system service. Of note, each instance of our `PreferenceFragment` gets its own fresh `PreferenceManager`. This is why we need to check for, and set, the `PreferenceDataStore` on the `PreferenceManager` for the `PreferenceFragment` each time.

Second, we have no way of associating a `PreferenceDataStore` with the default `SharedPreferences` obtained from `PreferenceManager.getDefaultSharedPreferences()`. That will always use the standard XML backing store. The initial activity contents are in the form of a `PreferenceContentsFragment` that reads from the default `SharedPreferences` in

## ADVANCED PREFERENCES

---

`onResume()`. Normally, that would cause changes that we make via our `PreferenceFragment` to show up when the `PreferenceContentsFragment` is resumed. In this specific sample, that does not happen, as the `PreferenceContentsFragment` is using the default XML data store, and our data is really in the `SillyDataStore`.

This illustrates the fatal flaw of this system: you can never really use the `SharedPreferences`. You cannot create `PreferenceManager` instances yourself, as it has no public constructors. All of the code that gives you `SharedPreferences` objects back *other* than through a `PreferenceManager` has no way of associating a `PreferenceDataStore` with the `SharedPreferences`.

Instead of using `SharedPreferences`... you have to read and write from your `PreferenceDataStore` itself. This, in turn, loses everything that you normally associate with `SharedPreferences`, such as atomicity of updates and preference-change listeners.

Worse, since `PreferenceDataStore` has no API telling you when to persist changes, you would have to do that yourself... somehow.

These can be overcome, with a sufficiently-robust `PreferenceDataStore` implementation and lots of documentation. However, for casual use, other than perhaps for test mocks, `PreferenceDataStore` is not a well-engineered solution and probably should be avoided.

# Custom Dialogs and Preferences

---

Android ships with a number of dialog classes for specific circumstances, like `DatePickerDialog` and `ProgressDialog`. Similarly, Android comes with a smattering of Preference classes for your `PreferenceActivity`, to accept text or selections from lists and so on.

However, there is plenty of room for improvement in both areas. As such, you may find the need to create your own custom dialog or preference class. This chapter will show you how that is done.

We start off by looking at creating a [custom `AlertDialog`](#), not by using `AlertDialog.Builder`, but via a custom subclass. Then, we show how to create your [own dialog-style Preference](#), where tapping on the preference pops up a dialog to allow the user to customize the preference value.

## Prerequisites

Understanding this chapter requires that you have read [the chapter on dialogs](#), along with [the chapter on the preference system](#). Also, the samples here use the custom `ColorMixer` View described [in another chapter](#).

## Your Dialog, Chocolate-Covered

For your own application, the simplest way to create a custom `AlertDialog` is to use `AlertDialog.Builder`, as described [in a previous chapter](#). You do not need to create any special subclass — just call methods on the Builder, then `show()` the resulting dialog.

## CUSTOM DIALOGS AND PREFERENCES

---

However, if you want to create a reusable `AlertDialog`, this may become problematic. For example, where would this code to create the custom `AlertDialog` reside?

So, in some cases, you may wish to extend `AlertDialog` and supply the dialog's contents that way, which is how `TimePickerDialog` and others are implemented. Unfortunately, this technique is not well documented. This section will illustrate how to create such an `AlertDialog` subclass, as determined by looking at how the core Android team did it for their own dialogs.

The sample code is `ColorMixerDialog`, a dialog wrapping around the `ColorMixer` widget shown in a previous chapter. The implementation of `ColorMixerDialog` can be found in the [CWAC-ColorMixer](#) GitHub repository, as it is part of the CommonsWare Android Components.

Using this dialog works much like using `DatePickerDialog` or `TimePickerDialog`. You create an instance of `ColorMixerDialog`, supplying the initial color to show and a listener object to be notified of color changes. Then, call `show()` on the dialog. If the user makes a change and accepts the dialog, your listener will be informed.

*Figure 599: The ColorMixerDialog*

## Basic AlertDialog Setup

The ColorMixerDialog class is not especially long, since all of the actual color mixing is handled by the ColorMixer widget:

```
package com.commonware.cwac.colormixer;

import android.app.AlertDialog;
import android.content.Context;
import android.content.DialogInterface;
import android.os.Bundle;

public class ColorMixerDialog extends AlertDialog
    implements DialogInterface.OnClickListener {
    static private final String COLOR="c";
    private ColorMixer mixer=null;
    private int initialColor;
    private ColorMixer.OnColorChangeListener onSet=null;

    public ColorMixerDialog(Context ctxt,
        int initialColor,
        ColorMixer.OnColorChangeListener onSet) {

        super(ctxt);

        this.initialColor=initialColor;
        this.onSet=onSet;

        mixer=new ColorMixer(ctxt);
        mixer.setColor(initialColor);

        setView(mixer);
        setButton(ctxt.getText(R.string.cwac_colormixer_set),
            this);
        setButton2(ctxt.getText(R.string.cwac_colormixer_cancel),
            (DialogInterface.OnClickListener)null);
    }

    @Override
    public void onClick(DialogInterface dialog, int which) {
        if (initialColor!=mixer.getColor()) {
            onSet.onColorChange(mixer.getColor());
        }
    }

    @Override
    public Bundle onSaveInstanceState() {
        Bundle state=super.onSaveInstanceState();
```

```
state.putInt(COLOR, mixer.getColor());

return(state);
}

@Override
public void onRestoreInstanceState(Bundle state) {
    super.onRestoreInstanceState(state);

    mixer.setColor(state.getInt(COLOR));
}
}
```

We extend the `AlertDialog` class and implement a constructor of our own design. In this case, we take in three parameters:

1. A `Context` (typically an `Activity`), needed for the superclass
2. The initial color to use for the dialog, such as if the user is editing a color they chose before
3. A `ColorMixer.OnColorChangeListener` object, just like `ColorMixer` uses, to notify the dialog creator when the color is changed

We then create a `ColorMixer` and call `setView()` to make that be the main content of the dialog. We also call `setButton()` and `setButton2()` to specify a “Set” and “Cancel” button for the dialog. The latter just dismisses the dialog, so we need no event handler. The former we route back to the `ColorMixerDialog` itself, which implements the `DialogInterface.OnClickListener` interface.

### Handling Color Changes

When the user clicks the “Set” button, we want to notify the application about the color change...if the color actually changed. This is akin to `DatePickerDialog` and `TimePickerDialog` only notifying you of date or times if the user clicks Set and actually changed the values.

The `ColorMixerDialog` tracks the initial color via the `initialColor` data member. In the `onClick()` method — required by `DialogInterface.OnClickListener` — we see if the mixer has a different color than the `initialColor`, and if so, we call the supplied `ColorMixer.OnColorChangeListener` callback object:

```
@Override
public void onClick(DialogInterface dialog, int which) {
```

```
if (initialColor!=mixer.getColor()) {
    onSet.onColorChange(mixer.getColor());
}
}
```

### State Management

Dialogs use `onSaveInstanceState()` and `onRestoreInstanceState()`, just like activities do. That way, if the screen is rotated, or if the hosting activity is being evicted from RAM when it is not in the foreground, the dialog can save its state, then get it back later as needed.

The biggest difference with `onSaveInstanceState()` for a dialog is that the `Bundle` of state data is not passed into the method. Rather, you get the `Bundle` by chaining to the superclass, then adding your data to the `Bundle` it returned, before returning it yourself:

```
@Override
public Bundle onSaveInstanceState() {
    Bundle state=super.onSaveInstanceState();

    state.putInt(COLOR, mixer.getColor());

    return(state);
}
```

The `onRestoreInstanceState()` pattern is much closer to the implementation you would find in an Activity, where the `Bundle` with the state data to restore is passed in as a parameter:

```
@Override
public void onRestoreInstanceState(Bundle state) {
    super.onRestoreInstanceState(state);

    mixer.setColor(state.getInt(COLOR));
}
```

### Preferring Your Own Preferences, Preferably

The Android Settings application, built using the Preference system, has lots of custom Preference classes. You too can create your own Preference classes, to collect things like dates, numbers, or colors. Once again, though, the process of creating such classes is not well documented. This section reviews one recipe for

making a Preference — specifically, a subclass of `DialogPreference` – based on the implementation of other Preference classes in Android.

The result is `ColorPreference`, a Preference that uses the `ColorMixer` widget. As with the `ColorMixerDialog` from the previous section, the `ColorPreference` is from the CommonsWare Android Components, and its source code can be found in the [CWAC-ColorMixer](#) GitHub repository.

One might think that `ColorPreference`, as a subclass of `DialogPreference`, might use `ColorMixerDialog`. However, that is not the way it works, as you will see.

### The Constructor

A Preference is much like a [custom View](#), in that there are a variety of constructors, some taking an `AttributeSet` (for the preference properties), and some taking a default style. In the case of `ColorPreference`, we need to get the string resources to use for the names of the buttons in the dialog box, providing them to `DialogPreference` via `setPositiveButton()` and `setNegativeButton()`.

Here, we just implement the standard two-parameter constructor, since that is the one that is used when this preference is inflated from a preference XML file:

```
public ColorPreference(Context ctxt, AttributeSet attrs) {
    super(ctxt, attrs);

    setPositiveButton(ctxt.getText(R.string.cwac_colormixer_set));
    setNegativeButton(ctxt.getText(R.string.cwac_colormixer_cancel));
}
```

### Creating the View

The `DialogPreference` class handles the pop-up dialog that appears when the preference is clicked upon by the user. Subclasses get to provide the View that goes inside the dialog. This is handled a bit reminiscent of a `CursorAdapter`, in that there are two separate methods to be overridden:

- `onCreateDialogView()` works like `newView()` of `CursorAdapter`, returning a View that should go in the dialog
- `onBindDialogView()` works like `bindView()` of `CursorAdapter`, where the custom Preference is supposed to configure the View for the current preference value

In the case of `ColorPreference`, we use a `ColorMixer` for the View:

```
@Override
protected View onCreateDialogView() {
    mixer=new ColorMixer(getContext());

    return(mixer);
}
```

Then, in `onBindDialogView()`, we set the mixer's color to be `lastColor`, a private data member:

```
@Override
protected void onBindDialogView(View v) {
    super.onBindDialogView(v);

    mixer.setColor(lastColor);
}
```

We will see later in this section where `lastColor` comes from – for the moment, take it on faith that it holds the user's chosen color, or a default value.

### Dealing with Preference Values

Of course, the whole point behind a Preference is to allow the user to set some value that the application will then use later on. Dealing with values is a bit tricky with `DialogPreference`, but not too bad.

#### Getting the Default Value

The preference XML format has an `android:defaultValue` attribute, which holds the default value to be used by the preference. Of course, the actual data type of the value will differ widely — an `EditTextPreference` might expect a `String`, while `ColorPreference` needs a color value.

Hence, you need to implement `onGetDefaultValue()`. This is passed a `TypedArray` — similar to how a custom View uses a `TypedArray` for getting at its custom attributes in an XML layout file. It is also passed an index number into the array representing `android:defaultValue`. The custom Preference needs to return an Object representing its interpretation of the default value.

In the case of `ColorPreference`, we simply get an integer out of the `TypedArray`,

representing the color value, with an overall default value of 0xFFA4C639 (a.k.a., Android green):

```
@Override
protected Object onGetDefaultValue(TypedArray a, int index) {
    return(a.getInt(index, 0xFFA4C639));
}
```

### Setting the Initial Value

When the user clicks on the preference, the `DialogPreference` supplies the last-known preference value to its subclass, or the default value if this preference has not been set by the user to date.

The way this works is that the custom `Preference` needs to override `onSetInitialValue()`. This is passed in a boolean flag (`restoreValue`) indicating whether or not the user set the value of the preference before. It is also passed the `Object` returned by `onGetDefaultValue()`. Typically, a custom `Preference` will look at the flag and choose to either use the default value or load the already-set preference value.

To get the existing value, `Preference` defines a set of type-specific getter methods — `getPersistedInt()`, `getPersistedString()`, etc. So, `ColorPreference` uses `getPersistedInt()` to get the saved color value:

```
@Override
protected void onSetInitialValue(boolean restoreValue, Object defaultValue) {
    lastColor=(restoreValue ? getPersistedInt(lastColor) : (Integer)defaultValue);
}
```

Here, `onSetInitialValue()` stores that value in `lastColor` — which then winds up being used by `onBindDialogView()` to tell the `ColorMixer` what color to show.

### Closing the Dialog

When the user closes the dialog, it is time to persist the chosen color from the `ColorMixer`. This is handled by the `onDialogClosed()` callback method on your custom `Preference`:

```
@Override
protected void onDialogClosed(boolean positiveResult) {
    super.onDialogClosed(positiveResult);
}
```

```
if (positiveResult) {
    if (callChangeListener(mixer.getColor())) {
        lastColor=mixer.getColor();
        persistInt(lastColor);
    }
}
}
```

The passed-in boolean indicates if the user accepted or dismissed the dialog, so you can elect to skip saving anything if the user dismissed the dialog. The other `DialogPreference` implementations also call `callChangeListener()`, which is somewhat ill-documented. Assuming both the flag and `callChangeListener()` are true, the Preference should save its value to the persistent store via `persistInt()`, `persistString()`, or `kin`.

### Using the Preference

Given all of that, using the custom Preference class in an application is almost anticlimactic. You simply add it to your preference XML, with a fully-qualified class name:

```
<PreferenceScreen
    xmlns:android="http://schemas.android.com/apk/res/android">
    <com.commonware.cwac.colormixer.ColorPreference
        android:key="favoriteColor"
        android:defaultValue="0xFFA4C639"
        android:title="Your Favorite Color"
        android:summary="Blue. No yel-- Auuuuuuuugh!" />
</PreferenceScreen>
```

At this point, it behaves no differently than does any other Preference type. Since `ColorPreference` stores the value as an integer, your code would use `getInt()` on the `SharedPreferences` to retrieve the value when needed.

## CUSTOM DIALOGS AND PREFERENCES

---

The user sees an ordinary preference entry in the PreferenceActivity:

*Figure 600: A PreferenceActivity, showing the ColorPreference*

## CUSTOM DIALOGS AND PREFERENCES

---

When tapped, it brings up the mixer:

*Figure 601: The ColorMixer in a custom DialogPreference*

Choosing a color and clicking “Set” persists the color value as a preference.

# Progress Indicators

---

Sometimes, we make the user wait. And wait. And wait some more.

Often, in these cases, it is useful to let the user know that something they requested is something that we are diligently working on. To do this, we can use some form of progress indicator. We saw basic use of a `ProgressBar` in the tutorials earlier in this book — now is the time to take a much closer look at `ProgressBar` and other means of displaying progress.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having read the chapters on [dialogs](#), [custom drawables](#), and [animators](#) is also a good idea.

## Progress Bars

The classic way to tell the user that we are doing something for them is to use a `ProgressBar` widget, much as we briefly displayed one in the `EmPubLite` sample app in the tutorials.

However, a `ProgressBar` is much more than a simple spinning image. We can use it to display either indeterminate progress (“we will be done... sometime”) or specific progress (“we are 34% complete”). We can use it either as a circle or as a classic horizontal bar, the latter typically used for specific progress. And, for specific progress, we can actually show two tiers of progress, known as “primary” and “secondary” (e.g., primary for the progress in copying a directory’s worth of files, secondary for the progress on a specific file).

In this section, we will take a look at these different ways of using `ProgressBar`.

### Circular vs. Horizontal

As the name suggests, a `ProgressBar` denotes progress. As the name does not suggest, a `ProgressBar` is not a bar, by default — it is a circle. Hence, the following element from an XML layout resource:

```
<ProgressBar
    android:id="@+id/progressCI"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_horizontal"
    android:layout_marginBottom="20dp"
    android:layout_marginTop="20dp"/>
```

(from [Progress/BarSampler/app/src/main/res/layout/activity\\_main.xml](#))

## PROGRESS INDICATORS

---

gives us:

However, referencing `style="?android:attr/progressBarStyleHorizontal"` in the element:

```
<ProgressBar
  android:id="@+id/progressHI"
  style="?android:attr/progressBarStyleHorizontal"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:layout_marginBottom="20dp"
  android:indeterminate="true"/>
```

(from [Progress/BarSampler/app/src/main/res/layout/activity\\_main.xml](#))

gives us a horizontal bar:

*Figure 604: Android 5.1 ProgressBar, Horizontal Style*

*Figure 605: Android 4.0 ProgressBar, Horizontal Style*

Note that the look-and-feel of these widgets have changed over the years. On Android 1.x and 2.x, they will look like this:

*Figure 606: Android 2.3.3 ProgressBar, Both Styles*

### **Specific vs. Indeterminate**

Typically, you use the circular `ProgressBar` style for indeterminate progress, where the circle simply spins in place to let the user know that work is proceeding and the device (or activity) has not frozen. The horizontal `ProgressBar` style is used to illustrate specific amounts of progress, from 0 to a value you choose.

However, while those patterns are typical, the choice of whether to use indeterminate or some specific amount of progress is independent of the style of the widget.

## PROGRESS INDICATORS

---

The `android:indeterminate` attribute controls whether the `ProgressBar` will render an indeterminate look or a specific look. For the latter, calls to `setMax()` (or the `android:max` attribute) will set the upper end of the progress range (the default is 100), and `setProgress()` or `incrementProgressBy()` will set how much progress along that range is illustrated.

*Figure 607: Android 5.1 ProgressBar, Horizontal Style, Indeterminate and Specific*

*Figure 608: Android 4.0 ProgressBar, Horizontal Style, Indeterminate and Specific*

*Figure 609: Android 2.3.3 ProgressBar, Horizontal Style, Indeterminate and Specific*

### Primary vs. Secondary

For specific progress, you actually have two independent amounts of progress. `setProgress()`, `incrementProgressBy()`, and `android:progress` control the primary progress, while `setSecondaryProgress()`, `incrementSecondaryProgressBy()`, and `android:secondaryProgress` control the secondary progress. Here, “primary progress” refers to the progress along an entire piece of work (e.g., copying a folder’s worth of files), while “secondary progress” refers the progress along a discrete chunk of the overall work (e.g., copying an individual file).

## PROGRESS INDICATORS

---

A `ProgressBar` will render these with different colors, though primary trumps secondary, and so the secondary progress will only be visible when its value exceeds that of the primary progress:

Figure 610: Android 4.0 `ProgressBar`, Horizontal Style, Primary-Only and Primary-Plus-Secondary

Figure 611: Android 2.3.3 `ProgressBar`, Horizontal Style, Primary-Only and Primary-Plus-Secondary

## ProgressBar and Threads

Normally, you cannot update the UI of a widget from a background thread.

`ProgressBar` is an exception. You *can* safely call `setProgress()` and `incrementProgressBy()` from a background thread to update the primary progress, and you can safely call `setSecondaryProgress()` and `incrementSecondaryProgressBy()` from a background thread to update the secondary progress.

To see this in action, take a look at the [Progress/BarSampler](#) sample project.

This project has a single activity (`MainActivity`), whose layout (`activity_main.xml`) contains four `ProgressBar` widgets, two indeterminate and two for specific progress:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <ProgressBar
    android:id="@+id/progressCI"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_horizontal"
    android:layout_marginBottom="20dp"
```

## PROGRESS INDICATORS

---

```
        android:layout_marginTop="20dp"/>

<ProgressBar
    android:id="@+id/progressHI"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginBottom="20dp"
    android:indeterminate="true"/>

<ProgressBar
    android:id="@+id/progressHS"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginBottom="20dp"
    android:indeterminate="false"
    android:max="100"/>

<ProgressBar
    android:id="@+id/progressHS2"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:max="100"/>

</LinearLayout>
```

(from [Progress/BarSampler/app/src/main/res/layout/activity\\_main.xml](#))

The activity gets access to the latter two `ProgressBar` widgets and sets up a `ScheduledThreadPoolExecutor` to get control every second in a background thread, which calls our `run()` method. The `run()` method will increment both `ProgressBar` widgets primary progress by 2 each time, and the secondary progress by 10 (dropping back to the starting point when the secondary progress reaches the maximum of 100). When the primary progress gets to 100, we cancel our scheduled work in the `ScheduledThreadPoolExecutor`:

```
package com.commonware.android.progress;

import android.app.Activity;
import android.os.Bundle;
import android.widget.ProgressBar;
import java.util.concurrent.ScheduledThreadPoolExecutor;
import java.util.concurrent.TimeUnit;

public class MainActivity extends Activity implements Runnable {
```

## PROGRESS INDICATORS

---

```
private static final int PERIOD_SECONDS=1;
private ScheduledThreadPoolExecutor executor=
    new ScheduledThreadPoolExecutor(1);
private ProgressBar primary=null;
private ProgressBar secondary=null;

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    primary=(ProgressBar)findViewById(R.id.progressHS);
    secondary=(ProgressBar)findViewById(R.id.progressHS2);

    executor.setExecuteExistingDelayedTasksAfterShutdownPolicy(false);
    executor.scheduleAtFixedRate(this, 0, PERIOD_SECONDS,
        TimeUnit.SECONDS);
}

@Override
public void onDestroy() {
    executor.shutdown();

    super.onDestroy();
}

@Override
public void run() {
    if (primary.getProgress() < 100) {
        primary.incrementProgressBy(2);
        secondary.incrementProgressBy(2);

        if (secondary.getSecondaryProgress() == 100) {
            secondary.setSecondaryProgress(10);
        }
        else {
            secondary.incrementSecondaryProgressBy(10);
        }
    }
    else {
        executor.remove(this);
    }
}
}
```

(from [Progress/BarSampler/app/src/main/java/com/commonsware/android/progress/MainActivity.java](#))

The net effect is that you see the progress march across the screen, with the

---

secondary progress going through five passes for the primary progress' single pass through the 0-100 range.

## Tailoring Progress Bars

The stock `ProgressBar` look and feel is decent, if perhaps not spectacular. Often times, the stock look is sufficient for your needs. If you wish to have greater control over the look of your `ProgressBar`, the following sections will demonstrate some possibilities.

### Changing the Progress Colors

The `ProgressBar` uses different colors for primary and secondary specific progress. By default, those colors are defined by the theme you are using, and the stock themes have firmware-defined colors (e.g., yellows for Android 1.x and 2.x, blues for Android 3.x and higher).

However, you can change the colors by using a [LayerListDrawable](#) and associating it with a `ProgressBar` by means of the `android:progressDrawable` attribute.

The `ProgressBar` background image needs to be a `LayerListDrawable` with three specific layers:

- `android:id="@android:id/background"` for the background color of the bar
- `android:id="@android:id/progress"` for the primary progress
- `android:id="@android:id/secondaryProgress"` for the secondary progress

Whether those layers are defined as [ShapeDrawable structures](#), or as [nine-patch PNG files](#) is up to you, but they will need the ability to stretch to fit however big your bar winds up being.

To see what this means, let's take a look at the [Progress/Styled](#) sample project. This is a near-clone of the `Progress/BarSampler` project from earlier, using custom backgrounds for the bars. Here, we will look at the horizontal `ProgressBar` widgets — in [the next section](#), we will look at how to change the background of a circular indefinite `ProgressBar`.

For the first horizontal `ProgressBar` (`progressHS`), for Android 4.x, we will use a custom style created by the [Android Holo Colors Generator](#), a Web site set up to help us create custom versions of the holographic widget theme.

## PROGRESS INDICATORS

---

When you visit this site in Google Chrome (note: other browsers are not supported at this time), you can fill in a name for your theme (e.g., “AppTheme”), the color scheme to use for the theme, and the foundation theme to use (light or dark):

## PROGRESS INDICATORS

---

You can then toggle on and off which widgets you intend to use, so the generator will create custom styles for them:

*Figure 613: Android Holo Colors Generator, Widget Selection*

Then, the generator will create a ZIP file that you can download that contains the generated resources for your custom styles.

The Progress/Styled project contains the files generated by the generator, replacing the original style resources. Note that the generator does not create a .DarkActionBar version of the style resource, so the values-v14 resource directory in the project has one hand-crafted based upon a regular generated style resource.

On Android 5.0+, we will use a theme with the same name, but where we are using tints in the theme to affect the colors of the progress indicators.

Our manifest points to our AppTheme as being how we wish to style widgets in this application:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.android.progress"
  android:versionCode="1"
  android:versionName="1.0">
```

## PROGRESS INDICATORS

---

```
<uses-sdk
    android:minSdkVersion="8"
    android:targetSdkVersion="15" />

<application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
        android:name=".MainActivity"
        android:label="@string/title_activity_main">
        <intent-filter>
            <action android:name="android.intent.action.MAIN" />

            <category android:name="android.intent.category.LAUNCHER" />
        </intent-filter>
    </activity>
</application>

</manifest>
```

(from [Progress/Styled/app/src/main/AndroidManifest.xml](#))

That theme, defined in `apptheme_themes.xml`, points to style resources for horizontal `ProgressBar` widgets:

```
<?xml version="1.0" encoding="utf-8"?>

<!-- Generated (in part) with http://android-holo-colors.com -->
<resources xmlns:android="http://schemas.android.com/apk/res/android">

    <style name="AppTheme" parent="android:Theme.Holo.Light.DarkActionBar">

        <item name="android:progressBarStyleHorizontal">@style/ProgressBarAppTheme</item>

    </style>

</resources>
```

(from [Progress/Styled/app/src/main/res/values-v14/apptheme\\_themes.xml](#))

The `ProgressBarAppTheme` style resource is defined in a separate `apptheme_styles.xml` resource:

```
<?xml version="1.0" encoding="utf-8"?>

<!-- Generated with http://android-holo-colors.com -->
<resources xmlns:android="http://schemas.android.com/apk/res/android">

    <style name="ProgressBarAppTheme" parent="android:Widget.Holo.Light.ProgressBar.Horizontal">
```

## PROGRESS INDICATORS

---

```
<item name="android:progressDrawable">@drawable/progress_horizontal_holo_light</item>
<item name="android:indeterminateDrawable">@drawable/
progress_indeterminate_horizontal_holo_light</item>
</style>
</resources>
```

(from [Progress/Styled/app/src/main/res/values-v11/apptHEME\\_styles.xml](#))

Here, we say that we want the `android:progressDrawable` property to be a `progress_horizontal_holo_light` drawable resource. We also set the `android:indeterminateDrawable` property — used for indeterminate bars — to a `progress_indeterminate_horizontal_holo_light` drawable resource.

Those are defined as XML-based drawables, in the `res/drawable/` directory in the project. The `progress_horizontal_holo_light` resource is defined as:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2010 The Android Open Source Project

distributed under the License is distributed on an "AS IS" BASIS,
WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
See the License for the specific language governing permissions and
limitations under the License.
-->
<layer-list xmlns:android="http://schemas.android.com/apk/res/android">

    <item android:id="@android:id/background"
          android:drawable="@drawable/progress_bg_holo_light" />

    <item android:id="@android:id/secondaryProgress">
        <scale android:scaleWidth="100%"
              android:drawable="@drawable/progress_secondary_holo" />
    </item>

    <item android:id="@android:id/progress">
        <scale android:scaleWidth="100%"
              android:drawable="@drawable/progress_primary_holo" />
    </item>
```

## PROGRESS INDICATORS

---

```
</layer-list>
```

(from [Progress/Styled/app/src/main/res/drawable/progress\\_horizontal\\_holo\\_light.xml](#))

The generator creates our `LayerListDrawable` resource with our three layers, each pointing to a nine-patch PNG file (with different versions for different densities) that contains our desired custom color. The `progress` and `secondaryProgress` layers use [ScaleDrawable definitions](#) to ensure that the images are measured against the complete width of the background layer, which in turn will be sized according to the size of the `ProgressBar` itself.

We will take a look at the `progress_indeterminate_horizontal_holo_light` drawable resource in [the next section](#).

Note that you could skip the custom theme and style if you wished, and simply add the `android:progressDrawable` attribute to the `ProgressBar` widget definition in its layout XML resource.

Regardless, the result is that our progress bars have the desired purple color scheme:

Figure 614: Custom `ProgressBar` Style, Primary and Secondary

Also, you can have your `LayerListDrawable` use `ShapeDrawable` layers, to avoid creating nine-patch PNG files, if you prefer, using a resource like this:

```
<?xml version="1.0" encoding="utf-8"?>
<layer-list xmlns:android="http://schemas.android.com/apk/app/src/main/res/android">
  <item android:id="@android:id/background">
    <shape>
      <stroke android:width="1dip" android:color="#FF333333" />
      <gradient
        android:startColor="#FF9C9E9C"
        android:centerColor="#FF5A5D5A"
        android:centerY="0.71"
        android:endColor="#FF6B716B"
        android:angle="270"
      />
    </shape>
  </item>
  <item android:id="@android:id/secondaryProgress">
    <clip>
```

## PROGRESS INDICATORS

---

```
<shape>
  <stroke android:width="1dip" android:color="#FF333333" />
  <gradient
    android:startColor="#4cffffff"
    android:centerColor="#4cE7E7E7"
    android:centerY="0.71"
    android:endColor="#4cFFFBFF"
    android:angle="270"
  />
</shape>
</clip>
</item>
<item android:id="@android:id/progress">
  <clip>
    <shape>
      <stroke android:width="1dip" android:color="#FF333333" />
      <gradient
        android:startColor="#FFFFFFF"
        android:centerColor="#FFE7E7E7"
        android:centerY="0.71"
        android:endColor="#FFFFFFBFF"
        android:angle="270"
      />
    </shape>
  </clip>
</item>
</layer-list>
```

On Android 5.0+, we have it much easier, as `ProgressBar` automatically adopts the accent tint. So we go with a much simpler theme definition:

```
<resources>

  <style name="AppTheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>

</resources>
```

(from [Progress/Styled/app/src/main/res/values-v21/styles.xml](#))

This references colors from a separate `colors.xml` resource:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
```

## PROGRESS INDICATORS

---

```
<color name="primary">#3f51b5</color>
<color name="primary_dark">#1a237e</color>
<color name="accent">#ffee58</color>
</resources>
```

(from [Progress/Styled/app/src/main/res/values-v21/colors.xml](#))

The result are yellow-tinted progress bars:

Figure 615: Material ProgressBar Style, Primary and Secondary

### Changing the Indeterminate Animation

Similarly, for indefinite progress “bars”, changing the progress drawable will let you change the way they look. However, in this case, the drawable also needs to implement the animation itself. You can accomplish this either by using an [AnimationDrawable](#) or by using some other type of drawable wrapped in an animation, such as [a ShapeDrawable wrapped in a <rotate> animation](#).

For example, the Android 4.x custom theme created by the Android Holo Colors Generator assigns the following drawable resource to `android:indeterminateDrawable` in the theme:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
/*
** Copyright 2011, The Android Open Source Project
**
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
**
**     http://www.apache.org/licenses/LICENSE-2.0
**
** Unless required by applicable law or agreed to in writing, software
** distributed under the License is distributed on an "AS IS" BASIS,
** WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
** See the License for the specific language governing permissions and
** limitations under the License.
*/
-->
<animation-list
```

## PROGRESS INDICATORS

---

```
xmlns:android="http://schemas.android.com/apk/res/android"
android:oneshot="false">
<item android:drawable="@drawable/progressbar_indeterminate_holo1" android:duration="50" />
<item android:drawable="@drawable/progressbar_indeterminate_holo2" android:duration="50" />
<item android:drawable="@drawable/progressbar_indeterminate_holo3" android:duration="50" />
<item android:drawable="@drawable/progressbar_indeterminate_holo4" android:duration="50" />
<item android:drawable="@drawable/progressbar_indeterminate_holo5" android:duration="50" />
<item android:drawable="@drawable/progressbar_indeterminate_holo6" android:duration="50" />
<item android:drawable="@drawable/progressbar_indeterminate_holo7" android:duration="50" />
<item android:drawable="@drawable/progressbar_indeterminate_holo8" android:duration="50" />
</animation-list>
```

(from [Progress/Styled/app/src/main/res/drawable/progress\\_indeterminate\\_horizontal\\_holo\\_light.xml](#))

Hence, every horizontal indeterminate ProgressBar will use that AnimationDrawable. The individual images in the animation are PNG files, with different versions for different densities.

Circular ProgressBar widgets also need a custom progress drawable, though obviously the image will need to be circular, not a bar. You can certainly use an AnimationDrawable for this, or you can use a ShapeDrawable, such as the `res/drawable/progress_circular.xml` resource shown below:

```
<?xml version="1.0" encoding="utf-8"?>
<rotate xmlns:android="http://schemas.android.com/apk/res/android"
    android:fromDegrees="0"
    android:pivotX="50%"
    android:pivotY="50%"
    android:toDegrees="360">

    <shape
        android:innerRadiusRatio="3"
        android:shape="ring"
        android:thicknessRatio="8"
        android:useLevel="false">
        <gradient
            android:centerColor="#4c737373"
            android:centerY="0.50"
            android:endColor="#ff9933CC"
            android:startColor="#4c737373"
            android:type="sweep"
            android:useLevel="false"/>
        </shape>
    </rotate>
```

(from [Progress/Styled/app/src/main/res/drawable/progress\\_circular.xml](#))

Here, we have a ring ShapeDrawable, with a certain thickness and radius, filled with

---

## PROGRESS INDICATORS

---

a gradient. Half of the fill is actually a solid color (#4c7373), as the start and center colors are the same. The other half is a sweep gradient from the starting color to the same purple shade that is used by the other bar styles. This ring is then wrapped in a rotate animation. This yields a simple gradient-filled ring, that rotates smoothly to indicate progress:

*Figure 616: Custom ProgressBar Styles, Including Circular Indefinite*

Note that the Android Holo Colors Generator does not generate circular indefinite ProgressBar resources as of the time of this writing.

## PROGRESS INDICATORS

---

Once again, Android 5.0+ can leverage `Theme.Material` and get rid of all the extra clutter. Just having an accent color defined will have your indefinite progress bars adopt that same color:

## Progress Dialogs

One use of a `ProgressBar` is to have it wrapped in a `ProgressDialog`. Like all dialogs, `ProgressDialog` is modal, preventing the user from interacting with an underlying activity while the dialog is displayed. From a UI design standpoint, a `ProgressDialog` is an easy way to temporarily show progress without having to find a spot for a `ProgressBar` widget somewhere in the UI. Also, since usually there are things in the activity that are dependent upon the work being done in the background, having the dialog in place prevents anyone from trying to use things that are not yet ready.

However, modal dialogs are not a great design approach, as they aggressively limit the user's options. `ProgressDialog` is perhaps the worst in this regard, as the user can do nothing except wait. While *part* of your app may not yet be ready, other parts surely are, such as reading the documentation, or adjusting settings, or clicking on

## PROGRESS INDICATORS

---

your ad banners. Hence, using *anything* else other than `ProgressDialog`, while perhaps a bit more work, will be an improvement in the usability of your app.

That being said, let us see how to set up a `ProgressDialog`. The [Progress/Dialog](#) sample project is a near-clone of the [Dialogs/DialogFragment](#) sample project from [the chapter on dialogs](#). The only difference is the `onCreateDialog()` method of our `DialogFragment`, where we directly create a `ProgressDialog` instead of using an `AlertDialog.Builder` to create an `AlertDialog` as before:

```
@Override
public Dialog onCreateDialog(Bundle savedInstanceState) {
    ProgressDialog dlg=new ProgressDialog(getActivity());

    dlg.setMessage(getActivity().getString(R.string.dlg_title));
    dlg.setIndeterminate(true);
    dlg.setProgressStyle(ProgressDialog.STYLE_SPINNER);

    return(dlg);
}
```

(from [Progress/Dialog/app/src/main/java/com/commonsware/android/progdlg/SampleDialogFragment.java](#))

We create the `ProgressDialog` via its constructor, set the message explaining what we are waiting for via `setMessage()`, indicate that the `ProgressBar` should be an indeterminate one via `setIndeterminate()`, and indicate that we want a circular “spinner” `ProgressBar` rather than a horizontal one by calling `setProgressStyle(ProgressDialog.STYLE_SPINNER)`. There are a variety of other things you could configure on the `ProgressDialog` if desired, and `ProgressDialog` inherits from `AlertDialog`, so some things you could configure on an `AlertDialog` will also be available on the `ProgressDialog`.

The result is a dialog that you may have seen from other apps in Android:

*Figure 618: ProgressDialog*

## Title Bar and Action Bar Progress Indicators

Another place to let users know that you are doing something on their behalf is to put a progress indicator in the title bar or action bar of your activity. This avoids your having to put an indeterminate `ProgressBar` somewhere in your activity's UI. It is also very simple to set up, as we can see in the [Progress/TitleBar](#) sample project.

```
package com.commonware.android.titleprog;

import android.app.Activity;
import android.os.Bundle;
import android.view.Window;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        getWindow().requestFeature(Window.FEATURE_INDETERMINATE_PROGRESS);
        super.onCreate(savedInstanceState);
    }
}
```

## PROGRESS INDICATORS

---

```
setContentView(R.layout.activity_main);
setProgressBarIndeterminateVisibility(true);
}
}
```

(from [Progress/TitleBar/app/src/main/java/com/commonsware/android/titleprog/MainActivity.java](#))

Up front, as the first thing that you do in your `onCreate()` call, you need to call:

```
getWindow().requestFeature(Window.FEATURE_INDETERMINATE_PROGRESS);
```

This tells Android to reserve space in your title bar or action bar for an indeterminate progress indicator, though the indicator does not appear at this point.

Later on, when you want the indicator to actually appear, call `setProgressBarIndeterminateVisibility(true)` on your activity, and later call `setProgressBarIndeterminateVisibility(false)` to make the indicator go away.

This particular application has `android:targetSdkVersion` set to 11 or higher, but it is not using an action bar backport. Hence, when you run it on an older Android environment, you get a classic title bar with the progress indicator on the right:

*Figure 619: Progress Indicator in Title Bar*

## PROGRESS INDICATORS

---

When you have an action bar, you get the same basic effect, albeit with a larger indicator to match the larger bar:

*Figure 620: Progress Indicator in Action Bar*

Note that this approach is not supported by `Theme.Material` or the `appcompat-v7` action bar backport, which makes it far less commonly used today.

## Direct Progress Indication

Sometimes, the best way to let the user know about updates is to simply update the data in place. Rather than have some separate indicator, let the core UI itself convey the work being done.

We saw this in [the chapter on threads](#), where we populated a `ListView` in “real time” as we loaded in data into its adapter. Other variations on this theme include:

- Updating a page count `TextView` to show the number of downloaded pages, while the user is reading earlier pages, perhaps with some sort of style (e.g., italics) or color coding (e.g., red) to indicate data that is being loaded.
- Simply disabling the buttons, action bar items, and other ways that the user

## PROGRESS INDICATORS

---

could navigate to a point in your app where you need the data that is being loaded in the background. The key here is to make sure that users understand *why* those items are disabled, and sometimes that is not obvious. Hence, while this step may be necessary, it is often tied in with progress indicators in the title bar or action bar or other means of indicating to the user the *reason* they cannot perform certain operations.

# More Fun with Pagers

---

In earlier chapters, we saw [basic uses of ViewPager](#). However, there are other ways to apply ViewPager and integrate it into the rest of your application, some of which we will examine in this chapter.

## Prerequisites

This chapter assumes that you have read the core chapters, particularly the one showing [how to use ViewPager](#).

## Hosting ViewPager in a Fragment

If you have a ViewPager use fragments for pages and also be itself *in* a fragment, you are using nested fragments: one fragment holds another fragment. This was not originally possible with fragments, but that capability was added to the library implementation of fragments in 2014 or so.

However, using nested fragments requires a minor modification to the way we set up a PagerAdapter, as is illustrated in the [ViewPager/Nested](#) sample project. This is the same project as ViewPager/Indicator, with the twist that the pages are fragments and the ViewPager is inside a fragment.

Our activity now implements the standard add-the-fragment-if-it-does-not-exist pattern that we have seen previously:

```
package com.commonware.android.pagernested;

import android.os.Bundle;
import android.support.v4.app.FragmentActivity;
```

## MORE FUN WITH PAGERS

---

```
public class ViewPagerIndicatorActivity extends FragmentActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
            getSupportFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new PagerFragment()).commit();
        }
    }
}
```

(from [ViewPager/Nested/app/src/main/java/com/commonsware/android/pagernested/ViewPagerIndicatorActivity.java](#))

This loads a PagerFragment, which contains most of the logic from our original activity:

```
package com.commonsware.android.pagernested;

import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class PagerFragment extends Fragment {
    @Override
    public View onCreateView(LayoutInflater inflater,
        ViewGroup container,
        Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.pager, container, false);
        ViewPager pager=(ViewPager)result.findViewById(R.id.pager);

        pager.setAdapter(buildAdapter());

        return(result);
    }

    private PagerAdapter buildAdapter() {
        return(new SampleAdapter(getActivity(), getChildFragmentManager()));
    }
}
```

(from [ViewPager/Nested/app/src/main/java/com/commonsware/android/pagernested/PagerFragment.java](#))

The biggest difference is that our call to the constructor of SampleAdapter no longer uses getSupportFragmentManager(). Instead, it uses getChildFragmentManager().

This allows `SampleAdapter` to use fragments hosted by `PagerFragment`, rather than ones hosted by the activity as a whole.

No other code changes are required, and from the user's standpoint, there is no visible difference.

## Pages and the Action Bar

Fragments that are pages inside a `ViewPager` can participate in the action bar, supplying items to appear as toolbar buttons, in the overflow menu, etc. This is not significantly different than [how any fragment participates in the action bar](#):

- Call `setHasOptionsMenu()` early in the fragment lifecycle (e.g., `onCreateView()`) to state that the fragment wishes to contribute to the action bar contents
- Override `onCreateOptionsMenu()` and `onOptionsItemSelected()`, much as you would with an activity

`ViewPager` and `FragmentManager` will manage the contents of the action bar, based upon the currently-visible page. That page's contributions will appear in the action bar, then will be removed when the user switches to some other page.

To see this in action, take a look at the [ViewPager/ActionBar](#) sample project. This is the same as the `ViewPager/Indicator` project from before, except:

- In `onCreateView()`, for even-numbered page positions (0, 2, etc.), we call `setHasOptionsMenu(true)`:

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);
    EditText editor=(EditText)result.findViewById(R.id.editor);

    position=getArguments().getInt(KEY_POSITION, -1);
    editor.setHint(getTitle(getActivity(), position));

    if ((position % 2)==0) {
        setHasOptionsMenu(true);
    }
}
```

## MORE FUN WITH PAGERS

---

```
return(result);  
}
```

(from [ViewPager/ActionBar/app/src/main/java/com/commonsware/android/pagerbar/EditorFragment.java](#))

- In `onCreateOptionsMenu()`, we inflate a `res/menu/actions.xml` menu resource:

```
@Override  
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {  
    inflater.inflate(R.menu.actions, menu);  
  
    super.onCreateOptionsMenu(menu, inflater);  
}
```

(from [ViewPager/ActionBar/app/src/main/java/com/commonsware/android/pagerbar/EditorFragment.java](#))

Normally, we would also implement `onOptionsItemSelected()`, to find out when the action bar item was tapped, though this is skipped in this sample.

The result is that when we have an even-numbered page position — equating to an odd-numbered title and hint — we have items in the action bar:

*Figure 621: A ViewPager, PagerTabStrip, and Action Bar Item on Android 4.1*

...but as soon as we swipe to an odd-numbered page position — equating to an even-numbered title and hint — our action bar item is removed, as that fragment did not call `setHasOptionsMenu(true)`:

Figure 622: A ViewPager and PagerTabStrip, Sans Action Bar Item on Android 4.1

## ViewPagers and Scrollable Contents

There are other things in Android that can be scrolled horizontally, besides a ViewPager:

- `HorizontalScrollView`
- `WebView`, for content that is wider than the width of the screen
- the deprecated `Gallery` widget
- maps from many mapping engines, such as Google Maps
- various third-party widgets

The challenge then comes in terms of dealing with horizontal swipe events. The ideal situation is for you to be able to swipe horizontally on the material inside the page, until you hit some edge (e.g., end of the `HorizontalScrollView`), then have swipe events move you to the adjacent page.

You can assist `ViewPager` in handling this scenario by subclassing it and overriding the `canScroll()` method. This will be called on a horizontal swipe, and it is up to

you to indicate if the contents can be scrolled (returning `true`) or not (returning `false`). If the built-in logic is insufficient, tailoring `canScroll()` to your particular needs can help.

We will see an example of this elsewhere in the book, when [we put some maps into a ViewPager](#).

## Showing More Pages

In some cases, when the `ViewPager` is on a larger screen, we simply want larger pages — a digital book reader, for example, would simply have a larger page in a bigger font for easier reading.

Sometimes, though, we might not be able to take advantage of the full space offered by the large screen, particularly when our `ViewPager` takes up the whole screen. In cases like this, it might be useful to allow `ViewPager`, in some cases, to show more than one page at a time. Each “page” is then designed to be roughly phone-sized, and we choose whether to show one, two, or perhaps more pages at a time based upon the available screen space.

Mechanically, allowing `ViewPager` to show more than one page is fairly easy, involving overriding one more method in our `PagerAdapter`: `getPageWidth()`. To see this in action, take a look at the [ViewPager/MultiView1](#) sample project.

Each page in this sample is simply a `TextView` widget, using the activity’s style’s “large appearance”, centered inside a `LinearLayout`:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:gravity="center"
    android:orientation="vertical">

    <TextView
        android:id="@+id/text"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textAppearance="?android:attr/textAppearanceLarge"/>

</LinearLayout>
```

(from [ViewPager/MultiView1/app/src/main/res/layout/page.xml](#))

## MORE FUN WITH PAGERS

---

The activity, in `onCreate()`, gets our `ViewPager` from the `res/layout/activity_main.xml` resource, and sets its adapter to be a `SampleAdapter`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    pager=findViewById(R.id.pager);
    pager.setAdapter(new SampleAdapter());
    pager.setOffscreenPageLimit(6);
}
```

(from [ViewPager/MultiView/app/src/main/java/com/commonsware/android/myp1/MainActivity.java](#))

In this case, `SampleAdapter` is not a `FragmentPagerAdapter`, nor a `FragmentStatePagerAdapter`. Instead, it is its own implementation of the `PagerAdapter` interface:

```
/*
 * Inspired by
 * https://gist.github.com/8cbe094bb7a783e37ad1
 */
private class SampleAdapter extends PagerAdapter {
    @Override
    public Object instantiateItem(ViewGroup container, int position) {
        View page=
            getLayoutInflater().inflate(R.layout.page, container, false);
        TextView tv=page.findViewById(R.id.text);
        int blue=position * 25;

        final String msg=
            String.format(getString(R.string.item), position + 1);

        tv.setText(msg);
        tv.setOnClickListener(new OnClickListener() {
            @Override
            public void onClick(View v) {
                Toast.makeText(MainActivity.this, msg, Toast.LENGTH_LONG)
                    .show();
            }
        });

        page.setBackgroundColor(Color.argb(255, 0, 0, blue));
        container.addView(page);

        return(page);
    }
}
```

## MORE FUN WITH PAGERS

---

```
}

@Override
public void destroyItem(ViewGroup container, int position,
                        Object object) {
    container.removeView((View)object);
}

@Override
public int getCount() {
    return(9);
}

@Override
public float getPageWidth(int position) {
    return(0.5f);
}

@Override
public boolean isViewFromObject(View view, Object object) {
    return(view == object);
}
}
```

(from [ViewPager/MultiView1/app/src/main/java/com/commonsware/android/mvpi/MainActivity.java](#))

To create your own PagerAdapter, the big methods that you need to implement are:

- `instantiateItem()`, where you create the page itself and add it to the supplied container. In this case, we inflate the page, set the text of the `TextView` based on the supplied position, set the background color of the page itself to be a different shade of blue based on the position, set up a click listener to show a `Toast` when the `TextView` is tapped, and use that for our page. We return some object that identifies this page; in this case, we return the inflated `View` itself. A fragment-based `PagerAdapter` would probably return the fragment.
- `destroyItem()`, where we need to clean up a page that is being removed from the pager, where the page is identified by the `Object` that we had previously returned from `instantiateItem()`. In our case, we just remove it from the supplied container.
- `isViewFromObject()`, where we confirm whether some specific page in the pager (represented by a `View`) is indeed tied to a specific `Object` returned from `instantiateItem()`. In our case, since we return the `View` from `instantiateItem()`, we merely need to confirm that the two objects are indeed one and the same.

## MORE FUN WITH PAGERS

---

- `getCount()`, as with the built-in `PagerAdapter` implementations, to return how many total pages there are.

In our case, we also override `getPageWidth()`. This indicates, for a given position, how much horizontal space in the `ViewPager` should be given to this particular page. In principle, each page could have its own unique size. The return value is a `float`, from `0.0f` to `1.0f`, indicating what fraction of the pager's width goes to this page. In our case, we return `0.5f`, to have each page take up half the pager.

The result is that we have two pages visible at a time:

*Figure 623: Two Pages in a ViewPager on Android 4.0.3*

It is probably also a good idea to call `setOffscreenPageLimit()` on the `ViewPager`, as we did in `onCreate()`. By default (and at minimum), `ViewPager` will cache three pages: the one presently visible, and one on either side. However, if you are showing more than one at a time, you should bump the limit to be 3 times the number of simultaneous pages. For a page width of `0.5f` — meaning two pages at a time — you would want to call `setOffscreenPageLimit(6)`, to make sure that you had enough pages cached for both the current visible contents and one full swipe to either side.

`ViewPager` even handles “partial swipes” — a careful swipe can slide the right-hand

page into the left-hand position and slide in a new right-hand page. And `ViewPager` stops when you run out of pages, so the last page will always be on the right, no matter how many pages at a time and how many total pages you happen to have.

The biggest downside to this approach is that it will not work well with the current crop of indicators. `PagerTitleStrip` and `PagerTabStrip` assume that there is a single selected page. While the indicator will adjust properly, the visual representation shows that the left-hand page is the one selected (e.g., the tab with the highlight), even though two or more pages are visible. You can probably overcome this with a custom indicator (e.g., highlight the selected tab and the one to its right).

Also note that this approach collides a bit with `setPageMargin()` on `ViewPager`. `setPageMargin()` indicates an amount of whitespace that should go in a gutter between pages. In principle, this would work great with showing multiple simultaneous pages in a `ViewPager`. However, `ViewPager` does not take the gutter into account when interpreting the `getPageWidth()` value. For example, suppose `getPageWidth()` returns `0.5f` and we `setPageMargin(20)`. On a 480-pixel-wide `ViewPager`, we will actually use 500 pixels: 240 for the left page, 240 for the right page, and 20 for the gutter. As a result, 20 pixels of our right-hand page are off the edge of the pager. Ideally, `ViewPager` would subtract out the page margin *before* applying the page width. One workaround is for you to derive the right `getPageWidth()` value based upon the `ViewPager` size and gutter yourself, rather than hard-coding a value. Or, build in your gutter into your page contents (e.g., using `android:layout_marginLeft` and `android:layout_marginRight`) and skip `setPageMargin()` entirely.

### Columns or Pages

Another pattern — using pages for smaller screens and having the “pages” side-by-side in columns for larger screens — will be explored [later in the book](#).

### The Grid Pattern

Yet another approach for taking advantage of larger screen sizes is to always show a full-size master and a full-size detail — perhaps using different activities — but to use a grid rather than a list for the master. This works well when the data being shown in the grid can be represented as “cards”, often dominated by some photo or other image.

---

## MORE FUN WITH PAGERS

---

The basic approach is to use fewer grid columns (e.g., 1 or 2) on smaller screen sizes and more grid columns (e.g., 3 or 4) on larger screen sizes. This way, the application flow is identical across screen sizes, yet the screen usage on larger screens is more effective. This is particularly true if you use one of the “staggered” grid widgets available from third parties, like [Etsy’s AndroidStaggeredGrid](#) or [Maurycy Wojtowicz’s StaggeredGridView](#):

Figure 624: StaggeredGridView Demo (image courtesy of Maurycy Wojtowicz)

## Columns for Large, Pages for Small

In some cases, you can take better advantage of larger screens by using ViewPager more judiciously. In [a previous chapter](#), we explored having ViewPager itself display more than one page at a time. A variation on that same theme is to only use a ViewPager on screen sizes where you lack sufficient room for everything, and to put those same pages on the screen at the same time when you have room for all of them.

For example, a Twitter client for Android could use the columns-or-pages support for displaying various streams of tweets: your timeline, your @ mentions, hashtags you follow, etc. Each stream is represented by a typical ListView, with one row per

tweet. On a phone, since screen space is at a premium, those `ListView` widgets are set up in a `ViewPager`, with one list per page. Users can swipe between the lists, or use tabs to navigate the available lists. However, tablets offer more room, so the app could show three `ListView` widgets side-by-side in landscape mode, so you can take in three sets of content without further interaction with the screen.

The [ViewPager/Columns1](#) sample project will demonstrate how you can accomplish the same basic approach in your own app... with some limitations.

### The Layouts

Our main activity layout — cunningly named `main` — has a `ViewPager`-based definition in `res/layout/main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v4.view.ViewPager android:id="@+id/pager"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <android.support.v4.view.PagerTabStrip
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_gravity="top"/>

</android.support.v4.view.ViewPager>
```

(from [ViewPager/Columns1/app/src/main/res/layout/main.xml](#))

However, in `res/layout-large/`, for 5-inch devices on up, we have a horizontal `LinearLayout` with three `FrameLayout` containers, each representing an equal-sized slot for one of our “pages”:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:baselineAligned="false"
  android:orientation="horizontal">

  <FrameLayout
    android:id="@+id/editor1"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1"/>
```

```
<FrameLayout
    android:id="@+id/editor2"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1"/>

<FrameLayout
    android:id="@+id/editor3"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1"/>

</LinearLayout>
```

(from [ViewPager/Columns/app/src/main/res/layout-large/main.xml](#))

Android will automatically inflate the proper layout when we call `setContentView(R.layout.main)`.

### The Activity

However, while Android handles the inflation for us, we obviously need to populate the contents a bit differently. In this sample, though, we are relying upon the fact that screen size will not change on the fly. Hence, an instance of our application will either show a `ViewPager` or show the horizontal `LinearLayout`, and not have to switch between those at runtime.

Our `SampleAdapter`, therefore, can remain unchanged, except for reducing the page count to 3:

```
package com.commonsware.android.pagercolumns;

import android.content.Context;
import android.support.v4.app.Fragment;
import android.support.v4.app.FragmentManager;
import android.support.v4.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
    Context ctxt=null;

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }
}
```

---

## MORE FUN WITH PAGERS

---

```
@Override
public int getCount() {
    return(3);
}

@Override
public Fragment getItem(int position) {
    return(EditorFragment.newInstance(position));
}

@Override
public String getPageTitle(int position) {
    return(EditorFragment.getTitle(ctxt, position));
}
}
```

(from [ViewPager/Columns/app/src/main/java/com/commonsware/android/pagercolumns/SampleAdapter.java](#))

Our MainActivity will still use the SampleAdapter, and if we have a ViewPager, it will use it the same way as before. However, if we do *not* have a ViewPager, we must be showing three panes of content side by side, in which case we just execute a FragmentTransaction to populate the three FrameLayout containers with the three items created by the SampleAdapter:

```
package com.commonsware.android.pagercolumns;

import android.os.Bundle;
import android.support.v4.app.FragmentActivity;
import android.support.v4.app.FragmentManager;
import android.support.v4.app.FragmentPagerAdapter;
import android.support.v4.view.ViewPager;

public class MainActivity extends FragmentActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        ViewPager pager=findViewById(R.id.pager);

        if (pager==null) {
            if (getSupportFragmentManager().findFragmentById(R.id.editor1)==null) {
                FragmentPagerAdapter adapter=buildAdapter();

                getSupportFragmentManager().beginTransaction()
                    .add(R.id.editor1,
                        adapter.getItem(0))
                    .add(R.id.editor2,
```

## MORE FUN WITH PAGERS

---

```
        adapter.getItem(1))
        .add(R.id.editor3,
            adapter.getItem(2)).commit();
    }
}
else {
    pager.setAdapter(buildAdapter());
}
}

private FragmentPagerAdapter buildAdapter() {
    return(new SampleAdapter(this, getSupportFragmentManager()));
}
}
```

(from [ViewPager/Columns1/app/src/main/java/com/commonsware/android/pagercolumns/MainActivity.java](#))

Of course, we skip the `FragmentManager` if the fragments already exist, such as due to a screen rotation configuration change.

## The Results

On a phone, the `ViewPager`-based layout looks pretty much as it did before:

*Figure 625: A ViewPager. Again.*

However, on a tablet, we get our three editors side-by-side:

Figure 626: Same App, Large-Screen Layout with Side-By-Side Editors

### The Limitations

The simplified large-screen layout does not contain any indicators above the three editors. This could be added by simple changes to the `res/layout-large/main.xml` layout resource, if desired.

The bigger limitation is that this only works if you want the same look in all configurations *except* screen size, and if the screen size never changes. However, it is eminently possible that you will want to have a different mix than that, such as using the three-column approach only on large-screen *landscape* layouts, using `ViewPager` everywhere else. In that case, our approach breaks down, as we will have different fragments inside the pager and outside the pager, meaning that we will lose our data on a configuration change. Addressing this issue is covered in the next two sections.

# **Focus Management and Accessibility**

As developers, we are very used to creating apps that are designed to be navigated by touch, with users tapping on widgets and related windows to supply input.

However, not all Android devices have touchscreens, and not all Android users use touchscreens.

Internationalization (i18n) and localization (L10n) give you opportunities to expand your user base to audiences beyond your initial set, based on language. Similarly, you can expand your user base by offering support for non-touchscreen input and output. Long-term, the largest user base of these features may be those with televisions augmented by Android, whether via Android TV, OUYA consoles, or whatever. Short-term, the largest user base of these features may be those for whom touchscreens are rarely a great option, such as the blind. Supporting those with unusual requirements for input and output is called *accessibility (a11y)*, and represents a powerful way for you to help your app distinguish itself from competitors.

In this chapter, we will first examine how to better handle focus management, and then segue into examining what else, beyond supporting keyboard-based input, can be done in the area of accessibility.

## **Prerequisites**

Understanding this chapter requires that you have read the core chapters and are familiar with the concept of widgets having focus for user input.

## Prepping for Testing

To test focus management, you will need an environment that supports “arrow key” navigation. Here, “arrow key” also includes things like D-pads or trackballs – basically, anything that navigates by key events instead of by touch events.

Examples include:

- The Android emulator, with the `Dpad support hardware` property set to `yes`
- Phones that have actual D-pads, trackballs, arrow keys, or the like
- Television-based Android environments, such as Android TV or the OUYA console
- Devices that have dedicated keyboard accessories, such as the keyboard “slice” available for the ASUS Transformer series of tablets
- A standard Android device accessed via a Bluetooth keyboard, gamepad, or similar sort of pointing device

Hence, even if the emulator will be insufficient for your needs, you should be able to set up a hardware test environment relatively inexpensively. Most modern Android devices support Bluetooth keyboards, and such keyboards frequently can be obtained at low relative cost.

For accessibility beyond merely focus control, you will certainly want to enable TalkBack, via the Accessibility area of the Settings app. This will cause Android to verbally announce what is on the screen, by means of its text-to-speech engine.

On Android 4.0 and higher devices, enabling Talkback will also optionally enable “Explore by Touch”. This allows users to tap on items (e.g., icons in a `GridView`) to have them read aloud via TalkBack, with a double-tap to actually perform what ordinarily would require a single-tap without “Explore by Touch”.

## Controlling the Focus

Android tries its best to have intelligent focus management “out of the box”, without developer involvement. Many times, what it offers is sufficient for your needs. Other times, though, the decisions Android makes are inappropriate:

- Trying to navigate in a certain direction (e.g., right) moves focus to a widget that is not logically what should have the focus
- Focus has other side effects, like showing the soft keyboard on an `EditText`

widget, that is not desirable

Hence, if you feel that you need to take more control over how focus management is handled, you have many means of doing so, covered in this section.

### Establishing Focus

In order for a widget to get the focus, it has to be focusable.

You might think that the above sentence was just a chance for the author to be witty. It was... a bit. But there are actually two types of “focusable” when it comes to Android apps:

- Is it focusable when somebody is using a pointing device or the keyboard?
- Is it focusable in touch mode?

There are three major patterns for the default state of a widget:

1. Some are initially focusable in both cases (e.g., `EditText`)
2. Some are focusable in non-touch mode but are not focusable in touch mode (e.g., `Button`)
3. Some are not focusable in either mode (e.g., `TextView`)

So, when a `Button` is not focusable in touch mode, that means that while the button will take the focus when the user navigates to it (e.g., via keys), the button will *not* take the focus when the user simply taps on it.

You can control the focus semantics of a given widget in four ways:

- You can use `android:focusable` and `android:focusableInTouchMode` in a layout
- You can use `setFocusable()` and `setFocusableInTouchMode()` in Java

We will see examples of these shortly.

### Requesting (or Abandoning) Focus

By default, the focus will be granted to the first focusable widget in the activity, starting from the upper left. Often times, this is a fine solution.

If you want to have some other widget get the focus (assuming that the widget is

focusable, per the section above), you have two choices:

1. Call `requestFocus()` on the widget in question
2. You can give the widget's layout element a child element, named `[requestFocus /]`, to stipulate that this widget should be the one to get the focus

Note that this is a child element, not an attribute, as you might ordinarily expect.

For example, let's look at the [Focus/Sampler](#) sample project, which we will use to illustrate various focus-related topics.

Our main activity, creatively named `MainActivity`, loads a layout named `request_focus.xml`, and demonstrates the `[requestFocus /]` element:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <Button
        android:id="@+id/button1"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/a_button"/>

    <EditText
        android:id="@+id/editText1"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/first_field"
        android:hint="@string/str_1st_field"
        android:inputType="text"/>

    <EditText
        android:id="@+id/editText2"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/second_field"
        android:hint="@string/str_2nd_field"
        android:inputType="text">

        <requestFocus/>
    </EditText>
```

```
</LinearLayout>
```

(from [Focus/Sampler/app/src/main/res/layout/request\\_focus.xml](#))

Here, we have three widgets in a horizontal `LinearLayout`: a `Button`, and two `EditText` widgets. The second `EditText` widget has the `[requestFocus /]` child element, and so it gets the focus when we display our launcher activity:

*Figure 627: Focus Sampler, Showing Requested Focus*

If we had skipped the `[requestFocus /]` element, the focus would have wound up on the first `EditText`... assuming that we are working in touch mode. If the activity had been launched via the pointing device or keyboard, then the `Button` would have the focus, because the `Button` is focusable in non-touch mode by default.

Calling `requestFocus()` from Java code gets a bit trickier. There are a few flavors of the `requestFocus()` method on `View`, of which two will be the most popular:

- An ordinary zero-argument `requestFocus()`
- A one-argument `requestFocus()`, with the argument being the direction in which the focus should theoretically be coming from

## FOCUS MANAGEMENT AND ACCESSIBILITY

---

You might look at the description of the second flavor and decide that the zero-argument `requestFocus()` looks a lot easier. And, sometimes it will work. However, sometimes it will not, as is the case with our second activity, `RequestFocusActivity`.

In this activity, our layout (`focusable_button`) is a bit different:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <EditText
        android:id="@+id/editText1"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/first_field"
        android:hint="@string/str_1st_field"
        android:inputType="text"/>

    <EditText
        android:id="@+id/editText2"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/second_field"
        android:hint="@string/str_2nd_field"
        android:inputType="text">
    </EditText>

    <Button
        android:id="@+id/button1"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:focusableInTouchMode="true"
        android:text="@string/a_button"/>

</LinearLayout>
```

(from [Focus/Sampler/app/src/main/res/layout/focusable\\_button.xml](#))

Here, we put the `Button` last instead of first. We have no `[requestFocus /]` element anywhere, which would put the default focus on the first `EditText` widget. And, our `Button` has `android:focusableInTouchMode="true"`, so it will be focusable regardless of whether we are in touch mode or not.

In `onCreate()` of our activity, we use the one-parameter version of `requestFocus()`

to give the Button the focus:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.focusable_button);
    initActionBar();

    button=findViewById(R.id.button1);
    button.requestFocus(View.FOCUS_RIGHT);
    button.setOnClickListener(this);
}
```

(from [Focus/Sampler/app/src/main/java/com/commonsware/android/focus/RequestFocusActivity.java](#))

If there were only the one `EditText` before the `Button`, the zero-argument `requestFocus()` works. However, with a widget between the default focus and our `Button`, the zero-argument `requestFocus()` does not work, but using `requestFocus(View.FOCUS_RIGHT)` does. This tells Android that we want the focus, and it should be as if the user is moving to the right from where the focus currently lies.

All of our activities inherit from a `BaseActivity` that manages our action bar, with an overflow menu to get to the samples and the app icon to get to the original activity.

So, if you run the app and choose “Request Focus” from the overflow menu, you will see:

*Figure 628: Focus Sampler, Showing Manually-Requested Focus*

We also wire up the Button to the activity for click events, and in `onClick()`, we call `clearFocus()` to abandon the focus:

```
@Override
public void onClick(View v) {
    button.clearFocus();
}
```

(from [Focus/Sampler/app/src/main/java/com/commonsware/android/focus/RequestFocusActivity.java](#))

What `clearFocus()` will do is return to the original default focus for this activity, in our case the first `EditText`:

*Figure 629: Focus Sampler, After Clearing the Focus*

### Focus Ordering

Beyond manually placing the focus on a widget (or manually clearing that focus), you can also override the focus order that Android determines automatically. While Android's decisions usually are OK, they may not be optimal.

A widget can use `android:nextFocus...` attributes in the layout file to indicate the widget that should get control on a focus change in the direction indicated by the ... part. So, `android:nextFocusDown`, applied to Widget A, indicates which widget should receive the focus if, when the focus is on Widget A, the user “moves down” (e.g., presses a DOWN key, presses the down direction on a D-pad). The same logic holds true for the other three directions (`android:nextFocusLeft`, `android:nextFocusRight`, and `android:nextFocusUp`).

For example, the `res/layout/table.xml` resource in the `FocusSampler` project is based on the `TableLayout` sample from early in this book, with a bit more focus control:

## FOCUS MANAGEMENT AND ACCESSIBILITY

---

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1">

    <TableRow>

        <TextView android:text="@string/url"/>

        <EditText
            android:id="@+id/entry"
            android:layout_span="3"
            android:inputType="text"
            android:nextFocusRight="@+id/ok"/>
    </TableRow>

    <TableRow>

        <Button
            android:id="@+id/cancel"
            android:layout_column="2"
            android:text="@string/cancel"/>

        <Button
            android:id="@+id/ok"
            android:text="@string/ok"/>
    </TableRow>

</TableLayout>
```

(from [Focus/Sampler/app/src/main/res/layout/table.xml](#))

In the original `TableLayout` sample, by default, pressing either `RIGHT` or `DOWN` while the `EditText` has the focus will move the focus to the “Cancel” button. This certainly works. However, it does mean that there is no single-key means of moving from the `EditText` to the “OK” button, and it would be nice to offer that, so those using the pointing device or keyboard can quickly move to either button.

This is a matter of overriding the default focus-change behavior of the `EditText` widget. In our case, we use `android:nextFocusRight="@+id/ok"` to indicate that the “OK” button should get the focus if the user presses `RIGHT` from the `EditText`. This gives `RIGHT` and `DOWN` different behavior, to reach both buttons.

## Scrolling and Focusing Do Not Mix

Let's suppose that you have a UI design with a fixed bar of widgets at the top (e.g., action bar), a `ListView` dominating the activity, and a panel of widgets at the bottom (e.g., a `Toolbar`). This is a common UI pattern on iOS, though it is relatively uncommon on Android nowadays. You used to see it with the so-called “split action bar”, which is now officially deprecated as a pattern:

*Figure 630: Split Action Bar*

However, this UI pattern does not work well for those using pointing devices or keyboards for navigation. In order to get to the bottom panel of widgets, they will have to scroll through the entire list first, because scrolling trumps focus changes. So while this is easy to navigate via a touchscreen, it is a major problem to navigate for those not using a touchscreen.

Similarly, if the user has scrolled down the list, and now wishes to get to the action bar at the top, the user would have to scroll all the way to the top of the list first.

Workarounds include:

- Overriding focus control such that left and right navigation from the list

moves you to the action bar or bottom Toolbar (e.g., left moves you to the action bar, right moves you to the Toolbar)

- In a television setup, having the “action bar” be vertical down the left, and the tools be vertical down the right, so you automatically get the left/right navigation to move between these “zones”
- Eliminating the Toolbar entirely, moving those items instead to the action bar, or perhaps an [action mode](#) (a.k.a., contextual action bar) if the items are only relevant if the user checks one or more items in the list
- Offer a hotkey, separate from navigation, that repositions the focus (e.g.,  to jump to the action bar), if you believe that users will read your documentation to discover this key combination

## Accessibility and Focus

People suffering from impaired vision, including the blind, have had to rely heavily on proper keyboard navigation for their use of Android apps, at least prior to Android 4.0 and “Explore by Touch”. These users need focus to be sensible, so that they can find their way through your app, with TalkBack supplying prompts for what has the focus. Having widgets that are unreachable in practice will eliminate features from your app for this audience, simply because they cannot get to them.

“Explore by Touch” provides accessibility assistance without reliance upon proper focus. However:

- “Explore by Touch” is new to Android 4.0, and a few visually-impaired users will be using older devices
- “Explore by Touch” is less reliable than keyboard-based navigation, insofar as users have to remember specific screen locations (and get to them without seeing those locations), rather than simply memorizing certain key combinations
- “Explore by Touch”, by requiring additional taps (e.g., double-tap to tap a Button), may cause some challenges when the UI itself requires additional taps (e.g., a double-tap on a widget to perform an action — is this now a triple-tap in “Explore by Touch” mode?)
- “Explore by Touch” is mostly for the visually impaired, and does not help others that might benefit from key-based navigation (e.g., people with limited motor control)

So, even though “Explore by Touch” will help people use apps that cannot be navigated purely through key events, the better you can support keyboards, the

better off your users will be.

## Accessibility Beyond Focus

While getting focus management correct goes a long way towards making your application easier to use, it is not the only thing to consider for making your application truly accessible by all possible users. This section covers a number of other things that you should consider as part of your accessibility initiatives.

### Content Descriptions

For TalkBack to work, it needs to have something useful to read aloud to the user. By default, for most widgets, all it can say is the type of widget that has the focus (e.g., “a checkbox”). That does not help the TalkBack-reliant user very much.

Please consider adding `android:contentDescription` attributes to most of your widgets, pointing to a string resource that briefly describes the widget (e.g., “the Enabled checkbox”). This will be used in place of the basic type of widget by TalkBack.

Classes that inherit from `TextView` will use the text caption of the widget by default, so your `Button` widgets may not need `android:contentDescription` if their captions will make sense to TalkBack users.

However, with an `EditText`, since the text will be what the user types in, the text is not indicative of the widget itself. Android will first use your `android:hint` value, if available, falling back to `android:contentDescription` if `android:hint` is not supplied.

Also, bear in mind that if the widget changes purpose, you need to change your `android:contentDescription` to match. For example, suppose you have a media player app with an `ImageButton` that you toggle between “play” and “pause” modes by changing its image. When you change the image, you also need to change the `android:contentDescription` as well, lest sighted users think the button will now “pause” while blind users think that the button will now “play”.

### Labels

Sometimes, we have `TextView` widgets that serve as on-screen labels for some adjacent other widget, such as an `EditText`. In those cases, you can associate the two

by using `android:labelFor` on the `TextView`, supplying the ID of the widget for which the `TextView` is a label. This will help accessibility tools properly announce the widgets, as otherwise those tools do not know that these widgets are related.

### Custom Widgets and Accessibility Events

The engine behind TalkBack is an accessibility service. Android ships with some, like TalkBack, and third parties can create other such services.

Stock Android widgets generate relevant accessibility events to feed data into these accessibility services. That is how `android:contentDescription` gets used, for example — on a focus change, stock Android widgets will announce the widget that just received the focus.

If you are creating custom widgets, you may need to raise your own accessibility events. This is particularly true for custom widgets that draw to the Canvas and process raw touch events (rather than custom widgets that merely aggregate existing widgets).

The Android developer documentation provides [instructions for when and how to supply these sorts of events](#).

### Announcing Events

Sometimes, your app will change something about its visual state in ways that do not get picked up very well by any traditional accessibility events. For example, you might use `GestureDetector` to handle some defined library of gestures and change state in your app. Those state changes may have visual impacts, but `GestureDetector` will not know what those are and therefore cannot supply any sort of accessibility event about them.

To help with this, API Level 16 added `announceForAccessibility()` as a method on `View`. Just pass it a string and that will be sent out as an “announcement” style of `AccessibilityEvent`. Your code leveraging `GestureDetector`, for example, could use this to explain the results of having applied the gesture.

### Font Selection and Size

For users with limited vision, being able to change the font size is a big benefit. Android 4.0 finally allows this, via the Settings app, so users can choose between

small, normal, large, and huge font sizes. Any place where text is rendered and is measured in sp will adapt.

The key, of course, is the sp part.

sp is perhaps the most confusing of the available dimension units in Android. px is obvious, and dp (or dip) is understandable once you recognize the impacts of screen density. Similarly, in, mm, and pt are fairly simple, at least once you remember that pt is 1/72nd of an inch.

If the user has the font scale set to “normal”, sp equates to dp, so a dimension of 30sp and 30dp will be the same size. However, values in dp do not change based on font scale; values in sp will increase or decrease in physical size based upon the user’s changes to the font scale.

We can see how this works in the [Accessibility/FontScale](#) sample project.

In our layout (res/layout/activity\_main.xml), we have six pieces of text: two each (regular and bold) measured at 30px, 30dp, and 30sp:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:id="@+id/LinearLayout1"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginTop="10dp"
    android:text="@string/normal_30px"
    android:textSize="30px"
    tools:context=".MainActivity"/>

  <TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/bold_30px"
    android:textSize="30px"
    android:textStyle="bold"
    tools:context=".MainActivity"/>

  <TextView
    android:layout_width="match_parent"
```

```
    android:layout_height="wrap_content"
    android:layout_marginTop="10dp"
    android:text="@string/normal_30dp"
    android:textSize="30dp"
    tools:context=".MainActivity" />

<TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/bold_30dp"
    android:textSize="30dp"
    android:textStyle="bold"
    tools:context=".MainActivity" />

<TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginTop="10dp"
    android:text="@string/normal_30sp"
    android:textSize="30sp"
    tools:context=".MainActivity" />

<TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/bold_30sp"
    android:textSize="30sp"
    android:textStyle="bold"
    tools:context=".MainActivity" />

</LinearLayout>
```

(from [Accessibility/FontScale/app/src/main/res/layout/activity\\_main.xml](#))

You will be able to see the differences between 30px and 30dp on any Android OS release, simply by running the app on devices with different densities. To see the changes between 30dp and 30sp, you will need to run the app on an Android 4.0+ device or emulator and change the font scale from the Settings app (typically in the Display section).

Here is what the text looks like with a normal font scale:

*Figure 631: Fonts at Normal Scale*

As you can see, 30dp and 30sp are equivalent.

If we raise the font scale to “large”, the 30sp text grows to match:

*Figure 632: Fonts at Large Scale*

Moving to “huge” scale increases the 30sp text size further:

*Figure 633: Fonts at Huge Scale*

In the other direction, some users may elect to drop their font size to “small”, with a corresponding impact on the 30sp text:

*Figure 634: Fonts at Small Scale*

As a developer, your initial reaction may be to run away from sp, because you do not control it. However, just as Web developers should deal with changing font scale in Web browsers, Android developers should deal with changing font scale in Android apps. Remember: the user is changing the font scale because the *user* feels that the revised scale is easier for them to use. Blocking such changes in your app, by avoiding sp, will not be met with love and adoration from your user base.

Also, bear in mind that changes to the font scale represent a configuration change. If your app is in memory at the time the user goes into Settings and changes the scale, if the user returns to your app, each activity that comes to the foreground will undergo the configuration change, just as if the user had rotated the screen or put the device into a car dock or something.

### Widget Size

Users with ordinary sight already have trouble with tiny widgets, as they are difficult to tap upon.

Users trying to use the Explore by Touch facility added in Android 4.1 have it worse, as they cannot even see (or see well) the tiny target you are expecting them to tap upon. They need to be able to reliably find your widget based on its relative position on the screen, and their ability to do so will be tied, in part, on widget size.

The [Android design guidelines recommend](#) 7-10mm per side minimum sizes for tappable widgets. In particular, they recommend 48dp per side, which results in a size of about 9mm per side.

You also need to consider how closely packed your widgets are. The closer the tap targets lie, the more likely it is that all users — whether using Explore by Touch or not — will accidentally tap on the wrong thing. Google recommends 8dp or more of margin between widgets. Also note that the key is *margins*, as while increasing padding might visually separate the widgets, the padding is included as part of the widget from the standpoint of touch events. While padding may help users with ordinary sight, margins provide similar help while also being of better benefit to those using Explore by Touch.

### Gestures and Taps

If you employ gestures, be careful when employing the same gesture in different spots for different roles, particularly within the same activity.

For example, you might use a horizontal swipe to the right to switch pages in a `ViewPager` in some places and remove items from a `ListView` in others. While there may be visual cues to help explain this to users with ordinary sight, it may be far less obvious what is going on for TalkBack users. This is even more true if you are somehow combining these things (e.g., the `ListView` in question is in a page of the `ViewPager`).

Also, be a bit careful as you “go outside the box” for tap events. You might decide that a double-tap, or a two-finger tap, has special meaning on some widgets. Make sure that this still works when users use Explore by Touch, considering that the first tap will be “consumed” by Explore by Touch to announce the widget being tapped upon.

### Enhanced Keyboard Support

All else being equal, users seeking accessibility assistance will tend to use keyboards when available. For users with limited (or no) sight, tactile keyboards are simply easier to use than touchscreens. For users with limited motor control, external

devices that interface as keyboards may allow them to use devices that otherwise they could not.

Of course, plenty of users will use keyboards outside of accessibility as well. For example, devices like the ASUS Transformer series form perfectly good “netbook”-style devices when paired with their keyboards.

Hence, consider adding hotkey support, to assist in the navigation of your app. Some hotkeys may be automatically handled (e.g., `Ctrl-C` for copy in an `EditText`). However, in other cases you may wish to add those yourself (e.g., `Ctrl-C` for “copy” with respect to a checklist and its selected rows, in addition to a “copy” action mode item).

API Level 11 adds `KeyEvent` support for methods like `isCtrlPressed()` to detect meta keys used in combination with regular keys.

### Audio and Haptics

Of course, another way to make your app more accessible is to provide alternative modes of input and output, beyond the visual.

Audio is popular in this regard:

- Using tones or clicks to reinforce input choices
- Integrating your own text-to-speech to augment TalkBack
- Integrating speech recognition for simple commands

However, bear in mind that deaf users will be unable to hear your audio. You are better served using both auditory and visual output, not just one or the other.

In some cases, haptics can be helpful for input feedback, by using the `Vibrator` system service to power the vibration motor. While most users will be able to feel vibrations, the limitation here is whether the device is capable of vibrating:

- Some tablets lack a vibration motor
- Television-based Android environment may or may not have some sort of vibration output (e.g., remote controls probably will not, but game controllers might)
- Devices not held in one’s hand, such as those in a dock, will make haptics less noticeable

So, audio and vibration can help augment visual input and output, though they should not be considered complete replacements except in rare occurrences.

### Color and Color Blindness

[Approximately 8% of men \(and 0.5% of women\)](#) in the world are colorblind, meaning that they cannot distinguish certain close colors:

...It's not that colorblind people (in most cases) are incapable or perceiving "green," instead they merely distinguish fewer shades of green than you do. So where you see three similar shades of green, a colorblind user might only see one shade of green.

(from ["Tips for Designing for Colorblind Users"](#))

Hence, relying solely on colors to distinguish different items, particularly when required for user input, is not a wise move.

Make sure that there is something more to distinguish two pieces of your UI than purely a shift in color, such as:

- Labels or icons
- Textures (e.g., solid vs. striped)
- Borders (e.g., drop shadow)

### Accessibility Beyond Impairment

Accessibility is often tied to impaired users: ones with limited (or no) sight, ones with limited (or no) hearing, ones with limited motor control, etc.

In reality, accessibility is for *situations* where users may have limitations. For example, a user who might not normally think of himself as "impaired" has limited sight, hearing, and motor control when those facilities are already in use, such as while driving.

Hence, offering features that help with accessibility can benefit *all* your users, not just ones you think of as "impaired". For example:

- Offer a UI mode with an eye towards use in low-visibility situations that can either be manually invoked (e.g., via a preference) or automatically invoked

## FOCUS MANAGEMENT AND ACCESSIBILITY

---

- (e.g., via a car dock)
- Offer voice input (commands) and output (text-to-speech) — iOS's Siri is not just for the blind, after all
  - Offer hotkeys, not only to help those requiring a keyboard as their primary mode of input (e.g., blind users minimizing touchscreen use), but to help those who opt into using it for input (e.g., using a keyboard with an Android tablet in lieu of a traditional notebook or netbook)

# Miscellaneous UI Tricks

---

While well-written GUI frameworks are better organized than [XKCD's take on home organization](#), there are always a handful of tidbits that do, indeed, get categorized as “miscellaneous”.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having an appreciation for XKCD is welcome, but optional.

## Full-Screen and Lights-Out Modes

Full-screen mode, in Android parlance, means removing any system-supplied “bars” from the screen: title bar, action bar, status bar, system bar, navigation bar, etc. You might use this for games, video players, digital book readers, or other places where the time spent in an activity is great enough to warrant removing some of the normal accouterments to free up space for whatever the activity itself is doing.

Lights-out mode, in Android parlance, is where you take the system bar or navigation bar and dim the widgets inside of them, such that the bar is still usable, but is less visually distracting. This is a new concept added in Android 3.0 and has no direct analogue in Android 1.x or 2.x.

## Android 1.x/2.x

To have an activity be in full-screen mode, you have two choices:

1. Having the activity use a theme of `Theme.NoTitleBar.Fullscreen` (or some

## MISCELLANEOUS UI TRICKS

---

- custom theme that inherits from `Theme.NoTitleBar.Fullscreen`)
2. Execute the following statements in `onCreate()` of your activity *before* calling `setContentView()`:

```
requestWindowFeature(Window.FEATURE_NO_TITLE);
getWindow().setFlags(WindowManager.LayoutParams.FLAG_FULLSCREEN,
    WindowManager.LayoutParams.FLAG_FULLSCREEN);
```

The first statement removes the title bar or action bar. The second statement indicates that you want the activity to run in full-screen mode, hiding the status bar.

### Android 4.0+

Things got significantly more messy once we started adding in the system bar (and, later, the navigation bar as the replacement for the system bar). Since these bars provide the user access to HOME, BACK, etc., it is usually important for them to be available. Android's behavior, therefore, varies in how you ask for something to happen and what then happens, based upon whether the device is a phone or a tablet.

The [Activities/FullScreen](#) sample project tries to enumerate some of the possibilities. On an Android 4.0 device, we have three `RadioButtons`:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <RadioGroup
        android:id="@+id/screenStyle"
        android:layout_width="match_parent"
        android:layout_height="wrap_content">

        <RadioButton
            android:id="@+id/normal"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:checked="true"
            android:text="@string/display_normal"/>

        <RadioButton
            android:id="@+id/lowProfile"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content">
```

## MISCELLANEOUS UI TRICKS

---

```
    android:text="@string/display_low_profile"/>

    <RadioButton
        android:id="@+id/hideNav"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/display_hide_navigation"/>
</RadioGroup>

<Button
    android:id="@+id/button"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentBottom="true"
    android:text="@string/something_at_the_bottom"/>

</RelativeLayout>
```

(from [Activities/FullScreen/app/src/main/res/layout/main.xml](#))

*Figure 635: Sample UI, As Initially Launched on Android 4.0*

...while on Android 4.1 or higher, we have another two possibilities:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
```

## MISCELLANEOUS UI TRICKS

---

```
xmlns:tools="http://schemas.android.com/tools"
android:layout_width="match_parent"
android:layout_height="match_parent">

<RadioGroup
    android:id="@+id/screenStyle"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <RadioButton
        android:id="@+id/normal"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:checked="true"
        android:text="@string/display_normal"/>

    <RadioButton
        android:id="@+id/lowProfile"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/display_low_profile"/>

    <RadioButton
        android:id="@+id/hideNav"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/display_hide_navigation"/>

    <RadioButton
        android:id="@+id/hideStatusBar"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/hide_status_bar"/>

    <RadioButton
        android:id="@+id/fullScreen"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/display_full_screen"/>
</RadioGroup>

<Button
    android:id="@+id/button"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentBottom="true"
    android:text="@string/something_at_the_bottom"/>
```

## MISCELLANEOUS UI TRICKS

---

`</RelativeLayout>`

(from [Activities/FullScreen/app/src/main/res/layout-v16/main.xml](#))

*Figure 636: Sample UI, As Initially Launched on a Nexus 4/Android 4.2*

## MISCELLANEOUS UI TRICKS

---

Controlling the full-screen and lights-out modes is managed via a call to `setSystemUiVisibility()`, a method on `View`. You pass in a value made up of an OR'd (`|`) set of flags indicating what you want the visibility to be, with the default being normal operation. Hence, in the screenshot above, you see a Nexus 4 in normal mode. Here is the same UI on a Nexus 10 in normal mode:

*Figure 637: Sample UI, As Initially Launched on a Nexus 10/Android 4.2*

## MISCELLANEOUS UI TRICKS

---

Lights-out, or low-profile mode, is achieved by calling `setSystemUiVisibility()` with the `View.SYSTEM_UI_FLAG_LOW_PROFILE` flag. This will dim the navigation or system bar, so the bar is there and the buttons are still active, but that they are less visually intrusive:

*Figure 638: Sample UI, Lights-Out Mode, Nexus 4/Android 4.2*

## MISCELLANEOUS UI TRICKS

---

*Figure 639: Sample UI, Lights-Out Mode, Nexus 10/Android 4.2*

## MISCELLANEOUS UI TRICKS

---

You can temporarily hide the navigation bar (or system bar) by passing `View.SYSTEM_UI_FLAG_HIDE_NAVIGATION` to `setSystemUiVisibility()`. The bar will disappear, until the user touches the UI, in which case the bar reappears:

*Figure 640: Sample UI, Hidden-Navigation Mode, Nexus 4/Android 4.2*

## MISCELLANEOUS UI TRICKS

---

*Figure 641: Sample UI, Hidden-Navigation Mode, Nexus 10/Android 4.2*

## MISCELLANEOUS UI TRICKS

---

Similarly, you can hide the status bar by passing `View.SYSTEM_UI_FLAG_FULLSCREEN` to `setSystemUiVisibility()`. However, despite this flag's name, it does not affect the navigation or system bar:

*Figure 642: Sample UI, “Full-Screen” Mode, Nexus 4/Android 4.2*

## MISCELLANEOUS UI TRICKS

---

## MISCELLANEOUS UI TRICKS

---

Hence, to hide both the status bar and the navigation or system bar, you need to pass both flags (`View.SYSTEM_UI_FLAG_FULLSCREEN` | `View.SYSTEM_UI_FLAG_HIDE_NAVIGATION`):

Note that showing and hiding the `ActionBar` is also possible, via calls to `show()` and `hide()`, respectively.

## Offering a Delayed Timeout

Android makes it easy for activities to keep the screen on while the activity is in the foreground, by means of `android:keepScreenOn` and `setKeepScreenOn()`.

However, these are very blunt instruments, and too many developers simply ask to keep the screen on constantly, even when that is not needed and can cause excessive battery drain. That is because it is very easy to *always* keep the screen on.

Say, for example, you are playing a game. Keeping the screen on while the game is being played is probably a good thing, particularly if the game does not require constant interaction with the screen. However, if you press the in-game pause button, the game might keep the screen on while the game is paused. This might lead you to press pause, put down your tablet (expecting it to fall asleep in a normal period of time), and then have the tablet keep going and going and going... until the battery runs dead.

## MISCELLANEOUS UI TRICKS

---

Whether you use `setKeepScreenOn()` or directly use a `WakeLock`, it is useful to think of three tiers of user interaction.

The first tier is when your app is doing its “one big thing”: playing the game, playing the video, displaying the digital book, etc. If you expect that there will be periods of time when the user is actively engaged with your app, but is not interacting with the screen, keep the screen on.

The second tier is when your app is delivering something to the user that *probably* would get used without interaction in the short term, but not indefinitely. For example, a game might reasonably expect that 15 seconds could be too short to have the screen time out, but if the user has not done anything in 5-10 minutes, most likely they are not in front of the game. Similarly, a digital book reader should not try to keep the screen on for an hour without user interaction.

The third tier is when your app is doing anything other than the main content, where normal device behavior should resume. A video player might keep the screen on while the video is playing, but if the video ends, normal behavior should resume. After all, if the person who had been watching the video fell asleep, they will not be in position to press a power button.

The first and third tiers are fairly easy from a programming standpoint. Just `acquire()` and `release()` the `WakeLock`, or toggle `setKeepScreenOn()` between `true` and `false`.

The second tier — where you are willing to have a screen timeout, just not too quickly — requires you to add a bit more smarts to your app. A simple, low-overhead way of addressing this is to have a `postDelayed()` loop, to get a `Runnable` control every 5-10 seconds. Each time the user interacts with your app, update a `lastInteraction` timestamp. The `Runnable` compares `lastInteraction` with the current time, and if it exceeds some threshold, release the `WakeLock` or call `setKeepScreenOn(false)`. When the user interacts again, though, you will need to re-acquire the `WakeLock` or call `setKeepScreenOn(true)`. Basically, you have your own inactivity timing mechanism to control when you are inhibiting normal inactivity behavior or not.

To see the second tier in action, take a look at the [MiscUI/DelayedTimeout](#) sample project.

The UI is a simple button. We want to keep the screen awake while the user is using the button, but let it fall asleep after a period of inactivity that we control. To

## MISCELLANEOUS UI TRICKS

---

accomplish this, we will use a `postDelayed()` loop, to get control every 15 seconds to see if there has been user activity:

```
package com.commonware.android.timeout;

import android.app.Activity;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;

public class MainActivity extends Activity implements Runnable {
    private static int TIMEOUT_POLL_PERIOD=15000; // 15 seconds
    private static int TIMEOUT_PERIOD=300000; // 5 minutes
    private View content=null;
    private long lastActivity=SystemClock uptimeMillis();

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        content=findViewById(android.R.id.content);
        content.setKeepScreenOn(true);
        run();
    }

    @Override
    public void onDestroy() {
        content.removeCallbacks(this);

        super.onDestroy();
    }

    @Override
    public void run() {
        if ((SystemClock uptimeMillis() - lastActivity) > TIMEOUT_PERIOD) {
            content.setKeepScreenOn(false);
        }

        content.postDelayed(this, TIMEOUT_POLL_PERIOD);
    }

    public void onClick(View v) {
        lastActivity=SystemClock uptimeMillis();
    }
}
```

(from [MiscUI/DelayedTimeout/app/src/main/java/com/commonware/android/timeout/MainActivity.java](#))

## MISCELLANEOUS UI TRICKS

---

In `onCreate()`, we call `setKeepScreenOn(true)` to keep the screen on, regardless of what the user's default timeout is. Then, we call the `run()` method from our `Runnable` interface (implemented on the activity itself). `run()` sees if 5 minutes has elapsed since the last bit of user activity (initially set to be the time the activity launches). If 5 minutes has elapsed, we revert to normal screen-timeout behavior with `setKeepScreenOn(false)`. We also schedule ourselves, as a `Runnable`, to get control again in 15 seconds, to see if 5 minutes has elapsed since the last-seen activity. Our button's `onClick()` method simply updates the last-seen timestamp, and `onDestroy()` cleans up our `postDelayed()` loop by calling `removeCallbacks()` to stop invoking our `Runnable`.

The net is that the device's screen will remain on for 5 minutes since the last time the user taps the button, even if the user's default screen timeout is set to shorter than 5 minutes. Yet, at the same time, we do not keep the screen on *forever*, causing unnecessary battery drain.

Note that to test this, you will probably need to unplug your USB cable after installing the app on the device (since many developers have it set up to keep the screen on while plugged in). Also, you will need to set your device's screen timeout to be under 5 minutes, if it is not set that way already.

This is a primitive implementation, missing lots of stuff that you would want in production code (e.g., it never calls `setKeepScreenOn(true)` if we flipped it to `false` but *then* tap the button). And the complexity of determining if the user interacted with the screen will be tied to the complexity of your UI.

That being said, by having a more intelligent use of `WakeLock` and `setKeepScreenOn()`, you can deliver value to the user while not accidentally causing excessive battery drain. Users do not always remember to press the power button, so you need to make sure that just because the user made a mistake, that you do not make it worse.

# Event Bus Alternatives

---

[Earlier in the book](#), we covered the concept of an event bus as a way of communicating between portions of our app, focusing on one event bus implementation: greenrobot's EventBus. Later, in the chapter on broadcast Intent objects, we [briefly covered LocalBroadcastManager](#).

However, those are not the only event buses available for Android, and others may fit your needs better. In this chapter, we will explore these and other event bus implementations, to compare and contrast.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly the chapters on [basic event bus usage](#), [broadcast Intents](#), [AlarmManager and the scheduled service pattern](#), and [Notifications](#).

## A Brief Note About the Sample Apps

The sample apps in this chapter are generally designed to run forever.

It is unlikely that you really want them to run forever, though. Hence, please uninstall each sample after experimenting with it, particularly if you are testing on hardware, such as your personal phone. Your battery will appreciate it.

## Standard Intents as Event Bus

You can think of the standard Intent and <intent-filter> system as a three-channel event bus:

## EVENT BUS ALTERNATIVES

---

- One channel is used for starting activities
- One channel is used for starting or binding to services
- One channel is used for more ad-hoc “broadcast” events

The component starting an activity does not need to communicate directly with code for that activity — in fact, often times this is impossible, as they are separate apps running in separate processes. Instead, the component starting an activity sends an event indicating the particular operation to be performed (e.g., view this URL), and Android and the user determine which of candidate consumers is the one to process that event.

However, broadcast Intent objects are a closer analogue to a real “event bus”, in that an event produced by somebody can be consumed by zero, one, or several subscribed consumers, based upon the filtering provided by `<intent-filter>` elements in the manifest or `IntentFilter` objects for use with `registerReceiver()`.

In theory, you could use broadcast Intent objects as the backbone for a fairly flexible event bus within your app. In practice, this is not usually a good idea:

- Each broadcast involves inter-process communication (IPC), even if the event producer and consumer(s) are in the same process. This adds overhead.
- Because broadcasts are intrinsically IPC, you have to take security into account, to ensure only authorized producers can publish events that the consumers pick up.

However, if you specifically need a cross-process event bus, such as between a suite of related apps, using a broadcast Intent is a very likely choice.

## LocalBroadcastManager as Event Bus

As was briefly noted [earlier in the book](#), the Android Support package offers a `LocalBroadcastManager`. This is designed to offer an event bus with a feel very similar to classic broadcast Intent objects, but local to your process. Not only does this avoid IPC overhead, but it improves security, as other apps have no means of spying on your internal communications.

`LocalBroadcastManager` is supplied by both the `support-v4` and `support-v13` libraries. Generally speaking, if your `minSdkVersion` is less than 13, you probably should choose `support-v4`.

### A Simple LocalBroadcastManager Sample

Let's see LocalBroadcastManager in action via the [Intents/Local](#) sample project.

Here, our LocalActivity sends a command to a NoticeService from onCreate():

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    notice=(TextView)findViewById(R.id.notice);
    startService(new Intent(this, NoticeService.class));
}
```

(from [Intents/Local/app/src/main/java/com/commonsware/android/localcast/LocalActivity.java](#))

The NoticeService simply delays five seconds, then sends a local broadcast using LocalBroadcastManager:

```
package com.commonsware.android.localcast;

import android.app.IntentService;
import android.content.Intent;
import android.os.SystemClock;
import android.support.v4.content.LocalBroadcastManager;

public class NoticeService extends IntentService {
    public static final String BROADCAST=
        "com.commonsware.android.localcast.NoticeService.BROADCAST";
    private static Intent broadcast=new Intent(BROADCAST);

    public NoticeService() {
        super("NoticeService");
    }

    @Override
    protected void onHandleIntent(Intent intent) {
        SystemClock.sleep(5000);
        LocalBroadcastManager.getInstance(this).sendBroadcast(broadcast);
    }
}
```

(from [Intents/Local/app/src/main/java/com/commonsware/android/localcast/NoticeService.java](#))

Specifically, you get at your process' singleton instance of LocalBroadcastManager by

## EVENT BUS ALTERNATIVES

---

calling `getInstance()` on the `LocalBroadcastManager` class.

Our `LocalActivity` registers for this local broadcast in `onStart()`, once again using `getInstance()` on `LocalBroadcastManager`:

```
@Override
public void onStart() {
    super.onStart();

    IntentFilter filter=new IntentFilter(NoticeService.BROADCAST);

    LocalBroadcastManager.getInstance(this).registerReceiver(onNotice,
                                                             filter);
}
```

(from [Intents/Local/app/src/main/java/com/commonsware/android/localcast/LocalActivity.java](#))

`LocalActivity` unregisters for this broadcast in `onStop()`:

```
@Override
public void onStop() {
    super.onStop();

    LocalBroadcastManager.getInstance(this).unregisterReceiver(onNotice);
}
```

(from [Intents/Local/app/src/main/java/com/commonsware/android/localcast/LocalActivity.java](#))

The `BroadcastReceiver` simply updates a `TextView` with the current date and time:

```
private BroadcastReceiver onNotice=new BroadcastReceiver() {
    public void onReceive(Context ctxt, Intent i) {
        notice.setText(new Date().toString());
    }
};
```

(from [Intents/Local/app/src/main/java/com/commonsware/android/localcast/LocalActivity.java](#))

If you start up this activity, you will see a “(waiting...)” bit of placeholder text for about five seconds, before having that be replaced by the current date and time.

The `BroadcastReceiver`, the `IntentFilter`, and the `Intent` being broadcast are the same as we would use with full broadcasts. It is merely how we are using them — via `LocalBroadcastManager` — that dictates they are local to our process versus the standard device-wide broadcasts.

### A More Elaborate Sample

That sample is not terribly realistic, but it is simple.

A somewhat more realistic sample is the one using AlarmManager and JobIntentService from [elsewhere in the book](#). However, that app is also fairly unrealistic, at least in terms of its output, as LogCat is not very useful to users. A more typical approach for a background service like this is to notify a foreground Activity, if there is one, about work that was accomplished, and otherwise display a Notification. We described that pattern in [the chapter on Notifications](#).

In the [EventBus/LocalBroadcastManager](#) sample project, we blend:

- Having a service wake up every so often to do some work
- Arranging to let the user know of background accomplishments via an Activity or a Notification
- Using LocalBroadcastManager to keep the communications in-process

### The Activity

The EventDemoActivity that is our app's entry point is a bit similar to the one used in the AlarmManager demo, in that it calls `scheduleAlarms()` on `PollReceiver` to set up the AlarmManager schedule:

```
package com.commonware.android.eventbus.lbm;

import android.support.v4.app.FragmentActivity;
import android.os.Bundle;

public class EventDemoActivity extends FragmentActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
            getSupportFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new EventLogFragment()).commit();

            PollReceiver.scheduleAlarms(this);
        }
    }
}
```

(from [EventBus/LocalBroadcastManager/app/src/main/java/com/commonware/android/eventbus/lbm/EventDemoActivity.java](#))

However, we also put an `EventLogFragment` on the screen, if it is not already there,

## EVENT BUS ALTERNATIVES

---

via a `FragmentManager`. This is where we will display events coming from the service, while our activity is in the foreground. We will examine `EventLogFragment` and how it participates in the event bus shortly.

### The PollReceiver

`PollReceiver` is largely unchanged from its `AlarmManager` demo original edition. This `BroadcastReceiver` will be used both for getting control at boot time (to reschedule the alarms, wiped on the reboot) and for sending the work to the `ScheduledService` for processing:

```
package com.commonware.android.eventbus.lbm;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class PollReceiver extends BroadcastReceiver {
    private static final int PERIOD=60000; // 1 minute
    private static final int INITIAL_DELAY=5000; // 5 seconds

    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (i.getAction() == null) {
            ScheduledService.enqueueWork(ctxt);
        }
        else {
            scheduleAlarms(ctxt);
        }
    }

    static void scheduleAlarms(Context ctxt) {
        AlarmManager mgr=
            (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
        Intent i=new Intent(ctxt, PollReceiver.class);
        PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

        mgr.setRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
            SystemClock.elapsedRealtime() + INITIAL_DELAY,
            PERIOD, pi);
    }
}
```

---

## EVENT BUS ALTERNATIVES

---

(from [EventBus/LocalBroadcastManager/app/src/main/java/com/commonsware/android/eventbus/lbm/PollReceiver.java](#))

### ScheduledService and Sending Events

Before, our ScheduledService just dumped a message to LogCat. This was crude but effective for what that demo required. Now, we want our service to let the UI layer know about some work that was accomplished, or to raise a Notification.

In this case, the “work” is generating a random number.

```
package com.commonsware.android.eventbus.lbm;

import android.app.Notification;
import android.app.NotificationChannel;
import android.app.NotificationManager;
import android.app.PendingIntent;
import android.content.Context;
import android.content.Intent;
import android.os.Build;
import android.support.v4.app.JobIntentService;
import android.support.v4.app.NotificationCompat;
import android.support.v4.content.LocalBroadcastManager;
import java.util.Calendar;
import java.util.Random;

public class ScheduledService extends JobIntentService {
    private static int NOTIFY_ID=1337;
    private static final int UNIQUE_JOB_ID=1337;
    private static final String CHANNEL_WHATEVER="channel_whatever";
    private Random rng=new Random();

    static void enqueueWork(Context ctxt) {
        enqueueWork(ctxt, ScheduledService.class, UNIQUE_JOB_ID,
            new Intent(ctxt, ScheduledService.class));
    }

    @Override
    public void onHandleWork(Intent i) {
        Intent event=new Intent(EventLogFragment.ACTION_EVENT);
        long now=Calendar.getInstance().getTimeInMillis();
        int random=rng.nextInt();

        event.putExtra(EventLogFragment.EXTRA_RANDOM, random);
        event.putExtra(EventLogFragment.EXTRA_TIME, now);

        if (!LocalBroadcastManager.getInstance(this).sendBroadcast(event)) {
            NotificationManager mgr=
                (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

            if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
                mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
                mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
                    "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
            }

            NotificationCompat.Builder b=new NotificationCompat.Builder(this, CHANNEL_WHATEVER);
```

---

## EVENT BUS ALTERNATIVES

---

```
Intent ui=new Intent(this, EventDemoActivity.class);

b.setAutoCancel(true).setDefaults(Notification.DEFAULT_SOUND)
  .setTitle(getString(R.string.notif_title))
  .setText(Integer.toHexString(random))
  .setSmallIcon(android.R.drawable.stat_notify_more)
  .setTicker(getString(R.string.notif_title))
  .setContentIntent(PendingIntent.getActivity(this, 0, ui, 0));

mgr.notify(NOTIFY_ID, b.build());
}
}
```

(from [EventBus/LocalBroadcastManager/app/src/main/java/com/commonsware/android/eventbus/lbm/ScheduledService.java](#))

LocalBroadcastManager, as we have seen, uses the same Intent and IntentFilter and BroadcastReceiver structures as are used with regular broadcasts, just via a singleton message bus (LocalBroadcastManager.getInstance()) instead of the framework's IPC engine. Hence, we need an Intent that represents the message, so we create one, using an action string published by the EventLogFragment. We also attach two extras to this Intent, using keys published by EventLogFragment: the random number, plus the time of this event.

We then call sendBroadcast() on the singleton LocalBroadcastManager. This returns a boolean value, true indicating that one or more locally-registered receivers were delivered the Intent, false otherwise. Hence, if sendBroadcast() returns true, we can assume that somebody in the UI layer picked up our message and is now responsible for displaying these results to the user.

Conversely, if sendBroadcast() returns false, we must assume that the UI layer did not receive the message, and so the service should inform the user directly, in this case via a Notification, showing the random number as the text in the notification drawer.

### EventLogFragment and Receiving Events

EventLogFragment, therefore, is responsible for:

- Registering (and unregistering) to receive the broadcasts to be sent locally by the service
- Doing something with those events to inform the user about the all-important random numbers

In this case, we use a retained ListFragment with a ListView set into transcript mode, meaning that entries are added at the bottom, and older entries scroll off the

## EVENT BUS ALTERNATIVES

    static final String EXTRA_TIME="t";
    static final String ACTION_EVENT="e";
    private EventLogAdapter adapter=null;

    @Override
    public void onCreate(@Nullable Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        setRetainInstance(true);
    }

    @Override
    public void onViewCreated(@NonNull View view,
                             @Nullable Bundle savedInstanceState) {
        super.onViewCreated(view, savedInstanceState);

        getListView().setTranscriptMode(ListView.TRANSCRIPT_MODE_NORMAL);

        if (adapter == null) {
            adapter=new EventLogAdapter();
        }
    }
}
```

## EVENT BUS ALTERNATIVES

---

```
}

    setListAdapter(adapter);
}

@Override
public void onStart() {
    super.onStart();

    IntentFilter filter=new IntentFilter(ACTION_EVENT);

    LocalBroadcastManager.getInstance(getActivity())
        .registerReceiver(onEvent, filter);
}

@Override
public void onStop() {
    LocalBroadcastManager.getInstance(getActivity())
        .unregisterReceiver(onEvent);

    super.onStop();
}

class EventLogAdapter extends ArrayAdapter<Intent> {
    DateFormat fmt=new SimpleDateFormat("HH:mm:ss", Locale.US);

    public EventLogAdapter() {
        super(getActivity(), android.R.layout.simple_list_item_1,
            new ArrayList<Intent>());
    }

    @SuppressWarnings("DefaultLocale")
    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        TextView row=
            (TextView)super.getView(position, convertView, parent);
        Intent event=getItem(position);
        Date date=new Date(event.getLongExtra(EXTRA_TIME, 0));

        row.setText(String.format("%s = %x", fmt.format(date),
            event.getIntExtra(EXTRA_RANDOM, -1)));

        return(row);
    }
}

private BroadcastReceiver onEvent=new BroadcastReceiver() {
    @Override
```

## EVENT BUS ALTERNATIVES

```
public void onReceive(Context context, Intent intent) {  
    adapter.add(intent);  
}  
};  
}
```

(from [EventBus/LocalBroadcastManager/app/src/main/java/com/commonsware/android/eventbus/lbm/EventLogFragment.java](#))

The ListAdapter for the ListView is an EventLogAdapter, an ArrayAdapter for Intent objects, where in getView() we populate the list rows with the time and random value.

In onStart() and onStop(), we register for (and unregister from) the desired broadcast, pointing to an onEvent BroadcastReceiver that adds the incoming Intent to the EventLogAdapter. That, in turn, updates the ListView.

The result is that while the activity is in the foreground, the events will be displayed to the user directly:

*Figure 646: LocalBroadcastManager as Event Bus, Demo Activity*

## EVENT BUS ALTERNATIVES

---

Whereas if events are processed while the activity is not in the foreground, a Notification will be shown with the last results:

*Figure 647: LocalBroadcastManager as Event Bus, Demo Notification*

### Reference, Not Value

When you send a “real” broadcast Intent, your Intent is converted into a byte array (courtesy of [the Parcelable interface](#)) and transmitted to other processes. This occurs even if the recipient of the Intent is within your own process — that is what makes LocalBroadcastManager faster, as it avoids the inter-process communication.

However, since LocalBroadcastManager does not need to send your Intent between processes, that means it does not turn your Intent into a byte array. Instead, it just passes the Intent along to any registered BroadcastReceiver with a matching IntentFilter. In effect, while “real” broadcasts are pass-by-value, local broadcasts are pass-by-reference.

This can have subtle side effects.

For example, there are a few ways that you can put a collection into an Intent extra, such as `putStringArrayListExtra()`. This takes an `ArrayList` as a parameter. With

a real broadcast, once you send the broadcast, it does not matter what happens to the original `ArrayList` — the rest of the system is working off of a copy. With a local broadcast, though, the `Intent` holds onto the `ArrayList` you supplied via the setter. If you change that `ArrayList` elsewhere (e.g., clear it for reuse), the recipient of the `Intent` will see those changes.

Similarly, if you put a `Parcelable` object in an extra, the `Intent` holds onto the actual object while it is being broadcast locally, whereas a real broadcast would have resulted in a copy. If you change the object while the broadcast is in progress, the recipient of the broadcast will see those changes.

This can be a feature, not a bug, when used properly. But, regardless, it is a non-trivial difference, one that you will need to keep in mind.

### Limitations of Local

While `LocalBroadcastManager` is certainly useful, it has some serious limitations.

The biggest is that it is purely local. While traditional broadcasts can either be internal (via `setPackage()`) or device-wide, `LocalBroadcastManager` only handles the local case. Hence, anything that might involve other processes, such as a `PendingIntent`, will not use `LocalBroadcastManager`. For example, you cannot register a receiver through `LocalBroadcastManager`, then use a `getBroadcast()` `PendingIntent` to try to reach that `BroadcastReceiver`. The `PendingIntent` will use the regular broadcast `Intent` mechanism, which the local-only receiver will not respond to.

Similarly, since a manifest-registered `BroadcastReceiver` is spawned via the operating system upon receipt of a matching true broadcast, you cannot use such receivers with `LocalBroadcastManager`. Only a `BroadcastReceiver` registered via `registerReceiver()` on the `LocalBroadcastManager` will use the `LocalBroadcastManager`.

Also, `LocalBroadcastManager` does not offer ordered or sticky broadcasts.

## greenrobot's EventBus 3.x

`LocalBroadcastManager` has two major advantages:

1. It is part of the Android Support package, and therefore it is part of the

## EVENT BUS ALTERNATIVES

---

- officially-supported corner of the Android ecosystem
2. It works like traditional broadcasts, which will make it easier for some developers to “wrap their heads around” it

However, that same dependency on the Intent and IntentFilter structure adds bulk and limits flexibility. Hence, it is not surprising that there are alternative event buses to LocalBroadcastManager.

Java, outside of Android, has had a few event bus implementations. One of the more popular ones in recent years has been the event bus that is part of [Google’s Guava family of libraries](#). However, while a Java event bus perhaps can be used on Android, it may not be *optimal* for Android. Hence, a few projects have started with Guava’s event bus implementation and have extended it to be a bit more Android-aware, or perhaps even Android-centric.

[greenrobot’s EventBus](#) is one such event bus.

**NOTE:** For the purposes of this chapter, “greenrobot’s EventBus” refers to the library, and “EventBus” refers to the EventBus Java class in that library.

### Basic Usage and Sample App

With LocalBroadcastManager, you work with a singleton instance, calling methods like registerReceiver() and sendBroadcast() upon it to subscribe to and raise events, respectively.

With greenrobot’s EventBus, you work with an EventBus instance, calling methods like register() and post() upon it to subscribe to and raise events, respectively. Usually, we use the singleton instance of EventBus that we get by calling getDefault() on the EventBus class, but you are welcome to have different EventBus objects, representing distinct communications channels, if you wish.

Hence, at the core, greenrobot’s EventBus behaves much like LocalBroadcastManager. What differs is in the nature of the events and the subscribers.

With LocalBroadcastManager, events are Intent objects. With greenrobot’s EventBus, an event can be whatever data type you like. Hence, you can create your own . . . Event classes, holding whatever bits of data, in whatever data types suit you — you are not restricted to things that can go in an Intent extra. However, as has been noted on occasion, [“with great power comes great responsibility”](#), and so you

## EVENT BUS ALTERNATIVES

---

will need to ensure that you use this carefully and do not wind up creating some sort of memory leak as a result. For example, do not pass something from an Activity to a Service via a custom event, where the Service will hold onto that information for a long time, if that “something” holds a reference back to the Activity.

With `LocalBroadcastManager`, subscribers are `BroadcastReceivers`, who use an `IntentFilter` to identify which events they are interested in. With greenrobot’s `EventBus`, subscribers are any class you want. A special `@Subscribe` annotation is used to both indicate what sorts of events the subscriber is interested in (based on the parameter to the annotated method) and what method should be invoked when a matching event is raised (the annotated method itself). Hence, not only do you use custom event classes to allow you to carry along custom data, but you use them as a filtering mechanism, much like you would use custom action strings with `LocalBroadcastManager`.

To see how this works, take a look at the [EventBus/GreenRobot3](#) sample project, which is a clone of the `EventBus/LocalBroadcastManager` demo, but one where we substitute in greenrobot’s `EventBus` as a replacement for `LocalBroadcastManager`. Our activity and `PollReceiver` are unchanged: they did not directly interact with `LocalBroadcastManager` and do not need to interact with greenrobot’s `EventBus`. The changes are isolated in our `ScheduledService` and `EventLogFragment`.

### ScheduledService and Sending Events

We will need an `EventBus` instance, one that serves the same basic role as does the singleton `LocalBroadcastManager` retrieved by `getInstance()`. As noted above, you can call `getDefault()` on `EventBus` to get a singleton `EventBus` instance, and this suffices in most cases.

When it comes time for us to send a message, we can call `post()` on the `EventBus`, supplying whatever sort of event object that we want:

```
EventBus.getDefault().post(randomEvent);
```

(from [EventBus/GreenRobot3/app/src/main/java/com/commonsware/android/eventbus/greenrobot/ScheduledService.java](#))

Here, we are posting an instance of a `RandomEvent`:

```
package com.commonsware.android.eventbus.greenrobot;

import java.util.Calendar;
import java.util.Date;
```

## EVENT BUS ALTERNATIVES

---

```
public class RandomEvent {
    Date when=Calendar.getInstance().getTime();
    int value;

    RandomEvent(int value) {
        this.value=value;
    }
}
```

(from [EventBus/GreenRobot3/app/src/main/java/com/commonsware/android/eventbus/greenrobot/RandomEvent.java](#))

### EventLogFragment and Receiving Events

Over in our EventLogFragment, rather than register and unregister a BroadcastReceiver in onStart() and onStop(), we register and unregister the fragment itself with the EventBus:

```
@Override
public void onStart() {
    super.onStart();

    EventBus.getDefault().register(this);
}

@Override
public void onStop() {
    EventBus.getDefault().unregister(this);

    super.onStop();
}
```

(from [EventBus/GreenRobot3/app/src/main/java/com/commonsware/android/eventbus/greenrobot/EventLogFragment.java](#))

Now, we can use the @Subscribe annotation to arrange to receive any event we want that is delivered via this EventBus, based on event class. Since we want to receive RandomEvent messages, we merely need to have a public void method, taking a RandomEvent parameter, marked with the @Subscribe annotation, such as onRandomEvent():

```
@Subscribe(threadMode = ThreadMode.MAIN)
public void onRandomEvent(final RandomEvent event) {
    adapter.add(event);
}
```

(from [EventBus/GreenRobot3/app/src/main/java/com/commonsware/android/eventbus/greenrobot/EventLogFragment.java](#))

---

## EVENT BUS ALTERNATIVES

---

Note that the method name can be anything we want, as it is the annotation, not the method name, that identifies this as being an event handling method.

Since Java annotations can take key-value pairs for configuration, EventBus 3.x uses that to configure the behavior of `@Subscribe`. Here, we use `@Subscribe(threadMode = ThreadMode.MAIN)`, to indicate that we want this event to be delivered to this method on the main application thread.

In this method, we can do what we need to with our `RandomEvent`. In our case, `EventLogAdapter` has been modified to be an `ArrayAdapter` of `RandomEvent`, as opposed to being an `ArrayAdapter` of `Intent` as in the earlier sample. What we want to do is append the new `RandomEvent` to the end of the adapter.

### Handling the “Nobody’s Home” Scenario

What is missing, though, is the logic we used in `LocalBroadcastManager` to determine if somebody received our message, where we raised a `Notification` if that is not the case.

The solution for this with greenrobot’s `EventBus` is to call `hasSubscriberForEvent()`, with the Java `Class` object of the event that we would like to `post()`. If this returns `true`, we have a current subscriber; otherwise, we do not.

So, the full `onHandleWork()` implementation uses `hasSubscriberForEvent()` and either uses `post()` to raise the event or displays a `Notification` itself:

```
@Override
public void onHandleWork(Intent i) {
    RandomEvent randomEvent=new RandomEvent(rng.nextInt());

    if (EventBus.getDefault().hasSubscriberForEvent(randomEvent.getClass())) {
        EventBus.getDefault().post(randomEvent);
    }
    else {
        NotificationManager mgr=
            (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

        if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
            mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
            mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
                "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
        }

        NotificationCompat.Builder b=new NotificationCompat.Builder(this, CHANNEL_WHATEVER);
        Intent ui=new Intent(this, EventDemoActivity.class);
```

---

## EVENT BUS ALTERNATIVES

---

```
b.setAutoCancel(true).setDefaults(Notification.DEFAULT_SOUND)
    .setTitle(getString(R.string.notif_title))
    .setText(Integer.toHexString(randomEvent.value))
    .setSmallIcon(android.R.drawable.stat_notify_more)
    .setTicker(getString(R.string.notif_title))
    .setContentIntent(PendingIntent.getActivity(this, 0, ui, 0));

mgr.notify(NOTIFY_ID, b.build());
}
}
```

(from [EventBus/GreenRobot3/app/src/main/java/com/commonsware/android/eventbus/greenrobot/ScheduledService.java](#))

There is a race condition, though. Since our `hasSubscriberForEvent()` call is happening on a background thread, it is possible that between the `hasSubscriberForEvent()` call and the `post()` call that the subscriber unsubscribes. This is an unlikely occurrence here, but it is worth keeping in mind.

### Other Notable Capabilities

In addition to the threading features, greenrobot's EventBus has a few other noteworthy bells and whistles:

- Other thread modes are available, including `ThreadMode.POSTING` (events are delivered on the same thread they are posted from) and `ThreadMode.BACKGROUND` (events are delivered on a background thread, with EventBus using its own thread if the event was posted from the main application thread).
- `postSticky()` and `registerSticky()` allow you to have sticky events, much like sticky broadcasts with the classic broadcast Intent system.
- Ordered event processing as an option, akin to ordered broadcasts. You accomplish this by assigning a priority to the event handling method (e.g., `@Subscribe(priority = 1)`). If a higher-priority handler wants to consume the event, it can call `cancelEventDelivery()` on the EventBus, passing in the event object.

### Hey, What About Otto?

For a few years, a third major event bus implementation was popular: Square's Otto. Like greenrobot's EventBus, Otto was based off of Guava's EventBus class and was tuned towards Android app development. It shared some characteristics with greenrobot's EventBus, owing to the shared heritage. On the whole, greenrobot's EventBus was a bit more complex to use but offered greater flexibility.

## EVENT BUS ALTERNATIVES

---

Square has since discontinued work on Otto, so unless you have existing legacy code that uses Otto, you should use some other event bus implementation.

One of the most confusing aspects of Android to deal with is the concept of tasks. Fortunately, the automatic management of tasks is *almost* enough to get by, without you having to do much customization. However, some developers will need to tailor how their app interacts with the task system. Understanding what is possible and how to do it is not easy. It is made even more complicated by changes to Android, from both engineering and design perspectives, over the years.

This chapter will attempt to untie the knot of knowledge surrounding Android’s task system, explaining why things are the way they are. However, there will be a few places where the knot turns a bit [Gordian](#), and we will have to settle for more about “how” and less about “why” the task system works as it does.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

One sample app makes heavy use of [the PackageManager system service](#) and refers in a few places to the Launcha1ot sample app profiled in that chapter.

## First, Some Terminology

It will be useful to establish some common definitions of terms that you will encounter, both in this chapter and in other materials that describe the task system.

### Task

So, what exactly *is* a “task”?

The [Android developer documentation](#) describes it as:

A task is a collection of activities that users interact with when performing a certain job. The activities are arranged in a stack (the back stack), in the order in which each activity is opened.

In that sense, a task is reminiscent of a tab in a tabbed browser. As the user navigates, clicking links and submitting forms, the user advances into other Web pages. Those pages could be on the same site as they started or could be on different sites. The browser BACK button is supposed to reverse the navigation, allowing the user to return from whence they came.

### Back Stack

The user perceives tasks mostly in the form of pressing the BACK button, using this to return to previous “screens” that they had been on previously.

Sometimes, BACK button processing is handled within a single activity, such as when you put a dynamic fragment onto the “back stack” via `addToBackStack()` on a `FragmentManager`. Or, the activity could override `onBackPressed()` and do special stuff in certain scenarios. Those are part of the user experience of pressing BACK. From the standpoint of the task system, though, internal consumption of the BACK button presses do not affect the task.

At the task level, the “back stack” refers to a chain of activities. This matches the behavior of Web sites, where while pressing the browser BACK button *might* trigger in-page behavior, usually it returns you to the previous page. Similarly, while pressing BACK on an Android device *might* trigger in-activity behavior, usually it triggers a call to `finish()` on the foreground activity and returns control to whatever had preceded it on the back stack.

### Recent Tasks

In a tabbed Web browser, if we have several tabs open, we think of all of them as being “running”. Frequently, we do not really even think about the concept, any more than we might think about the state of tabs in an IDE other than the one that

## TASKS

---

we are working in right now. However, if you have ever had some browser tab all of a sudden start playing audio, such as from a reloaded page pulling in an audio-enabled ad banner, you are well aware that tabs are “running”, while you are also “running” to try to figure out what tab is playing the audio so you can get rid of it.

However, that is the behavior on a desktop Web browser. A desktop Web browser is not subject to heap size limitations the way Android apps are. And, historically, mobile devices had less system RAM than did their desktop and notebook counterparts, though that is rapidly changing.

In Android, therefore, developers are used to the notion that their processes may be terminated, while in the background, to free up memory for other processes. This is being done to allow for more apps to deliver more value in less system RAM.

However, from a multitasking standpoint, having apps just up and vanish is awkward. Hence, Android has the notion of “recent tasks”. These are tasks, with their corresponding back stacks, that the user has been in “recently”. How far back “recently” goes depends a bit on the version of Android – there could be as few as eight items. These “recent tasks” may or may not have a currently-running *process* associated with them. However, if the user chooses to return to one of those recent tasks, and there is no process for it, Android will seamlessly fork a fresh process, to be able to not only start up those apps, but return the user to where they were, in terms of UI contents (e.g., saved instance state `Bundle`) and in terms of back stack contents (e.g., where the user goes if the user now presses `BACK`).

### Overview Screen

In a tabbed Web browser, you can navigate between different tabs in some browser-specific way. Some tabs may have the actual “tab” visible around the address bar. Some tabs might only be reachable via some sort of scrolling operation, or via a drop-down list, for people who have lots and lots of tabs open. Regardless, there is some UI means to pick the tab that you want to be viewing in the main browser area.

In Android, the “overview screen” is where the user can view the recent tasks and choose to return to one of them. Many people, including this author, refer to this as the “recent tasks list”, but apparently [the official term is “overview screen”](#).

The way the overview screen has looked and worked has changed over the years.

## TASKS

---

### Android 1.x/2.x

In the early days of Android, long-pressing the HOME button would bring up the overview screen, with up to eight recent tasks:

*Figure 648: Overview Screen, from Android 2.3.3*

And... that was pretty much it.

### Android 3.x/4.x

The overall move to the holographic theme for Android brought with us a new icon, for a dedicated way to get to the overview screen:

*Figure 649: Overview Screen/Recent Tasks Navigation Bar Icon, from Android 4.3*

Devices that offered a navigation bar at the bottom would have this button. Devices that chose to have off-screen affordances for BACK and HOME might have a similar button for the overview screen. For those that neither had a navigation bar nor a dedicated off-screen button for the overview screen, long-pressing HOME would bring up the overview screen.

## TASKS

---

The overview screen could have more apps (15 or so) before old tasks would be dropped:

*Figure 650: Overview Screen, from Android 4.3*

The overview screen also added more improvements:

- Thumbnails of the top activity in each task's back stack, except for those activities that [used FLAG\\_SECURE](#) to block this, and except on some emulator images
- Swiping an entry off the list would remove that recent task

### **Android 5.x**

Functionally, the Android 5.x overview screen functions much like its 4.x counterpart, with the ability to see previews of tasks and remove tasks from the screen.

## TASKS

---

However, there are some differences, starting with the navigation bar icon used to bring up the overview screen:

*Figure 651: Overview Screen/Recent Tasks Navigation Bar Icon, from Android 5.0*

Also, the previews are larger and stacked like cards, more so than being a classically vertically-scrolling list:

*Figure 652: Overview Screen, from Android 5.0*

More importantly:

## TASKS

---

- The roster of recent tasks will be restored after a reboot, and
- If there is a limit on how many entries can appear in the list, the author has not run into it yet

### Running Tasks

A running task is a task that has running process(es) associated with it. Recent tasks may or may not be running.

### And Now, a Bit About Task Killers

In October 2008, the first Android device was publicly released (the T-Mobile G1, a.k.a., HTC Dream).

Around December of 2008, the first task killers appeared on the Android Market (now the Play Store).

While the techniques used in 2008 to kill tasks were removed in later releases, some amount of task management behavior still exists in Android. Having a task killer is useful for understanding how tasks (and their killers) behave on Android. In particular, it is useful to have a way to emulate an app's process being terminated due to low memory conditions... which is exactly what modern task killers do.

So, in this section, we will explore the concept of task killers, including how to implement one, before using this tool to help us explore the overall Android task system.

### What Do Task Killers Do?

Despite the name, task killers do not kill tasks.

Rather, task killers terminate background processes. This does not impact the task, insofar as it will still be in the recent tasks roster and will still show up on the overview screen. However, the process for the app associated with the task will shut down.

Task killers can only request to terminate background processes. If your app is in the foreground (i.e., has the foreground activity), it cannot be terminated by a task killer.

## TASKS

---

To terminate background processes, task killers need to hold the `KILL_BACKGROUND_PROCESSES` permission, via a `<uses-permission>` element in their manifests. That enables them to be able to call the `killBackgroundProcesses()` method on `ActivityManager`. Supplied an application ID, `killBackgroundProcesses()` will terminate any background process(es) associated with that application. Normally, there will only be one such process, but if the app in question is using the `android:process` attribute in the manifest to have multiple processes, then all the app's processes will be terminated.

This termination is done using the same internal mechanism that is used by the “out-of-memory killer”, which is responsible for freeing up system RAM due to low memory conditions.

### Killing vs. Force-Stopping

For ordinary users, there are a few options for terminating background processes. Using a task killer, or swiping the task off the overview screen on Android 4.0+, will terminate background processes. Both use `killBackgroundProcesses()` (or internal equivalents).

However, users can also go into the Settings app, find the app in the list of installed apps, and click a “Force Stop” button associated with that app. On the surface, this has a similar effect to the above techniques, as the background process is terminated. However, force-stopping the app also unschedules any `AlarmManager` or `JobScheduler` events for that app, plus moves the app back into the “stopped state”, blocking manifest-registered broadcast receivers. Hence, force-stopping an app has a much larger impact than does merely using a task killer.

A few devices have manufacturer-supplied task managers (a.k.a., task killers), where stopping an app from those apps actually does a force stop behind the scenes, rather than `killBackgroundProcesses()`. This is not a good idea, as force-stopping an app has the aforementioned side effects. Fortunately, third-party task killers cannot force-stop apps, barring any security flaws in Android that might make this possible.

### Why Use One?

Nowadays, normally, users do not need task killers. Occasionally one can be useful, to stop a background process for a poorly-written app (e.g., one that powers on GPS but fails to let go of GPS when the app moves to the background). On most modern Android devices, swiping the app off the overview screen usually suffices, and so

task killers are not nearly as crucial as they were in Android 1.x/2.x, where there was no such built-in background process management solution.

For developers, the problem with swiping an app off the overview screen is that it not only terminates background processes, but it also removes the task entirely. This makes it difficult to see what the behavior is when apps' processes terminate for more conventional reasons (e.g., out-of-memory killer) and how tasks tie into that. While developers have the ability to stop processes through development tools (e.g., the process list in DDMS), that just terminates the process, and it may do so slightly differently than does the out-of-memory killer. Hence, having a task killer around can be useful for experimentation purposes.

And, since getting a task killer on an emulator can be challenging (since emulators do not have access to the Play Store), having the source code for a simple task killer is useful for developers. So, let's look at how to implement a task killer.

## A Canary for the Task's Coal Mine

In order to see some of the effects of fussing with our tasks, we need an app where we can see when our saved instance state comes and goes. To that end, we have the [Tasks/TaskCanary](#) sample application. It consists of a single activity, with a UI that is merely a full-screen EditText. In addition to the automatic saving of the EditText contents in the saved instance state Bundle, we also keep track of the time we first worked with that Bundle, in a data member named `creationTime`, backed by a `STATE_CREATION_TIME` entry in the Bundle itself:

```
package com.commonware.android.task.canary;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.provider.Settings;
import android.util.Log;
import android.view.Menu;
import android.view.MenuItem;

public class MainActivity extends Activity {
    private static final String STATE_CREATION_TIME="creationTime";
    private long creationTime=-1L;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
```

## TASKS

---

```
        setContentView(R.layout.activity_main);
    }

    @Override
    protected void onRestoreInstanceState(Bundle savedInstanceState) {
        super.onRestoreInstanceState(savedInstanceState);

        dumpBundleToLog("restore", savedInstanceState);
        creationTime=savedInstanceState.getLong(STATE_CREATION_TIME, -1L);
    }

    @Override
    protected void onSaveInstanceState(Bundle outState) {
        super.onSaveInstanceState(outState);

        outState.putLong(STATE_CREATION_TIME, getCreationTime());
        dumpBundleToLog("save", outState);
    }

    @Override
    public boolean onCreateOptionsMenu(Menu menu) {
        getMenuInflater().inflate(R.menu.actions, menu);

        return(super.onCreateOptionsMenu(menu));
    }

    @Override
    public boolean onOptionsItemSelected(MenuItem item) {
        if (item.getItemId()==R.id.settings) {
            startActivity(new Intent(Settings.ACTION_DATE_SETTINGS));
        }
        else if (item.getItemId()==R.id.other) {
            startActivity(new Intent(this, OtherActivity.class));
        }

        return(super.onOptionsItemSelected(item));
    }

    private long getCreationTime() {
        if (creationTime==-1L) {
            creationTime=System.currentTimeMillis();
        }

        return(creationTime);
    }

    // inspired by http://stackoverflow.com/a/14948713/115145
```

---

## TASKS

---

```
private void dumpBundleToLog(String msg, Bundle b) {
    Log.d(getClass().getSimpleName(),
        String.format("Task ID #%d", getTaskId()));

    for (String key: b.keySet()) {
        Log.d(getClass().getSimpleName(),
            String.format("(%s) %s: %s", msg, key, b.get(key)));
    }
}
```

(from [Tasks/TaskCanary/app/src/main/java/com/commonsware/android/task/canary/MainActivity.java](#))

Each time we save and restore the instance state, we dump the Bundle to Logcat, so we can see what is in that Bundle. We wind up with lines like:

```
D/MainActivity: (save) android:viewHierarchyState: Bundle[...]
D/MainActivity: (save) creationTime: 1427032894794
D/MainActivity: (restore) android:viewHierarchyState: Bundle[...]
D/MainActivity: (restore) creationTime: 1427032894794
```

(where the ... is a bit long to reproduce in the book and is not essential for the sample)

This way, both in the UI and in the logs, we can confirm that our state is being saved and restored as expected... or perhaps not as expected, in some cases.

You will notice that we have a pair of action bar items. One will bring up a screen from the Settings app, which we will use to see [how this affects our task](#). The other one will bring up another activity from our app, which we will use to explore [how to start a clean task](#).

## The Default User Experience

With all that behind us, let's start talking about tasks, focusing first on what behavior the developer gets "out of the box", with no task-specific logic in the app. In other words, what is the default user experience for an ordinary Android app?

NOTE: if you wish to reproduce the results described here, you will want to have the Task Canary installed on your device or emulator.

### Starting from the Home Screen

Assume that we are “starting from scratch”. For example, the user has installed your app (or bought a device with your app pre-installed) but has never run your app before. Or, perhaps the overview screen is cleared of all tasks.

If the user taps your home screen launcher icon, not only is a process forked to run your app, but a new task is created, and your app’s task will appear in the overview screen.

(see! that wasn’t so hard!)

To reproduce this behavior:

- Clear the overview screen of all tasks, by swiping them off the screen. Note that this may take some time on an Android 5.x device that is really being used (versus just being some test device), as there may be a *lot* of tasks to clear.
- Run your app, from the home screen or IDE.

### Resuming from the Overview Screen

Eventually, the user wanders away from your app. Then, later on, the user returns to your app, by finding the task associated with your app in the overview screen and tapping upon it.

In the end, you wind up in the same state as before: you have a process for your app, and your task is still in the overview screen. How we get there depends a bit on what happened with your process, in between when you had been in the foreground and when the user taps on your task in the overview screen.

If your app’s process was still running, nothing much happens of note, other than you return to the foreground. From a state standpoint, your app would be called with `onSaveInstanceState()` when the user left your app, but you will not be called with `onRestoreInstanceState()`, because your activity was not destroyed yet. Note that this assumes that you did not undergo a configuration change (e.g., user originally was in your app in portrait, then returned to you from the overview screen while the device was in landscape). In the case of a configuration change, your activity would be destroyed and recreated by default, and you *would* be called with `onRestoreInstanceState()`, but that would be due to the configuration change more so than the use of the task and the overview screen.

## TASKS

---

To reproduce the above behavior, given that your device was in the state after the “Starting from the Home Screen” section above:

- Press HOME to move your app to the background, and notice the “(saved)” entries being reported to Logcat.
- Quickly press RECENTS (or, if you have no such option, long-press HOME) to bring up the overview, and tap on your task there.

However, it is entirely possible that while your task is around that your process is terminated to free up memory for other processes. If the user returns to your app via the overview screen, a fresh process will be forked for your app. This would trigger a call to `onRestoreInstanceState()`, because your old activity no longer exists, because its process no longer exists.

Note that if you leave a task for an extended period of time — say, 30 minutes or so — the task may be “cleared” when you return to it. This means that you are taken back to whatever the “root” activity of the task is, where by “root” we mean the original activity put into the task.

### Starting Another App

Some apps only start up other activities within the same app. However, many apps start up activities from other apps, either directly via `startActivity()` or indirectly (e.g., clicking on links in a `WebView`). For example, the Task Canary app has an item in the action bar overflow that, when clicked, brings up the Settings screen for adjusting date and time settings.

You might think that when the user taps on this overflow item, and Task Canary calls `startActivity()`, that a new task is created. After all, the Settings app is a completely separate app from the Task Canary app.

However, try this:

- Clear the overview screen
- Launch Task Canary
- Choose the Settings action bar overflow item to bring up the date-and-time Settings screen
- Press HOME to bring up the home screen
- Press RECENTS or otherwise bring up the overview screen

You will see one entry in the overview screen, for Task Canary, rather than two.

## TASKS

---

Furthermore, particularly on Android 5.x devices, you will see the Settings screen as the top-most activity within the Task Canary task:

*Figure 653: The Task Canary Task, on Android 5.1*

## TASKS

---

However, suppose that instead of using `ACTION_DATE_SETTINGS` for the Intent, we used `ACTION_APN_SETTINGS` instead, to allow the user to view mobile access point names and such. You might think, given the above flow, that we would wind up with just one task, as we did with `ACTION_DATE_SETTINGS`. In reality, you will see two tasks, instead of just one:

Figure 654: Two Tasks on Android 5.1

This is where things start to get a bit confusing.

## Explaining the Default Behavior

With the user experience as background, let's now dive into what is really going on with these operations.

### When Tasks are Created

A task is not created just because an activity is started. Otherwise, even individual apps would have lots of tasks, one per activity.

A task is not created just because a task from a different app is started. Otherwise, the two Settings scenarios above would have both resulted in a new task.

Instead, tasks are created when somebody *asks* for a task to be created. That "somebody" could be the author of the app calling `startActivity()` or the author of

the activity being started.

There are three major approaches for indicating that a new task should be started: flags on the Intent used with `startActivity()`, task affinity values, and launch modes. We will get into launch modes [later in this chapter](#), as the normally-used launch modes have no impact on tasks. Instead, we will focus on the other two approaches here.

### Task-Management Intent Flags

If you want to start an activity, and ensure that the activity starts in a new task, add `Intent.FLAG_ACTIVITY_NEW_TASK` to the flags on the Intent being used with `startActivity()`:

```
startActivity(new Intent(SOME_ACTION_STRING)
    .addFlags(Intent.FLAG_ACTIVITY_NEW_TASK))
```

What will happen, when you call `startActivity()` with `FLAG_ACTIVITY_NEW_TASK`, is that Android will see if there is a task that already has this activity in it. If there is, that task will be brought to the foreground, and the user will see whatever is on the top of that task's stack. Otherwise, if there is no task with this activity in it, Android will create a new task and associate a new instance of the activity with this task.

This is what home screen launchers do. When you tap on a home screen launcher icon, if there is a task that has a copy of your home screen activity in it, that task is brought back to the foreground. Otherwise, a new task is started.

If you *also* add `Intent.FLAG_ACTIVITY_MULTIPLE_TASK`, then Android skips the search for existing tasks and unconditionally launches the activity into a new task. This is generally not a good idea, as the user can wind up with many copies of this activity, not know which one is which, and perhaps have difficulty getting back to the right one.

### Task Affinities

By default, if Android needs to create a new task as a result of `FLAG_ACTIVITY_NEW_TASK`, it just creates a task. And, if there is no such flag on the Intent, Android will put the activity into the task of whoever called `startActivity()`.

If, however, the activity has an `android:taskAffinity` attribute in its `<activity>`

## TASKS

---

element in the manifest, then Android will specifically start this activity in a certain task, identified by the string value of the attribute. Other activities with the same task affinity will also go into this task.

The reason why the two Settings screens behave differently is that the `ACTION_APN_SETTINGS` activity has a certain task affinity value, while `ACTION_DATE_SETTINGS` does not. The task affinity of the `ACTION_APN_SETTINGS` activity is shared by many, though not all, activities within the Settings app. Those activities, when started, will always go into the task identified by the affinity. Hence, when we start `ACTION_DATE_SETTINGS`, it goes in *our* task (because that activity has no affinity and we did not include `FLAG_ACTIVITY_NEW_TASK`), but when we start the `ACTION_APN_SETTINGS` activity, it goes into a Settings-specific task.

Note that you can also have the `android:taskAffinity` value defined on the `<application>` element, to provide a default task affinity for all activities. The overall default is "", or no affinity.

### When Tasks are Removed

On Android 3.0 and higher, the user can get rid of a task by swiping the task off of the overview screen.

Otherwise, prior to Android 5.0, a task would automatically go away after some amount of user activity, as there were only so many “slots” available for tasks.

On Android 5.0+, though, it is unclear if there is an upper bound to how many tasks can exist. Beyond that, tasks survive a reboot, as information about those tasks is persisted. We will get more into the ramifications of this, and how you can take advantage of it, [later in this chapter](#).

### When Tasks (and Processes) are Resumed

A task will be resumed and brought back to the foreground in several situations, including:

- the user manually requests it via the overview screen, by clicking on one of the recent tasks
- if `FLAG_ACTIVITY_NEW_TASK` is added (without `FLAG_ACTIVITY_MULTIPLE_TASK`) to the Intent used to start an activity, and there is a task containing the activity in question
- if the `taskAffinity` for the activity being started ties it to another task

## TASKS

---

- if the [launch mode](#) for the activity being started ties it to another task

However, just because the task exists does not mean that the process(es) exist for the activities in the task. As needed, Android will fork fresh processes, to be able to load in the app's code and start the necessary activities. Android will deliver to the newly-created activities the same Intent that was used to create the original incarnation of the activity (via `getIntent()`) and the saved instance state Bundle.

### What Happens to Services

In theory, services are immune to task behavior. Tasks can come and go, and services are usually oblivious to this.

A service should be called with `onTaskStopped()` if a task associated with one or more of the app's activities is removed. The service might use that as a signal that it too should shut itself down.

There appears to be [a quasi-documented `android:stopWithTask` attribute](#) on the `<service>` element in the manifest. The default is `false`, but if you override it to be `true` on your `<service>`, then `onTaskStopped()` will not be called, and Android will simply destroy your service when the task is removed.

However, as of Android 4.4, there are many reports that services may be destroyed when a task is removed, even without `android:stopWithTask="true"`, though on a slight delay. Developers concerned about this should keep an eye on [this issue](#) and [this issue](#), both for various hacky workarounds and for any signs that this is being permanently addressed.

### What's Up with `onDestroy()`?

If the user swipes away the task using the overview screen, `onDestroy()` will be called on all outstanding activities. If a "task killer" terminates your background process, your `onDestroy()` methods will *not* be called when your process is terminated by those apps.

So, removing a *task* is a graceful exit, and Android calls `onDestroy()`, but an explicit termination of your process by another is a not-so-graceful exit, and Android skips `onDestroy()`.

As a result, as previously advised in this book and elsewhere, you cannot count on your `onDestroy()` methods being called, and you need to take this into account in

terms of what sorts of code you put in them.

## Basic Scenarios for Changing the Behavior

In many cases, the default behavior of tasks is just fine. However, there are many scenarios in which we may want to override the default behavior, routing activities to specific tasks, to have a better flow for the user.

### Reusing an Activity

By default, each time you call `startActivity()`, a new instance of the activity is created. Depending upon the user flow, that may not be a bad approach. For example, it may be that the only logical path out of the started activity will be to press BACK and destroy it.

However, there will be plenty of cases where we will not want to keep creating new activity instances. For example, if you elect to have several activities reachable via a nav drawer, you do not want to create fresh instances of activities that the user has already visited via that drawer. Otherwise, they will keep piling up, continuing to consume heap space. Instead, it would be better to try to reuse an existing activity instance, if one is available, creating a fresh one only if needed.

The most flexible approach for accomplishing this involves using a flag on the Intent used to start the activity: `Intent.FLAG_ACTIVITY_REORDER_TO_FRONT`. This tells Android to bring an existing activity matching our Intent to the foreground, if one already exists in our task. If there is no such activity, then go ahead and create a new instance.

The [Tasks/RoundRobin](#) sample application demonstrates this. It consists of two activities (`FirstActivity` and `SecondActivity`), each of whose UI consists of one really big button. Clicking the button should start the other activity, so clicking the button in `FirstActivity` should start an instance of `SecondActivity`. But, we want to reuse activity instances where available, and confirm that indeed we *are* reusing those instances.

`FirstActivity` accomplishes that by adding `FLAG_ACTIVITY_REORDER_TO_FRONT` to the Intent used to start `SecondActivity` when the button is clicked:

```
package com.commonware.android.tasks.roundrobin;
import android.app.Activity;
```

## TASKS

---

```
import android.content.Intent;
import android.os.Bundle;
import android.util.Log;
import android.view.View;

public class FirstActivity extends Activity implements View.OnClickListener {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        setContentView(R.layout.first);
        findViewById(R.id.button).setOnClickListener(this);

        Log.d(getClass().getSimpleName(),
            String.format("onCreate for %x", hashCode()));
    }

    @Override
    protected void onResume() {
        super.onResume();

        Log.d(getClass().getSimpleName(),
            String.format("onResume for %x", hashCode()));
    }

    @Override
    protected void onDestroy() {
        Log.d(getClass().getSimpleName(),
            String.format("onDestroy for %x", hashCode()));

        super.onDestroy();
    }

    @Override
    public void onClick(View view) {
        startActivity(new Intent(this, SecondActivity.class)
            .addFlags(Intent.FLAG_ACTIVITY_REORDER_TO_FRONT));
    }
}
```

(from [Tasks/RoundRobin/app/src/main/java/com/commonsware/android/tasks/roundrobin/FirstActivity.java](#))

SecondActivity has a nearly identical implementation, just routing back to FirstActivity.

If you run the app, the user's perspective is that clicking the button "ping-pongs" the user between the two activities. Looking at Logcat, you will see new instances

## TASKS

---

created the first time the user visits an activity, courtesy of the `Log.d()` call in `onCreate()`. But, if the user returns to an existing instance via the button click, you will see that `onCreate()` is not called, and that the `hashCode()` reported in `onResume()` matches the `hashCode()` of the previously-created instance of this activity:

```
D/FirstActivity: onCreate for b31b9430
D/FirstActivity: onResume for b31b9430
D/SecondActivity: onCreate for b31eb8a8
D/SecondActivity: onResume for b31eb8a8
D/FirstActivity: onResume for b31b9430
D/SecondActivity: onResume for b31eb8a8
```

Note that [launch modes](#) offer another way to control this behavior, having the activity being started indicate that its instance should always be reused. However, this is a specialty case, one that most apps will not require.

### Forcing a Clean Task

Let's suppose that you have an app that requires in-app authentication, via some form of login screen. For example, your app's data is held in [SQLCipher for Android](#), and so you need the user to supply a passphrase for the database.

In the beginning, when your app is launched from the home screen, your LAUNCHER activity appears. If that is your login screen, all is good. You collect the passphrase, create your singleton instance of the SQLCipher-enabled `SQLiteOpenHelper`, and you can access the database.

Eventually, the user presses HOME, and time passes. Android terminates your process to free up system RAM. The user then tries returning to your existing task, such as via the overview screen. Android creates a fresh process for you and takes you to the activity on the top of that task's back stack. But at this point, your singleton `SQLiteOpenHelper` is gone, and you need to collect a passphrase again.

You might think that this is purely a UI issue. Rather than collecting the passphrase in an activity, you collect it in a fragment, one that your LAUNCHER activity uses directly, and one that other activities can use via a `DialogFragment`. This way, you can arrange for every activity to be able to complete the re-initialization of your process and give you access to the encrypted database again.

Another approach would be to say that you want to wipe out this task and start over, routing the user back to the LAUNCHER activity for authentication.

## TASKS

---

There are two main approaches for implementing this: setting Intent flags or using `android:clearTaskOnLaunch` in the manifest.

### Starting a Cleared Task Yourself

One way to do that is to have each activity check to see if a new task is needed (e.g., “is the `SQLiteOpenHelper` singleton null?”). When that situation is detected, you call `startActivity()` for your LAUNCHER activity, with two flags: `FLAG_ACTIVITY_NEW_TASK` and `FLAG_ACTIVITY_CLEAR_TASK`.

For example, the [Tasks/Taskسالot](#) sample application is a straight-up clone of `Launchalot` with only one change of substance: using `FLAG_ACTIVITY_CLEAR_TASK` instead of `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED`:

```
@Override
protected void onItemClick(ListView l, View v,
                            int position, long id) {
    ResolveInfo launchable=adapter.getItem(position);
    ActivityInfo activity=launchable.activityInfo;
    ComponentName name=new ComponentName(activity.applicationInfo.packageName,
                                         activity.name);

    Intent i=new Intent(Intent.ACTION_MAIN);

    i.addCategory(Intent.CATEGORY_LAUNCHER);
    i.setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
              Intent.FLAG_ACTIVITY_CLEAR_TASK);
    i.setComponent(name);

    startActivity(i);
}
```

(from [Tasks/Taskسالot/app/src/main/java/com/commonsware/android/tasksalot/MainActivity.java](#))

To see this in action:

- Run the `TaskCanary` sample app and use the overflow to bring up `OtherActivity`
- Press HOME
- Run `Taskسالot`
- Click on the “Task Canary” entry in `Taskسالot`

At this point, you will see the `TaskCanary` sample app return to the screen. From the logs in Logcat, you will see it is the same task ID as before. Yet, you are seeing the `FirstActivity`. `OtherActivity` was removed from the task as part of

## TASKS

---

FLAG\_ACTIVITY\_CLEAR\_TASK processing.

This differs from what you see in a home screen, with FLAG\_ACTIVITY\_RESET\_TASK\_IF\_NEEDED. If you run the same test, but rather than use Taskalot, you tap on the “Task Canary” icon in the home screen launcher, the task will return to the foreground, but you will be taken to OtherActivity. FLAG\_ACTIVITY\_CLEAR\_TASK *always* clears the task and makes the activity that you are starting up be the root of the newly-cleared task.

### Always Starting a Cleared Task

Perhaps you *always* want to start with a cleared task, whenever the user returns to the task after having left it previously. In other words, you always want to start back at whatever your task’s root activity is, which is typically your launcher activity.

To do this, simply have android:clearTaskOnLaunch="true" on that launcher activity. Then, for any task where that activity is the root, when the user returns to the task, any other activities in the task are [reparented](#) (if applicable) or dropped.

Note, though, that this does not mean that you get a new *process*. Hence, any singletons you had before may or may not still be there.

So, in the authentication scenario described above, using android:clearTaskOnLaunch="true" would take the user back to your initial activity, where you can perform the authentication. However, if you detect that the SQLiteOpenHelper still exists, and therefore you do not need the user to log in again, you could switch over to showing your initial content (e.g., run a FragmentTransaction).

This is far simpler than having the detect-the-null-singleton-on-each-activity approach. However, the downside is that the user loses context. If they were six activities deep into your app, and they get interrupted by a phone call, when they come back to your app, they are back at the beginning.

### Launching an App Into a New Task

A home screen launcher app, when it invokes the user’s selected activity, will use code something like this from the Launchalot sample:

```
@Override
protected void onItemClick(ListView l, View v,
```

## TASKS

---

```
        int position, long id) {
    ResolveInfo launchable=adapter.getItem(position);
    ActivityInfo activity=launchable.activityInfo;
    ComponentName name=new ComponentName(activity.applicationInfo.packageName,
                                         activity.name);

    Intent i=new Intent(Intent.ACTION_MAIN);

    i.addCategory(Intent.CATEGORY_LAUNCHER);
    i.setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
               Intent.FLAG_ACTIVITY_RESET_TASK_IF_NEEDED);
    i.setComponent(name);

    startActivity(i);
}
```

(from [Introspection/Launchalot/app/src/main/java/com/commonsware/android/lauchalot/Launchalot.java](https://github.com/Introspection/lauchalot/blob/master/app/src/main/java/com/commonsware/android/lauchalot/Launchalot.java))

Here, we:

- Create a ComponentName identifying the specific activity in the specific app to be started (in this case, based on the ResolveInfo that the user chose)
- Create an Intent for the MAIN action and the LAUNCHER category
- Set the FLAG\_ACTIVITY\_NEW\_TASK and the FLAG\_ACTIVITY\_RESET\_TASK\_IF\_NEEDED flags in the Intent
- Attach the ComponentName to the Intent, to convert it from an implicit Intent into an explicit Intent
- Start the activity using the Intent

FLAG\_ACTIVITY\_NEW\_TASK indicates that we want the activity being started to be the root of a new task. If there is no outstanding task for this app, a new task will be created, a new activity instance will be created, and that activity will be the root of the task. Here, “root” means that if the user presses BACK and destroys the activity, the task itself is removed and the user returns to the home screen.

However, despite its name, FLAG\_ACTIVITY\_NEW\_TASK does not necessarily create a new task. If there is an existing task for this app containing this activity, that task is brought back to the foreground and is left intact. The activity we request is not created, let alone brought to the foreground.

That is where FLAG\_ACTIVITY\_RESET\_TASK\_IF\_NEEDED comes in. It ensures that the task that is brought to the foreground is showing the requested activity. This may involve [reparenting activities](#) as well.

Another possibility, instead of FLAG\_ACTIVITY\_RESET\_TASK\_IF\_NEEDED, is

`FLAG_ACTIVITY_MULTIPLE_TASK`. This *always* starts a fresh task, with a fresh instance of the requested activity in the root of that task. However, this now may mean that the user has multiple tasks for the same app, which may be confusing in some circumstances. However, this also lies at the core of [Android 5.0's documents-as-tasks support](#) and therefore may become more familiar to users over time.

### The Invisible Activity

Several sample apps in this book use an “invisible activity”, one with the theme set to `Theme.Translucent.NoTitleBar`. These are useful in cases where something outside your app needs an activity, but you do not really have a UI that you want to display. In the case of the book samples, having a LAUNCHER activity makes it much easier for readers like you to simply run the samples from the IDE.

However, those sample apps usually do not have any other activities. The invisible activity is just there to kick-start something else, such as `AlarmManager` events.

However, if you have a mix of invisible and regular activities in an app, your invisible activities still wind up potentially having a visible impact.

For example, suppose that we have an ordinary Android app, with regular activities. However, we want a home screen shortcut icon to allow the user to start something in the background, such as playing music. While an app widget would allow us to control what happens when the user taps on an icon in that app widget, a home screen shortcut icon *always* launches an activity. So, we make the start-the-music activity invisible via `Theme.Translucent.NoTitleBar`.

If the user taps on that shortcut, and none of our other activities are part of a task, things proceed as expected: the music starts and the user sees nothing (other than perhaps a `Toast` that we show to let the user know that we are responding to their request).

But, if one or more of our activities are in some task, launching the invisible activity *brings the task back to the foreground*. While our invisible activity is still invisible, the user now sees whatever other activity of ours they had last been in. It is possible that this is a feature, and not a bug, for some apps. But, in other cases, we might want the invisible activity to not have this effect.

The solution: task affinity.

Your ordinary activities can use the default task affinity, or have other task affinities

as needs dictate. Your invisible activity, though, would have an `android:taskAffinity` value that is distinct from all others, to force it into its own task. That way, when the user taps on the shortcut, the invisible activity routes to its own task. That task will not yet exist, so the invisible activity causes the task to be created. When the invisible activity calls `finish()` to destroy itself after kicking off the background work, the task is now empty and is removed. Since this was a new task, no existing UI would be brought back to the foreground, and since the task is removed in the end, we are “reset” for the next time the user taps on the shortcut.

### Reparenting Tasks

One of the more unusual features of Android’s task system is the ability for activities to be “reparented”, or moved from one task to another. On the surface, this feels a bit odd, as if a Web page on one browser tab might magically show up in a separate browser tab, just via navigation. And, in truth, it is a specialized use case, but one that could conceivably apply to your app.

Suppose that you were writing an SMS client. You have an activity that is your message composer, where the user can type in a text message to send to somebody. You export that activity, with Intent actions like `ACTION_SEND` and `ACTION_SENDTO`. A third-party app, using one of those Intent actions, starts up your message composer activity. In the absence of a `taskAffinity` to stipulate otherwise, by default, your message composer activity will be in the task of the third-party app.

Now, suppose that the user fails to actually send a message, such as by pressing HOME from the third-party app’s task. Some time later, the user taps on your app’s home screen launcher icon. At this point, there are two possibilities as to what happens:

1. You may decide that you want to have the already-running message composer activity appear, to remind the user that they were in the middle of composing a text message and failed to either send it or explicitly BACK out of the activity.
2. You may decide that you do not care, and you are willing to ignore that outstanding message composer activity instance.

The default is option #2. If, instead, you want to offer option #1, that is where task reparenting comes into play.

On your `<activity>` (or on `<application>` to set an app-wide default), you can have `android:allowTaskReparenting="true"`. This indicates to Android that the message

## TASKS

---

composing activity, that is on some other app's task, can move to your app's task when that task is created.

The trigger for this “reparenting” is the task affinity. If you do not specify a task affinity for an activity, the default affinity is for a task rooted in one of your app's activities, typically the launcher activity. In some circumstances, when a task for your app is created, Android will search through other tasks to see if there is any activity, in another task, that has an affinity for your task and allows reparenting. If there is a match, that activity is brought into your task.

The “some circumstances” mentioned in the preceding paragraph is something using two Intent flags when calling `startActivity()`:

- `FLAG_ACTIVITY_NEW_TASK`, to create a new task if one is needed, and
- `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED`, to clear out the task if it already has contents *and* reparent any activities in other tasks to this one if appropriate

As it turns out, home screen launchers are supposed to use this pair of flags when they respond to the user tapping on a home screen launcher icon.

The [Tasks/ReparentDemo](#) sample Android Studio project contains a pair of applications as modules that demonstrate this effect, based on David Wasser's [epic Stack Overflow answer](#).

One module, `app/`, contains an application with two activities, where the second activity (`ReparentableActivity`) has `android:allowTaskReparenting="true"`:

```
<manifest
  xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.android.tasks.reparent">

  <application
    android:allowBackup="true"
    android:label="@string/app_name"
    android:icon="@drawable/ic_launcher">
    <activity android:name=".MainActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>
        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
    <activity
      android:name=".ReparentableActivity"
      android:allowTaskReparenting="true">
```

## TASKS

---

```
<intent-filter>
  <action android:name="com.commonware.android.tasks.reparent.WHEEEEE" />
  <category android:name="android.intent.category.DEFAULT" />
</intent-filter>
</activity>
</application>
</manifest>
```

(from [Tasks/ReparentDemo/app/src/main/AndroidManifest.xml](#))

The two activities just display static messages, indicating which of those two activities you are seeing in the foreground. They also log process and task IDs to Logcat. MainActivity does that in onCreate():

```
package com.commonware.android.tasks.reparent;

import android.app.Activity;
import android.os.Bundle;
import android.util.Log;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        Log.d(getApplicationInfo().loadLabel(getPackageManager()).toString(),
            String.format("Process ID %d, Task ID %d",
                android.os.Process.myPid(), getTaskId()));
    }
}
```

(from [Tasks/ReparentDemo/app/src/main/java/com/commonware/android/tasks/reparent/MainActivity.java](#))

ReparentableActivity logs the same information in onResume():

```
package com.commonware.android.tasks.reparent;

import android.app.Activity;
import android.os.Bundle;
import android.util.Log;

public class ReparentableActivity extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.reparent);
    }
}
```

## TASKS

---

```
}

@Override
public void onResume() {
    super.onResume();

    Log.d(getClass().getSimpleName(),
        String.format("Process ID %d, Task ID %d",
            android.os.Process.myPid(), getTaskId()));
}
}
```

(from [Tasks/ReparentDemo/app/src/main/java/com/commonsware/android/tasks/reparent/ReparentableActivity.java](#))

The other module, `app2/`, contains an application with one activity, whose UI consists of one really big button. Clicking that button triggers a `launch()` method that calls `startActivity()` on an Intent identifying the `ReparentableActivity` from the first app:

```
package com.commonsware.android.tasks.reparent.app2;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.util.Log;
import android.view.View;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        Log.d(getApplicationInfo().loadLabel(getPackageManager()).toString(),
            String.format("Process ID %d, Task ID %d",
                android.os.Process.myPid(), getTaskId()));
    }

    public void launch(View v) {
        startActivity(new Intent("com.commonsware.android.tasks.reparent.WHEEEEE"));
    }
}
```

(from [Tasks/ReparentDemo/app2/src/main/java/com/commonsware/android/tasks/reparent/app2/MainActivity.java](#))

To see this behavior in action, install both apps. If you run them straight from your IDE, you will want to clear out all relevant tasks, either by swiping them off the recent-tasks list (or by rebooting the device or emulator, if it runs Android 4.4 or lower).

Then, start up the “Reparent Demo Aux” app (from the `app2/` module). Click the

## TASKS

---

button, and you will see the `ReparentableActivity` appear. If you press HOME, bring up the recent-tasks list, and go back to this task, you will see the same `ReparentableActivity`. The task, however, is for “Reparent Demo Aux”.

Now, press HOME, then start up the “Reparent Demo” app (from the `app/` module). Rather than seeing the `MainActivity` from that app, you see the `ReparentableActivity` instance from before. The logs will illustrate that your process ID has not changed, but that the task ID for this activity *has* changed, from the task ID used by the `app2/` app to the task ID created for `app/`. The activity has been reparented.

The use of `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED` may sound a lot like `FLAG_ACTIVITY_CLEAR_TASK`. The “if needed” part comes into play in two cases:

- If a new task is being created, the “reset” work is really the reparenting described above
- If an existing task is being brought back to the foreground, then get rid of resettable activities

Here, by “resettable activities”, we mean:

- Activities launched with the `FLAG_ACTIVITY_CLEAR_WHEN_TASK_RESET` flag
- Any activities that are higher on the back stack than other explicitly resettable activities

So, if our back stack consists of activities A-B-C-D, and C was started with `FLAG_ACTIVITY_CLEAR_WHEN_TASK_RESET`, and we start up one of these activities (say, A) with `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED`, and this existing task is coming back to the foreground, C and D will be cleared from the task. The user ordinarily would be taken to activity D, but instead will be taken to activity B, because C is explicitly resettable and D is higher on the back stack.

### The Self-Destructing Activity

Sometimes, you only want an activity around while it is in the foreground and the user can see it. Once the user leaves the app, you no longer want that activity to exist. For example, a bank app showing bank account details might want this behavior, so that highly-sensitive information like this does not hang around. Or, you might want this for certain activities that are memory-intensive, so they release their heap space and reduce the odds of an `OutOfMemoryError`.

## TASKS

---

You could attempt to manage this yourself, via timely calls to `finish()`, but catching all the cases when `finish()` is needed could get troublesome.

Instead, Android has a pair of options to have no-history activities: activities that automatically finish when the user leaves them:

- An activity can decide for itself that it should be removed upon a task switch via the `android:noHistory` attribute on the `<activity>` in the manifest
- You can decide ad-hoc to have activities exhibit this behavior by adding `Intent.FLAG_ACTIVITY_NO_HISTORY` on the `Intent` used to start those activities

You can see these in action in the [Tasks/NoHistory](#) sample application. This is a near-clone of a simple two-activity app that we saw back when we first learned about [how to have multiple activities](#).

There are only two real differences in this version of the sample app.

First, the launcher activity (`MainActivity`) has `android:noHistory="true"` on its `<activity>` element:

```
<activity
  android:name=".MainActivity"
  android:label="@string/app_name"
  android:noHistory="true">
  <intent-filter>
    <action android:name="android.intent.action.MAIN"/>

    <category android:name="android.intent.category.LAUNCHER"/>
  </intent-filter>
</activity>
```

(from [Tasks/NoHistory/app/src/main/AndroidManifest.xml](#))

Second, when that activity goes to start `OtherActivity`, it adds `FLAG_ACTIVITY_NO_HISTORY` to the `Intent` used with `startActivity()`:

```
public void showOther(View v) {
  Intent other=new Intent(this, OtherActivity.class);

  other.putExtra(OtherActivity.EXTRA_MESSAGE,
    getString(R.string.other));
  other.addFlags(Intent.FLAG_ACTIVITY_NO_HISTORY);
```

## TASKS

---

- Add `android:excludeFromRecents="true"` to `MainActivity` in the TaskCanary sample
- Run the sample app
- Press HOME and note the task ID that shows up in Logcat
- Press RECENTS and note that the task does not show up there
- Return to the home screen, find TaskCanary in the launcher, and tap on the launcher icon
- Press HOME again and note the task ID that shows up in Logcat

You will see that those task IDs are the same. So, the task is there, and we can return to that task, but the task is merely suppressed from the listing shown in the overview screen.

## Dealing with the Persistent Tasks

As noted previously in this chapter, on Android 5.0+, tasks live forever, insofar as they survive a reboot. That, coupled with a seemingly-infinite roster of recent tasks — compared with rather finite lists in earlier versions of Android — means that your app usually will be brought back from an existing task on Android 5.0+.

However, there are a few key differences.

### The State of Your State

For normal process termination, in between device reboots, the `Bundle` that we get in `onSaveInstanceState()` is held onto in RAM by some core OS process. Of course, on a reboot, that process is terminated along with everything else. And a `Bundle` can hold onto objects that, while perhaps `Parcelable`, are not designed to be persisted.

The default behavior is that when your task is brought back to the foreground after a reboot, only the task's root activity is created, and that is the only activity in the task. This effectively mimics the behavior of pre-Android 5.0 versions of Android.

However, if you want to, you can control a bit more how your task behaves on a reboot.

Your `<activity>` element in the manifest can have [a largely-undocumented `android:persistableMode` attribute](#). If you set this to `persistAcrossReboots` on the activity that serves as the root of your task (e.g., your launcher activity), then you will be able to override three additional methods on your `Activity`:

## TASKS

---

- `onCreate()`
- `onSaveInstanceState()`
- `onRestoreInstanceState()`

Right now, you may think that the author of this book is drunk, as we covered those methods already, far earlier in the book.

However, what API Level 21 adds, for `persistAcrossReboots` activities, are flavors of those methods that take two parameters: a `Bundle` (as normal) and a `PersistableBundle`. Values that you store in the latter parameter will be delivered to you when your activity is re-created as part of your task coming back to the foreground, even after a reboot.

Note that all of the above requires that you set your `compileSdkVersion` to 21 or higher.

`PersistableBundle` allows you to save `int`, `long`, `double`, and `String` values, along with arrays of each. On Android 5.1+, you can also save `boolean` and arrays of `boolean` values. Notably, you cannot put a `Parcelable` (or, strangely, a `Serializable`) in a `PersistableBundle`.

If your activity has `persistAcrossReboots` set — as does `MainActivity` in the [Tasks/PersistentCanary](#) sample application — you will be called both with the single-parameter and dual-parameter versions of those methods, in that order. Unless your app has a `minSdkVersion` of 21 or higher, you will probably wind up overriding both versions of each method, where you put stuff in the `Bundle` in the single-parameter method and you put stuff in the `PersistableBundle` in the dual-parameter method. Since versions of Android prior to 5.0 do not know about `PersistableBundle` or methods that take one, only the single-parameter versions of those methods will be called on those devices. If your `minSdkVersion` is 21 or higher, though, you could just override the dual-parameter versions of the methods and work with both `Bundle` and `PersistableBundle` as needed.

### Where You Return To

Normally, if your task is in the overview screen, and the user returns to it, the user will be taken to whatever activity was at the top of the back stack.

However, if the device reboots, and the user returns to your task, what happens depends on that semi-documented `persistableMode` value:

## TASKS

---

- If the value for the root activity of the task is `persistNever`, the task is not persisted across reboots
- If the value for the root activity of the task is `persistRootOnly`, the task will be persisted, but only for that root activity; other activities higher on the back stack are discarded
- If the value for the root activity of the task is `persistAcrossReboots`, then not only is the task persisted for the root activity, but other activities on the back stack are also persisted if they too have `persistAcrossReboots` (and were not launched with the `FLAG_CLEAR_TASK_WHEN_RESET` flag)

So, in the case of `PersistentCanary`, even if you use the overflow to bring up the date-and-time Settings screen, since that activity has the default `persistRootOnly` value for `persistableMode`, only the `MainActivity` will be in the task after a reboot.

## Documents As Tasks

Tasks used to be relatively app-centric. By and large, each app had its own task, and just one task.

Android 5.0 extended the task system to support the notion of “documents” as tasks. Now, an app may be in several tasks, with different tasks focused on different “documents” or other specific contexts.

The vision is that this would be used by:

- Web browsers, where different browser tabs would be represented as separate tasks
- Editors, where different editing sessions on different content could be represented as separate tasks
- And so on

The benefit to the user is a standard way to switch between these different contexts, by means of the overview screen. The risk is that the overview screen becomes unwieldy, choked with too many entries to sift through.

## When You Should Do This

An app should open a new “document” based on some specific explicit “open” operation by the user. So, for example:

## TASKS

---

- If the user asks to open a new “tab” in a browser, that could start a new document
- If the user asks to open a new file into an editor, that *might* start a new document, if you feel that the user understands that there are N other documents out there already opened in this editor
- If the user launches one of your activities from outside of the home screen, such as by clicking on a link in a Web browser, that might start a new document, to keep that work separate from any past work that might be part of other active tasks

Conversely, an app should not open a new document based on pure navigation operations:

- Swiping to a new page in a ViewPager should not open a new document
- Choosing an item in a nav drawer should not open a new document
- Tapping on an action bar item on its own should not open a new document, though it might lead the user down a path to open a new document

## Adding a Document

You have a few options for launching an activity as a new document, indicating that it should have a separate entry on the Android 5.0+ overview screen.

### **android:documentLaunchMode**

If you always want this activity to form the basis of a new document, add `android:documentLaunchMode="always"` to the `<activity>` element of your manifest, and you are done. Every time you start up an instance, you will get a new document.

This can be seen in the [Tasks/Docs](#) sample application, which has an `EditorActivity` with the aforementioned attribute:

```
<activity
  android:name=".EditorActivity"
  android:documentLaunchMode="always"
  android:maxRecent="3"
  android:autoRemoveFromRecents="true"/>
```

(from [Tasks/Docs/app/src/main/AndroidManifest.xml](#))

(we will cover those other new attributes shortly)

## TASKS

---

There are four possible values for `android:documentLaunchMode`:

- `always`, as noted, always starts a new document
- `intoExisting`, which looks for an existing document, where the root activity is the same class and the Intent is for the same `Uri`, and brings it back to the foreground, or starts a new document if a match cannot be found
- `never` prevents this activity from ever being launched as a new document
- `none`, which is the default, indicates that the activity will only be launched as a new document if Intent flags indicate that it should, as will be explained shortly

Since `intoExisting` depends upon `Uri` matches, you only want to use `intoExisting` if you are passing `Uri` values into the activity when starting it. Otherwise, use `always`.

### **FLAG\_ACTIVITY\_NEW\_DOCUMENT**

To conditionally launch an activity as a new document, have its `android:documentLaunchMode` set to `none` (or missing, since that is the default), and add `Intent.FLAG_ACTIVITY_NEW_DOCUMENT` to the Intent that is used to start up the activity that would represent a new document. This will have the behavior akin to `intoExisting` for `android:documentLaunchMode`, meaning that Android will search for a matching document and bring it back to the foreground if the match is available.

To replicate `always` functionality, add both `Intent.FLAG_ACTIVITY_NEW_DOCUMENT` and `Intent.FLAG_ACTIVITY_MULTIPLE_TASK` to the Intent.

### **Capping the Number of Documents**

By default, you can launch as many documents as you want. However, unless you get rid of the document (as will be described below), or the user gets rid of the document (by swiping it off the overview screen), your roster of documents can keep piling up. Users may get frustrated if their overview screen is flooded by entries for your app.

You can employ an automatic least-recently-used (LRU) algorithm here by adding `android:maxRecents` to the `<activity>` that is the root of the task for the document. This indicates the maximum number of entries there should be in the overview screen for that activity, where Android will remove older tasks to make way for new

ones if needed.

So, in the Docs sample, `android:maxRecent="3"` limits the number of `EditorActivity` tasks to 3; if the user tries opening more than this, older ones are quietly removed.

Note that the default value for `android:maxRecent` is 16. Also, there is a cap, ranging from 25 to 50, depending on device RAM — you will be unable to set it higher than this.

### Removing and Retaining Documents

Android's default behavior is that the document will exist forever, or until the user swipes it off the overview screen.

It is rather unlikely that this is really the behavior that you or your users will want. Hence, you are going to want to take some steps to ensure that your documents will go away from the overview screen when they are no longer needed.

The simplest solution is to add `android:autoRemoveFromRecent="true"`. This indicates that once the root activity is finished (e.g., the user presses BACK), the document is removed. By default, pressing BACK does *not* remove the document, so you need to opt into this behavior.

However, that approach assumes that it is fairly easy for the user to get back to the task's root activity and press BACK. If you have a complex navigation of activities within the “document”, it may not be easy for the user to trigger document removal this way.

You can also forcibly get rid of the document by calling `finishAndRemoveTask()` yourself on an activity in the task. For example, in a tabbed Web browser, if you have a “close tab” UI element (e.g., action bar item), that could call `finishAndRemoveTask()` to get rid of the “document”.

### Other Task-Related Activity Properties

There are other attributes that you can place on your `<activity>` element in the manifest that have impacts on how that activity participates with the task system.

### launchMode

Occasionally, particular techniques become much too popular in Android development, courtesy of some blog posts or other resources touting them as “quick hacks” to address certain issues. The `android:launchMode` attribute is one of those. Most Android apps should have no need to change `launchMode` off of its default value of `standard`, or occasionally `singleTop`. Yet, because the Android task system is rather confusing, some developers latch onto other launch modes and use them in places where there are better, more fine-grained solutions.

That being said, let’s explore the launch modes, with the help from the fine people at [Novoda](#). The Novoda developers released [an app on the Play Store](#), and an [accompanying GitHub repo](#) that helps to illustrate the launch modes.

That app has four activities, one for each of the four launch modes:

- `standard`
- `singleTop`
- `singleTask`
- `singleInstance`

The launcher activity is the `standard` activity. Each activity has four buttons, to start up that activity via `startActivity()`, by default with no particular Intent flags (though there’s a legacy options menu that allows you to play with those as well). The color-coded UI for each activity also shows a unique identifier of the activity, the task ID of the task that the activity is in, the lifecycle methods that were invoked on that instance, and a set of stacked bars designed to illustrate what should be on the back stack for that task (using some techniques of dubious reliability, but the sort of thing that should be OK for a demo app like this).

## TASKS

---

So, when we launch the app, we get a green UI for a standard activity:

*Figure 655: Novoda Demo App, As Initially Launched*

### singleTop

Using `singleTop` for the `launchMode` has one effect: controlling whether a new instance of the activity is created. Normally, calling `startActivity()` will create a new instance of the activity, unless `Intent` flags dictate otherwise. With `singleTop`, if the activity being started is already at the top of its stack, that existing instance is simply called with `onNewIntent()`. Otherwise, `singleTop` behaves as does `standard`.

## TASKS

---

So, if we tap the button to launch a `singleTop` method in the Novoda demo app, from our earlier state, we get a blue `singleTop` activity:

*Figure 656: Novoda Demo App, After Starting singleTop Activity*

## TASKS

---

That worked just like standard. But, if we tap the same button again, we do *not* get a new instance of the activity. However, the transcript of lifecycle methods shows that `onNewIntent()` was called:

Figure 657: Novoda Demo App, After Starting singleTop Activity Again

Note that you can get a similar result by including `Intent.FLAG_ACTIVITY_SINGLE_TOP` on a `startActivity()` call. Using `launchMode` says you *always* want single-top behavior; using `FLAG_ACTIVITY_SINGLE_TOP` says that *this time* you want single-top behavior.

Pressing BACK returns you to the original green standard activity, with the blue singleTop activity having been destroyed.

### singleTask

A `launchMode` of `singleTask` says that this activity must *always* be the root activity of a task.

If the task does not have that activity, a new task is created. So, if we tap the button to launch the singleTask activity in the Novoda demo app, we get a new task (ID 978, compared to the previous 977), with an instance of the yellow singleTask

## TASKS

---

activity as its root:

*Figure 658: Novoda Demo App, After Starting singleTask Activity*

However, if the activity in question is already there as the root of the task, all other activities on the back stack are cleared, and we are taken to the `singleTask` activity again.

## TASKS

---

So, in the Novoda demo app, if after we start the `singleTask` activity, we tap the button to launch a standard activity or two:

*Figure 659: Novoda Demo App, Two standard Activities After singleTask Activity*

## TASKS

---

...then tap the button to launch the `singleTask` activity, we get largely the same screen as before, just with a few more lifecycle methods logged:

Figure 66o: Novoda Demo App, After Starting `singleTask` Activity Again

It is the same task and the same instance, but with the other activities removed.

### **singleInstance**

`singleInstance` works much like `singleTask`, except that the task will only ever hold this one activity. No other activities will be placed into the task.

## TASKS

---

So, tapping the button to start a `singleInstance` activity in the Novoda demo app brings up the red `singleInstance` UI:

*Figure 661: Novoda Demo App, After Starting singleInstance Activity*

Tapping the same button again just triggers `onNewIntent()` and other lifecycle methods on the same activity in the same task. If, however, you try tapping on the button for the `standard` activity, your activity will go to another task. Depending on when and how you try the Novoda demo app, this could be a prior task associated with our app (e.g., one you used for earlier `standard` tests), or it could be a new task (if you do not have any other ones). This is based on the `taskAffinity` of the activity being started.

In general, `singleTask` and `singleInstance` are for unusual use cases, and ordinary Android apps should have little reason to use them. Google [specifically urges you not to use them](#):

...`standard` is the default mode and is appropriate for most types of activities. `SingleTop` is also a common and useful launch mode for many types of activities. The other modes — `singleTask` and `singleInstance` — are not appropriate for most applications, since they result in an interaction model that is likely to be unfamiliar to users and is very different from most

other applications.

### **alwaysRetainTaskState**

As noted earlier in the chapter, tasks may be cleared by Android if the user has not been in the task for some time (e.g., 30+ minutes). In these cases, the user is taken back to the root activity.

If, however, the root activity has `android:alwaysRetainTaskState="true"` in its manifest entry, then Android will not apply this timeout rule. So long as the task exists, its entire state will be retained and used when the user returns to the task. This is useful for tasks where there is a lot of state that the user might regret losing.

## **Other Task-Related Activity Methods**

There are a handful of other task-related methods and such floating around the Activity class:

### **finishAffinity()**

This calls `finish()` not only on the current activity, but on all activities immediately behind it on the back stack for this task that have the same `taskAffinity` as does the current activity. Much of the time, the activities on the stack will all share an affinity, and therefore this will frequently finish all activities in the task. If the task has a mixed set of affinities (e.g., a mix of explicitly-named affinities and other activities using the default affinity), this method would only wipe out those behind the current with a specific match.

This method is not commonly used.

### **finishAndRemoveTask()**

This calls `finish()` on all activities in the task and removes the task outright.

For example, a “logout” operation might call `finishAndRemoveTask()` to flush the current task, then call `startActivity()` to launch the login activity. That login activity will wind up in a fresh task (since the current one will be removed), and the old activity instances will go away, so the user cannot somehow stumble into them when they are not yet logged in.

### **getTaskId()**

Returns a unique integer that identifies the task the activity resides in.

This method is not commonly used.

### **isTaskRoot()**

`isTaskRoot()` is a method on `Activity`. It will return `true` if this activity instance is at the root of a task, meaning that pressing `BACK` should remove the task and return the user to the home screen.

### **moveTaskToBack()**

This method moves the current task to the background. What comes to the foreground is undocumented but generally seems to be the task for the home screen. Some apps use this to offer a “minimize” or “go to background” option within the app, though this is superfluous, as the task will move to the background naturally as the user navigates their device.

### **setTaskDescription()**

For Android 5.0+, `setTaskDescription()` allows you to associate an `ActivityManager.TaskDescription` instance with your task. Here you can provide values that help drive what the task looks like on the overview screen. Specifically, you can provide the icon, title, and background color to use for the title bar over your thumbnail on the overview screen.

# The Assist API (“Now On Tap”)

---

Android 6.0 introduced the concept of the device “assistant”. The assistant can be triggered by a long-press of the HOME button or via a spoken phrase (if the user has always-on keyphrase detection) enabled. An assistant is a special app that has access to the content of the foreground activity and other visible windows, much like an accessibility service does.

For the vast majority of users of Google Play ecosystem devices running Android 6.0 or higher, the “assistant” is known as Now On Tap. On some devices, such as the Google Pixel series, this assistant is known simply as the “Google Assistant”. This is marketed as an extension of the Google Now UI, where Now On Tap/Google Assistant will take the data from the foreground activity and use that to find other relevant things for the user to do based upon that data.

(for the purposes of this chapter, this Google-supplied assistant will be referred to as “Now On Tap”, to distinguish Google’s assistant from assistants that others might write using these APIs)

For example, suppose the user receives a text message, suggesting dinner at a particular restaurant. The restaurant is merely named — no URL — and so the text messaging client would just display the name of the restaurant as part of the message. If the user invokes Now On Tap, Google will take the contents of this message (and anything else on the screen), and presumably send it to Google’s servers, sending back things like details about the restaurant (e.g., URL to Web site, Google’s scanned reviews of the restaurant, link to Google Maps for driving directions). Google’s search engine technology would scan the data from the app, recognize that the restaurant name appears to be something significant, and give Now On Tap details of what to offer the user.

As with many things from Google, Now On Tap is very compelling and very much a

privacy problem. Now On Tap is automatically installed and enabled on Android 6.0 devices — users have to go through some work to disable it. Users and app developers have limited ability to control Now On Tap, in terms of what data it collects and what it does with that data. On the other hand, certain apps (for which there are no privacy considerations) might wish to provide *more* data to Now On Tap, beyond what is visible in widgets, to help provide more context for Now On Tap to help users.

In this chapter, we will explore the Assist API, in terms of:

- what data gets collected
- how apps can add to that data
- how apps can block sensitive information from the assistant
- how to write your own assistant, as a Now On Tap replacement

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## What Data Gets Disclosed

Quite a bit of data is made available to Now On Tap or other assistants through the Assist API alone, as will be explored in this section.

Assistants are welcome to use other APIs as well, subject to standard Android permissions and such. So, for example, an app might not show the device’s location, and therefore an assistant could not get the location from the Assist API, but the assistant could use `LocationManager` or the Play Services location API to find out the device’s location.

There is also a risk of pre-installed assistants using undocumented means of getting at data beyond what the normal Android SDK would allow.

All that being said, assistants will get a lot of information about the currently-visible UI, just from what the Assist API provides.

## Screenshot

Assistants can get a screenshot of the current screen contents — minus the status

bar — when the user activated the assistant (e.g., long-pressed HOME). Developers can [block this](#) for select activities or other windows. Hence, an assistant cannot *assume* that it will get a screenshot, though frequently it will.

Presumably, the “vision” here is to use computer vision and other image recognition techniques on the screenshot to find things of interest. For example, the user might bring up Now On Tap for some activity that is showing a photo of a monument. The activity might not be showing any other details about the monument, such as its name. However, Google’s servers might well recognize what monument it is and therefore give the user links to Wikipedia pages about the monument, a map of where the monument is located, etc.

### View Structure

By far the largest dump of data that the assistant gets comes in the form of the view structure. This is represented by a tree of `AssistStructure.ViewNode` objects, one per widget or container within a window. These provide similar information as to what one gets from the accessibility APIs. For most assistants, the key data is the text or content description in the widget. In the case of text, this is available as a `CharSequence` and so may contain additional information (e.g., hyperlinks represented in `URLSpan` objects) beyond the words visible to the user.

Developers can [restrict what widgets and containers are disclosed](#), but that is something developers have to do explicitly. In other words, making data available to assistants is something a developer has to opt out of, not opt into.

### Other Data

In addition to the view structure and a largely-undocumented `Bundle`, the other piece of data supplied to the assistant is the `AssistContent`. Here is where an app can provide some additional context about the foreground activity.

Specifically, the app can provide:

- an `Intent` that represents the activity, replacing the `Intent` that was used to start the activity, if there is a better one for long-term use (e.g., the activity was started via a `Notification` action and you want to route the user through a different `Intent` for other scenarios)
- a `Uri` that points to some Web page of relevance for this activity
- a string of “structured data”, designed to be populated by a snippet of JSON using the [schema.org](#) specification, to provide details of the book, song,

- video, or whatever happens to be in the activity at the moment
- another undocumented Bundle
- an undocumented ClipData

Assistants can use this directly (e.g., offer a link to the `Uri` supplied in this content) or indirectly (e.g., using the `schema.org` JSON to find places where the user can purchase related content).

## Adding to the Data

You may wish to provide some additional information to Now On Tap or other assistants, such as the Intent or JSON described above. Or, you may just generally want to ensure that your app provides the maximum amount of information to these assistants, without necessarily trying to invent new data to provide.

There are a few options for accomplishing this.

### Accessibility

The big one is to ensure that your app provides text or content descriptions for everything visible. This will not only help these assistants, but this will make your app far more accessible to those using TalkBack or other accessibility services.

Mostly, this is a matter of ensuring that your `ImageView` widgets and other non-textual widgets have a content description, whether set via `android:contentDescription` attributes or by `setContentDescription()` in Java. `TextView` and its subclasses automatically use their text as the content description; `EditText` will use the hint if there is no text in the field at the moment.

More advice regarding accessibility can be found in [the chapter on accessibility and focus management](#).

### Assist-Specific Data

Beyond that, you can contribute to the `AssistContent` (where the Intent, `Uri`, and JSON live) and other assist-related information for a given invocation of the assistant by the user.

You have a few options of where to place this logic: in one spot globally, on a per-activity basis, and, for custom views, on a per-view basis.

### Globally

You can call `registerOnProvideAssistDataListener()` on the global `Application` object (retrieved by calling `getApplicationContext()` on some other `Context`, like your `Activity`). This takes an `OnProvideAssistDataListener` implementation, which in turn provides an `onProvideAssistData()` implementation, that will be called when the assistant is requested. You are passed the `Activity` of yours that is in the foreground, along with a `Bundle` that you can fill in.

However, the documentation only says that the `Bundle` will go into the `EXTRA_ASSIST_CONTEXT` extra on the `Intent` that invokes the assistant. What that `Bundle` is supposed to contain is undocumented.

### Per-Activity

Your primary hooks for customizing the assist data come in the form of two callbacks on your `Activity` subclasses: `onProvideAssistData()` and `onProvideAssistContent()`.

`onProvideAssistData()` is given the same `Bundle` that is given to the `OnProvideAssistDataListener` on a global basis. However, it is unclear what goes in that `Bundle`, and the contents of that `Bundle` do not appear to make it to the assistant, at least through the documented Assist API.

`onProvideAssistContent()`, though, is more relevant.

The [Assist/MoAssist](#) sample project is another version of the `ViewPager-of-editors` sample seen elsewhere in the book. The clone overrides `onProvideAssistData()` and `onProvideAssistContent()`:

```
@Override
public void onProvideAssistData(Bundle data) {
    super.onProvideAssistData(data);

    data.putInt("random-value", new SecureRandom().nextInt());
}

@TargetApi(23)
@Override
public void onProvideAssistContent(AssistContent outContent) {
    super.onProvideAssistContent(outContent);
}
```

## THE ASSIST API (“NOW ON TAP”)

---

```
outContent.setWebUri(Uri.parse("https://commonsware.com"));

try {
    JSONObject json=new JSONObject()
        .put("@type", "Book")
        .put("author", "https://commonsware.com/mmurphy")
        .put("publisher", "CommonsWare, LLC")
        .put("name", "The Busy Coder's Guide to Android Development");

    outContent.setStructuredData(json.toString());
}
catch (JSONException e) {
    Log.e(getClass().getSimpleName(),
        "Um, what happened here?", e);
}
}
```

(from [Assist/MoAssist/app/src/main/java/com/commonsware/android/assist/mo/MainActivity.java](#))

The `onProvideAssistData()` simply puts a random number into the `Bundle`. That random number does not appear anywhere in [the data collected by an assistant](#).

`onProvideAssistContent()` fills in two items in the `AssistContent`:

- a Web URL of relevance to the activity, in this case the home page of the book’s publisher
- a bit of JSON, following [the published schema.org Book structure](#), with metadata about this book

This information *is* supplied to assistants and can be used by them to do something useful, such as offer links for the user to click on to visit the sites.

### Per-View

If you are implementing your own custom views, particularly those that render their own text using low-level Canvas APIs, you may wish to override `onProvideStructure()` and/or `onProvideVirtualStructure()`. These will be called on your widgets to provide the `AssistStructure.ViewNode` details to be passed to the assistant.

However, in all likelihood, you would want to instead work with the accessibility APIs to publish data to be used by accessibility services, such as the text that you are rendering. If you do that, the default implementations of `onProvideStructure()` and `onProvideVirtualStructure()` should suffice.

## Removing from the Data

While some developers may embrace Now On Tap, others may specifically want to prevent Now On Tap or other assistants from “spying” on application data. You have a few options for controlling what is provided to assistants; however, all require work and some have side effects. For example, there is nothing in the manifest that you can specify to make your activities opt out of providing assist data.

### FLAG\_SECURE

The standard approach for making private activities *really* private is to [use FLAG\\_SECURE](#):

```
public class FlagSecureTestActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        getWindow().setFlags(LayoutParams.FLAG_SECURE,
            LayoutParams.FLAG_SECURE);

        setContentView(R.layout.main);
    }
}
```

Call `setFlags()` before `setContentView()`, in this case setting `FLAG_SECURE`.

The classic effect of `FLAG_SECURE` is to block screenshots, both user-initiated ones and system-initiated ones (e.g., the screenshots used in the overview/recent-tasks screen on Android 4.0+).

If the user triggers an assistant for a secure activity, the assistant will not get the full view structure (i.e., no widgets and no text) and will not get a screenshot.

### Password Fields

An `EditText` that is set up as a password field will have its text blocked from the view structure. The widget will be listed, but its text will be `null`.

Presumably, this relies on the `EditText` using a `PasswordTransformationMethod`, as that is Android’s typical approach for determining whether or not an `EditText` is deemed to be secure. If you have implemented your own `TransformationMethod`

(e.g., with a different approach for shrouding the user input), either have it extend `PasswordTransformationMethod` or use other approaches to prevent this field’s contents from being published to assistants.

### NoAssistFrameLayout

The apparently-official way to block a widget or container from participating in the assist API is to create a subclass of it and override `dispatchProvideStructure()`. The stock implementation of this triggers the calls to `onProvideStructure()` and `onProvideVirtualStructure()`. Plus, for a `ViewGroup`, it will iterate over the children and call `dispatchProvideStructure()` on each of them.

If you are creating your own custom view, and you want it eliminated from the view structure, just override `dispatchProvideStructure()` and have it do nothing.

Or, you can create a container that is there solely to block the assist data collection. The [Assist/NoAssist](#) sample project does this, in the form of a `NoAssistFrameLayout`:

```
package com.commonware.android.assist.no;

import android.annotation.TargetApi;
import android.content.Context;
import android.os.Build;
import android.util.AttributeSet;
import android.view.ViewStructure;
import android.widget.FrameLayout;

public class NoAssistFrameLayout extends FrameLayout {
    public NoAssistFrameLayout(Context context) {
        super(context);
    }

    public NoAssistFrameLayout(Context context,
                               AttributeSet attrs) {
        super(context, attrs);
    }

    public NoAssistFrameLayout(Context context,
                               AttributeSet attrs,
                               int defStyleAttr) {
        super(context, attrs, defStyleAttr);
    }
}
```

## THE ASSIST API (“NOW ON TAP”)

---

```
@TargetApi(Build.VERSION_CODES.LOLLIPOP)
public NoAssistFrameLayout(Context context,
    AttributeSet attrs,
    int defStyleAttr,
    int defStyleRes) {
    super(context, attrs, defStyleAttr, defStyleRes);
}

@Override
public void dispatchProvideStructure(ViewStructure structure) {
    // no, thanks
}
}
```

(from [Assist/NoAssist/app/src/main/java/com/commonsware/android/assist/no/NoAssistFrameLayout.java](#))

EditorFragment — responsible for showing a large multi-line EditText for the user to type into — will conditionally use a NoAssistFrameLayout, specifically on the third tab (a ViewPager position of 2):

```
@Override
public View onCreateView(LayoutInflater inflater,
    ViewGroup container,
    Bundle savedInstanceState) {
    int position=getArguments().getInt(KEY_POSITION, -1);
    View result;

    if (position==2) {
        ViewGroup doctorNo=new NoAssistFrameLayout(getActivity());
        inflater.inflate(R.layout.editor, doctorNo);
        result=doctorNo;
    }
    else {
        result=inflater.inflate(R.layout.editor, container, false);
    }

    EditText editor=result.findViewById(R.id.editor);

    editor.setHint(getTitle(getActivity(), position));

    if (position==1) {
        editor.
            setTransformationMethod(PasswordTransformationMethod.
                getInstance());
    }

    return(result);
}
```

## THE ASSIST API (“NOW ON TAP”)

---

```
}
```

(from [Assist/NoAssist/app/src/main/java/com/commonsware/android/assist/no/EditorFragment.java](#))

If we are on the third tab, we create a `NoAssistFrameLayout` and inflate our `EditText` into it. Otherwise, we inflate the layout normally.

Note that this sample also applies a `PasswordTransformationMethod` for the second page of the `ViewPager` (a position of 1), to illustrate the null text that will be recorded as a result.

## Blocking Assist as a User

It is possible that your reaction to all of this is that you want to opt out of Now On Tap as a user. Or, perhaps you want to provide some instructions to your users on how to opt out of Now On Tap.

Go to `Settings > Apps`. There should be an option for advanced app configuration actions (on Nexus-series devices, this is a gear icon in the action bar). Tap that, then choose “Default Apps” to bring up categories of default apps for various actions:

*Figure 662: Android 6.0 Default Apps Screen in Settings*

## THE ASSIST API (“NOW ON TAP”)

---

In there, tap on “Assist & voice input”. By default, you should see “Google App” as the chosen option, which means that Now On Tap is active:

*Figure 663: Android 6.0 Assist & Voice Input Screen in Settings*

---

## THE ASSIST API (“NOW ON TAP”)

---

Tapping on that entry will bring up a list of available options, including “None”:

*Figure 664: Android 6.0 Assist & Voice Input Options in Settings*

## Implementing Your Own Assistant

While Now On Tap is pre-installed and pre-activated, and while users can disable Now On Tap, another option for users is to activate some other assistant. Any app that implements the proper pieces of the Assist API will appear in the roster of available assistants for the user to choose from, as described in the previous section. The [Assist/AssistLogger](#) sample project represents one such app.

Primarily, this app is for diagnostic purposes, showing you exactly what your activity is “leaking” to assistants. It was essential in figuring out how the APIs shown in earlier examples in this chapter worked, for instance. However, it also serves as a demonstration of the minimum requirements to implement an assistant in general.

Creating an assistant is technically part of a larger bit of work on handling voice interactions in Android. However, if all you want is an assistant, you can ignore the voice-related bits.

### A Stub VoiceInteractionService

Some of what is needed to set up an assistant is some boilerplate.

For example, the entry point for assistants and voice interactions is a custom subclass of `VoiceInteractionService`. If you only are concerned with implementing an assistant, your `VoiceInteractionService` can be empty:

```
package com.commonware.android.assist.logger;

import android.service.voice.VoiceInteractionService;

public class AssistLoggerService extends VoiceInteractionService {
}
```

(from [Assist/AssistLogger/app/src/main/java/com/commonware/android/assist/logger/AssistLoggerService.java](#))

However, it needs to exist, and in particular it needs to have its `<service>` entry in your manifest:

```
<service
  android:name=".AssistLoggerService"
  android:permission="android.permission.BIND_VOICE_INTERACTION">
  <meta-data
    android:name="android.voice_interaction"
    android:resource="@xml/assist_service"/>
  <intent-filter>
    <action android:name="android.service.voice.VoiceInteractionService"/>
  </intent-filter>
</service>
```

(from [Assist/AssistLogger/app/src/main/AndroidManifest.xml](#))

The keys to the manifest entry are:

- It needs to have the `android:permission` attribute, limiting it clients that hold the `BIND_VOICE_INTERACTION` permission, which should limit clients to those that are part of the device firmware
- It needs to have the `<intent-filter>` advertising that it supports the `android.service.voice.VoiceInteractionService` action string
- It needs an `android.voice_interaction <meta-data>` element, pointing to an XML resource that further configures the voice interaction/assistant implementation

## THE ASSIST API (“NOW ON TAP”)

---

The sample project has that metadata in `res/xml/assist_service.xml`:

```
<voice-interaction-service
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:recognitionService="com.commonware.android.assist.logger.AssistLoggerService"
  android:sessionService="com.commonware.android.assist.logger.AssistLoggerSessionService"
  android:supportsAssist="true"/>

<!--
  android:settingsActivity="com.android.test.voiceinteraction.SettingsActivity"
-->
```

(from [Assist/AssistLogger/app/src/main/res/xml/assist\\_service.xml](#))

There are three attributes required on the `<voice-interaction-service>` root element to enable an assistant:

- `android:recognitionService` points back to your `VoiceInteractionService` subclass
- `android:sessionService` points to a subclass of `VoiceInteractionSessionService` (we will examine the project’s implementation shortly)
- `android:supportsAssist` should be true

If you want, you can also have an `android:settingsActivity` attribute, shown in this XML as a commented-out snippet at the end of the file. This can point to an activity in your app. If you have this, a gear icon will appear on the “Assist & voice input” Settings screen that, when tapped, will bring up this activity, to configure the behavior of your assistant. The sample app skips this.

### A Trivial `VoiceInteractionSessionService`

The service pointed to by `android:sessionService` in the metadata needs to be a subclass of `VoiceInteractionSessionService`. The only method that you need to override is `onNewSession()`, where you can return an instance of a `VoiceInteractionSession`:

```
package com.commonware.android.assist.logger;

import android.os.Bundle;
import android.service.voice.VoiceInteractionSession;
import android.service.voice.VoiceInteractionSessionService;

public class AssistLoggerSessionService extends
  VoiceInteractionSessionService {
  @Override
```

## THE ASSIST API (“NOW ON TAP”)

---

```
public VoiceInteractionSession onNewSession(Bundle args) {
    return(new AssistLoggerSession(this));
}
}
```

(from [Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerSessionService.java](#))

Here, we return an instance of `AssistLoggerSession`, which is where all of our real business logic resides for our assistant.

Note that this service also should use `android.permission` to limit clients to those that hold the `android.permission.BIND_VOICE_INTERACTION` permission:

```
<service
    android:name=".AssistLoggerSessionService"
    android:permission="android.permission.BIND_VOICE_INTERACTION" />
```

(from [Assist/AssistLogger/app/src/main/AndroidManifest.xml](#))

## The VoiceInteractionSession

`VoiceInteractionSession` has a *lot* of methods that you can override, both for voice interactions and for assistant invocations. The sample app overrides the minimum required for an assistant, as its mission simply is to log all of the data received by our assistant to files on external storage, for diagnostic purposes.

**NOTE: Running this sample app on hardware that is actually used with private data is stupid beyond words. Any app can then read the files on external storage and see what information is published by whatever apps are in the foreground at the times when you invoke the assistant. Please use this only on test environments.**

### Basic Setup

Akin to components, a `VoiceInteractionSession` has an `onCreate()` method, called as part of setting up the session. In there, `AssistLoggerSession` sets up an output directory for logging the results, assuming that external storage is available:

```
@Override
public void onCreate() {
    super.onCreate();

    if (Environment.MEDIA_MOUNTED
        .equals(Environment.getExternalStorageState())) {
```

## THE ASSIST API (“NOW ON TAP”)

---

```
String logDirName=
    "assistlogger_"+
        new SimpleDateFormat("yyyyMMdd'-'HHmmss").format(new Date());

logDir=
    new File(getContext().getExternalCacheDir(), logDirName);
logDir.mkdirs();
}
}
```

(from [Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerSession.java](#))

### onHandleScreenshot()

If the user invokes your assistant, you will be called with `onHandleScreenshot()`. Usually, you will be passed a `Bitmap` that contains the screenshot. However, if the foreground activity is using `FLAG_SECURE`, the `Bitmap` that is passed to you will be `null`, so make sure you check it before doing anything with it.

The `AssistLoggerSession` forks a `ScreenshotThread` to save this screenshot in the background:

```
@Override
public void onHandleScreenshot(Bitmap screenshot) {
    super.onHandleScreenshot(screenshot);

    if (screenshot!=null) {
        new ScreenshotThread(getContext(), logDir, screenshot).start();
    }
}
```

(from [Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerSession.java](#))

`ScreenshotThread`, in turn, just uses `compress()` on `Bitmap` to write the image out as a PNG to the directory that we are using for logging:

```
private static class ScreenshotThread extends Thread {
    private final File logDir;
    private final Bitmap screenshot;
    private final Context ctxt;

    ScreenshotThread(Context ctxt, File logDir, Bitmap screenshot) {
        this.ctxt=ctxt.getApplicationContext();
        this.logDir=logDir;
        this.screenshot=screenshot;
    }
}
```

## THE ASSIST API (“NOW ON TAP”)

---

```
@Override
public void run() {
    if (logDir!=null) {
        try {
            File f=new File(logDir, "screenshot.png");
            FileOutputStream fos=new FileOutputStream(f);

            screenshot.compress(Bitmap.CompressFormat.PNG, 100, fos);
            fos.flush();
            fos.getFD().sync();
            fos.close();

            MediaScannerConnection
                .scanFile(ctxt,
                    new String[] {f.getAbsolutePath()},
                    new String[] {"image/png"}, null);

            Log.d(getClass().getSimpleName(),
                "screenshot written to: "+f.getAbsolutePath());
        }
        catch (IOException e) {
            Log.e(getClass().getSimpleName(),
                "Exception writing out screenshot", e);
        }
    }
    else {
        Log.d(getClass().getSimpleName(),
            String.format("onHandleScreenshot: %dx%d",
                screenshot.getWidth(), screenshot.getHeight()));
    }
}
}
```

(from [Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerSession.java](#))

### onHandleAssist()

onHandleAssist() is your other main assistant callback. Here is where you get:

- a Bundle of undocumented stuff
- the AssistStructure outlining the contents of the windows, including the view hierarchy
- the AssistContent with the Intent, Web Uri, JSON, and so on

AssistLoggerSession kicks off an AssistDumpThread to record this data in the

## THE ASSIST API (“NOW ON TAP”)

---

background:

```
@Override
public void onHandleAssist(Bundle data,
                          AssistStructure structure,
                          AssistContent content) {
    super.onHandleAssist(data, structure, content);

    new AssistDumpThread(getContext(), logDir, data, structure,
                        content).start();
}
```

(from [Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerSession.java](#))

AssistDumpThread itself is a *long* class that generates a JSON file containing the information found in the parameters to onHandleAssist():

```
package com.commonsware.android.assist.logger;

### Making a Real Assistant

AssistLogger is a faithful implementation of an assistant, but it does not really assist the user, except in seeing what sorts of information Google gets via Now On Tap.

If you wanted to make an actual assistant that is a true replacement for Now On Tap, you would also need to implement methods like:

- `onCreateContentView()`, where you can inflate a layout or otherwise assemble the basic UI to be shown to the user when your assistant is invoked
- `onShow()`, where you can populate that UI with the details for this particular assist request
- `onHide()`, called when your UI is no longer visible to the user

...and so on.

### Determining the Active Assistant

If you elect to create your own assistant, you might be interested in knowing

## THE ASSIST API (“NOW ON TAP”)

---

whether or not your app has been chosen as the user’s assistant. Unfortunately, there is no documented and supported means of doing this.

So, here is the undocumented and unsupported approach that works on Android 6.0.

**WARNING:** this code may not work on all Android 6.0 devices, let alone on future versions of Android, as it relies a bit on internal implementation that could be changed by device manufacturers or custom ROM authors. Please use this *very carefully* and do not be shocked if it stops working.

`Settings.Secure` holds the details of the currently-chosen assistant. However, the key under which those details are stored is a hidden entry in `Settings.Secure`, and so it does not show up in the Android SDK. The key is `"voice_interaction_service"`. The value is the `ComponentName` of the assistant, serialized (or “flattened”) into a `String`. So, to get the `ComponentName` of the assistant, you can use:

```
String assistant=
    Settings.Secure.getString(getContentResolver(),
        "voice_interaction_service");

boolean areWeGood=false;

if (assistant!=null) {
    ComponentName cn=ComponentName.unflattenFromString(assistant);
}
```

`cn` will then hold the `ComponentName`.

### Leading the User to Make an Assistant Change

If you implement your own assistant, and at the moment you are not the user’s chosen assistant, you might have the need to lead the user over to the spot in the Settings app where they can change this. Once again, this is not explicitly documented.

However, for Android 6.0, `Settings.ACTION_VOICE_INPUT_SETTINGS` contains the action string that opens up the screen where the user can choose their assistant implementation. So, you could call:

```
startActivity(new Intent(Settings.ACTION_VOICE_INPUT_SETTINGS));
```

## THE ASSIST API (“NOW ON TAP”)

---

to lead the user to that screen, plus use a Toast or something to remind the user to tap on the “Assist app” entry to choose the assistant.

However:

- Since `Settings.ACTION_VOICE_INPUT_SETTINGS` is not guaranteed to be on all devices, please wrap the `startActivity()` call in an `ActivityNotFoundException` try/catch block and deal with the missing action accordingly
- There is no guarantee that `Settings.ACTION_VOICE_INPUT_SETTINGS` will lead the user to the correct screen on all Android 6.0+ devices, as the Settings app might be altered by the device manufacturer or custom ROM author

# The Autofill API

---

Many Web browsers, such as Chrome, offer “autofill”. The browser remembers things that you have typed into certain fields, like addresses, and offers to fill those back in when you go to fill in the same form again... or even a different form with similar fields.

Android 8.0 adds autofill capability to Android via the Autofill Framework. Values that users enter into your forms will be remembered and offered again when the user returns to your form, or to other forms that they encounter in other apps on the device. This all happens without any changes to your code... in theory. In practice, you may need some changes to your code.

However, Android itself does not store the form data, nor offer it as suggestions for autofilling in a form. Android is merely serving as a conduit between your app and a third-party autofill service. It is the service that is responsible for determining what could be autofilled in your form and saving prior entries. As with [the Assist API](#), the user can choose an autofill service, and none ship by default with the O Developer Preview. In all likelihood, a Google-branded autofill implementation will be part of the production rollout of Android 8.0, but the user could choose other autofill apps... or perhaps none at all, for privacy reasons.

In this chapter, we will explore the AutoFill API, in terms of:

- what data gets collected
- how apps can block sensitive information from autofill
- how apps can better integrate with autofill

**NOTE:** O Developer Preview 2 renamed many of the Autofill Framework classes and methods to make the *f* in *Autofill* lowercase. So, for example, `AutoFillService` became `AutofillService`. Materials written based on O Developer Preview 1 (blog

posts, Stack Overflow answers, etc.) will have a capital F instead.

### Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

There are commonalities between autofill and [the Assist API](#), and so this chapter will refer back to that one from time to time.

### The Pieces of the Puzzle

Android 8.0 provides a framework for apps with a UI to participate in autofill, by denoting roles that some of those widgets have (e.g., “this is the field for the username”). However, Android itself does not save any user input for later use with autofill, nor does Android itself decide what values are candidates for autofill. Instead, Android delegates that work to a separate autofill service. This works akin to how accessibility services and input method editors work:

- Android provides the conduit for apps and pluggable service implementations to communicate
- Android provides a UI in Settings for the user to choose which service implementation(s) to use for a particular role
- App developers provide the actual service implementations

## THE AUTOFILL API

---

Hence, with autofill, there are three pieces: the app with the UI, Android itself, and the autofill service:

*Figure 665: Pieces of Autofill*

Here, `onFillRequest()` and `onSuccess()` are part of the API for autofill service implementations.

## The User Experience

Before we get into the implementation, let's see how this looks from the standpoint of the user.

**NOTE:** These screenshots and explanations are from the O Developer Preview 4. It is possible that this flow will change by the time Android O ships in final form, or even in future developer previews.

### While Completing a Form

If an autofill service is activated, and the user visits a screen with a form to be filled in, the user may get a drop-down list from the form, indicating possible “datasets” to use to complete the form:

*Figure 666: Autofill Datasets for User to Choose From*

The actual presentation here (“dataset-2”) comes from the autofill service. It is actually a RemoteViews, not just some text, and so different autofill services will use different formats here.

### After Completing a Form

After the user has completed a form, with data not represented in one of those datasets, once the activity containing the form is destroyed, the user gets a “bottom sheet” panel asking if the data should be saved for later autofill use:

This works akin to the pop-up dialog a desktop Web browser might use to ask if certain data should be saved (e.g., authentication credentials) for future visits to that page.

### What Data Gets Disclosed

The Assist API discloses [quite a bit of data](#) to the user’s chosen assistant app.

The autofill API discloses a bit less. Mostly, it is the view hierarchy, in the form of a `ViewStructure`.

An autofill service gets information about what is in the UI at two points:

1. When it is time to determine if there is anything that could be autofilled-in
2. When it is time to save data for future autofill requests

Here is what an autofill service might see from a small form with username, password, and cc fields (the latter for a credit card number), along with related labels and a “save” button, when it is time to determine if there is anything that could be autofilled-in:

```
{
```

```

Roughly speaking, you get all the same information that an accessibility service might. Most of this information is likely to be useless to an autofill service, but a few elements, such as `idEntry` (the widget ID) and `text` (the contents of a `TextView` or things inheriting from `TextView`) will be of importance.

## Blocking Autofill as a User

The O Developer Preview 3 ships with an “Autofill with Google” autofill service, pre-installed and pre-enabled. Presumably, many devices that ship with Android 8.0 will ship with an autofill service pre-installed, whether that is one from Google, from the device manufacturer, or from another party.

## THE AUTOFILL API

---

If you, as a user, do not trust the autofill service, you can disable it or switch to a different one via the Settings app. Specifically, Settings > System > Languages & input > Advanced has an “Autofill service” preference:

*Figure 668: Advanced “Languages & input” in Settings, Showing “Autofill service”*

---

## THE AUTOFILL API

---

Tapping the gear icon next to the configured autofill service (if there is one) will allow you to configure the service. Tapping the rest of the list row brings up a dialog for you to choose an autofill service from the available candidates, or “None” to opt out of autofill entirely:

Figure 669: “Autofill service” Selection in Settings

## Supporting Autofill with Standard Widgets

The documentation suggests that apps do not need to be modified to work with the Autofill Framework. That is incorrect, at least in general. Layouts do need some modification to work with autofill services, to help those autofill services identify the roles of those widgets and how those roles tie into saved data that could be autofilled-in.

The thing to bear in mind about autofill is that we have three parties to the content negotiation:

- Your app
- The Android Autofill Framework
- The autofill service implementation

This requires some common ground, as otherwise the autofill service will not know what is and is not to be considered candidates for autofill.

### Identifying Roles via Hints

The primary thing that you need to do is to identify the roles of various widgets in your form. After all, a field containing a user ID might be called `userid`, `userId`, `uid`, `username`, `user_name`, `login`, or anything else. An autofill service needs to know that your `EditText` with an `android:id` of `@+id/snicklefritz` represents a user ID, for example.

To do this, use `android:autofillHints` in a layout resource, or `setAutofillHints()` from Java. These indicate, for the particular `View` you are configuring what role or role(s) the `View` holds within the world of autofill.

Autofill hint values are strings. Typically, a given widget only needs one hint, and so you can set the hints to that particular string. If, for whatever reason, a widget qualifies for more than one hint, use a comma-delimited list as the value for `android:autofillHints`, or pass multiple strings to `setAutofillHints()` via `varargs`.

The roster of possible hints, by name and Java `View` constant, are:

---

## THE AUTOFILL API

---

Value	View Constant
creditCardExpirationDate	AUTOFILL_HINT_CREDIT_CARD_EXPIRATION_DATE
creditCardExpirationDay	AUTOFILL_HINT_CREDIT_CARD_EXPIRATION_DAY
creditCardExpirationMonth	AUTOFILL_HINT_CREDIT_CARD_EXPIRATION_MONTH
creditCardExpirationYear	AUTOFILL_HINT_CREDIT_CARD_EXPIRATION_YEAR
creditCardNumber	AUTOFILL_HINT_CREDIT_CARD_NUMBER
creditCardSecurityCode	AUTOFILL_HINT_CREDIT_CARD_SECURITY_CODE
emailAddress	AUTOFILL_HINT_EMAIL_ADDRESS
name	AUTOFILL_HINT_NAME
password	AUTOFILL_HINT_PASSWORD
phone	AUTOFILL_HINT_PHONE
postalAddress	AUTOFILL_HINT_POSTAL_ADDRESS
postalCode	AUTOFILL_HINT_POSTAL_CODE
username	AUTOFILL_HINT_USERNAME

Here, name is for a real name (e.g., “Mark Murphy”), whereas username is for something more like a login value (e.g., “commonsguy”).

Since these are strings, and since the Android Autofill Framework (probably) does not care about the specific values, it is theoretically possible for autofill services to document additional hints that they honor (e.g., birthDate).

### Indicating Importance

Independent from the hint system is `android:importantForAutofill` and the corresponding `setImportantForAutofill()` method. These indicate whether you, as the developer of the UI, think that certain widgets should or should not be considered for autofill purposes. For example, you might have a form that a user

## THE AUTOFILL API

---

might fill out repeatedly and might want autofill capability, but some fields do not fit specific roles governed by the hint system, and so the autofill service might ignore them by default.

The default importance is auto, meaning that the autofill service will make its own guess, probably based on whether there is an autofill hint or not. This maps to `IMPORTANT_FOR_AUTOFILL_AUTO` in `setImportantForAutofill()`.

There are four alternatives:

XML Attribute Value	Java Constant	Role
no	<code>IMPORTANT_FOR_AUTOFILL_NO</code>	widget should be ignored from an autofill standpoint
<code>noExcludeDescendants</code>	<code>IMPORTANT_FOR_AUTOFILL_NO_EXCLUDE_DESCENDANTS</code>	widget and all its children should be ignored
yes	<code>IMPORTANT_FOR_AUTOFILL_YES</code>	widget should always be considered for autofill
<code>yesExcludeDescendants</code>	<code>IMPORTANT_FOR_AUTOFILL_YES_EXCLUDE_DESCENDANTS</code>	widget and all its children should be considered

For example:

- To block autofill from seeing the value of a sensitive widget, use

---

## THE AUTOFILL API

---

`android:importantForAutofill="no"` or  
`setImportantForAutofill(View.IMPORTANT_FOR_AUTOFILL_NO)` on the  
affected View

- To block autofill for an entire activity, use this in `onCreate()` of the activity:

```
getWindow()  
    .getDecorView()  
    .setImportantForAutofill(View.IMPORTANT_FOR_AUTOFILL_NO_EXCLUDE_DESCENDANTS);
```

## Supporting Autofill with Custom Widgets

Other than having identifiable roles via hints, standard widgets are handled automatically via the Autofill Framework. However, the framework has no idea how to handle custom views of your own design, particularly those that use low-level drawing APIs like Canvas to render their contents.

The O Developer Preview documentation has [some instructions](#), for developers of custom views to follow, if and where those views should be participating in autofill.

## Dealing with Dynamic Changes

Sometimes, the form content changes significantly on the fly as the user is interacting with it. For example, you might dynamically add some widgets based on user input (e.g., tapping a “+” icon to add a row to a table). Hence, there may be cases when you need to tell the Autofill Framework more explicitly when it should do (or re-do) its work.

There is an `AutofillManager` system service that is your gateway to the Autofill Framework. You can obtain an instance from `getSystemService(AutofillManager.class)` called on a convenient Context, such as your activity.

Then:

- If you need to tell the Autofill Framework to discard any existing autofill logic applied to the current form (e.g., the user did something to reset the form contents), call `cancel()` on the `AutofillManager`
- If you want to ask the Autofill Framework specifically to re-apply the autofill logic for the current form, call `requestAutofill()` on the `AutofillManager`
- If you want to do something differently depending upon whether or not

---

## THE AUTOFILL API

---

- autofill is enabled, call `isEnabled()` on the `AutofillManager`
- If you want the Autofill Framework to complete its processing of the current form contents, without waiting for the activity to be destroyed, call `commit()` on the `AutofillManager`

So, for example, if you want to bail out of your activity right away if autofill is enabled — for example, you are concerned that you cannot adequately defend the privacy of your users — you could have the following code snippet in `onCreate()` of the activity:

```
if (getSystemService(android.view.autofill.AutofillManager.class).isEnabled()) {
    Toast.makeText(this, "Ick!", Toast.LENGTH_LONG).show();
    finish();
}
```

(where you would replace the `Toast` with something else to explain the situation to the user)

Or, if you wanted to ensure that the contents of your form were not submitted to the autofill service — again, with privacy in mind — you can `cancel()` the autofill operation in `onBackPressed()`, or perhaps in other lifecycle methods:

```
@Override
public void onBackPressed() {
    getSystemService(android.view.autofill.AutofillManager.class).cancel();

    super.onBackPressed();
}
```

## Security Requirements of Autofill Services

Of course, a poorly written autofill provider can leak sensitive data.

That quote is from [a comment](#) on [a security issue](#) regarding a security flaw in Android 8.0's autofill implementation. While those links may not work for you, as the issue is still locked as of February 2019, it contains a long chain of comments about this flaw and how Google expects the Android ecosystem to deal with the flaw.

### First, the Flaw

Autofill will fill in widgets that the user cannot see, because:

## THE AUTOFILL API

---

- The widget is marked as invisible (`android:visibility="invisible"`)
- The widget has no size (width and height of 0dp) or is impossibly tiny (width and height of 1dp)
- The widget has negative margins that cause it to display off-screen
- The widget is behind some other opaque widget (on the Z axis), and so the widget cannot be seen

There may be other similar scenarios. For example some discussion on the issue suggests that autofill will supply data for a widget that does not exist at all in the view hierarchy, but rather is faked by the activity as part of how it populates the `ViewStructure` of information that goes to the autofill service.

Given this flaw, a malicious activity could obtain data that the user does not realize will go to that activity. For example, the activity might have a field for the user to confirm their postal code and have hidden widgets that collect other data, such as the rest of the address, credit card details, usernames/passphrases, etc.

This flaw can be demonstrated using [Google's own sample autofill service](#), though in the future that sample should be updated to show a more secure implementation.

A copy of the flawed autofill service sample, along with a client demonstrating how malicious activities can obtain data covertly from the autofill service, can be found in [this GitHub repo](#). Instructions for reproducing the problem can be found there as well.

### Google's Response

Google's engineers on the security issue admit that the flaw exists and that it would be difficult, if not impossible, to defend against malicious activities.

As such, Google is taking the approach of dumping this issue on the laps of the developers of autofill services. That is the context for the quote at the top; Google believes that well-crafted autofill services will resolve this issue. In the issue, Google has stated that their own autofill service implementation that ships pre-installed and pre-enabled on Android 8.0 will be well-crafted.

There are two problems:

1. At present, there is little documentation or sample code on what a well-crafted autofill service looks and works like, so many other developers looking to implement autofill services are left in the dark

2. Their advice will not resolve the problem completely, though it will reduce the scope

### What Secure Autofill Services Need To Do

Unfortunately, the documentation for writing autofill services is limited and does not address very well the issue of how to write a secure autofill service.

Instead, Google “work<s> closely with most major autofill providers”, focusing on that instead of documentation, sample code, and public test suites. This approach is difficult to defend, given that there may be entire markets for which Google’s efforts have no impact (e.g., China, if none of the “major autofill providers” distribute their apps there).

So, what is it that Google is expecting autofill service developers to do?

### Partition the Dataset

The one bit of advice that Google has published publicly (as of the time this was written) was to partition the dataset. This involves two steps:

1. Cluster the possible requested autofill hints into partitions (e.g., address/ phone versus credit card versus username/password)
2. Only hand back the data for one partition at a time, based on what widget has the focus at the time the autofill request is made of the service

So, for example, suppose the form has fields for address, phone number, and the typical batch of credit card details (number, name, expiration date, etc.) A poorly-crafted autofill service provides autofill data for all of that when Android asks for it... despite the fact that this is what the API would appear to expect the autofill service to do. Instead, you need to:

- Identify which widget has the focus
- Determine which partition (address/phone or credit card) that widget belongs to
- Only supply autofill data for that partition on this request

Later on, if the user puts the focus on a field that is eligible for autofill but for which you did not provide the data previously, you will get a second chance at the same form, where you repeat the process, only supplying autofill data for the partition associated with the now-focused partition.

See the “Data Partitioning” section in [the AutofillService JavaDocs](#) for complete details.

### **Only Give Data Back to the App That Supplied It**

Another bit of advice: only give data back to the app that supplied it, for anything that you or the user might consider to be sensitive.

On the Web, some autofill works across all domains. Data that you fill into a form on one Web site can be captured by the browser and offered up as candidate responses on other sites, including ones that you have never visited before. If the user fills in an email address for Site A, that email address is available to supply via autofill to Site B.

The equivalent behavior with Android’s autofill would be for the autofill service to have a single pool of data that could be autofilled-in for any app. If the user fills in an email address for App A, that email address is available to supply via autofill to App B.

Google feels that this is fine, so long as the data is not something that the user would consider to be sensitive. In particular, they recommend that usernames and passwords be locked to an individual app and not pooled, which makes perfect sense. For such sensitive content, an autofill service must only provide data back to the specific app that supplied it, via a combination of the `applicationId` (“package”) of the app and the public signing key of that app:

An autofill provider must verify the *package+signature* to prevent phishing - this guarantees that even if a sideloaded app uses another app’s package name and mimics its UI cannot get access to sensitive data associated with it.

At the present time, this “only give data back to the app that supplied it” requirement is undocumented, outside of the aforementioned security issue. According to the developers, it will be documented sometime in the future.

### **Hint to the User What Data Is Being Autofilled In**

The autofill service API has support for the service to require authentication before actually providing the autofill data. In a nutshell, the service creates a `PendingIntent` pointing to the authentication activity associated with the autofill

service and includes that `PendingIntent` in its response to an autofill request. If the user elects to proceed, the `PendingIntent` is used to display the authentication activity. If the user successfully authenticates, the user is returned to the activity they had been on previously, but now the secured autofill data should now be available for use.

For anything that is deemed sensitive, Google not only recommends that autofill services use this authentication flow, but that the authentication activity display details of exactly what data will be released. This way, for whatever autofill request triggered the authentication, the user will be informed about all fields that would be filled in... including those that the user cannot see.

This requirement is also undocumented at this time.

### What Google's Advice Does Not Solve

There are gaps in Google's advice.

First, there is no real enforcement that any autofill service follow the advice. This might be checked manually for the Play Store:

However, we'll have a manual procedure in place to verify such compliance for apps that want to be list as an Autofill service option in the "Add Autofill Service" Play Store page that is launched from Settings.

How well this works, and whether any other app distribution channel will implement similar checks, remains to be seen. Similarly, whether any security firms or other independent parties offer some sort of compliance check remains to be seen.

Second, the "only give data back to the app that supplied it" rule will fail for apps for whom the form and the data come from outside the app... such as for Web browsers. There, the app is the *browser*, not the Web site. The autofill service has no obvious means of distinguishing one site from another, or even that there is a concept of "site" that needs to be taken into account.

Third, what the *user* considers to be sensitive data, what *Google* considers to be sensitive data, and what *autofill service developers* consider to be sensitive may differ. For example, the user might be rather concerned about their address being made available. But if the autofill service developers do not consider that to be sensitive data, Google's recommendations may be ignored. In particular, if you implement the

## THE AUTOFILL API

---

partitioning, but do not limit data sharing between apps, a malicious activity can still steal data within a single partition, such as obtaining all the credit card details when just asking visibly for the expiration year.

Fourth, the hint-when-authenticating approach helps, but a malicious activity can defeat simple implementations, by requesting multiple partitions and setting the focus such that an innocuous partition is requested first. For example, the malicious activity's form might have visible fields for email address and postal code, followed by invisible fields for the rest of the address. Putting the email address field first and giving it the focus will cause any authentication to happen for the email partition. If the authentication activity only hints to the user about fields that will be autofilled in from that one partition, the user will only be told about the visible email address field. Authentication should not be required when the user advances to the postal code field, as the user just authenticated, and so the user might not receive the hint about the hidden address fields after the postal code field.

# The Data Binding Framework

---

To quote [Rudyard Kipling](#):

East is East and West is West, and never the twain shall meet

In many programming environments, including classical Android development, one could paraphrase Kipling as “models are models and views are views, and never the twain shall meet, except by means of some controller or presenter or something”. The result is a fair amount of code that populates views with model-supplied data and updates those models as the user alters the data in the views (e.g., types something in an `EditText` widget).

Data binding, in general, refers to frameworks or libraries designed to help simplify some of this data migration, where the definitions of the models and views can be used to automatically “bind” them without as much custom controller- or presenter-style logic.

Interest in data binding spiked in 2015, when Google released the first beta editions of data binding support via Android Studio, the Android Gradle Plugin, and a new data-binding support library.

This chapter explores Google’s data binding support and how to use it to simplify your Android app development.

## Prerequisites

This chapter requires that you have read the core chapters of this book. In particular, the sample apps are based off of samples from [the chapter on Internet access](#). Also, some samples use [RecyclerView](#).

## The What, Now?

In this book, we have examined a few variations of a sample app that retrieved the latest android questions from Stack Overflow and displayed them in a `ListView`. Our `QuestionsFragment` would populate a `ListView` or `RecyclerView` with the questions. For example, here is a `getView()` implementation that uses Picasso to populate a question:

```
@Override
public View getView(int position, View convertView, ViewGroup parent) {
    View row=super.getView(position, convertView, parent);
    Item item=getItem(position);
    ImageView icon=row.findViewById(R.id.icon);

    Picasso.with(getActivity()).load(item.owner.profileImage)
        .fit().centerCrop()
        .placeholder(R.drawable.owner_placeholder)
        .error(R.drawable.owner_error).into(icon);

    TextView title=row.findViewById(R.id.title);

    title.setText(Html.fromHtml(getItem(position).title));

    return(row);
}
```

(from [HTTP/Picasso/app/src/main/java/com/commonsware/android/picasso/QuestionsFragment.java](http://Picasso/app/src/main/java/com/commonsware/android/picasso/QuestionsFragment.java))

Some parts of this are clearly distinct for this application, notably using Picasso to download the question asker's avatar and using `Html.fromHtml()` to handle HTML-style entities in the title.

However, the general process used here is fairly rote:

- Get the widget out of the row
- Stuff the data into the widget for the row
- Do the above for each widget needing to be updated as part of binding data to the row (a.k.a., “lather, rinse, repeat”)

Data binding, as a general technique, aims to reduce that rote coding by declaratively telling a framework how to pull data from model objects (e.g., instances of `Item`) and pour that data into widgets (e.g., `ImageView` and `TextView`).

### The Basic Steps

With that in mind, let's examine what it takes to convert this sample over to using Google's data binding system.

The code samples shown in this section come from the [DataBinding/Basic](#) sample project.

### Setting Up the Toolchain

Data binding only really works well with up-to-date versions of Android Studio (1.3 or higher) and the Android Gradle Plugin (1.5.0 or higher recommended).

The data binding system consists of two pieces: another plugin for Gradle, and a library that gets bundled with our app. However, we do not need to set those up manually. Instead, we simply tell the Android Gradle Plugin that we want data binding, and it adds the requisite plugin and library for us.

All we need is a small `dataBinding` closure, where we set the `enabled` property to `true`:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit2:converter-gson:2.3.0'
    implementation 'com.android.support:support-fragment:27.1.1'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
        versionCode 1
        versionName "1.0"
    }

    dataBinding {
        enabled = true
    }
}
```

(from [DataBinding/Basic/app/build.gradle](#))

Once you do this, future times that you open this project in Android Studio may result in you getting a “Source folders generated at incorrect location” message:

*Figure 670: Data Binding Gradle Sync Message*

This is due to [a bug](#) that, in the fullness of time, may get fixed. However, the messages appear to be benign, and they should not cause any problems with your app.

## Augmenting the Layout... and the Model

The real fun begins with the layout for our `ListView` row. The original edition of this layout resource was a typical `LinearLayout` with an `ImageView` and `TextView`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">

    <ImageView
        android:id="@+id/icon"
        android:layout_width="@dimen/icon"
        android:layout_height="@dimen/icon"
        android:layout_gravity="center_vertical"
        android:contentDescription="@string/icon"
        android:padding="8dip"/>

    <TextView
        android:id="@+id/title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="20sp"
        android:layout_gravity="left|center_vertical"/>

</LinearLayout>
```

(from [HTTP/Picasso/app/src/main/res/layout/row.xml](#))

We need to make some changes to that in order to leverage data binding:

```
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android">

  <data>

    <variable
      name="item"
      type="com.commonware.android.databind.basic.Item"/>
  </data>

  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">

    <ImageView
      android:id="@+id/icon"
      android:layout_width="@dimen/icon"
      android:layout_height="@dimen/icon"
      android:layout_gravity="center_vertical"
      android:contentDescription="@string/icon"
      android:padding="8dip"/>

    <TextView
      android:id="@+id/title"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:layout_gravity="left|center_vertical"
      android:text="@{item.title}"
      android:textSize="20sp"/>

  </LinearLayout>
</layout>
```

(from [DataBinding/Basic/app/src/main/res/layout/row.xml](#))

First, the entire resource file gets wrapped in a `<layout>` element, on which we can place the android namespace declaration.

That `<layout>` element then has two children. The second child is our `LinearLayout`, representing the root `View` or `ViewGroup` for the resource. The first child is a `<data>` element, and that is where we configure how data binding should proceed when this layout resource gets used. Specifically, the `<variable>` element indicates that we want to bind data from an `Item` object into widgets defined in this

layout.

Then, if you look at the `TextView`, you will see that it now has an `android:text` attribute that the original layout resource lacked. More importantly, the value for `android:text` is unusual: `@{item.title}`. The `@{}` syntax indicates that rather than interpreting the value as a plain string, or even a reference to a string resource, that the value is really an expression, in a data binding expression language, that should be computed at runtime to get the value to assign to the text of the `TextView`.

In this case, the expression is `item.value`. `item` is the name given to the `Item` object in the `<variable>` element. Any place where we want to pull data from that `Item` object, we can use dot notation to reference things on the `item` expression language variable.

`item.value` means “get the value from the `item`”. At runtime, the data binding library will attempt to get this value either from a public getter method (`getValue()`) or a public field (`value`) on the `Item` class. The original project had a `value` field, but it was not public, so the revised project marks the `Item` fields as public, so we can use them in data binding:

```
package com.commonware.android.databind.basic;

public class Item {
    public String title;
    public Owner owner;
    public String link;

    @Override
    public String toString() {
        return(title);
    }
}
```

(from [DataBinding/Basic/app/src/main/java/com/commonware/android/databind/basic/Item.java](#))

As we will see in this chapter, the expression language used here is much more complex than simply referencing JavaBean-style properties on objects, but for now, this will suffice.

### Applying the Binding

The layout configures one side of the binding: pulling data into widgets. We still need to do some work to configure the other side of the binding: supplying the

## THE DATA BINDING FRAMEWORK

---

source of that data. In the case of this example, we need to provide the `Item` object for this layout resource.

That is handled via some modifications to the `getView()` method of the `ItemsAdapter` from its original version:

```
@Override
public View getView(int position, View convertView, ViewGroup parent) {
    RowBinding rowBinding=
        DataBindingUtil.getBinding(convertView);

    if (rowBinding==null) {
        rowBinding=
            RowBinding.inflate(getActivity().getLayoutInflater(),
                parent, false);
    }

    Item item=getItem(position);
    ImageView icon=rowBinding.icon;

    rowBinding.setItem(item);

    Picasso.with(getActivity()).load(item.owner.profileImage)
        .fit().centerCrop()
        .placeholder(R.drawable.owner_placeholder)
        .error(R.drawable.owner_error).into(icon);

    return(rowBinding.getRoot());
}
```

(from [DataBinding/Basic/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

There are four changes here: we create the binding, provide the model (`Item`) to the binding, retrieve other widgets from the binding, and retrieve the root view of the layout.

### Creating the Binding

When we use `<layout>` in a layout resource and set up the layout side of the data binding system, the build system code-generates a Java class associated with that layout file. The class name is derived from the layout name, where names\_like\_this get converted into `NamesLikeThis` and have `Binding` appended. So, since our layout resource was `row.xml`, we get `RowBinding`. This is code-generated into a `databinding` Java sub-package of the package name from the manifest. Hence, the fully-qualified import statement for this class is:

```
import com.commonware.android.databind.basic.databinding.RowBinding;
```

This is a subclass of `ViewDataBinding`, supplied by the `databinding` library that is added to your project by enabling data binding in your `build.gradle` file.

Creating an instance of the binding also inflates the associated layout. Your binding class has a number of factory methods for inflating the layout and creating the binding. These mirror other methods that you have used elsewhere:

- `setContentView()`, taking an `Activity` and the layout resource ID as parameters, inflates the layout, passes the result to `setContentView()` on the `Activity`, and creates the binding
- `inflate()`, with a variety of parameter list options, just inflates the layout using a `LayoutInflater`, and creates the binding

Here, we use the three-parameter flavor of `inflate()`, which takes a `LayoutInflater` (obtained from the hosting activity), the parent container, and `false`. This mirrors the `inflate()` one would use on `LayoutInflater` itself, except that it also gives us our binding.

Of course, this is a `ListView`, and so we have to deal with the possibility that rows get recycled. The `DataBindingUtil` class has a `getBinding()` method that returns the binding for a given root view from the inflated layout — in this case, our `convertView`. So, we try to get the existing binding first, then fall back to inflating a new one if and only if that is necessary. Since `getBinding()` properly handles `null` values for `convertView`, we do not need to check for `null` ourselves explicitly.

### Pouring the Model into the Binding

The generated binding class will have setters for each `<variable>` in our `<data>` element in the layout. Setter names are generated from the variable names using standard JavaBean conventions, so our `item` variable becomes `setItem()`. When we call `setItem()`, the data binding system will use that `Item` object to populate our `TextView`, applying the binding expression from our `android:text` attribute.

### Retrieving Widgets from the Binding

However, we did not do anything related to data binding for the `ImageView` widget in the layout (though we will, later in this chapter). Hence, we still need to manage that manually, getting Picasso to fetch the avatar asynchronously and put it in the `ImageView`.

However, that implies that we *have* the `ImageView`. Normally, we would call `findViewById()` on the inflated layout's root `View` to obtain that.

However, our binding class has code-generated public fields on it for each widget in the layout resource that has an `android:id` value (at least for `@id/...` and `@+id/...` values). Our `ImageView` has an `android:id` value of `@+id/icon`, and so the `RowBinding` class has an `icon` field that holds our `ImageView`. We can simply reference it, rather than doing the `findViewById()` lookup ourselves.

### Getting the Actual View

Since `getView()` is supposed to return the inflated layout's root view, we need some way to get that from the binding. Fortunately, `ViewDataBinding` has a `getRoot()` method that our generated class inherits, so we can just call that to get the value to return from `getView()`.

### Results

Visually, this app is the same as before (though this version uses `Theme.Material` on compatible devices). Functionally, the app is the same as before. And, from a code complexity standpoint, the app is probably *worse* than before, as we went through a lot of work just to avoid calling `findViewById()` a couple of times and `setText()` once.

Hence, while the data binding system is nice, it really only adds value to larger projects, particularly those with complex layouts. By the end of this chapter, you should have a better sense for when data binding is useful and when it is overkill.

## The Extended Layout Resource

As we saw in the preceding example, much of the knowledge that we impart into our app to power the data binding comes in the form of an extended layout resource syntax. The last child of the root `<layout>` element is what our layout resources used to hold: the `View` or `ViewGroup` at the root of the view hierarchy of this layout. Other children of `<layout>` configure the data binding behavior (and perhaps other features in the future).

With that in mind, let's explore a bit more about what you can do with elements in the `<layout>`.

### Imports and Statics

The preceding example lost one feature with respect to the sample app that served as its starting point: handling HTML in titles. While Stack Overflow does not serve HTML tags in question titles, it *does* serve HTML entities in question titles. A question title of “Foo & Bar” would come to us in the JSON as “Foo & Bar”. The examples in the chapter on Internet access handle that via `Html.fromHtml()`. However, we do not have that in our data binding.

One way to address this is to add a getter-style method to `Item` that returns the title after passing through `Html.fromHtml()`. For example, we could have a `getInterpretedTitle()` or `getTitleWithEntitiesFixed()` or `getTitleAfterHavingRunItThroughHtmlFromHtml()`. We would then refer to that method in our android:text expression (e.g., `@{item.interpretedTitle}`).

However, this blurs the line dividing the responsibilities of model objects and the UI layer. The model itself does not care that the title has HTML entities in it, and some ways of using that model data (e.g., displaying in a `WebView`) might specifically *need* those HTML entities. The fact that we need to convert those HTML entities is a UI responsibility, because the UI chose to use a `TextView`, which does not handle those entities automatically.

A fairly easy way to get our `Html.fromHtml()` logic back in would be to apply it in the layout resource itself. It would be cool if we could have our expression be `@{Html.fromHtml(item.title)}`, for example.

The good news is: that is eminently possible.

However, if you just used that syntax without other changes, the data binding framework would complain that it does not know what `Html` is. In effect, we need to teach the layout resource where to import `Html` from.

To do that, we need to add `[import type="android.text.Html"/]` into the `<data>` element of our layout resource. Now, the generated code will contain that `import` statement and our references to `Html` will resolve.

You can see that in the [DataBinding/Static](#) sample project. This is a clone of `DataBinding/Basic` with the two changes (expression and `<import>` applied), giving us the following layout resource:

```
<?xml version="1.0" encoding="utf-8"?>
```

## THE DATA BINDING FRAMEWORK

---

```
<layout xmlns:android="http://schemas.android.com/apk/res/android">

  <data>

    <import type="android.text.Html" />

    <variable
      name="item"
      type="com.commonware.android.databind.basic.Item" />
  </data>

  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">

    <ImageView
      android:id="@+id/icon"
      android:layout_width="@dimen/icon"
      android:layout_height="@dimen/icon"
      android:layout_gravity="center_vertical"
      android:contentDescription="@string/icon"
      android:padding="8dip" />

    <TextView
      android:id="@+id/title"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:layout_gravity="left|center_vertical"
      android:text="@{Html.fromHtml(item.title)}"
      android:textSize="20sp" />

  </LinearLayout>
</layout>
```

(from [DataBinding/Static/app/src/main/res/layout/row.xml](#))

If you run this version of the app, and it so happens that there is a Stack Overflow question with an HTML entity in its title among the recent questions, you will see that entity show up properly in the `ListView`. On the other hand, if you run the previous sample, the HTML entity will show up in HTML source form (e.g., `&amp;` instead of `&`).

The rules for imports here are reminiscent of those of regular Java:

- Do not have conflicting imports (e.g., `android.view.Menu` and

- com.myrestaurant.Menu)
- Do not try to import classes that are automatically imported (e.g., java.lang.String)

### Variables

As we saw in the preceding samples, you can have `<variable>` elements representing objects that can be referenced by binding expressions.

The type attribute for the `<variable>` element can be:

- a fully-qualified class name, as seen in the `item` variable from the examples
- the name of a class that you added via an `<import>` element
- the name of any class automatically imported into all Java classes (e.g., Integer)

So, for example, instead of:

```
<data>
  <variable
    name="item"
    type="com.commonware.android.databind.basic.Item"/>
</data>
```

we could have:

```
<data>
  <import type="com.commonware.android.databind.basic.Item"/>

  <variable
    name="item"
    type="Item"/>
</data>
```

If you have different versions of the same layout in different resource sets for different configurations (e.g., `res/layout/` and `res/layout-land/`), your `<layout>` element needs to be compatible between them. This particularly holds true with respect to variables. If you define a variable `foo` as a `String` in one version of the resource, you cannot define `foo` to be a `Restaurant` in another version of the resource. There is one binding class created for each layout resource, spanning all of the different versions of that resource, and that class cannot have two separate, conflicting definitions for the same variable.

## The Binding Expression Language

To a basic approximation, the binding expression language that you can use in layout resources works just like its Java counterpart. If you can include it in a Java expression, you can include it in a binding expression. This not only covers your typical mathematical, logical, and string concatenation operations, but also:

- Casts
- Using parentheses for grouping (e.g., `@{((Location)(restaurant.location)).latitude}`)
- Calling methods, both on objects in the expression and static methods on imported classes
- Accessing fields by name, both on objects and on static classes that you have imported
- Accessing array contents using square-bracket notation, including using other variables as the index (e.g., `@{movie.actor<index>.fullName}`)
- Using the ternary operator for inline if-style branching (e.g., `@{movie.isNew ? View.VISIBLE : View.GONE}`)

### Stuff You Won't Find in Java

The expression language contains a few conveniences that go beyond what you will see in standard Java.

One of these has already been mentioned: JavaBean-style accessor usage. So, `foo.bar` will try to find a field named `bar` on the `foo` object. If that is not found, `foo.bar` will try to find a `getBar()` method on the `foo` object. This allows the model object to decide whether or not to expose the data via a field or getter method; the binding expression works with either.

If you have a variable that is a `Map`, you can use square-bracket notation to access the map by key, instead of having to call `get()`.

If you try accessing a field or calling a method on `null`, you normally would get a `NullPointerException`. The expression evaluator tries to mitigate that:

- If the field or method is designed to return some primitive, the result of accessing the field or calling the method on `null` returns whatever the default primitive value is (e.g., `int` and `long` values are `0`)
- Otherwise, if the field or method returns some object, the result of accessing

the field or calling the method on `null` returns `null`

Another way of working with `null` values is the `??` “null coalescing operator”. In the expression `foo ?? bar`, the result is:

- `foo`, if `foo` is not `null`
- `bar`, if `foo` is `null`

This is useful when you want to replace some optional value with a default when the optional value is `null`. For example, you might use `sub.expirationDate ?? @string/not_yet_subscribed` to either show the expiration date of some subscription, or pull in the value of a string resource to use if there is no expiration date.

That example demonstrates yet another feature of the expression language: references to resources. In general, you reference them just as you would without the data binding system. So, these are equivalent:

- `android:text="@string/foo"`
- `android:text="@{string/foo}"`

Of course, the power comes in when using those resources in actual expressions, such as using a boolean resource with the ternary operator (e.g., `@{boolean/i_can_haz_foo ? foo : bar}`).

Note that a few resource types use different names in the binding expressions, as the expression evaluator needs to know the data type. So, for example, you normally reference array resources as simply `@array/name`. In binding expressions, you replace `@array` with a different symbol to indicate the type, such as `@stringArray` or `@intArray`.

### Caveats

Of course, if all of this were simple, it wouldn't be Android...

### Handling String Literals

Numeric literals and `null` can be used in expressions easily enough. String literals get interesting, as the standard Java `"` quotation system runs afoul of the default XML `"` quotation system for attribute values. Your options are:

- Use single quotes for the XML attribute, so you can use double quotes for the string literal (e.g., `android:text="@{foo["bar"]}"`)
- Use backticks for the string delimiter instead of double quotes
- Use HTML-style `&quot;` entities for the string delimiter (e.g., `android:text="@{foo[&quot;bar&quot;]}"`)

Of the three, the latter one is your worst choice, in terms of readability.

### Watch Out For Mis-Interpreted Integers

Suppose that you want to have the `android:text` attribute of a `TextView` hold a numeric value, pulled from a variable. You might try using something like `android:text="@{question.score}"`, where `score` is an `int`.

When you try it, you will crash at runtime, with an error indicating that there is no resource with the ID of some hex value, where that hex value *happens* to be your `score`.

That is because `android:text` supports strings *or string resources*. The integer value for `score` will be interpreted as a reference to a string resource, not converted into a string itself.

You then might try `android:text="@{question.score.toString()}"`. That fails to compile, if `score` is an `int`, as Java primitives do not support methods, let alone `toString()`.

The right solution is to use static methods on `Integer` to convert the `int` into a string: `android:text="@{Integer.toString(question.score)}"`

### Other Caveats

Because this stuff appears in plain XML, you will need to escape any `[` or `]` signs used in the expressions as `&lt;` and `&gt;`, respectively, which is aggravating.

You cannot use the `new` operator to create objects. However, you are welcome to call methods that happen to create new objects. So, in a pinch, create yourself a factory method somewhere to create the object that you were trying to instantiate via `new`. All things considered, though, the more object instantiation you do in layout binding, the slower that binding can become, particularly for oft-inflated layouts like rows in a rapidly-scrolling list.

You do not have access to this or super, as these would be with reference to the generated binding class itself.

## Observables and Updating the Binding

Variables, and the fields or method results that you access on them, can populate View properties, as we have seen so far in this chapter. This is interesting, but it may not “move the needle” for you in terms of adopting data binding. While there may be some minor code maintenance benefit, it hardly seems worth it.

Where data binding really shines, though, is when the variables, and the fields or method results that you access on them, are observable objects (i.e., ones implementing `android.databinding.Observable`). Then, not only do the expressions update your View properties when the layout resources are inflated, **but also when the data changes**. If you have observable models, simply updating those model objects automatically propagates those changes to any live View objects looking at those models.

For example, suppose that you are writing a to-do sort of checklist. The user can tap a `CheckBox` widget to indicate that the particular task is completed, and at that point you want to change the rendering of the task overall in its `RecyclerView` row in addition to updating the model object representing the task. Since the `CheckBox` is part of that same row, bound to the model for the row, handling both the UI updates and the model updates in the same `OnClickListener` may be easy. However, what happens if you do not want to update the rendering until the model change has been saved to the database or the network? Now, some arbitrary number of milliseconds *after* `OnClickListener` returns, you need to update some row of the `RecyclerView`... if there happens to be a row pointing at this model object. After all, the user might have scrolled, or even left this `RecyclerView` entirely, in which case the original row should not be changed.

The obvious tradeoff is defining your model objects to use `Observable`. The less-obvious tradeoff is in reorganizing your code to have *durable model objects*, where operations like Web service calls update those model objects in place, rather than replace those model objects with brand-new instances. The latter approach breaks data binding in general, but it is a much bigger problem when trying to update your UI from those models.

### Observable Primitives

The entire model object itself does not have to be `Observable`. Whatever your binding expressions use, in terms of data, has to be `Observable`. That could be individual fields, if you are willing to publish those fields as `Observable` objects, such as by having them be `public final`.

An easy way to make a field be `Observable`, if the field is a primitive value (e.g., `int`), is to replace the field with the equivalent `Observable... class` (e.g., `ObservableInt`):

```
public final ObservableInt score=new ObservableInt();
```

Your code can use `get()` and `set()` methods on the `Observable... primitive wrappers` to get and set the primitive value itself. Calling `set()` also notifies all registered observers that the data has changed, and the data binding system uses that to find out that it needs to update your UI.

While this may sound a bit clunky, Java developers have used this pattern in other places. A common example are the `Atomic... classes` (e.g., `AtomicInteger`), that make modifying a primitive be guaranteed to be atomic, when that value might be get and set on multiple parallel threads.

### ObservableField

For non-primitive values, but where the entire value changes in unison, you can use the generic `ObservableField` approach. In particular, a `String` is not a primitive, yet it is immutable, so changing the value means replacing the old `String` object with a new `String` object. `ObservableField` lets you set up observable strings:

```
public final ObservableField<String> title=  
    new ObservableField<String>();
```

(from [DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/Question.java](#))

This only works when you are replacing the entire object with a new object. So, for example, wrapping a `Location` in an `ObservableField` only works if you change the location by replacing the `Location`, instead of calling `setLatitude()` and `setLongitude()` on the existing `Location`. Replacing the `Location` outright triggers `ObservableField` to tell observers about the change. In contrast, `ObservableField` has no way to know that you called a method on the wrapped object that changes its state in a way that observers need to know about.

### ObservableArrayList and ObservableArrayMap

The data binding system ships with two Observable classes that are collections.

One, ObservableArrayList, is fairly straightforward: it lets you add and remove members of the list, and it informs observers about those changes. Once again, it has no means of knowing if you change the state of a given list member, only if you change the state of the list itself.

The other is ObservableArrayMap. Android added the ArrayMap class in API Level 19. Functionally, ArrayMap works like a HashMap, as a collection of values accessed via keys, albeit with some additional APIs for working with the contents by numerical index, as you see with ArrayList. The implementation, though, trades off CPU time for memory efficiency. ObservableArrayMap adds Observable characteristics, such that changes to the contents of the ArrayMap are reported to observers.

### Custom Observables

You can create your own class implementing the Observable interface. Most likely, you would do that by extending BaseObservable.

On the one hand, this does not have to be too complicated. For example, here is the implementation of ObservableBoolean from the data binding support library:

```

 */
package android.databinding;
import android.os.Parcel;
import android.os.Parcelable;
import java.io.Serializable;
/**
 * An observable class that holds a primitive boolean.
 * <p>
 * Observable field classes may be used instead of creating an Observable object:
 * <pre><code>public class MyDataObject {
 *     public final ObservableBoolean isAdult = new ObservableBoolean();
```

## THE DATA BINDING FRAMEWORK

---

```
* }</code></pre>
* Fields of this type should be declared final because bindings only detect changes in the
* field's value, not of the field itself.
* <p>
* This class is parcelable and serializable but callbacks are ignored when the object is
* parcelled / serialized. Unless you add custom callbacks, this will not be an issue because
* data binding framework always re-registers callbacks when the view is bound.
*/
public class ObservableBoolean extends BaseObservable implements Parcelable, Serializable {
    static final long serialVersionUID = 1L;
    private boolean mValue;
    /**
     * Creates an ObservableBoolean with the given initial value.
     *
     * @param value the initial value for the ObservableBoolean
     */
    public ObservableBoolean(boolean value) {
        mValue = value;
    }
    /**
     * Creates an ObservableBoolean with the initial value of <code>>false</code>.
     */
    public ObservableBoolean() {
    }
    /**
     * @return the stored value.
     */
    public boolean get() {
        return mValue;
    }
    /**
     * Set the stored value.
     */
    public void set(boolean value) {
        if (value != mValue) {
            mValue = value;
            notifyChange();
        }
    }
    @Override
    public int describeContents() {
        return 0;
    }
    @Override
    public void writeToParcel(Parcel dest, int flags) {
        dest.writeInt(mValue ? 1 : 0);
    }
    public static final Parcelable.Creator<ObservableBoolean> CREATOR
        = new Parcelable.Creator<ObservableBoolean>() {
        @Override
        public ObservableBoolean createFromParcel(Parcel source) {
            return new ObservableBoolean(source.readInt() == 1);
        }
        @Override
        public ObservableBoolean[] newArray(int size) {
            return new ObservableBoolean[size];
        }
    };
}
```

A lot of that code is dealing with making `ObservableBoolean` [be Parcelable](#). The key, from the standpoint of `BaseObservable`, is the call to `notifyChange()` in the `set()` method. This tells `BaseObservable` to tell all observers that stuff inside this `Observable` changed, and if they are tied to this `Observable`, they should go do something. Usually, “do something” will be to re-evaluate a binding expression and update a property of a `View`, such as updating the text of a `TextView` where a binding expression was used in the `android:text` attribute.

However, creating more complex custom observables is not especially well documented, and so we will explore that more [later in this chapter](#).

### An Observable Example

With all that behind us, let’s look at another rendition of the Stack Overflow sample.

There are lots of values that are published for questions via the Stack Exchange API, beyond the ones used so far. One is the score, representing the net of upvotes and downvotes on the question. Of the question properties that we had been using before, only the title has a chance of changing in real time, and that does not happen very often. On the other hand, scores are far more likely to change on the fly.

So, the [DataBinding/Scored](#) sample project starts from the `DataBinding/Static` project and adds in support for the score property. It also makes the title and score `Observable` and adds a refresh action bar item. Tapping that item will update the data for the questions loaded in the app; any changes to titles or scores will be reflected directly, without additional code, by updating the models.

Of course, this sample app was not written with data binding in mind. While the previous two samples added on bits of data binding without significantly changing the app, this time we will have to take a chainsaw to our code to get what we want.

### The Limitations of Earlier Examples

The specific problem we have to work around is the nature of our data model.

The previous versions of this sample would request the model objects via Retrofit and then slap them into an adapter to show in the `ListView`. From that point onward, the models were static — no code existed to add new questions, modify existing questions, etc.

However, Retrofit is designed to create new model objects on every call to a Web

service interface. So, if we call once to get the latest questions, and then make another call to get updated versions of those questions, we wind up with two separate collections of model objects.

If we were not trying to use data binding, we could take a “caveman” approach: just replace the contents of the adapter with the new model collection. This would work, albeit with some impacts on the user experience (e.g., perhaps scrolling the list back to the top).

However, with data binding, we are effectively tying our *original* data model objects to our views more tightly. This means that when we get a new set of model objects from Retrofit, we cannot use them directly. Instead, we have to use them as a source of data, to be poured into our original model objects. Through the Observable mechanism, we can update the original models and not worry about the ListView rows, as data binding will take care of that for us. But this does mean that we need to have one “magic” set of model objects that represent the bound data, distinct from any model objects representing updates to that data.

### Questions vs. Items

We could address the above problem by giving Item the ability to update its state from another Item. Our original query to get the most recent questions would create a collection of Item objects that would be our “durable” model, the one that we bind our UI to. Later updates that create new Item objects would be used solely to update the original durable Item objects’ contents, not replace those objects.

But now we run into another problem: the Observable requirements of the data binding system may run counter to requirements imposed elsewhere.

In the case of this sample, Item is being populated by Gson, after Retrofit receives the JSON response from the server. Gson does not know anything about ObservableField, ObservableInt, or any such things. There are two main approaches for dealing with this problem:

1. Use Gson’s system of type adapters to try to teach Gson how to take JSON properties and update corresponding ObservableField, ObservableInt, etc. fields in the model. Most likely, this is the right direction for long-term use, though it is conceivable that something about Gson has irreconcilable differences with something about observable elements.
2. Have separate “model” objects. One represents the result of the Web service call (and gets populated by Gson), while the other represents the durable

model (and has observable properties).

This revised edition of the sample takes the second approach. There is a new model class, `Question`, which models a Stack Overflow question. Our data binding will be applied to `Question`. `Item` is still there, but it represents the response from the Stack Exchange Web service call.

### Keeping Score (and the ID)

Beyond dealing with the duality of `Question` and `Item`, we have two more JSON properties from the Web service response that we need to track. One is the `score`, as mentioned earlier. The other is the `question_id`, a unique ID for the question. We need this in order to be able to update an existing `Question` with data from a new `Item`, when we retrieve updates for our models.

The easy part is getting the new data from Retrofit and Gson. We just need to add two more fields to `Item`, for the `score` and `question ID`:

```
package com.commonware.android.databind.basic;

import com.google.gson.annotations.SerializedName;

public class Item {
    String title;
    Owner owner;
    String link;
    int score;
    @SerializedName("question_id") String id;
}
```

(from [DataBinding/Scored/app/src/main/java/com/commonware/android/databind/basic/Item.java](#))

In the case of the question ID, the JSON property is `question_id`. In Java, we will use `id` instead, using Gson's `@SerializedName` annotation to teach Gson to fill `question_id` properties into the `id` field.

We now also have a `Question` class that will be our observable, durable data model:

```
package com.commonware.android.databind.basic;

import android.databinding.ObservableField;
import android.databinding.ObservableInt;

public class Question {
```

## THE DATA BINDING FRAMEWORK

---

```
public final ObservableField<String> title=
    new ObservableField<String>();
public final Owner owner;
public final String link;
public final ObservableInt score=new ObservableInt();
public final String id;

Question(Item item) {
    updateFromItem(item);
    owner=item.owner;
    link=item.link;
    id=item.id;
}

void updateFromItem(Item item) {
    title.set(item.title);
    score.set(item.score);
}
}
```

(from [DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/Question.java](#))

It holds the same five values as does Item, except that title and score are now Observable, via ObservableField and ObservableInt, respectively. The owner, link, and id values should be immutable, and we are not binding on them anyway, so keeping them as ordinary fields is fine.

Question has a constructor and an updateFromItem() method that both copy data from a Item into the Question. updateFromItem() handles the two Observable fields, and we will use this when we eventually fetch updates to the question. The constructor calls updateFromItem() plus populates the three final non-observable fields.

QuestionsFragment now has a more apropos name, as we will have it show the list of Question objects. Among other things, this requires changes to QuestionsAdapter, to work off of Question objects instead of Item objects:

```
class QuestionsAdapter extends ArrayAdapter<Question> {
    QuestionsAdapter(List<Question> items) {
        super(getActivity(), R.layout.row, R.id.title, items);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        RowBinding rowBinding=
            DataBindingUtil.getBinding(convertView);
    }
}
```

## THE DATA BINDING FRAMEWORK

---

```
if (rowBinding==null) {
    rowBinding=
        RowBinding.inflate(getActivity().getLayoutInflater(),
            parent, false);
}

Question question=getItem(position);
ImageView icon=rowBinding.icon;

rowBinding.setQuestion(question);

Picasso.with(getActivity()).load(question.owner.profileImage)
    .fit().centerCrop()
    .placeholder(R.drawable.owner_placeholder)
    .error(R.drawable.owner_error).into(icon);

return(rowBinding.getRoot());
}
}
```

(from [DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

Similarly, the `<variable>` in `row.xml` needs to be a `Question` now:

```
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android">

    <data>

        <import type="android.text.Html"/>

        <variable
            name="question"
            type="com.commonsware.android.databind.basic.Question"/>
    </data>

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal">

        <ImageView
            android:id="@+id/icon"
            android:layout_width="@dimen/icon"
            android:layout_height="@dimen/icon"
            android:layout_gravity="center_vertical"
            android:contentDescription="@string/icon">
```

```
        android:padding="8dip" />

    <TextView
        android:id="@+id/title"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_gravity="left|center_vertical"
        android:layout_weight="1"
        android:text="@{Html.fromHtml(question.title)}"
        android:textSize="20sp" />

    <TextView
        android:id="@+id/score"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:layout_marginLeft="8dp"
        android:layout_marginRight="8dp"
        android:text="@{Integer.toString(question.score)}"
        android:textSize="40sp"
        android:textStyle="bold" />

</LinearLayout>
</layout>
```

(from [DataBinding/Scored/app/src/main/res/layout/row.xml](#))

You will note that the binding expression for the score TextView is `@{Integer.toString(question.score)}`. That is because the score field on Question is an int, and by default, the data binding system will think that is a reference to a string resource. We have to convert the score into a String to get the results that we want. We will see this more [later in this chapter](#).

### Refreshing the Data

Of course, having a QuestionsAdapter that adapts Question object only works if we *have* Question objects.

QuestionsFragment now holds onto two collections of Question objects: an ArrayList in the order that we get them from the Web service API, and a HashMap to find a Question object given its ID:

```
private ArrayList<Question> questions
    =new ArrayList<Question>();
private HashMap<String, Question> questionMap=
```

## THE DATA BINDING FRAMEWORK

---

```
new HashMap<String, Question>();
```

(from [DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

Our call to the `questions()` method on our `StackOverflowInterface` still returns a collection of `Item` objects. In `onCreateView()`, where we call `questions()`, we arrange to use those `Item` objects to create the corresponding group of `Question` objects:

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    View result=
        super.onCreateView(inflater, container,
            savedInstanceState);

    so.questions("android").enqueue(new Callback<SOQuestions>() {
        @Override
        public void onResponse(Call<SOQuestions> call,
                               Response<SOQuestions> response) {
            for (Item item : response.body().items) {
                Question question=new Question(item);

                questions.add(question);
                questionMap.put(question.id, question);
            }

            setListAdapter(new QuestionsAdapter(questions));
        }

        @Override
        public void onFailure(Call<SOQuestions> call, Throwable t) {
            onError(t);
        }
    });

    return(result);
}
```

(from [DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

## THE DATA BINDING FRAMEWORK

That is sufficient to get our app to run again, showing the scores along with the question titles and asker avatars:

Figure 671: Stack Overflow Questions with Scores

However, we wanted to allow the user to refresh the data for these questions, so we can see a score being updated in real time via the data binding system. That requires a different call to the Stack Exchange API. It is still `/2.1/questions`, but now we have an additional path segment, one that takes a semi-colon-delimited list of question IDs. So, we add a new `@GET` method to `StackOverflowInterface` for this:

```
package com.commonware.android.databind.basic;

import retrofit2.Call;
import retrofit2.http.GET;
import retrofit2.http.Path;
import retrofit2.http.Query;

public interface StackOverflowInterface {
    @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
    Call<SOQuestions> questions(@Query("tagged") String tags);

    @GET("/2.1/questions/{ids}?site=stackoverflow")
    Call<SOQuestions> update(@Path("ids") String tags);
}
```

---

## THE DATA BINDING FRAMEWORK

---

(from [DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/StackOverflowInterface.java](#))

Note the use of `@Path("ids")` on the first parameter, corresponding to the `{ids}` placeholder in the path expressed in the `@GET` annotation. `@Path("ids")` says “the following parameter can be injected as a path segment into the URL”, and `{ids}` indicates specifically where that parameter’s value should go. Note, though, that it is a `String`, not a `String` array or `ArrayList` of strings. That is because we do not have a way to teach Retrofit how to concatenate a collection of strings into a single path segment.

In addition, this sample now has a menu resource directory, with an `actions.xml` resource in it, defining a single “refresh” menu item. The `QuestionsFragment` opts into participating in the action bar and, in `onCreateOptionsMenu()`, applies the `actions` menu resource. In `onOptionsItemSelected()`, if the user chose our refresh menu item, we call a private `updateQuestions()` method. This method needs to use the new `update()` method on `StackOverflowInterface` to update our collection of questions:

```
private void updateQuestions() {
    ArrayList<String> idList=new ArrayList<String>();

    for (Question question : questions) {
        idList.add(question.id);
    }

    String ids=TextUtils.join(";", idList);

    so.update(ids).enqueue(new Callback<SOQuestions>() {
        @Override
        public void onResponse(Call<SOQuestions> call,
            Response<SOQuestions> response) {
            for (Item item : response.body().items) {
                Question question=questionMap.get(item.id);

                if (question!=null) {
                    question.updateFromItem(item);
                }
            }
        }

        @Override
        public void onFailure(Call<SOQuestions> call, Throwable t) {
            onError(t);
        }
    });
}
```

```
}
```

(from [DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

We collect all of the question IDs, then use `TextUtils.join()` to give us a single `String` with all the question IDs concatenated with semicolons. That, in turn, is passed to `update()`. For each returned `Item`, we find the corresponding `Question` in the `HashMap` and update it with the new data from the `Item`.

What we do *not* do is touch our UI.

However, if you run the app, choose a good question out of the list of questions, upvote the question, and refresh the list, you will see the new score appear immediately after the refresh. The data binding system handled that for us, without additional manual intervention on our part.

## Two-Way Binding

So far, the focus has been on getting data from models into views. That is the most common scenario, as usually a subset of views accept user input, and plenty of user interfaces are read-only.

Plus, the original version of the data binding system only handled populating views from models.

But, in 2016, the data binding system was updated with “two-way binding”, where views can populate models, in addition to having models populate views. While this feature [is presently undocumented](#), we have some limited information on how to make it work.

The change to the layout resources is very simple: use `@=` instead of `@`:  
`android:checked="@={question.expanded}"`.

This configures the attribute (the checked state of a `CompoundButton`) with the initial value of the `expanded` property on a `question` variable. It also *updates* the property if the user checks or unchecks the `CompoundButton`.

To make this work, you cannot use a simple `public` field for the property. It needs to either have a setter method (e.g., `setExpanded()`) or be a `public Observable` field.

For example, the [DataBinding/TwoWay](#) sample project is a clone of the `DataBinding/`

## THE DATA BINDING FRAMEWORK

---

Scored sample project from earlier in this chapter. However, now the `Question` will track some local state, information not obtained from the Stack Exchange API. Specifically, it will track a boolean value named `expanded`:

```
package com.commonware.android.databind.basic;

import android.databinding.ObservableBoolean;
import android.databinding.ObservableField;
import android.databinding.ObservableInt;

public class Question {
    public final ObservableField<String> title=
        new ObservableField<String>();
    public final Owner owner;
    public final String link;
    public final ObservableInt score=new ObservableInt();
    public final String id;
    public ObservableBoolean expanded=new ObservableBoolean(true);

    Question(Item item) {
        updateFromItem(item);
        owner=item.owner;
        link=item.link;
        id=item.id;
    }

    void updateFromItem(Item item) {
        title.set(item.title);
        score.set(item.score);
    }
}
```

(from [DataBinding/TwoWay/app/src/main/java/com/commonware/android/databind/basic/Question.java](#))

Our row layout resource now has a `Switch` widget, bound to the `expanded` property using the `@=` syntax shown above:

```
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">

    <data>

        <import type="android.text.Html" />

        <variable
            name="question"
            type="com.commonware.android.databind.basic.Question" />
```

## THE DATA BINDING FRAMEWORK

---

```
<variable
  name="controller"
  type="com.commonware.android.databind.basic.QuestionController" />
</data>

<android.support.v7.widget.CardView xmlns:cardview="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:layout_margin="4dp"
  cardview:cardCornerRadius="4dp">

  <LinearLayout
    android:id="@+id/row_content"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:background="?android:attr/selectableItemBackground"
    android:gravity="center_vertical"
    android:onClick="@{()->controller.showQuestion(question)}"
    android:onTouch="@{(v,event)->controller.onTouch(v,event)}"
    android:orientation="horizontal">

    <Switch
      android:id="@+id/expanded"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:checked="@={question.expanded}" />

    <ImageView
      android:id="@+id/icon"
      android:layout_width="@dimen/icon"
      android:layout_height="@dimen/icon"
      android:layout_gravity="center_vertical"
      android:contentDescription="@string/icon"
      android:padding="8dip"
      app:error="@{drawable/owner_error}"
      app:imageUrl="@{question.owner.profileImage}"
      app:placeholder="@{drawable/owner_placeholder}" />

    <TextView
      android:id="@+id/title"
      android:layout_width="0dp"
      android:layout_height="wrap_content"
      android:layout_gravity="left|center_vertical"
      android:layout_weight="1"
      android:text="@{Html.fromHtml(question.title)}"
      android:textSize="20sp" />

    <TextView
      android:id="@+id/score"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:layout_gravity="center_vertical"
      android:layout_marginLeft="8dp"
      android:layout_marginRight="8dp"
      android:text="@{Integer.toString(question.score)}"
      android:textSize="40sp"
      android:textStyle="bold" />

  </LinearLayout>
</android.support.v7.widget.CardView>
```

```
</layout>
```

(from [DataBinding/TwoWay/app/src/main/res/layout/row.xml](#))

If you run the sample project, all of the switches will be checked at the outset, as we are defaulting expanded to true. If you uncheck some of them, and scroll around, you will see that the checked/unchecked state is handled properly, even though rows are being recycled along the way. And we did not have to add any Java code, other than the new property — in particular, neither our `ViewHolder` nor our `Adapter` need to worry about the `Switch`.

## Other Features of Note

There are a number of other “bells and whistles” that you can utilize in the data binding system.

### Obtaining Views via the Binding Class

The sample apps have been retrieving the `ImageView` widget for the row from the `RowBinding`. Any `View` in the layout file that has an `android:id` value will have a corresponding field in the `...Binding` generated class. So, for cases like the Picasso scenario, where we cannot use data binding to populate the `ImageView` and have to resort to classic bind-it-in-the-adapter logic, we do not have to do the `findViewById()` call ourselves. Instead, we just access the field in the binding class.

### Manipulating Variables in the Binding

We have seen using a setter method to bind an object to a layout via the generated binding class. In the sample apps, we have been calling `setItem()` or `setQuestion()` to provide the model object to use in binding expressions. If needed, though, there is also a corresponding getter method (`getItem()`, `getQuestion()`) to retrieve the last-set value.

### Views, Setters, and Binding

We have seen the use of `android:text` with a binding expression, to set the text for a `TextView`.

What really is going on is:

- The binding system evaluates the expression. This not only gives us the value

- to be bound, but also determines the data type of that value (e.g., `String`, `int`).
- The data binding system looks for a setter named `set...()`, where the `...` part is based on the name of the attribute (minus any namespace), where the data type matches the data type of the expression result. So, in the case where the binding expression generates a `String` for an `android:text` attribute, the data binding system will look for `setText(String)` on the widget, in our case a `TextView`. If the binding expression were to return an `int`, instead, the data binding system would look for `setText(int)`. In the case of `TextView`, that exists, and it is expecting the `int` to be a string resource. That is why, in the `Scored` sample app, we needed to convert the `int` to a `String`.

Of course, this is just the simple scenario.

### Synthetic Properties

The data binding system maps attribute names to setters. But, what happens if you use an attribute name that does not actually exist?

Like the [honey badger](#), the data binding system don't care.

All the data binding system is doing is using the attribute name to try to find an associated setter method. The fact that the attribute name is not actually part of the `LayoutInflater`-supported XML structure is irrelevant.

This means that you can use *any* attribute that maps to a setter method.

For example, `ViewPager` has no XML attributes of its own, beyond those it inherits from `View` or `ViewGroup`. But, you are welcome to use attributes like `app:currentItem` or `app:pageMargin` in your data binding-enhanced layout resources (where `app` points to a custom namespace of yours). `LayoutInflater` will parse them, but `ViewPager` will ignore them. However, the data binding system will happily let you bind values to them, triggering calls to `setCurrentItem()` and `setPageMargin()`, respectively.

Hence, do not feel that you are limited to only those attributes that are officially supported by `LayoutInflater` and the widgets. If the data binding system can find a setter, you can use it.

However, there is one key limitation with these synthetic properties: the value has to

be a binding expression. That is true even if you are not really evaluating much of an expression.

For example, this will not work:

```
<ImageView
    android:id="@+id/icon"
    android:layout_width="@dimen/icon"
    android:layout_height="@dimen/icon"
    android:layout_gravity="center_vertical"
    android:contentDescription="@string/icon"
    android:padding="8dip"
    app:error="@drawable/owner_error"
    app:imageUrl="{question.owner.profileImage}"
    app:placeholder="@drawable/owner_placeholder"/>
```

Here, we have three synthetic properties, `app:error`, `app:imageUrl`, and `app:placeholder`. Only `app:imageUrl` is using a binding expression, and its use of one makes sense, as we are pulling in data from a variable (`question`). The other two refer to drawables. Ideally, this would work. In practice, it does not work, as the binding system ignores the properties, and then Android complains that the attribute is not recognized.

This, however, works:

```
<ImageView
    android:id="@+id/icon"
    android:layout_width="@dimen/icon"
    android:layout_height="@dimen/icon"
    android:layout_gravity="center_vertical"
    android:contentDescription="@string/icon"
    android:padding="8dip"
    app:error="@{@drawable/owner_error}"
    app:imageUrl="{question.owner.profileImage}"
    app:placeholder="@{@drawable/owner_placeholder}"/>
```

Now, `app:error` and `app:placeholder` use binding expressions... that happen to just return a drawable resource reference. This works, if one of two things are true:

1. There are setter methods for those properties (e.g., `setError()`) on `ImageView`, which in this case, there isn't, or
2. We use other techniques to tell the data binding system that those attributes get routed elsewhere, as will be seen in the next two sections

### Using Different Methods

Of course, finding a setter may be a challenge. Frequently, the attribute name and the setter name follow the described convention (`android:foo` maps to `setFoo()`). Every now and then, though, the attribute name and setter name differ.

For example, `View` has an `android:fadeScrollbars` attribute, used to determine whether or not the scrollbars for a scrollable widget should automatically fade out after a stable period when the widget is not scrolling. However, the associated setter method is not `setFadeScrollbars()`, but instead `setScrollbarFadingEnabled()`. By default, in theory, the data binding system will not find the appropriate setter for `android:fadeScrollbars`.

In practice, the documentation suggests that Google has already fixed up all of the standard attributes from Android framework classes. However, there may still be gaps, particularly in Android Support-supplied classes, let alone third-party widgets.

To overcome the mis-matched attribute/setter pair, you can teach the data binding system how to find the setter for the attribute. To do this, you are supposed to be able to define a class-level `@BindingMethods` annotation, containing one or more `@BindingMethod` annotations, which in turn map an attribute on a type to a setter method name:

```
@BindingMethods({
    @BindingMethod(type = "android.view.View",
        attribute = "android:fadeScrollbars",
        method = "setScrollbarFadingEnabled"),
})
```

### BindingAdapters, and the Picasso Scenario

Sometimes, even that is insufficient. Perhaps the setter method takes additional parameters, even though in your case they could be simply hard-coded or pulled from elsewhere in the widget. Perhaps the “setter method” is not really setting a property, but arranging to do some work related to the property.

For example, so far, we have not been able to use data binding with the `ImageView`. While the URL to the image is *related* to the `android:src` attribute, `android:src` does not take a URL, and we want to use Picasso to retrieve the image asynchronously anyway. Hence, we have been stuck with configuring the `ImageView` “the old-fashioned way” in `getView()`, by retrieving the `ImageView` and then telling

## THE DATA BINDING FRAMEWORK

---

Picasso how to populate it.

However, the data binding system can handle this too, by defining a custom `@BindingAdapter`.

Let's take a look at the [DataBinding/Picasso](#) sample project. This starts with the Scored sample from before, but now uses the data binding system to update the `ImageView`.

The `ImageView` XML from a little bit ago appears in our revised `row.xml` layout resource:

```
<?xml version="1.0" encoding="utf-8"?>
<layout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">

    <data>

        <import type="android.text.Html"/>

        <variable
            name="question"
            type="com.commonware.android.databind.basic.Question"/>
    </data>

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal">

        <ImageView
            android:id="@+id/icon"
            android:layout_width="@dimen/icon"
            android:layout_height="@dimen/icon"
            android:layout_gravity="center_vertical"
            android:contentDescription="@string/icon"
            android:padding="8dip"
            app:error="@{@drawable/owner_error}"
            app:imageUrl="@{question.owner.profileImage}"
            app:placeholder="@{@drawable/owner_placeholder}"/>

        <TextView
            android:id="@+id/title"
            android:layout_width="0dp"
            android:layout_height="wrap_content">
```

## THE DATA BINDING FRAMEWORK

---

```
        android:layout_gravity="left|center_vertical"
        android:layout_weight="1"
        android:text="@{Html.fromHtml(question.title)}"
        android:textSize="20sp"/>

<TextView
    android:id="@+id/score"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:layout_marginLeft="8dp"
    android:layout_marginRight="8dp"
    android:text="@{Integer.toString(question.score)}"
    android:textSize="40sp"
    android:textStyle="bold"/>

</LinearLayout>
</layout>
```

(from [DataBinding/Picasso/app/src/main/res/layout/row.xml](#))

Here, we have three synthetic properties: attributes that are not really part of `ImageView`, but that we are using with the help of the data binding system.

To make that work, the data binding system has to know what to do with those three values. `ImageView` lacks setters for those, and so in the absence of anything else, the data binding system will trigger a compilation error, complaining that it does not know what to do with the values we have in the layout.

To make this work, we need a static method somewhere, with the `@BindingAdapter` annotation. In this case, we have it defined on `QuestionsFragment`:

```
@BindingAdapter({"app:imageUrl", "app:placeholder", "app:error"})
public static void bindImageView(ImageView iv,
    String url,
    Drawable placeholder,
    Drawable error) {
    Picasso.with(iv.getContext())
        .load(url)
        .fit()
        .centerCrop()
        .placeholder(placeholder)
        .error(error)
        .into(iv);
}
```

## THE DATA BINDING FRAMEWORK

---

(from [DataBinding/Picasso/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

The method name does not matter, so call it whatever will help remind you of its role. It needs to return void, and take as parameters:

- the View type that the synthetic properties will appear on (in this case, ImageView)
- the values of those properties, in the order that they appear in the list of strings in the @BindingAdapter annotation

In our case, app:placeholder and app:error are resolving to Drawable resources, while app:imageUrl is resolving to a String.

This declaration teaches the data binding framework to call this method any time it finds a View of the designated type (ImageView) with the list of synthetic properties, instead of trying to find setter methods for those properties. Since the <ImageView> element in our layout file meets those criteria, the bindImageView() method will be called.

In that method, it is our job to do whatever it is that we need to do to consume those synthetic property values and apply their results to the supplied View. In this case, we have the snippet of Picasso code formerly found in the getView() method. However, before, the values of the drawables (placeholder and error) were hard-coded in Java. Now, they are in the layout XML file, which is a bit more flexible, particularly if we are using different layout resources for different configurations.

This means we can junk the last of the manual binding code from getView(), leaving behind only the connection from our ArrayAdapter to the RowBinding:

```
class QuestionsAdapter extends ArrayAdapter<Question> {
    QuestionsAdapter(List<Question> items) {
        super(getActivity(), R.layout.row, R.id.title, items);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        RowBinding rowBinding=
            DataBindingUtil.getBinding(convertView);

        if (rowBinding==null) {
            rowBinding=
                RowBinding.inflate(getActivity().getLayoutInflater(),
                    parent, false);
        }
    }
}
```

## THE DATA BINDING FRAMEWORK

---

```
        rowBinding.setQuestion(getItem(position));

        return(rowBinding.getRoot());
    }
}
```

(from [DataBinding/Picasso/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

Note, though, that to make this sample work, we needed to make one other change. `app:imageUrl` refers to the `profileImage` field on the `Owner` class. Formerly, that was package-private, which means that the data binding generated code could not access it. Instead, we had to make it public:

```
package com.commonsware.android.databind.basic;

import com.google.gson.annotations.SerializedName;

public class Owner {
    public @SerializedName("profile_image") String profileImage;
}
```

(from [DataBinding/Picasso/app/src/main/java/com/commonsware/android/databind/basic/Owner.java](#))

As an additional feature, a binding adapter can receive not only the new values for the properties, but the old ones as well (i.e., what had been used for a previous binding). To make that work, you double up all of the parameters, other than the View itself. First come the parameters that will be the old values, then come the parameters that will be the new values. If we wanted to use that in the sample shown in this section, we would have needed seven total parameters:

```
@BindingAdapter({"app:imageUrl", "app:placeholder", "app:error"})
public static void bindImageView(ImageView iv,
                                String oldUrl,
                                Drawable oldPlaceholder,
                                Drawable oldError,
                                String newUrl,
                                Drawable newPlaceholder,
                                Drawable newError) {

    // do good stuff here
}
```

For another example, the chapter on advanced keyboard and mouse support demonstrates [a BindingAdapter to add a focusMode option](#) to layouts, for a more flexible alternative to the `[requestFocus/]` XML element for controlling the widget

that gets the focus.

### Two-Way Binding and InverseBindingAdapter

[Two-way binding](#) works well in cases where the way you store the data in the models lines up well with the getters and setters of the associated widget. In the two-way binding example presented earlier, a boolean field in the model works well with the checked property of a CompoundButton like a Switch, as CompoundButton has an isChecked() method returning a boolean and a setChecked() accepting a boolean.

A BindingAdapter allows you to create other mappings between data types and properties, but only for the classic model->view binding. To accomplish the same thing in the reverse direction, you wind up creating an InverseBindingAdapter. As the name suggests, this serves the same basic role as a BindingAdapter, but in the inverse direction, taking data from the widget and preparing it for the model using custom code. Here, the “preparing it for the model” means converting it into a suitable data type for a setter, Observable field, etc. for your model.

This is fairly unusual.

The example used in some places is “what if I want to tie a float to an EditText?”. The InverseBindingAdapter would look something like this:

```
@InverseBindingAdapter(attribute = "android:text")
public static float getFloat(EditText et) {
    try {
        return(Float.parseFloat(et.getText().toString()));
    }
    catch (NumberFormatException e) {
        return(0.0f); // because, um, what else can we do?
    }
}
```

The problem is if the user types in something that is not a valid floating-point number, like snicklefritz. parseFloat() will fail with a NumberFormatException. You *should* let the user know that their data entry was invalid. However, two-way data binding does not support this, with a default value (e.g., 0.0f) being handed to the model instead.

### Event Handling

So far, we have focused on binding expressions returning data that populates

widgets, specifically by configuring how that widget looks.

But what about configuring how that widget *behaves*?

Whether this is a good idea is up for debate. On the one hand, it reduces the amount of boilerplate Java code necessary to wire up widgets. On the other hand, some might worry about a blurring of the lines separating views from things like controllers or presenters.

A 2016 update to the data binding system made it easier to set up these sorts of connections, though at the present time, this feature [is undocumented](#).

### Thinking Back to android:onClick

In the beginning, there was `android:onClick`, and it was good.

You could add the `android:onClick` attribute to a view in your layout resource XML, with a value of a method name in the activity that used the layout. That method needed to be public, return void, and take a `View` as a parameter — the same basic method signature as `onClick()` of an `OnClickListener`. When the user clicked the view, the method named in `android:onClick` would be called, without having to call `setOnClickListener()` in Java with an `OnClickListener` implementation.

Over time, `android:onClick` faded in utility, as other things, such as fragments, started being where we wanted the click events to go. `android:onClick` could *only* call a method on the hosting activity, not a method on an arbitrary other class. No other attributes were created for other event handlers (long-click, touch, etc.), suggesting that this was a one-off experiment that would fade into oblivion.

And it did fade... until 2016, when the data binding system brought back the concept.

### Tying Events to Methods Directly

For most events that you will care about with views, you can use a data binding expression to identify a method, on one of your variables, that will be called when the event is raised. Because this ties back to your variables, the method can be on any object that you inject into the binding, not just the activity.

It does make the syntax a bit more verbose. Instead of `android:onClick="doSomething"`, it becomes

`android:onClick="@{controller::doSomething}"`, where `controller` is some object that you want to respond to the event (e.g., an MVC-style controller, an MVP-style presenter).

The methods referenced this way must have the same basic signature as the corresponding listener methods, just implemented on a custom class and with a custom name. So, for example, `onLongClick()` of an `OnLongClickListener` needs to return a `boolean`, indicating whether the event is consumed. If you use `android:onClick` to route that event to some custom method, that method must also return a `boolean`. Overall:

- The method must be `public`
- The method must take the same parameters as does the corresponding method on the regular listener class for this event
- The method must have the same return type as does the corresponding method on the regular listener class for this event

### Tying Events to Methods via Lambda Expressions

Those restrictions on the methods tied in via data binding expressions can be a pain. In particular, you have no way of passing additional information from bound variables into the method, since those would not be part of the standard event handling method parameters.

However, the data binding system has another option for tying in event handlers: Java 8-style lambda expressions. So, you can have `android:onClick="@{()->controller::doSomething(thing)}"`, where `thing` is some variable in your layout resource, or a view (based on its `android:id` value), or the magic name `context` to provide a `Context`. It could also involve expressions using any of those as part of calculations (e.g., concatenating two strings).

You can also blend in parameters that are normally available to the event, such as `android:onClick="@{(v)->controller::doSomething(v, thing)}"`.

However, the argument list in the lambda function (the left-hand set of parentheses) either needs to be:

- empty, or
- have one entry for every parameter to the event handling method, even if you do not want all of those objects

## THE DATA BINDING FRAMEWORK

---

For example, the `onCheckedChanged()` method on `OnCheckedChangeListener` for a `CompoundButton` takes two parameters: the `View` whose state changed, and a `boolean` indicating the new state. You cannot have `android:onCheckedChanged="@{(state)->controller::heyNow(state, thing)}"` or `android:onCheckedChanged="@{(view)->controller::heyNow(view, thing)}"`.

Instead, if you want either of those, you need to declare both, then just ignore the one that you do not need, such as `android:onCheckedChanged="@{(v, state)->controller::heyNow(state, thing)}"`.

Also, the method that you call still has to be `public` and still has to return the proper return type based on the event (e.g., `void` for `onClick`, `boolean` for `onLongClick()`).

With that in mind, the [DataBinding/RecyclerView](#) sample project demonstrates how this can work, along with how to use the data binding system to populate a `RecyclerView` instead of an `AdapterView`.

### Converting to a RecyclerView/CardView UI

First, independent of data binding, we need to migrate the app over to use `RecyclerView`. Along the way, we can also add in support for `CardView`, to make the individual elements of the vertically-scrolling list look like cards, complete with rounded corners, drop shadows, and the like.

To that end, we add `recyclerview-v7` and `cardview-v7` to our roster of dependencies in `build.gradle`:

```
dependencies {
    implementation 'org.greenrobot:eventbus:3.1.1'
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit2:converter-gson:2.3.0'
    implementation 'com.android.support:recyclerview-v7:27.1.1'
    implementation 'com.android.support:cardview-v7:27.1.1'
    implementation 'com.android.support:support-v4:27.1.1'
```

(from [DataBinding/RecyclerView/app/build.gradle](#))

Our previous samples had used `ListFragment`. We do not have a `RecyclerViewFragment` given to us by the `recyclerview-v7` library. But, we can have our own, copied from one of the `RecyclerView` sample projects:

```
package com.commonware.android.databind.basic;
```

## THE DATA BINDING FRAMEWORK

---

```
import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.support.v7.widget.RecyclerView;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class RecyclerViewFragment extends Fragment {
    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup container,
        Bundle savedInstanceState) {
        RecyclerView rv=new RecyclerView(getActivity());

        rv.setHasFixedSize(true);

        return(rv);
    }

    public void setAdapter(RecyclerView.Adapter adapter) {
        getRecyclerView().setAdapter(adapter);
    }

    public RecyclerView.Adapter getAdapter() {
        return(getRecyclerView().getAdapter());
    }

    public void setLayoutManager(RecyclerView.LayoutManager mgr) {
        getRecyclerView().setLayoutManager(mgr);
    }

    public RecyclerView getRecyclerView() {
        return((RecyclerView)getView());
    }
}
```

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/RecyclerViewFragment.java](#))

All this does is manage a RecyclerView on our behalf, including allowing us to manipulate the adapter and the layout manager.

The revised QuestionsFragment now inherits from that RecyclerViewFragment. We configure the RecyclerView in onCreateView(), mostly just using the code from before, except that we also need to call setLayoutManager() to indicate how we want the items to be laid out — in this case, opting for a vertically-scrolling list:

```
@Override
```

---

## THE DATA BINDING FRAMEWORK

---

```
public void onCreateView(View view,
    Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(new LinearLayoutManager(getActivity()));

    so.questions("android").enqueue(new Callback<SQQuestions>() {
        @Override
        public void onResponse(Call<SQQuestions> call,
            Response<SQQuestions> response) {
            for (Item item : response.body().items) {
                Question question=new Question(item);

                questions.add(question);
                questionMap.put(question.id, question);
            }

            setAdapter(new QuestionsAdapter(questions));
        }

        @Override
        public void onFailure(Call<SQQuestions> call, Throwable t) {
            onError(t);
        }
    });
}
```

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

Our QuestionsAdapter also has to change, to be a RecyclerView.Adapter, instead of an ArrayAdapter:

```
class QuestionsAdapter
    extends RecyclerView.Adapter<QuestionController> {
    private final ArrayList<Question> questions;

    QuestionsAdapter(ArrayList<Question> questions) {
        this.questions=questions;
    }

    @Override
    public QuestionController onCreateViewHolder(ViewGroup parent,
        int viewType) {
        RowBinding rowBinding=
            RowBinding.inflate(getActivity().getLayoutInflater(),
                parent, false);

        return(new QuestionController(rowBinding));
    }
}
```

## THE DATA BINDING FRAMEWORK

---

```
    }

    @Override
    public void onBindViewHolder(QuestionController holder,
                                int position) {
        holder.bindModel(getItem(position));
    }

    @Override
    public int getItemCount() {
        return(questions.size());
    }

    Question getItem(int position) {
        return(questions.get(position));
    }
}
```

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

We take in the roster of questions in the constructor and stash that for later use. `getItemCount()` and `getItem()` simply access that roster of questions. Data binding takes place in `onCreateViewHolder()`, where we create the `RowBinding` and use that to set up a `QuestionController`. `QuestionController` is a subclass of `RecyclerView.ViewHolder` and serves as the local controller for the row in our list — we will look at `QuestionController` in greater detail shortly. `onBindViewHolder()` simply tells the `QuestionController` to bind to the supplied `Question` model object.

`RecyclerView.ViewHolder` requires the root `View` for the row be supplied to its constructor. So, in the `QuestionController` constructor, we call `getRoot()` to get that `View` from the `RowBinding` and supply that, along with stashing the `RowBinding` in a field:

```
private final RowBinding rowBinding;

public QuestionController(RowBinding rowBinding) {
    super(rowBinding.getRoot());

    this.rowBinding=rowBinding;
}
```

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionController.java](#))

And, in `bindModel()`, we use the `RowBinding` to bind our `Question`, so the binding expressions will pull the title, score, and so forth into our views:

## THE DATA BINDING FRAMEWORK

---

```
void bindModel(Question question) {
    rowBinding.setQuestion(question);
    rowBinding.setController(this);
    rowBinding.executePendingBindings();
}
```

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionController.java](#))

In a 2016 Google I|O presentation on data binding, Google engineers recommend that if you use RecyclerView, as part of onBindViewHolder() processing, that you call executePendingBindings() on the binding (e.g., RowBinding in the case of this example). This forces the data binding framework to get all of the bindings set up immediately, rather than waiting until the natural time to do it.

In our case, we just tuck that call into the bindModel() method of QuestionController, shown above.

You will notice that we also call a setController() method on the RowBinding. This is in support of our event handling binding work, as you will see next.

### What About the Event Listeners?

QuestionController has two event-related methods. One is onTouch(), for handling the ripple effect on Android 5.0+:

```
@Override
public boolean onTouch(View v, MotionEvent event) {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
        v
            .findViewById(R.id.row_content)
            .getBackground()
            .setHotspot(event.getX(), event.getY());
    }

    return false;
}
```

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionController.java](#))

The other is showQuestion(), which, surprisingly enough, will be called when we want to show the actual question:

```
public void showQuestion(Question question) {
    EventBus.getDefault().post(new QuestionClickedEvent(question));
}
```

---

## THE DATA BINDING FRAMEWORK

---

(from [DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionController.java](#))

It contains the EventBus logic to tell somebody to go show some specified Question.

Those are tied into our app via the data binding framework:

```
<LinearLayout
    android:id="@+id/row_content"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:background="?android:attr/selectableItemBackground"
    android:onClick="@{()->controller.showQuestion(question)}"
    android:onTouch="@{controller::onTouch}"
    android:orientation="horizontal">
```

(from [DataBinding/RecyclerView/app/src/main/res/layout/row.xml](#))

For `android:onClick`, we use the method-reference approach, asking the data binding framework to call `onTouch()` on our controller. For `android:onClick`, we use the lambda expression approach, calling `showQuestion()` on our controller, passing in the question variable, so we have our Question to go show.

And that's it. No other changes are needed to tie in these events, either in the `QuestionController` or in the `QuestionsAdapter`.

## Type Converters

The result of a binding expression gets cast to the data type expected by the setter, field, or binding adapter that the data binding system identified as being the one to use.

Hopefully, this works.

However, it is possible that you will need to change your binding expression, such as in the case cited earlier in this chapter, where `android:text` can accept an integer, but you wanted that integer to be shown as text, not be a reference to a string resource.

In other cases, there may not be a clear match. Google's documentation cites the case where your binding expression returns the ID of a color resource, but the setter takes a `Drawable`, such as is the case with `setBackground()` on `View`.

One way of addressing this disparity is via a `@BindingMethod`. This teaches the data

## THE DATA BINDING FRAMEWORK

---

binding system to use a different method for the setter (e.g., `setBackgroundColor()`). However, this is *always* used for that particular widget class and attribute combination. In the particular case of the `android:background` attribute, there are a variety of possible setters:

- `setBackground(Drawable)`
- `setBackgroundColor(int)` (taking the actual color, not a color resource)
- `setBackgroundDrawable(Drawable)` (as `setBackground(Drawable)` is new to API Level 16)
- `setBackgroundResource(int)`

You may not be in position to use one of these for `android:background` exclusively.

Hence, another approach is to teach the data binding system how to convert data from one type to another, using a `@BindingConversion`-annotated static method:

```
@BindingConversion
public static ColorDrawable colorToDrawable(int color) {
    return new ColorDrawable(color);
}
```

As with binding adapters, the name of the method does not matter. What matters is that it takes an `int` as input and returns a `ColorDrawable`. The data binding system will take this into account and use it if it has a case where the binding expression returned an `int` and it needs a `ColorDrawable`... or a `Drawable`.

Here, though, we start to run into problems with Google's insistence on using `int` values everywhere. This `colorToDrawable()` conversion method takes an `int`. That `int` could be a color. It could be a color resource ID, or a string resource ID, or a layout resource ID, or the score of a Stack Overflow question, or countless other things. The depicted `@BindingConversion`, therefore, may not be especially useful.

Another scenario for `@BindingConversion` is to be able to extract something from deep inside a model without exposing the whole model structure as `public`. For example, the [DataBinding/Conversion](#) sample project uses a `@BindingConversion` to allow an `Owner` to be turned into a `String`, by means of returning the `profileImage` value:

```
@BindingConversion
public static String ownerToString(Owner owner) {
    return(owner.profileImage);
}
```

---

## THE DATA BINDING FRAMEWORK

---

(from [DataBinding/Conversion/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java](#))

Once again, the method name does not matter; what matters is that this conversion knows how to handle taking an Owner and returning a String.

Now, the `app:imageUrl` attribute in the `ImageView` in the layout can refer to `question.owner` instead of `question.owner.profileImage`:

```
<ImageView
    android:id="@+id/icon"
    android:layout_width="@dimen/icon"
    android:layout_height="@dimen/icon"
    android:layout_gravity="center_vertical"
    android:contentDescription="@string/icon"
    android:padding="8dip"
    app:error="@{@drawable/owner_error}"
    app:imageUrl="@{question.owner}"
    app:placeholder="@{@drawable/owner_placeholder}"/>
```

(from [DataBinding/Conversion/app/src/main/res/layout/row.xml](#))

## Chained Expressions

The original edition of the data binding system allowed you to create expressions based on variables and static methods. An update to data binding in 2016 added in “chained expressions”, where expressions can refer to attributes of other widgets in the same layout resource. While this feature [is presently undocumented](#), the basics are straightforward enough: just refer to the widgets by ID.

For example, the [DataBinding/Chained](#) sample project is a clone of the `DataBinding/TwoWay` sample project from earlier in the chapter. There, we added a `Switch` widget tied to an expanded property on the `Question` model objects. The reason for the name “expanded” was in preparation for the `DataBinding/Chained` sample, where the visibility of the avatar icon and the score would be toggled based on the `Switch` status.

The `Switch` has an `android:id` of `expanded`:

```
<Switch
    android:id="@+id/expanded"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:checked="@={question.expanded}" />
```

(from [DataBinding/Chained/app/src/main/res/layout/row.xml](#))

---

## THE DATA BINDING FRAMEWORK

---

The `android:visibility` of the icon `ImageView` now is set based on a data binding expression, checking the checked state of the expanded widget, using a ternary operator to convert that into appropriate View values:

```
<ImageView
    android:id="@+id/icon"
    android:layout_width="@dimen/icon"
    android:layout_height="@dimen/icon"
    android:layout_gravity="center_vertical"
    android:contentDescription="@string/icon"
    android:padding="8dip"
    android:visibility="@{expanded.checked ? View.VISIBLE : View.GONE}"
    app:error="@{@drawable/owner_error}"
    app:imageUrl="@{question.owner.profileImage}"
    app:placeholder="@{@drawable/owner_placeholder}" />
```

(from [DataBinding/Chained/app/src/main/res/layout/row.xml](#))

Note that this requires us to import `View`, to be able to reference `View.VISIBLE` and `View.GONE`:

```
<import type="android.view.View" />
```

(from [DataBinding/Chained/app/src/main/res/layout/row.xml](#))

The score `TextView` could use the exact same expression as was used for the icon `ImageView`. However, in this case, the visibility of score depends upon the visibility of icon:

```
<TextView
    android:id="@+id/score"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:layout_marginLeft="8dp"
    android:layout_marginRight="8dp"
    android:text="@{Integer.toString(question.score)}"
    android:textSize="40sp"
    android:textStyle="bold"
    android:visibility="@{icon.visibility}" />
```

(from [DataBinding/Chained/app/src/main/res/layout/row.xml](#))

This way, if the rules for how we derive the visibility change, all we need to do is change icon, leaving score alone.

Now, as the user toggles the Switch, the visibility of the icon and the score toggles with it.

### Custom Binding Class Names

As noted earlier in this chapter, the binding class name for a layout resource is determined automatically by default. The layout filename is converted into a “Pascal case” rendition, then has Binding appended (e.g., `res/layout/foo_bar.xml` becomes `FooBarBinding`). This class goes in the `.databinding` sub-package under the base Java package for your app, as defined in the `package` attribute in your `<manifest>`.

However, this may result in awkward Java class names. Or, perhaps you want to have the classes be generated in some other Java package, for some reason. You can use the `class` attribute on the `<data>` element to control the actual Java class name used for the binding class.

This can come in one of three forms:

- `class="Foo"` will name the binding class `Foo` and will place it in the standard `.databinding` sub-package
- `class=".Foo"` will name the binding class `Foo`, but will place it in the base package for your app (as defined in the `package` attribute), instead of in the separate `.databinding` sub-package
- `class="this.is.fully.qualified.Foo"` will name the binding class `Foo` and place it in the designated Java package

### Extended Include Syntax

Android has supported `<include>` as a tag in layout resources since Android 1.0. The tag takes a `layout` attribute, pointing to a layout resource. The contents of the pointed-to layout resource are inserted into the view hierarchy of the original resource. So, if we have:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <include layout="@layout/foo"/>

    <!-- other widgets go here -->
```

```
</LinearLayout>
```

... then whatever is in the foo layout resource will be added to the `LinearLayout`, ahead of any other widgets in that `LinearLayout`.

With the data binding system, you can pass variables from the outer layout to the included one, without having to somehow bind the variable yourself in the included layout from Java code:

```
<layout xmlns:android="http://schemas.android.com/apk/res/android"
        xmlns:bind="http://schemas.android.com/apk/res-auto">
    <data>
        <variable name="foo" type="com.thingy.Foo"/>
    </data>

    <LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
        android:orientation="vertical"
        android:layout_width="match_parent"
        android:layout_height="match_parent">

        <include layout="@layout/foo" bind:bar="@{foo}"/>

        <!-- other widgets go here -->

    </LinearLayout>
</layout>
```

Here, if the foo layout resource has a variable named bar, it will be populated by evaluating the `@{foo}` binding expression, so the foo resource can refer to bar in its own binding expressions.

### Custom Observables

What you want may not fit any of these patterns. In that case, you are going to have to roll your own `Observable` implementation. The simplest way to do that is to extend `BaseObservable`, which handles all of the observer registration logic for you.

There are two types of changes for which you can notify observers:

- Changes to properties, which can be handled by the individual property observers described above, such as `ObservableField`
- Changes to other intrinsic aspects of the model itself, that cannot be captured in a simple `Observable` wrapper on some property

## THE DATA BINDING FRAMEWORK

---

For example, you might have a `Person` class that has `birthDate` field, of type `Date`, representing the date on which the person was born. If you wanted to use that date in a binding expression, you could have `birthDate` be `public`, or have a `getBirthDate()` that returned it. If you wanted a binding expression to be updated when the birth date changed (e.g., correcting a typo), you could have `birthDate` be an `ObservableField` wrapped around a `Date`.

However, suppose what you *really* want to use in the binding expression is the person's age. It is easy enough for `Person` to calculate that, based on the current date and `birthDate`. However, this would be awkward to publish via an `ObservableField`, since there should not be an age field — age is a derived value, not a stored value. Instead, you could say that your `getAge()` method publishes a simple `int`, and you will handle notifying observers whenever the age changes, either due to a change in `birthDate`, or if the date changed and it is now the person's birthday.

### Bindable Properties

On a `BaseObservable`, you can annotate getter-style methods with `@Bindable`. This tells the data binding framework that those methods represent values that can be bound. Because `BaseObservable` implements `Observable`, the data binding framework can call `addOnPropertyChangedCallback()` to register an `OnPropertyChangedCallback` to find out when `@Bindable` properties are changed.

To make that work, `BaseObservable` supplies a `notifyPropertyChanged()` method. You can call this from the setter method or other place where you are changing the value of the property, to let `BaseObservable` know that the property changed. This, in turn, will let all `OnPropertyChangedCallback` instances know about the change, which will trigger the data binding framework to re-evaluate any binding expressions tied to that property.

Unfortunately, this is broken in the 1.5.1 build of Android Studio and the 1.5.0 edition of the Android Gradle Plugin.

For example, here is a revised version of the `Question` model class that has it use `BaseObservable` and `notifyPropertyChanged()`:

```
package com.commonware.android.databind.basic;

import android.databinding.BaseObservable;
import android.databinding.Bindable;
import com.commonware.android.databind.basic.BR;
```

## THE DATA BINDING FRAMEWORK

---

```
public class Question extends BaseObservable {
    private String title;
    private final Owner owner;
    private final String link;
    private int score;
    private final String id;

    Question(Item item) {
        updateFromItem(item);
        owner=item.owner;
        link=item.link;
        id=item.id;
    }

    @Bindable
    public String getTitle() {
        return(title);
    }

    @Bindable
    public Owner getOwner() {
        return(owner);
    }

    @Bindable
    public String getLink() {
        return(link);
    }

    @Bindable
    public int getScore() {
        return(score);
    }

    @Bindable
    public String getId() {
        return(id);
    }

    void updateFromItem(Item item) {
        this.title=item.title;
        this.score=item.score;

        notifyPropertyChanged(BR.title);
        notifyPropertyChanged(BR.score);
    }
}
```

Here, BR is a generated class. According to the documentation:

The Bindable annotation generates an entry in the BR class file during compilation. The BR class file will be generated in the module package.

Unfortunately, while this is all true, Android Studio does not recognize any of the generated fields, and so while you can import BR, BR.title and BR.score — the int values identifying those properties – are not recognized and result in compile errors.

### Notifying About Intrinsic Changes

If the BaseObservable itself is what is used in the binding expression, or if you want to use bindable properties and need to work around the BR issue mentioned above, BaseObservable also offers notifyChange(), indicating that all binding expressions tied to the BaseObservable instance should be re-evaluated.

The [DataBinding/Observable](#) sample project is another variation of the sample project that we have been analyzing in this chapter. This one has Question extend BaseObservable. However, unlike the code snippet above, where we tried using BR and notifyPropertyChanged(), here we just settle for notifyChange():

```
package com.commonware.android.databind.basic;

import android.databinding.BaseObservable;
import android.databinding.Bindable;
import android.databinding.ObservableField;
import android.databinding.ObservableInt;
import com.commonware.android.databind.basic.BR;

public class Question extends BaseObservable {
    private String title;
    private final Owner owner;
    private final String link;
    private int score;
    private final String id;

    Question(Item item) {
        updateFromItem(item);
        owner=item.owner;
        link=item.link;
        id=item.id;
    }

    @Bindable
```

```
public String getTitle() {
    return(title);
}

@Bindable
public Owner getOwner() {
    return(owner);
}

@Bindable
public String getLink() {
    return(link);
}

@Bindable
public int getScore() {
    return(score);
}

@Bindable
public String getId() {
    return(id);
}

void updateFromItem(Item item) {
    this.title=item.title;
    this.score=item.score;

    notifyChange();
}
}
```

(from [DataBinding/Observable/app/src/main/java/com/commonsware/android/databind/basic/Question.java](#))

Even though we are storing title as a simple String and score as a simple int, we can use them in binding expressions, because their getters are @Bindable and we are notifying BaseObservable when their values change.

### Thinking Outside the Box

Data binding will usually be used for things like the text of a TextView, or the image shown in an ImageView. However, you are welcome to have other things vary based upon binding expressions. For example, perhaps you want a certain background color or color bar on a row in a list, based upon some category associated with the model objects. You could use data binding to set that color.

## THE DATA BINDING FRAMEWORK

---

Lisa Wray [pointed out](#) another inventive use of data binding: custom fonts.

Historically, using a custom Typeface required Java code. That Java code might be fairly limited, if you only need to update one `TextView`. Or, that Java code might pull in a library like [Calligraphy](#) to be able to apply arbitrary fonts to arbitrary widgets from within layout files.

The data binding framework can handle that for you, if you create a custom `BindingAdapter` for some synthetic property (e.g., `wray:font`). In your layout, you would have `wray:font` attributes that name the typeface that you want on relevant widgets (e.g., `TextView`):

```
<TextView
  wray:font="@{`MgOpenCosmetica.ttf`}"
  android:layout_width="wrap_content"
  android:layout_height="wrap_content"/>
```

The `BindingAdapter` would retrieve the `Typeface` for that font name, then apply it to the associated widget:

```
@BindingAdapter({"wray:font"})
public static void setFont(TextView tv, String font){
    String assetPath="fonts/" + font;
    Typeface type=Typeface.createFromAsset(tv.getContext().getAssets(), assetPath);

    tv.setTypeface(type);
}
```

This particular implementation has performance issues, as it creates a new `Typeface` object on every binding, which is inefficient. Lisa has [a complete sample app](#) that demonstrates caching the `Typeface` objects to reduce the performance overhead.

It is likely that the Android community will come up with other interesting tricks for simplifying code using fancy data binding adapters, converters, and the like.

# Drag and Drop

---

Desktop applications have long offered drag-and-drop, both within and between applications. Android has supported this for quite some time, but you could only drag and drop within a single activity. As a result, this was not especially popular.

However, starting in Android 7.0, you can drag and drop between applications, so long as their windows are visible in a multi-window environment. Not only does this make drag-and-drop more compelling in general, but in a freeform multi-window environment, users will expect Android apps to behave like their desktop counterparts. Hence, users will expect drag-and-drop capabilities where it makes sense.

In this chapter, we will explore Android’s drag-and-drop facility, including how to perform it between separate applications.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, as well as the chapter on [the clipboard](#).

One example uses RecyclerView, so reviewing [that chapter](#) is a good idea. Similarly, one sample uses StreamProvider, so you may wish to read [the section on it](#) as well.

## The Scope of Drag and Drop

Since the term “drag-and-drop” means different things to different people – including different developers used to different platforms — it will help if we understand exactly what Android’s definition of “drag-and-drop” is.

### What Are We Dragging and Dropping?

In Android, the focus is on dragging and dropping content, meaning some information identified by a `Uri` and an associated MIME type. We are using the drag-and-drop process to select some piece of content and inform something else about that content. Specifically, the content that we are dragging and dropping is represented by a `ClipData` object, the same as we could use with the clipboard.

Technically, the `ClipData` does not have to represent content. The clipboard supports plain text `ClipData` items, and nothing is stopping you from using drag and drop for plain text as a result. When dragging and dropping between apps, this may cause some compatibility issues, though the drag-and-drop framework takes steps to help deal with this. Within an app, options like plain text allow you to “cheat” to an extent, allowing drag-and-drop to support anything you want, so long as you can identify the specific “anything you want” by a string ID or key.

From the *user’s* standpoint, the user is dragging some visual representation of this content. That can be whatever bitmap you want, and you will have a few options for specifying what this bitmap is. This bitmap is referred to as the “shadow”.

### Where Are We Dragging From?

You will need to provide some UI that triggers a drag-and-drop operation, not only allowing the user to say “let’s drag this somewhere” but also “here is what ‘this’ I want to drag”.

A typical trigger for this is a long-click. So, for example, a long-click on a list row might trigger a drag-and-drop of the content identified by that row.

Usually, the trigger is tied to some view, as drag-and-drop intrinsically is a visual operation. Technically, this is not required, if you can find some other approach that users will understand and appreciate.

### Where Are We Dropping To?

You will need to identify possible drop targets, in the form of views. A view can be registered as a potential drop target, then stipulate whether it is a candidate for a *specific* drag-and-drop operation when that operation begins. For example, if you have two lists, and you want the user to drag items between the lists, both are potential drop targets. However, you might elect to say that the user cannot drag

from a list back into that same list, so if the content being dragged originated from the list, that list is not a candidate for that specific drag-and-drop operation.

## The Pieces of Drag-and-Drop

As noted above, what we are really dragging and dropping is a `ClipData`, which can represent whatever we want, so long as the recipient of that `ClipData` knows how to work with whatever the provider of that `ClipData` put in it.

However, there are a few other pieces to the drag-and-drop process.

### The Drag Shadow

The drag shadow is the visual representation of what the user is dragging and dropping. Programmatically, the shadow is defined as an instance of `View.DragShadowBuilder` (which, despite the name, does *not* implement a builder-style API).

You have two main choices for creating this shadow: use a `View`, or use a `Canvas`.

#### ...From a View

You can create a `View.DragShadowBuilder` via the constructor that takes a `View` as a parameter. This tells `View.DragShadowBuilder` that the drag shadow should be a translucent copy of whatever the `View` is showing at the time we start the drag-and-drop operation.

This is very easy to implement, and it works well if you have a `View` that makes for a likely visual representation of what is being dragged and dropped.

On the other hand, it will not handle all scenarios. Suppose that you want to allow the user to drag from a list. Furthermore, suppose that you want the user to be able to multi-select items in the list and drag the entire selection. Now you no longer have a single `View` that you can use as the basis for the drag shadow.

Also, keep the drag shadow relatively small. It needs to be big enough that the user can see it despite a finger potentially being in the way. However, it also needs to be small enough to make it clear where the user is dropping it. This is another reason why the multi-select list scenario does not work well with creating a `View.DragShadowBuilder` from a `View` — even if you chose the `ListView` or

RecyclerView as being the View from which to create the drag shadow, odds are that the list will be far too large.

### **...From a Canvas**

For cases where using a View as the basis of your drag shadow will not work, you can create your own subclass of `View.DragShadowBuilder` and define the drag shadow however you want.

To do this, you will override two methods. One is `onProvideShadowMetrics()`, where you fill in a pair of `Point` objects. The first represents the size of the drag shadow in pixels. The other represents the point within the drag shadow where the touch point will be — in other words, where is the drag shadow with respect to where the finger is touching the screen.

The other method is `onDragShadow()`, where you are given an appropriately-sized `Canvas` and you can draw whatever you want into that `Canvas` to serve as the drag shadow. For example, you might draw a `Bitmap` in `onDragShadow()` using the dimensions of the `Bitmap` and its center point in `onProvideShadowMetrics()`.

Technically, you can combine the two approaches. You create the `View.DragShadowBuilder` using a `View` but then override one or both of the aforementioned `View.DragShadowBuilder` methods to alter the default behavior a bit. For example, by default, the touch point will be the center of the `View`, but you might want the touch point to be offset towards one corner — you could handle this by overriding `onProvideShadowMetrics()`, chaining to the superclass, then updating the second `Point` object as you see fit.

### **The Drag Event Listener**

To react to drag events in a drop target `View`, you can call `setOnDragListener()`, supplying an implementation of `View.OnDragListener`. This interface has a single method, `onDrag()`, that you will need to implement.

The sample apps in this chapter implement `View.OnDragListener` on the activity that has the drop targets. Typically, you will implement `View.OnDragListener` on whatever object in your UI handles events raised by the widgets (e.g., a controller or presenter).

### The Drag Events

`onDrag()` of your `View.OnDragListener` is passed two objects: the `View` that you called `setOnDragListener()` on, and a `DragEvent` representing what is happening with respect to the drag-and-drop process.

The `DragEvent` contains an action `int` value, representing what the state change is in the drag-and-drop operation. Depending on the action, other aspects of the `DragEvent` may be available to you as well.

#### **ACTION\_DRAG\_STARTED**

When the user begins a drag-and-drop operation, and your window is visible (e.g., the user started the drag-and-drop within your own activity), you will receive a `DragEvent` whose action is `ACTION_DRAG_STARTED`.

Your primary job is to return `true` from `onDrag()` if you wish to be considered a drop target for this drag-and-drop operation. Prior to Android 7.0, you might always return `true`, since you are certain to be in control over both the drag and the drop. Starting with Android 7.0, you might conditionally return `true`, if the drag-and-drop operation looks like it might be one that you can handle. Unfortunately, your primary means of determining this is via `getClipDescription()` on the `DragEvent`, which gives you a `ClipDescription` describing the `ClipData` that is the content. This does not give you much to go on, as we will see in upcoming samples.

If you are a valid drop target, you might also consider adjusting the look and feel of this `View` to indicate to the user that this is a valid drop target. Android does not do anything on its own for this. You might tint the `View`, or add an outline, or something, to help clue the user in that dropping over your `View` might have a positive result.

If you return `true`, you will be notified about the progress of the drag-and-drop event through the other event actions listed below. If you return `false`, you are indicating that this drag-and-drop operation does not concern you, and you will not be given any further `DragEvents` for it.

#### **ACTION\_DRAG\_ENTERED**

You will receive a `DragEvent` with this action once it is possible for the user to drop in your `View`. This will come when the drag shadow enters the bounding box of the

## DRAG AND DROP

---

View (not necessarily only where pixels are drawn for the view).

If you are still interested in this drag-and-drop operation, you should:

- Return `true` from `onDrag()`, and
- Alter the widget's appearance yet again, to reflect the fact that if the user lifts her finger, the content will be dropped into this widget

If precise placement within the widget is important for the drag-and-drop operation (e.g., you wish to highlight some specific cell in a grid), you can call `getX()` and `getY()` on the `DragEvent` to try to determine where the drop point is. Unfortunately, it is not documented whether `getX()` and `getY()` are relative to your widget, the screen, or something else.

### **ACTION\_DRAG\_LOCATION**

If you return `true` from the `ACTION_DRAG_ENTERED` `DragEvent`, you may receive additional `DragEvents` with `ACTION_DRAG_LOCATION` actions, indicating that the user has moved within the bounding box of your widget. If you are using `getX()` and `getY()` to deal with the highlighting, these values will have changed, and so you will want to update the highlighting to match.

### **ACTION\_DRAG\_EXITED**

If you return `true` from the `ACTION_DRAG_ENTERED` `DragEvent`, you may receive a `DragEvent` for `ACTION_DRAG_EXITED`. This indicates that the user dragged the item outside of your widget without dropping it. Any state changes to your widget, such as a highlight, that you applied in `ACTION_DRAG_ENTERED` or `ACTION_DRAG_LOCATION` should be reverted. However, the drag-and-drop operation is still proceeding, so any highlight you use for that (e.g., in `ACTION_DRAG_STARTED`) should still be used.

### **ACTION\_DROP**

Of course, the fun action is `ACTION_DROP`, which means that the user dropped the content over this widget as the drop target. You can call `getClipData()` to get at the `ClipData` for this content, along with final `getX()` and `getY()` values.

If you return `true` in `onDrag()`, this indicates that you handled the drop request.

However, you may not be able to handle the drop request. For example, suppose you

---

## DRAG AND DROP

---

are looking to have a Uri pointing to a video be dropped into your app. All you can determine from the ClipDescription, in your ACTION\_DRAG\_STARTED processing, is that the ClipData has a Uri. So, you have to return true from onDrag() in your ACTION\_DRAG\_STARTED logic. But, then, in ACTION\_DROP processing, when you get the real Uri, you find out that it has a different MIME type (e.g., text/html, instead of video/\*). You will need to return false from onDrag() in your ACTION\_DROP logic. Unfortunately, what happens from this point forward is undocumented.

### ACTION\_DRAG\_ENDED

If you returned true from the ACTION\_DRAG\_STARTED DragEvent, you should receive a DragEvent when the drag-and-drop operation is over, with ACTION\_DRAG\_ENDED as the action. Any state change you made to your widget in ACTION\_DRAG\_STARTED should be reverted here. If it matters to you whether the user did a valid drop or not, call getResult() on the DragEvent to find out .

## Drag-and-Drop, within an Activity

The classic drag-and-drop scenario, prior to Android 7.0, was to drag-and-drop between widgets in a single activity.

The [DragDrop/Simple](#) sample project demonstrates this scenario. It is based on the RecyclerView/VideoList sample app from [the chapter on RecyclerView](#).

### The Landscape Layout

On smaller screens, we just have the RecyclerView as before. However, on larger screens (e.g., 9" tablets in landscape), we put a VideoView and an ImageView alongside the RecyclerView:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal">

    <android.support.v7.widget.RecyclerView android:id="@+id/video_list"
        xmlns:android="http://schemas.android.com/apk/res/android"
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="1" />
```

## DRAG AND DROP

---

```
<LinearLayout
  android:layout_width="0dp"
  android:layout_height="match_parent"
  android:layout_weight="1"
  android:orientation="vertical">

  <FrameLayout
    android:id="@+id/video_frame"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_marginBottom="4dp"
    android:layout_weight="1"
    android:padding="4dp">

    <VideoView
      android:id="@+id/player"
      android:layout_width="match_parent"
      android:layout_height="match_parent"
      android:layout_gravity="center" />
    </FrameLayout>

    <FrameLayout
      android:id="@+id/thumbnail_frame"
      android:layout_width="match_parent"
      android:layout_height="0dp"
      android:layout_weight="1"
      android:padding="4dp">

      <ImageView
        android:id="@+id/thumbnail_large"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:scaleType="centerInside" />
      </FrameLayout>
    </LinearLayout>
  </LinearLayout>
```

(from [DragDrop/Simple/app/src/main/res/layout-w800dp/main.xml](#))

The idea is that the user will be able to drag from the RecyclerView into the other two widgets, which will play the video or show a larger rendition of the thumbnail, respectively.

The VideoView and the ImageView are each wrapped in a FrameLayout. Mostly, that is to give us a place to render a border around the widgets, indicating that they are drop targets. We have a pair of <shape> drawables for this. One is a red dashed line indicating a potential drop target:

## DRAG AND DROP

---

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">
    <stroke
        android:width="2dp"
        android:dashGap="8dp"
        android:dashWidth="8dp"
        android:color="#ff0000" >
    </stroke>
</shape>
```

(from [DragDrop/Simple/app/src/main/res/drawable-nodpi/droppable.xml](#))

The other is a solid green line indicating a “live” drop target, used to indicate that dropping the content here should work:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">
    <stroke
        android:width="4dp"
        android:color="#2e7d32" >
    </stroke>
</shape>
```

(from [DragDrop/Simple/app/src/main/res/drawable-nodpi/drop.xml](#))

## Registering as Drop Targets

This version of the sample app avoids the `RecyclerViewActivity` used in the `RecyclerView/VideoList` sample app. Instead, `MainActivity` manages all of its widgets directly, including the `RecyclerView`.

In `onCreate()`, after inflating the layout, we attempt to retrieve the `VideoView` and `ImageView`. If we find them, we call `setOnDragListener()`, supplying our `MainActivity` instance itself as the `OnDragListener` implementation:

```
player=findViewById(R.id.player);

if (player!=null) {
    player.setOnDragListener(this);
}

thumbnailLarge=findViewById(R.id.thumbnail_large);

if (thumbnailLarge!=null) {
```

## DRAG AND DROP

---

```
thumbnailLarge.setOnDragListener(this);  
}
```

(from [DragDrop/Simple/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

We will examine the `onDrag()` method that `OnDragListener` requires shortly.

### Starting to Drag

This app supports a long-click on a row in our `RecyclerView` to enter drag-and-drop mode, as we call `setOnLongClickListener()` on the row itself, in `RowController` (our `RecyclerView.ViewHolder` for our list rows):

```
RowController(View row) {  
    super(row);  
  
    title=(TextView)row.findViewById(android.R.id.text1);  
    thumbnail=(ImageView)row.findViewById(R.id.thumbnail);  
  
    row.setOnClickListener(this);  
    row.setOnLongClickListener(this);  
}
```

(from [DragDrop/Simple/app/src/main/java/com/commonsware/android/dragdrop/RowController.java](#))

In `onLongClick()`, we:

- Create a `ClipData` based on the `Uri` obtained from `MediaStore` for the video, plus its caption (pulled from the `title` `TextView`)
- Create a drag shadow, using `View.DragShadowBuilder`, with the `thumbnail` `ImageView` as the basis
- Call `startDrag()` on the row itself, accessed via the `itemView` field on the `ViewHolder` base class

```
@Override  
public boolean onLongClick(View v) {  
    ClipData clip=ClipData.newRawUri(title.getText(), videoUri);  
    View.DragShadowBuilder shadow=new View.DragShadowBuilder(thumbnail);  
  
    itemView.startDrag(clip, shadow, Boolean.TRUE, 0);  
  
    return(true);  
}
```

(from [DragDrop/Simple/app/src/main/java/com/commonsware/android/dragdrop/RowController.java](#))

## DRAG AND DROP

---

Besides the `ClipData` and `View.DragShadowBuilder`, `startDrag()` takes two other parameters:

- An arbitrary `Object` referred to as the “local state”, which can provide additional information between the drag source and the drop target, but only when both are in the same window (usually meaning the same activity)
- A set of flags (here unused, so set to 0)

For the local state, we are using `Boolean.TRUE`. That is a fairly arbitrary choice, but it is a good idea to pass a non-null value here, for reasons that we will get into [later in this chapter](#).

### Reacting to Drag Events

Our `onDrag()` method in `MainActivity` will handle all of the events related to our registered drop targets:

```
@Override
public boolean onDrag(View v, DragEvent event) {
    boolean result=true;

    switch (event.getAction()) {
        case DragEvent.ACTION_DRAG_STARTED:
            if (event.getLocalState()==null) {
                result=false;
            }
            else {
                applyDropHint(v, R.drawable.droppable);
            }
            break;

        case DragEvent.ACTION_DRAG_ENTERED:
            applyDropHint(v, R.drawable.drop);
            break;

        case DragEvent.ACTION_DRAG_EXITED:
            applyDropHint(v, R.drawable.droppable);
            break;

        case DragEvent.ACTION_DRAG_ENDED:
            applyDropHint(v, -1);
            break;

        case DragEvent.ACTION_DROP:
            ClipData.Item clip=event.getClipData().getItemAt(0);
```

## DRAG AND DROP

---

```
Uri videoUri=clip.getUri();

if (v==player) {
    player.setVideoURI(videoUri);
    player.start();
}
else {
    Picasso.with(thumbnailLarge.getContext())
        .load(videoUri.toString())
        .fit().centerCrop()
        .placeholder(R.drawable.ic_media_video_poster)
        .into(thumbnailLarge);
}

break;
}

return(result);
}
```

(from [DragDrop/Simple/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

For most of the actions, we apply (or remove) a drawable from the FrameLayout containers wrapping our VideoView and ImageView widgets, via an applyDropHint() utility method:

```
private void applyDropHint(View v, int drawableId) {
    View parent=(View)v.getParent();

    if (drawableId>-1) {
        parent.setBackgroundResource(drawableId);
    }
    else {
        parent.setBackground(null);
    }
}
```

(from [DragDrop/Simple/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

Here, we use -1 as the “ID” of a resource meaning to remove any previous background.

In onDrag(), we ignore ACTION\_DRAG\_LOCATION events, as we are not using getX() and getY() and so do not care if those values change.

However, we do handle two actions a bit differently:

## DRAG AND DROP

---

- ACTION\_DRAG\_STARTED examines the local state and rejects any DragEvent where that state is null, for reasons that we will get into [later in this chapter](#)
- ACTION\_DROP retrieves the ClipData.Item for the ClipData we set as the drag content, retrieves the Uri of the video from the ClipData.Item, then either plays the video or shows the thumbnail, depending on which widget the user dropped the content into

### The Result

If you run the sample app on a large-enough device with a roster of videos, you will get the list of videos on one side, and the empty VideoView and ImageView on the other side:

## DRAG AND DROP

---

Once the user long-taps on a list row, a shadow based on the thumbnail appears under the user's finger, and the two drop targets show their red dashed outlines:

## DRAG AND DROP

If the user drags the drop shadow over one of the drop targets, it gets the `ACTION_DRAG_ENTERED` event and changes its outline to the green solid line:

*Figure 674: Simple Drag-and-Drop Demo, After Drag Enters Drop Target*

## DRAG AND DROP

---

Finally, if the user drops the item in one of the drop targets, it receives the `ACTION_DROP` event and can actually use the content:

Note that both widgets no longer show an outline, as they each received `ACTION_DROP_ENDED`, where they removed their outlines.

### The Android 9.0 Bug

Simply put, the local state [does not work on Android 9.0](#). `getLocalState()` always returns `null`. Reportedly, this is fixed for a future version of Android, but it is unlikely that this fix will ever make it to Android 9.0 devices.

As a result, you will need an alternative to the local state, at least for Android 9.0 devices.

### Drag-and-Drop, Between Apps

Android 7.0's multi-window capability ushers in a new era for drag-and-drop, where users drag-and-drop between apps. In theory, very little has to change to support

## DRAG AND DROP

---

drag-and-drop between apps.

However, there are challenges, the biggest one being permissions. The app with the drop target needs permission to work with whatever content is represented in the drag-and-drop operation. If that content is simply some plain text or something else that can be stuffed into a `ClipData`, permissions are part of drag-and-drop processing, as only the drop target selected by the user gets the `ACTION_DROP` event and can access that `ClipData`.

However, if the `ClipData` contains one or more `Uri` values, the app with the drop target needs access to that underlying content, just as it needs it for the clipboard or any other situation where a `Uri` is passed between apps.

The [DragDrop/Permissions](#) sample project demonstrates dragging and dropping between apps. This project has two app modules: `drag` and `drop`. As you might imagine, `drag` contains an activity that allows the user to drag something (in this case, an image), while `drop` contains an activity that accepts an image `Uri` and displays it.

Because cross-app drag-and-drop requires Android 7.0, both modules are set up with 7.0-compatible build settings in `build.gradle` — we will see the `drag/build.gradle` file shortly.

### The Drag App

The `drag` app has a very simple UI: a single `ImageView`, set to fill the available space:

```
<?xml version="1.0" encoding="utf-8"?>
<ImageView android:id="@+id/asset"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:scaleType="fitCenter" />
```

(from [DragDrop/Permissions/drag/src/main/res/layout/main.xml](#))

The idea is that the user will long-click the `ImageView` to start the drag-and-drop operation. Hence, this is reminiscent of the `DragDrop/Simple` app, just with a single image, rather than one per row in a list.

### The Custom Shadow

One problem with using the `ImageView` as the way to start the drag-and-drop operation comes with the drag shadow. In `DragDrop/Simple`, we used the image as the drag shadow. This worked well, because the image was a thumbnail, which usually is a good size for a drag shadow. In the drag app in `DragDrop/Permissions`, though, the `ImageView` is huge, far too large to use as the drag shadow. As a result, we cannot use the `ImageView` directly as before, but instead need to create a custom `View.DragShadowBuilder` subclass, named `ThumbDragShadow`:

```
private class ThumbDragShadow extends View.DragShadowBuilder {
    @Override
    public void onProvideShadowMetrics(Point shadowSize,
                                     Point shadowTouchPoint) {
        shadowSize.set(iv.getWidth()/8, iv.getHeight()/8);
        shadowTouchPoint.set(shadowSize.x/2, shadowSize.y/2);
    }

    @Override
    public void onDrawShadow(Canvas canvas) {
        iv.draw(canvas);
    }
}
```

(from [DragDrop/Permissions/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

This is a nested class inside `MainActivity`, and so it has access to the fields of `MainActivity`, such as our `ImageView`, named `iv`.

In `onProvideShadowMetrics()`, we set the size of the shadow to be 1/8th of the size of the `ImageView`. This is a sloppy approach and may wind up with too small of an image on smaller-screen devices. However, it does keep the aspect ratio of the `ImageView`. In addition, we set the touch point to be in the middle of the image — based on [some Google sample code](#), it appears that this is a reasonable algorithm.

In `onDrawShadow()`, we need to draw something on the supplied `Canvas` that represents the drag shadow. In this case, we ask the `ImageView` to draw itself into that `Canvas`. This results in a cropped image, as the `ImageView` is much larger than our `Canvas`, which is sized based on the `Point` values we populated in `onProvideShadowMetrics()`. A better implementation would work with a `Bitmap` and scale it so the entire image would be seen in the drag shadow; this approach is used here for simplicity.

### The StreamProvider

The image itself is stored in assets/. The photo is of [One World Trade Center](#) (a.k.a., “Freedom Tower”) in New York City.

The reason for storing it in assets/ is that not only do we need the image, but we need to provide other apps with access to the image. In this app, we will handle that using StreamProvider, from the author’s CWAC-Provider library, as described in [one of the chapters on the ContentProvider component](#).

To that end, we include the cwac-provider artifact in our drag/build.gradle file:

```
apply plugin: 'com.android.application'

dependencies {
    compile 'com.android.support:recyclerview-v7:25.3.1'
    compile 'com.squareup.picasso:picasso:2.5.2'
}

android {
    compileSdkVersion 24
    buildToolsVersion '26.0.2'

    defaultConfig {
        applicationId "com.commonware.android.dragdrop.drag"
        minSdkVersion 24
        targetSdkVersion 24
    }

    aaptOptions {
        noCompress 'jpg'
    }
}

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonware.com"
    }
}

dependencies {
    compile 'com.commonware.cwac:provider:0.4.0'
}
```

(from [DragDrop/Permissions/drag/build.gradle](#))

---

## DRAG AND DROP

---

Also note that we take steps to ensure that the build tools do not try to compress the JPEG further, by excluding jpg files from aapt compression via `noCompress` in `aaptOptions`

The manifest contains a `<provider>` element for our `StreamProvider`:

```
<provider
  android:name="com.commonware.cwac.provider.StreamProvider"
  android:authorities="${applicationId}.provider"
  android:exported="false"
  android:grantUriPermissions="true">
  <meta-data
    android:name="com.commonware.cwac.provider.STREAM_PROVIDER_PATHS"
    android:resource="@xml/provider"/>
  <meta-data
    android:name="com.commonware.cwac.provider.USE_LEGACY_CURSOR_WRAPPER"
    android:value="true"/>
</provider>
```

(from [DragDrop/Permissions/drag/src/main/AndroidManifest.xml](#))

That sets up the authority string to be the application ID with `.provider` appended. It also points `StreamProvider` to some XML metadata in `res/xml/provider.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<paths>
  <asset name="assets" />
</paths>
```

(from [DragDrop/Permissions/drag/src/main/res/xml/provider.xml](#))

Here, we say that we are willing to serve anything from `assets/`.

### The Drag Request

In `onCreate()`, we use `Picasso` to load the image out of `assets/` and display it. However, we also register a `Callback` to find out when that has been completed:

```
@Override
public void onCreate(Bundle state) {
  super.onCreate(state);
  setContentView(R.layout.main);
```

## DRAG AND DROP

---

```
iv=(ImageView)findViewById(R.id.asset);

Picasso.with(this)
    .load("file:///android_asset/FreedomTower-Morning.jpg")
    .fit().centerCrop()
    .into(iv, new Callback() {
        @Override
        public void onSuccess() {
            iv.setOnLongClickListener(MainActivity.this);
        }

        @Override
        public void onError() {
            // TODO
        }
    });
}
```

(from [DragDrop/Permissions/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

We only call `setOnLongClickListener()` once the image has been loaded successfully, as until then, the user would not know what she is dragging and dropping.

Then, in `onLongClick()`, we start the drag-and-drop operation:

```
@Override
public boolean onLongClick(View view) {
    Uri uri=PROVIDER
        .buildUpon()
        .appendEncodedPath(StreamProvider.getUriPrefix(AUTHORITY))
        .appendEncodedPath("assets/FreedomTower-Morning.jpg")
        .build();

    ClipData clip=ClipData.newRawUri(getString(R.string.msg_photo), uri);
    View.DragShadowBuilder shadow=new ThumbDragShadow();

    iv.startDragAndDrop(clip, shadow, Boolean.TRUE,
        View.DRAG_FLAG_GLOBAL|View.DRAG_FLAG_GLOBAL_URI_READ|
        View.DRAG_FLAG_GLOBAL_PERSISTABLE_URI_PERMISSION);

    return(true);
}
```

(from [DragDrop/Permissions/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

First, we need a `Uri` pointing to our asset. We build such a `Uri` from:

## DRAG AND DROP

---

- A static PROVIDER Uri, which incorporates our authority string:

```
private static final String AUTHORITY=  
    BuildConfig.APPLICATION_ID+".provider";  
private static final Uri PROVIDER=  
    Uri.parse("content://" + AUTHORITY);
```

(from [DragDrop/Permissions/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

- The unique prefix used for this app by StreamProvider (via `getUriPrefix()`)
- The path to our asset

We then build a `ClipData` from that Uri, plus a string pulled from a resource. Note that it is unclear where this string is used, though accessibility options is one likely candidate.

The drag shadow is an instance of the `ThumbDragShadow` shown above.

To start the drag-and-drop operation, we call `startDragAndDrop()`. This is simply a new name for the `startDrag()` method. `startDrag()` is marked as deprecated in Android 7.0, replaced with `startDragAndDrop()`. However, for older, in-app drag-and-drop, feel free to use `startDrag()`, as it is your only option for Android 6.0 and older devices.

This time, we pass in some flags:

- `DRAG_FLAG_GLOBAL` indicates that we want the drag-and-drop operation to work between apps. If we left the flags as 0, the drag-and-drop would be limited only to this app. In this respect, a drag is local by default, with cross-app drag-and-drop being something you have to explicitly opt into.
- `DRAG_FLAG_GLOBAL_URI_READ` indicates that we want the other app to be able to read the content identified by the Uri that we are putting into the `ClipData`. Without this, any app receiving the `DragEvent` would be unable to display the image. Note that there is an equivalent `DRAG_FLAG_GLOBAL_URI_WRITE` if you want to offer write access.
- `DRAG_FLAG_GLOBAL_PERSISTABLE_URI_PERMISSION` indicates that we want to grant the recipient app durable rights to the content identified by the Uri that we are putting into the `ClipData`. The term “persistable”, and the documentation for this flag, suggests that this access survives reboots. That may be excessive here. We will explore why we are using this flag when we look at the drop app.

### The Drop App

The drop app is a version of the drop logic from DragDrop/Simple, reduced to just handling the drop in an ImageView. However, it does have a few wrinkles, both related to drag-and-drop (permissions) and related to general Android development (configuration change support).

### The Layout

The revised layout is simply the ImageView, wrapped in the FrameLayout for the drop hint drawables:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout android:id="@+id/thumbnail_frame"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:layout_margin="4dp"
  android:padding="4dp">

  <ImageView
    android:id="@+id/thumbnail_large"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:scaleType="centerInside" />
</FrameLayout>
```

(from [DragDrop/Permissions/drop/src/main/res/layout/main.xml](#))

In onCreate() and onSaveInstanceState(), we load that layout, get the ImageView, and populate it (via the same showThumbnail() as before) if we have a thumbnailUri from our saved instance state Bundle:

```
@Override
public void onCreate(Bundle state) {
  super.onCreate(state);
  setContentView(R.layout.main);

  image=(ImageView)findViewById(R.id.thumbnail_large);
  image.setOnDragListener(this);

  if (state!=null) {
    imageUri=state.getParcelable(STATE_IMAGE_URI);

    if (imageUri!=null) {
```

## DRAG AND DROP

---

```
        showThumbnail();
    }
}

@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putParcelable(STATE_IMAGE_URI, imageUri);
}
```

(from [DragDrop/Permissions/drop/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

### The Drag Event

The `onDrag()` method is the same as before, except for two events: `ACTION_DRAG_STARTED` and `ACTION_DROP`.

We are expecting to get a `Uri` pointing to an image from the outside app via a drag-and-drop operation. Ideally, we would validate that in `ACTION_DRAG_STARTED`, returning `false` if the content is something else:

```
@Override
public boolean onDrag(View v, DragEvent event) {
    boolean result=true;

    switch (event.getAction()) {
        case DragEvent.ACTION_DRAG_STARTED:
            if (event
                .getClipDescription()
                .hasMimeType(ClipDescription.MIMETYPE_TEXT_URILIST)) {
                applyDropHint(v, R.drawable.droppable);
            }
            else {
                result=false;
            }

            break;

        case DragEvent.ACTION_DRAG_ENTERED:
            applyDropHint(v, R.drawable.drop);
            break;

        case DragEvent.ACTION_DRAG_EXITED:
            applyDropHint(v, R.drawable.droppable);
    }
}
```

## DRAG AND DROP

---

```
        break;

    case DragEvent.ACTION_DRAG_ENDED:
        applyDropHint(v, -1);
        break;

    case DragEvent.ACTION_DROP:
        requestDragAndDropPermissions(event);

        ClipData.Item clip=event.getClipData().getItemAt(0);

        imageUri=clip.getUri();
        showThumbnail();
        break;
    }

    return(result);
}
```

(from [DragDrop/Permissions/drop/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

Unfortunately, all we can do is determine that we are getting *some* Uri. The MIME type in our ClipDescription is *not* the MIME type of the content underlying our Uri, but rather will be ClipDescription.MIMETYPE\_TEXT\_URI\_LIST. This is because a ClipData can have several items, each with Uri values. We have no way, given just the ClipDescription to determine if we actually have an image Uri. So, as long as we are getting a Uri value, we assume that the drop might be meaningful and return true.

For ACTION\_DROP, we first call requestDragAndDropPermissions(), to grant our app the rights offered to us by whatever app initiated the drag-and-drop operation:

```
    case DragEvent.ACTION_DROP:
        requestDragAndDropPermissions(event);

        ClipData.Item clip=event.getClipData().getItemAt(0);

        imageUri=clip.getUri();
        showThumbnail();
        break;
```

(from [DragDrop/Permissions/drop/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

The requestDragAndDropPermissions() method returns a DragAndDropPermissions object. The JavaDocs for this class point out the lifetime of our permissions:

## DRAG AND DROP

---

The life cycle of the permissions is bound to the activity used to call `requestDragAndDropPermissions()`. The permissions are revoked when this activity is destroyed, or when `release()` is called, whichever occurs first.

However, the user could destroy your activity at any point in time, via a configuration change. As a result, you have three main options here:

1. Make a local copy of the content as soon as you get the `Uri`, hopefully before your activity gets destroyed via a configuration change
2. Opt out of the automatic destroy-and-recreate cycle for configuration changes for any activity that has drop targets, via `android:configChanges` in the manifest, and deal with all the problems that technique raises
3. Ignore the issue and hope that the app that started the drag-and-drop operation included `DRAG_FLAG_GLOBAL_PERSISTABLE_URI_PERMISSION` in its `startDragAndDrop()` call

But, after the `requestDragAndDropPermissions()` call, we grab the first `Uri` out of the `ClipData`, store that in the `imageUri` field, and have `showThumbnail()` display that image via Picasso. A better approach would examine each possible `Uri` in the `ClipItem` for one that represents an image (showing that one), and returning `false` from `onDrag()` if no such `Uri` is found, so the drag-and-drop operation remains active.

### The Results

If you run both apps, and have them both visible in a multi-window environment (e.g., split-screen mode on a phone or tablet), you will be able to drag and drop between them:

*Figure 676: Cross-App Drag-And-Drop, Showing Both Activities As Initially Launched*

## DRAG AND DROP

*Figure 677: Cross-App Drag-And-Drop, Showing Drag Shadow*

*Figure 678: Cross-App Drag-And-Drop, Showing Result of Drag-and-Drop*

## Detecting Cross-App Drag Events

In the DragDrop/Permissions sample, there is nothing in our `onDrag()` method, or anywhere else, that indicates that we want to allow drag events from third-party apps. **That happens by default, and there is no way to stop it.** Hence, *any* app implementing official drag-and-drop support *has* to support arbitrary apps passing in content. With luck, [this too will get changed](#).

We were given [this recipe](#) for detecting cross-app drag-and-drop:

- Fill in a non-null value for the local state in the call to `startDragAndDrop()`
- Check in `ACTION_DRAG_STARTED` to see if the local state is null, in which case, the drag-and-drop must have started from some other app

However, [this does not work well](#). The local state is local to a *window*, not an app or process. As a result, if your app is visible in more than one window — for example, you used `FLAG_ACTIVITY_LAUNCH_ADJACENT` to start up another activity in another window — then you will lose the local state even for in-app drag-and-drop across these windows.

In the Simple drag-and-drop sample from earlier, we check to see if the local state is null and reject the drag event if it is. There, we are not expecting to have activities in multiple windows, so all drag-and-drop work should be local. Conversely, we do *not* check the local state in the Permissions sample, where we specifically *want* cross-app drag-and-drop.

## Intra-App Cross-Window Drag-and-Drop

Drag-and-drop not only works between apps with Android 7.0's multi-window feature — it also works for two windows within the same app.

The [DragDrop/SplitScreen](#) sample project is a clone of the DragDrop/Permissions project. However, both the drag activity (`MainActivity`) and the drop activity (`DropActivity`) are in the same app module (`app/`).

Also, `MainActivity` now has an action bar with a “launch” item that, when tapped, will bring up the `DropActivity` in an adjacent window:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
```

## DRAG AND DROP

---

```
if (item.getItemId()==R.id.launch) {
    startActivity(new Intent(this, DropActivity.class)
        .setFlags(Intent.FLAG_ACTIVITY_LAUNCH_ADJACENT |
            Intent.FLAG_ACTIVITY_NEW_TASK |
            Intent.FLAG_ACTIVITY_MULTIPLE_TASK));

    return(true);
}

return(super.onOptionsItemSelected(item));
}
```

(from [DragDrop/SplitScreen/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

Launching MainActivity, entering multi-window mode, and launching DropActivity gives you those two activities in separate windows, such as in split-screen mode:

*Figure 679: Split-Screen Drag Demo, With Both Activities Showing*

## DRAG AND DROP

---

And, as in the cross-app scenario, you can drag from one window into the other:

*Figure 680: Split-Screen Drag Demo, Part-Way Through a Drag*

*Figure 681: Split-Screen Drag Demo, After Drag-and-Drop*

However, as was noted above, the local state data is lost in these cross-window drag-and-drop operations, making them indistinguishable from cross-app drag-and-drop operations.

## Pondering Legacy Multi-Window

In principle, cross-app drag-and-drop could work with Samsung's [legacy multi-window support](#). However, calling `startDrag()` (the pre-Android 7.0 equivalent of `startDragAndDrop()`) will not grant permissions to the other app to use the content associated with any `Uri`. The only way to make this work would be if the content identified by the `Uri` was readable by all apps, which is not great from a security standpoint.

LG's legacy multi-window support does not seem to support cross-app drag-and-drop.

Also, Chrome OS does not support cross-app drag-and-drop as of the August 2016 round of developer previews.

## Dragging and Dropping Simple Stuff

This chapter focuses on drag-and-drop of content, represented by a `Uri`. That is not your only option, just as that is not your only option for putting stuff onto, or removing stuff from, the clipboard.

A `ClipData` object contains one or more `ClipData.Item` objects. These can be of three main forms:

- Text, in the form of a `CharSequence`, including support for any standard Android [spans](#)
- An `Intent`, usually designed for creating some sort of shortcut to be able to launch an activity identified by the `Intent`
- A `Uri`

Outside of specialized cases (e.g., home screens), if you are not using `Uri`, probably you are using text.

If you are implementing a drop target, and all you know how to do is handle text, you can call `coerceToText()` on a `ClipData.Item` object to get the best text representation of whatever it is. For `Uri` values pointing to text content, `coerceToText()` will read in the content and return it. For anything else, you get `backToString()` on the content, more or less.

## Multi-Action Drag-and-Drop

The previous section brings up home screens as an example of drag-and-drop. On many Android home screen implementations, if you long-click on an icon in the launcher, you can drag-and-drop that icon into the home screen itself, thereby creating a shortcut. However, in addition to that, many home screens also offer special drop targets tied to specific actions, such as “Uninstall”. If the user drops the icon over the home screen area, a shortcut gets created; if the user drops the icon over a special drop target, the action for that target is performed.

You can do this too.

Mostly, it is a matter of arranging to show those special drop targets only during a drag-and-drop operation, then handling those drops specifically. However, due to the nature of Android’s view hierarchy and the drag-and-drop framework, you need to ensure that you show the special drop target’s view *before* you start the drag-and-drop operation. Otherwise, the special drop target’s view will never receive `ACTION_DRAG_ENTERED` or `ACTION_DROP` events.

We can see how this works in practice in the [DragDrop/Action](#) sample project. This is a clone of the `DragDrop/Simple` app from earlier in this chapter, except that we have added a special “Video Info” drop target.

### The Layout

The `-w800dp` layout is mostly as it was in the original app, except that we have added an `info TextView` above the `RecyclerView`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal">

    <LinearLayout
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:orientation="vertical">

        <TextView
            android:id="@+id/info"
```

## DRAG AND DROP

---

```
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_horizontal"
        android:layout_margin="8dp"
        android:padding="8dp"
        android:text="@string/label_video_info"
        android:textAppearance="?android:textAppearanceLarge"
        android:visibility="gone" />

<android.support.v7.widget.RecyclerView
    android:id="@+id/video_list"
    android:layout_width="match_parent"
    android:layout_height="match_parent" />
</LinearLayout>

<LinearLayout
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1"
    android:orientation="vertical">

    <FrameLayout
        android:id="@+id/video_frame"
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_marginBottom="4dp"
        android:layout_weight="1"
        android:padding="4dp">

        <VideoView
            android:id="@+id/player"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:layout_gravity="center" />
    </FrameLayout>

    <FrameLayout
        android:id="@+id/thumbnail_frame"
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="1"
        android:padding="4dp">

        <ImageView
            android:id="@+id/thumbnail_large"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:scaleType="centerInside" />
    </FrameLayout>
</LinearLayout>
```

---

## DRAG AND DROP

---

```
</FrameLayout>
</LinearLayout>
</LinearLayout>
```

(from [DragDrop/Action/app/src/main/res/layout-w800dp/main.xml](#))

However, this `TextView` has a visibility of gone at the outset, so it will not show up for users.

### Showing and Hiding the Action

`onCreate()` initializes an `info` field with the `TextView`, much as it initializes the fields for the `VideoView` and `ImageView`:

```
player=findViewById(R.id.player);

if (player!=null) {
    player.setOnDragListener(this);
}

thumbnailLarge=findViewById(R.id.thumbnail_large);

if (thumbnailLarge!=null) {
    thumbnailLarge.setOnDragListener(this);
}

info=findViewById(R.id.info);

if (info!=null) {
    info.setOnDragListener(this);
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

However, since `info` is gone, the user cannot drag anything over it. We need to arrange to make it visible.

You might try making it visible in `onDrag()`, when we get the `ACTION_DRAG_STARTED` event. After all, this would seem to describe what we want: when the drag begins, show the special drop target as an option for the user. Unfortunately, this does not work: while the user can see the `info` `TextView`, that `TextView` does not get any further `onDrag()` events.

Instead, we are forced to arrange to make the `info` view visible before starting the drag-and-drop operation. As a side effect, that requirement means that we cannot

## DRAG AND DROP

---

use this technique for cross-app drag-and-drop, since we have no idea when some other app starts the drag-and-drop operation.

In fact, it is even a bit awkward to handle in this app, as it is the RowController that initiates the drag-and-drop operation. The RowController knows nothing about the info view, nor should it. Instead, we need to have the RowController let the MainActivity know that a drag-and-drop operation is about to start, so the activity can show the view.

To that end, RowController defines an OnStartDragListener interface. It expects to get such a listener as a constructor parameter, storing it in a field for later use:

```
class RowController extends RecyclerView.ViewHolder
    implements View.OnClickListener, View.OnLongClickListener {
    interface OnStartDragListener {
        void onStartDrag();
    }

    final private TextView title;
    final private ImageView thumbnail;
    private Uri videoUri=null;
    private String videoMimeType=null;
    final private OnStartDragListener listener;

    RowController(View row, OnStartDragListener listener) {
        super(row);

        this.listener=listener;
        title=(TextView)row.findViewById(android.R.id.text1);
        thumbnail=(ImageView)row.findViewById(R.id.thumbnail);

        row.setOnClickListener(this);
        row.setOnLongClickListener(this);
    }
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/RowController.java](#))

Then, in onLongClick(), if we have a listener, we call onStartDrag() on it, to indicate that we are about to start a drag-and-drop operation:

```
@Override
public boolean onLongClick(View v) {
    if (listener!=null) {
        listener.onStartDrag();
    }
}
```

---

## DRAG AND DROP

---

```
ClipData clip=ClipData.newRawUri(title.getText(), videoUri);
View.DragShadowBuilder shadow=new View.DragShadowBuilder(thumbnail);

itemView.startDrag(clip, shadow, Boolean.TRUE, 0);

return(true);
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/RowController.java](#))

The RowController instances are created by the VideoAdapter. Fortunately, VideoAdapter is a nested class inside of MainActivity. So, we implement OnStartDragListener on MainActivity and pass the activity instance to the RowController constructor:

```
@Override
public RowController onCreateViewHolder(ViewGroup parent,
                                       int viewType) {
    return(new RowController(getLayoutInflater()
        .inflate(R.layout.row, parent, false), MainActivity.this));
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

All the onStartDrag() method does is make the info view visible:

```
public void onStartDrag() {
    info.setVisibility(View.VISIBLE);
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

If we make it visible, clearly we need to hide it again at some future point. That would be when the drag-and-drop operation has completed, and it is safe for us to mark info as GONE in our handling of ACTION\_DRAG\_ENDED in onDrag():

```
case DragEvent.ACTION_DRAG_ENDED:
    applyDropHint(v, -1);
    info.setVisibility(View.GONE);
    break;
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

## Handling Drag Events

We still want to show the drop hint backgrounds, but in this case, we apply them

## DRAG AND DROP

---

directly to the TextView, rather than going with a wrapping FrameLayout. So, we adjust `applyDropHint()` to only work with the parent of the view if this is not the info view:

```
private void applyDropHint(View v, int drawableId) {
    if (v!=info) {
        v=(View)v.getParent();
    }

    if (drawableId>-1) {
        v.setBackgroundResource(drawableId);
    }
    else {
        v.setBackground(null);
    }
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

And, in `ACTION_DROP` processing, if the user dropped the content over the info view, we simply show a Toast with the text of the `Uri`:

```
case DragEvent.ACTION_DROP:
    ClipData.Item clip=event.getClipData().getItemAt(0);
    Uri videoUri=clip.getUri();

    if (v==player) {
        player.setVideoURI(videoUri);
        player.start();
    }
    else if (v==info) {
        Toast
            .makeText(this, videoUri.toString(), Toast.LENGTH_SHORT)
            .show();
    }
    else {
        Picasso.with(thumbnailLarge.getContext())
            .load(videoUri.toString())
            .fit().centerCrop()
            .placeholder(R.drawable.ic_media_video_poster)
            .into(thumbnailLarge);
    }
}
```

(from [DragDrop/Action/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

### The Result

Now, when you run the app on a sufficiently-wide screen, and you start a drag-and-drop operation, the “Video Info” TextView appears and serves as a drop target:

### Nested Drop Targets

You may have a need for nested drop targets, where you are listening for drag events both on some container and on some view inside of that container. For example, if you are using the drag-and-drop APIs to support reordering items in a `LinearLayout` or `RecyclerView`, there is a good chance that you will need to have listeners both on that container and on existing items in the container (e.g., to animate them out of the way to allow the user to drop in the newly-vacant spot).

Alas, this is an area that has some undocumented behavior changes in Android 7.0, as Dan Lew uncovered in August 2016.

The [DragDrop/Nougat](#) sample project illustrates the old and new behavior, plus some code to get Android 7.0 to behave more like the older versions of Android.

## DRAG AND DROP

---

The behavior change is triggered by nested drop targets, which means we need a nested layout, such as this one:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout android:id="@+id/outer_container"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:background="@color/outer_normal"
  android:padding="48dp">

  <FrameLayout
    android:id="@+id/inner_container"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@color/inner_normal"
    android:padding="48dp">

    <ImageView
      android:id="@+id/thumbnail_large"
      android:layout_width="match_parent"
      android:layout_height="match_parent"
      android:background="@color/image_normal"
      android:contentDescription="@string/icon"
      android:scaleType="centerInside" />
    </FrameLayout>
  </FrameLayout>
</FrameLayout>
```

(from [DragDrop/Nougat/app/src/main/res/layout/bug.xml](#))

## DRAG AND DROP

---

Here, we have a `FrameLayout` holding onto another `FrameLayout`, which holds onto an `ImageView`, each with a different background color:

*Figure 683: Garish Background Colors*

Further, suppose that we are interested in drag events for all three of these, so we call `setOnDragListener()` for each of them. In the code, we set the background of a drop target to green when we get an `ACTION_DRAG_ENTERED` event for the target, and we revert to the original background in `ACTION_DRAG_EXITED`, `ACTION_DRAG_ENDED`, and `ACTION_DROP`.

### The Behavior Prior to Android 7.0

On Android 6.0 and earlier, drag events are inclusive. In other words, if the user has dragged an item into the inner `FrameLayout`, this is *also* considered to be inside the outer `FrameLayout`. From an event standpoint, the outer `FrameLayout` only gets an `ACTION_DRAG_EXITED` event when the dragged item leaves its outer boundaries.

## DRAG AND DROP

---

So, as the user drags an item into our nested drop targets, outer targets remain green, even as the item enters inner targets:

*Figure 684: Dragging Over Outer Drop Target on Android 6.0*

## DRAG AND DROP

*Figure 685: Dragging Over Inner Drop Target on Android 6.0*

*Figure 686: Dragging Over ImageView Drop Target on Android 6.0*

## Android 7.0 Behavior

However, on Android 7.0, drag events are exclusive. If the user drags an item into the inner FrameLayout, the item will *exit* the outer FrameLayout from a drag-and-drop perspective. So, as the user drags the item towards the inner-most drop target, the user exits the outer drop targets, and we restore the backgrounds along the way:

*Figure 687: Dragging Over Outer Drop Target on Android 7.0*

## DRAG AND DROP

Figure 688: Dragging Over Inner Drop Target on Android 7.0

Figure 689: Dragging Over ImageView Drop Target on Android 7.0

## Getting Inclusive on Android 7.0

Which approach is “correct” is somewhat immaterial, as we need consistency across Android OS versions.

The sample app offers one workaround for the discrepancy: a `DropTarget` class that provides inclusive behavior on Android 7.0. Basically, it serves as a composite `OnDragListener`, forwarding `onDrag()` calls to widgets as appropriate. This includes forwarding events to parents of widgets, if those parents are part of the `DropTarget` coverage:

```
package com.commonware.android.dragdrop;

import android.os.Build;
import android.view.DragEvent;
import android.view.View;
import android.view.ViewParent;
import java.util.ArrayList;

public class DropTarget implements View.OnDragListener {
    private ArrayList<View> views=new ArrayList<>();
    private View.OnDragListener listener;

    public DropTarget on(View... views) {
        for (View v : views) {
            this.views.add(v);
            v.setOnDragListener(this);
        }

        return(this);
    }

    public void to(View.OnDragListener listener) {
        this.listener=listener;
    }

    @Override
    public boolean onDrag(View view, DragEvent dragEvent) {
        if (Build.VERSION.SDK_INT<Build.VERSION_CODES.N) {
            return(listener.onDrag(view, dragEvent));
        }

        boolean result=listener.onDrag(view, dragEvent);
        ViewParent parent=view.getParent();

        while (parent!=null && parent instanceof View) {
```

## DRAG AND DROP

---

```
View parentView=(View)parent;

if (views.contains(parentView)) {
    listener.onDrag(parentView, dragEvent);
}

parent=parentView.getParent();
}

return(result);
}
}
```

(from [DragDrop/Nougat/app/src/main/java/com/commonsware/android/dragdrop/DropTarget.java](#))

For each of the views that DropTarget is set to monitor, the DropTarget sets itself up as the OnDragListener. In onDrag(), if we are on a pre-7.0 version of Android, DropTarget just forwards the event along normally. If, however, we are on Android 7.0 or higher, onDrag():

- Calls onDrag() for the listener attached to the DropTarget, using the View originally passed into onDrag(), and holding onto the result boolean
- Walks the chain of parents, calling onDrag() on the listener for each of those that are part of our monitored set of views
- Returns the value from the original (inner-most) onDrag() call on the listener

Then, instead of registering the activity as the OnDragListener like this:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    image=(ImageView)findViewById(R.id.thumbnail_large);
    image.setOnDragListener(this);
    findViewById(R.id.outer_container).setOnDragListener(this);
    findViewById(R.id.inner_container).setOnDragListener(this);
}
```

(from [DragDrop/Nougat/app/src/main/java/com/commonsware/android/dragdrop/BugActivity.java](#))

we can use DropTarget:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);
```

---

## DRAG AND DROP

---

```
image=(ImageView)findViewById(R.id.thumbnail_large);

new DropTarget()
    .on(image,
        findViewById(R.id.outer_container),
        findViewById(R.id.inner_container))
    .to(this);
}
```

(from [DragDrop/Nougat/app/src/main/java/com/commonsware/android/dragdrop/InclusiveActivity.java](#))

The result is more inclusive behavior. In the case of this sample app, it happens to be sufficient to allow Android 7.0 to behave as does Android 6.0 and earlier. More sophisticated drag-and-drop implementations may need a more sophisticated approach than `DropTarget` to achieve a similar workaround.

### The State of the Bugs

Both bugs filed by Dan Lew have been marked as “FutureRelease”, with a comment on one indicating that the new exclusive behavior would be restricted to apps with a `targetSdkVersion` of 24 or higher. It is unclear exactly when this change will be released. And, since many apps will have a `targetSdkVersion` of 24 or higher to avoid warning messages in Android 7.0+ multi-window, the proposed fixes may not help much.

### Pondering Standards

Framework-supplied drag-and-drop has not been all that popular to date. As a result, there are no common conventions for how to designate drop targets for the user. Similarly, as of mid-2016, there appears to be no recommendations for this in the Material Design guidelines from Google.

Eventually, the Android development community will start to coalesce around certain patterns, with or without Google’s assistance. Experiment now, but watch for conventions to emerge, then adopt those conventions, where they make sense for your app.

### Pondering Accessibility

Drag-and-drop is not particularly accessible. Visually-impaired users may have

## DRAG AND DROP

---

difficulty discerning where one can drag from and where one can drag to. Motor-impaired users may have difficulty doing the gesture to initiate drag-and-drop or in dragging the shadow to the desired location.

As a result, while drag-and-drop is a worthy feature, ensure that it is not the *only* option for performing some action. There should be some other way to do that action, and perhaps more than one other way to do that action, such as:

- Keyboard shortcuts
- Copy-and-paste, perhaps using action modes
- Direct manipulation (e.g., use drag-and-drop on overview screens with lists, plus offer an action bar item or other affordances on detail screens to perform the same action)

# Keyboard and Mouse Input

---

More and more Android users are starting to use external keyboards and mice with their devices. Sometimes, the device is designed for such use, such as [the Jide Remix Mini](#) or all-on-one units like [the HP Slate 21](#). Some people use Android devices designed for use with a TV as quasi-desktops. And, starting in 2016, we have Android available on some Chrome OS devices, most of which rely on keyboard and mouse/trackpad input.

Over time, more and more Android users are going to be expecting Android apps to behave like desktop apps with respect to keyboards and mice. Some of this capability will be built into Android. Some of this capability will need to be handled by apps or libraries.

In this chapter, we will explore various techniques for making your Android app more friendly to keyboards and mice.

## Prerequisites

Understanding this chapter requires that you have read the core chapters. Many of the examples use RecyclerView, so you may wish to review [that chapter](#) if you have not used RecyclerView very much. Also, some of the examples are based on drag-and-drop samples covered [elsewhere in the book](#).

## Offering Keyboard Shortcuts

One thing that users will expect from desktop-style apps is the ability to use keyboard shortcuts. Basic keyboard navigation comes “for free” for a lot of Android use cases, though in some situations you will need to add in your own keyboard

smarts, such as for [navigating a RecyclerView](#). And some keyboard shortcuts will come automatically, such as `Ctrl-C` and `Ctrl-V` for copy and paste within an `EditText`.

Anything beyond that, though, you would have to provide yourself.

### Action Bar Item Shortcuts

The simplest way to add keyboard shortcuts is to use `android:alphabeticShortcut` or `android:numericShortcut` on your `<item>` elements in a `<menu>` resource that you use to populate an action bar. Android will automatically support those in concert with the `Ctrl` key. So, for example, if you had:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/play_video"
    android:alphabeticShortcut="p"
    android:icon="@drawable/ic_movie_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_video" />
  <item
    android:id="@+id/show_thumbnail"
    android:alphabeticShortcut="t"
    android:icon="@drawable/ic_insert_photo_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_thumbnail" />
</menu>
```

(from [KBMouse/HotkeysN/app/src/main/res/menu/actions.xml](#))

then your `onOptionsItemSelected()` method would be called not only if the user taps on the action bar items on-screen, but also if the user pressed `Ctrl-P` or `Ctrl-T` on the keyboard.

As the names suggest, `android:alphabeticShortcut` takes a letter and `android:numericShortcut` takes a number. However, try to avoid overriding existing shortcuts with unrelated logic. For example, you might consider using `android:alphabeticShortcut="v"` for a “play video” action, but that would conflict with the `Ctrl-V` shortcut used for paste. You would be better off going with `android:alphabeticShortcut="p"` to avoid the conflict.

In Android 8.0+, in Java, we can call variations on `setAlphabeticShortcut()`,

`setNumericShortcut()`, and `setShortcuts()` that allow us to change the modifier keys from the default. There are equivalent `android:alphabeticModifiers` and `android:numericModifiers` attributes for `<item>` elements in a menu resource, to indicate the modifier keys to be used with alphabetic and numeric shortcuts.

### Arbitrary Hotkeys

You may find that the action bar approach is insufficient:

- It may not make sense to have action bar items for the particular operations that you want to offer keyboard shortcuts for
- You may want to support key combinations other than `Ctrl` and a letter or number

You are welcome to make anything be a keyboard shortcut or “hotkey”, by overriding the appropriate `KeyEvent` methods in an `Activity` or `View`.

The [KBMouse/Hotkeys](#) sample project is a clone of the `DragDrop/Simple` sample app from [the chapter on supporting drag-and-drop](#). As with the original app, we show a list of available videos on the device, which the user can play or view a larger thumbnail from the video. However, in addition to drag-and-drop as a way of doing those things, this sample app also supports keyboard shortcuts:

- `Alt-Right` to play the video
- `Ctrl-Right` to view the large thumbnail

However, these keyboard shortcuts imply that the user has chosen a video to play. So, this sample app blends in the keyboard-enabled `RecyclerView` code from [the corresponding section in the RecyclerView chapter](#). So, as the user presses the `Down` and `Up` arrow keys, the chosen row is highlighted. That will be the video that we work with, if the user then goes and presses `Alt-Right` or `Ctrl-Right`.

This means that we need our `play-the-video` and `show-the-large-thumbnail` code to be accessible from multiple entry points, so we pull those out into dedicated `playVideo()` and `showLargeThumbnail()` methods that take the video `Uri` as input:

```
private void playVideo(Uri videoUri) {
    player.setVideoURI(videoUri);
    player.start();
}
```

## KEYBOARD AND MOUSE INPUT

---

```
private void showLargeThumbnail(Uri videoUri) {
    Picasso.with(thumbnailLarge.getContext())
        .load(videoUri.toString())
        .fit().centerCrop()
        .placeholder(R.drawable.ic_media_video_poster)
        .into(thumbnailLarge);
}
```

(from [KBMouse/Hotkeys/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

We then use those from the ACTION\_DROP processing, for when the user drops the video into either the VideoView (referenced in the player field) or the ImageView:

```
case DragEvent.ACTION_DROP:
    ClipData.Item clip=event.getClipData().getItemAt(0);
    Uri videoUri=clip.getUri();

    if (v==player) {
        playVideo(videoUri);
    }
    else {
        showLargeThumbnail(videoUri);
    }

    break;
```

(from [KBMouse/Hotkeys/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

Handling the keyboard shortcuts is relatively straightforward, courtesy of the onKeyDown() callback that we override:

```
@Override
public boolean onKeyDown(int keyCode, KeyEvent event) {
    if (keyCode==KeyEvent.KEYCODE_DPAD_RIGHT && event.getRepeatCount()==0) {
        int position=adapter.getCheckedPosition();

        if (position>=0) {
            Uri videoUri=adapter.getVideoUri(position);

            if (event.isAltPressed()) {
                playVideo(videoUri);
            }
            else if (event.isCtrlPressed()) {
                showLargeThumbnail(videoUri);
            }
        }
    }
}
```

```
        return(true);
    }
}

return(super.onKeyDown(keyCode, event));
}
```

(from [KBMouse/Hotkeys/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

We are passed an `int` keycode (`keyCode`) and the full `KeyEvent` for whatever key that the user pressed. If the main key was `Right` (identified as `KEYCODE_DPAD_RIGHT` for historical reasons, and to support D-pad directional navigation options), we find out which row in the `RecyclerView` is checked, if any. If we have a checked row, we find out what the `Uri` is of the video, then call `isAltPressed()` and `isCtrlPressed()` on the `KeyEvent` to find out which modifier key was pressed in conjunction with `Right`, if any. If we have a match, we call the associated `playVideo()` or `showLargeThumbnail()` method.

`onKeyDown()` tends to model user expectations, in that the user expects the event to occur when the key is pressed. However, if the user continues holding down the key, we will get a stream of `onKeyDown()` calls. That is why we also check `getRepeatCount()`, to ignore the repeated keypresses, so we only try playing the video or showing the large thumbnail once if the user holds down `Alt-Right` or `Ctrl-Right`.

### Android 7.0 Keyboard Shortcuts Helper

The next challenge is letting the user know what keyboard shortcuts are available. Historically, our primary option would be to hope that the user reads the app's documentation.

(you can stop laughing now)

Android 7.0 recognizes this and provides a system-wide keyboard shortcuts helper. The user can invoke this using one keyboard shortcut that (hopefully) the user will remember: `Meta-/`. On a Windows-centric keyboard, the Meta key is the one with the Windows logo on it.

On pre-N devices, you could offer your own keyboard shortcut mapped to `Alt-/` and pop up your own keyboard shortcut dialog. Since `/` is neither a letter or a number, and since having a keyboard shortcut action bar item might not make

## KEYBOARD AND MOUSE INPUT

---

sense, you would do this using the `onKeyDown()` technique profiled in the previous section.

In the [KBMouse/HotkeysN](#) sample project, we will see how to:

- Add our own information to the keyboard shortcuts helper
- Show our own keyboard shortcuts helper on pre-N devices
- Use action bar item alphabetic shortcuts

Mostly, the project is a clone of the hotkey sample shown above, with the `build.gradle` file updated to build for Android 7.0:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.android.support:support-fragment:27.1.1'
    implementation 'com.android.support:recyclerview-v7:27.1.1'
    implementation 'com.squareup.picasso:picasso:2.5.2'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        applicationId "com.commonsware.android.kbmouse.hotkeys.n"
        minSdkVersion 23
        targetSdkVersion 27
    }
}
```

(from [KBMouse/HotkeysN/app/build.gradle](#))

We have a menu resource now for our action bar, which happens to be the one shown towards the start of this chapter:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/play_video"
        android:alphabeticShortcut="p"
        android:icon="@drawable/ic_movie_white_24dp"
        android:showAsAction="always"
        android:title="@string/menu_video" />
    <item
        android:id="@+id/show_thumbnail"
```

## KEYBOARD AND MOUSE INPUT

---

```
    android:alphabeticShortcut="t"
    android:icon="@drawable/ic_insert_photo_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_thumbnail" />
</menu>
```

(from [KBMouse/HotkeysN/app/src/main/res/menu/actions.xml](#))

We inflate that menu resource in `onCreateOptionsMenu()` using the typical recipe:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);

    return(super.onCreateOptionsMenu(menu));
}
```

(from [KBMouse/HotkeysN/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

In `onOptionsItemSelected()`, we need to confirm that the user has selected a row in the `RecyclerView` using the keyboard. If that is the case, we can play the video or show the thumbnail, depending upon which action bar item the user used. Otherwise, we show a `Toast` to point out the problem:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    int position=adapter.getCheckedPosition();

    if (item.getItemId()==R.id.play_video) {
        if (position>=0) {
            playVideo(adapter.getVideoUri(position));
        }
        else {
            Toast.makeText(this, R.string.msg_choose,
                Toast.LENGTH_LONG).show();
        }

        return(true);
    }
    else if (item.getItemId()==R.id.show_thumbnail) {
        if (position>=0) {
            showLargeThumbnail(adapter.getVideoUri(position));
        }
        else {
            Toast.makeText(this, R.string.msg_choose,
                Toast.LENGTH_LONG).show();
        }
    }
}
```

## KEYBOARD AND MOUSE INPUT

---

```
        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [KBMouse/HotkeysN/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

Alternatively, you might elect to disable or hide those action bar items until the user selects a row with the keyboard.

We do not need to do anything special in our code to handle the alphabetic shortcuts — those are applied by Android automatically, routing to the same `onOptionsItemSelected()`. In other words, whether the user chooses the action bar item via a keyboard, mouse, or touchscreen, our same code runs.

The user will find out about those shortcuts through a keyboard shortcuts helper. On Android 7.0 and higher, the system will provide one for us. Note that this helper is implemented as a system-supplied dialog-themed activity. As such, our activity is paused (as we no longer get input) but not stopped (as the helper dialog is not full-screen).

We do not need to do anything special in our code to enable the keyboard shortcuts helper on Android 7.0. However, that helper only knows about our action bar item alphabetic shortcuts, plus system-wide shortcuts. It does not know anything about the `Alt-Right` and `Ctrl-Right` shortcuts that we are handling ourselves. However, we can override `onProvideKeyboardShortcuts()` in our activity to add information to this dialog about our custom shortcuts:

```
@TargetApi(Build.VERSION_CODES.N)
@Override
public void onProvideKeyboardShortcuts(
    List<KeyboardShortcutGroup> data, Menu menu, int deviceId) {
    super.onProvideKeyboardShortcuts(data, menu, deviceId);

    List<KeyboardShortcutInfo> shortcuts=new ArrayList<>();
    String caption=getString(R.string.menu_video);

    shortcuts.add(new KeyboardShortcutInfo(caption,
        KeyEvent.KEYCODE_DPAD_RIGHT, KeyEvent.META_ALT_ON));

    caption=getString(R.string.menu_thumbnail);
    shortcuts.add(new KeyboardShortcutInfo(caption,
```

## KEYBOARD AND MOUSE INPUT

```
KeyEvent.KEYCODE_DPAD_RIGHT, KeyEvent.META_CTRL_ON));
data.add(new KeyboardShortcutGroup(getString(R.string.msg_custom),
shortcuts));
}
```

(from [KBMouse/HotkeysN/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

This is not especially well documented at this point. What seems to work is:

- Create a new List of KeyboardShortcutInfo objects
- Add one of those for each custom shortcut, via the KeyboardShortcutInfo constructor, where you provide a description, the primary key, and the modifier (e.g., META\_ALT\_ON) for the shortcut
- Wrap the List of KeyboardShortcutInfo objects in a KeyboardShortcutGroup, with your own caption for the group
- Add that KeyboardShortcutGroup to the passed-in List

This gives us:

Figure 690: Android 7.0 Keyboard Shortcuts Helper, With Custom Info

The alphabetic shortcuts from the menu appear in a group whose name matches our activity's label. That is followed by our "Custom App Hotkeys" group. Ideally, these

## KEYBOARD AND MOUSE INPUT

---

two groups would be merged, since both lists are fairly short and both pertain to this app. While we might be able to retrieve the existing group from the supplied list of `KeyboardShortcutGroup` objects and modify it, since that is not documented, that is not safe.

This shortcut helper dialog is only available on Android 7.0. For consistency, it might be nice to offer a similar helper on older devices. To do that, we need to find out when the user presses `Meta-/` on those older devices, which we handle in `onKeyDown()`:

```
@Override
public boolean onKeyDown(int keyCode, KeyEvent event) {
    if (event.getRepeatCount()==0) {
        if (keyCode==KeyEvent.KEYCODE_DPAD_RIGHT) {
            int position=adapter.getCheckedPosition();

            if (position>=0) {
                Uri videoUri=adapter.getVideoUri(position);

                if (event.isAltPressed()) {
                    playVideo(videoUri);
                }
                else if (event.isCtrlPressed()) {
                    showLargeThumbnail(videoUri);
                }

                return(true);
            }
        }
        else if (keyCode==KeyEvent.KEYCODE_SLASH &&
            event.isMetaPressed() &&
            Build.VERSION.SDK_INT<Build.VERSION_CODES.N) {
            new ShortcutDialogFragment().show(getSupportFragmentManager(),
                "shortcuts");

            return(true);
        }
    }
    return(super.onKeyDown(keyCode, event));
}
```

(from [KBMouse/HotkeysN/app/src/main/java/com/commonware/android/kbmouse/hotkeys/MainActivity.java](#))

On those devices, we show a `ShortcutDialogFragment`, which just displays an `AlertDialog` with some simple text about our shortcuts:

## KEYBOARD AND MOUSE INPUT

---

```
package com.commonware.android.kbmouse.hotkeys;

import android.annotation.TargetApi;
import android.app.AlertDialog;
import android.app.Dialog;
import android.os.Build;
import android.os.Bundle;
import android.support.v4.app.DialogFragment;

@TargetApi(Build.VERSION_CODES.HONEYCOMB)
public class ShortcutDialogFragment extends DialogFragment {
    @Override
    public Dialog onCreateDialog(Bundle savedInstanceState) {
        AlertDialog.Builder builder=new AlertDialog.Builder(getActivity());
        Dialog dlg=builder
            .setTitle(R.string.title_shortcuts)
            .setMessage(R.string.msg_shortcuts)
            .setPositiveButton(android.R.string.ok, null)
            .create();

        return(dlg);
    }
}
```

(from [KBMouse/HotkeysN/app/src/main/java/com/commonware/android/kbmouse/hotkeys/ShortcutDialogFragment.java](https://github.com/Commonware/android.kbmouse.hotkeys/blob/master/src/main/java/com/commonware/android/kbmouse/hotkeys/ShortcutDialogFragment.java))

Not every device will have a **Meta** key — the Pixel C’s keyboard dock, for example, lacks this key. However, we have no good way of determining if a given hardware keyboard has a **Meta** key. Our options would be:

- To offer keyboard shortcuts help using a different key combination, even if that is non-standard with respect to Android 7.0
- Ignore the problem, not offering keyboard shortcuts help on such devices, until such time as there is an official solution

## Custom Copy-and-Paste

Since the alphabetic shortcuts for action bar items are triggered via the **Ctrl** key, one can have action bar items for **Ctrl-C** and **Ctrl-V**, offering custom copy and paste shortcuts for your activity. This is particularly important for accessibility, when your app is reliant upon something else to get content from one point to another. For example, custom copy and paste options could be used as alternatives to [drag and drop](#), including Android 7.0’s cross-app drag-and-drop.

## KEYBOARD AND MOUSE INPUT

---

The [KBMouse/CopyPaste](#) sample project is a clone of [the cross-app drag-and-drop sample](#), with two app modules: drag/ and drop/. This time, though, we are also going to allow the photo to be copied to the clipboard in drag/ and pasted from the clipboard in drop/, as a more accessible alternative. As a side benefit, this will work even on single-window environments, whereas cross-app drag-and-drop assumes that both apps are visible at the same time.

The drag/ app has a menu resource that contains our copy item, with `android:alphabeticShortcut` set to `c`:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/copy"
    android:alphabeticShortcut="c"
    android:icon="@drawable/ic_content_copy_white_24dp"
    android:showAsAction="ifRoom"
    android:title="@android:string/copy" />
</menu>
```

(from [KBMouse/CopyPaste/drag/src/main/res/menu/actions.xml](#))

We load that resource in `onCreateOptionsMenu()` as normal. In `onOptionsItemSelected()`, we implement the copy by getting the `ClipboardManager` system service and calling `setPrimaryClip()` to populate the clipboard:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.copy) {
        getSystemService(ClipboardManager.class)
            .setPrimaryClip(buildClip());
        Toast
            .makeText(this, R.string.msg_copy, Toast.LENGTH_SHORT)
            .show();

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [KBMouse/CopyPaste/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

Note that we use the API Level 23+ edition of `getSystemService()`, the one that takes the Java class object for the system service as a parameter (instead of a service

## KEYBOARD AND MOUSE INPUT

---

name) and returns to us the system service already in the proper data type.

What we put on the clipboard is the result of `buildClip()`, which creates a `ClipData` around a `Uri` to the photo that we are publishing from this app:

```
private ClipData buildClip() {
    Uri uri=PROVIDER
        .buildUpon()
        .appendEncodedPath(StreamProvider.getUriPrefix(AUTHORITY))
        .appendEncodedPath("assets/FreedomTower-Morning.jpg")
        .build();

    return(ClipData.newRawUri(getString(R.string.msg_photo), uri));
}
```

(from [KBMouse/CopyPaste/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

We happen to be [using `StreamProvider`](#) to serve the photo straight from assets, and so we are building up a `Uri` pointing to that asset.

The drop/ app also has a menu resource, this one set up for a paste action tied to

 :

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/paste"
        android:alphabeticShortcut="v"
        android:icon="@drawable/ic_content_paste_white_24dp"
        android:showAsAction="ifRoom"
        android:title="@android:string/paste" />
</menu>
```

(from [KBMouse/CopyPaste/drop/src/main/res/menu/actions.xml](#))

And here, `onOptionsItemSelected()` handles the paste request by getting the `Uri` off the clipboard and using that, in much the same way that we use the `Uri` dropped on our UI:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.paste) {
        boolean handled=false;

        ClipData clip=
            getSystemService(ClipboardManager.class)
```

## KEYBOARD AND MOUSE INPUT

---

```
        .getPrimaryClip();

    if (clip!=null) {
        ClipData.Item clipItem=clip.getItemAt(0);

        if (clipItem!=null) {
            imageUri=clipItem.getUri();

            if (imageUri!=null) {
                showThumbnail();
                handled=true;
            }
        }
    }

    if (!handled) {
        Toast
            .makeText(this, "Could not paste an image!", Toast.LENGTH_LONG)
            .show();
    }

    return(handled);
}

return(super.onOptionsItemSelected(item));
}
```

(from [KBMouse/CopyPaste/drop/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

Note that we do not do any MIME type checking to see if the `Uri` points to an image that we can use. We are relying on Picasso to show an error image if it is unable to use the `Uri`, as part of the `showThumbnail()` processing:

```
private void showThumbnail() {
    Picasso.with(this)
        .load(imageUri)
        .fit().centerCrop()
        .placeholder(R.drawable.ic_photo_size_select_actual_black_24dp)
        .error(R.drawable.ic_error_black_24dp)
        .into(image);
}
```

(from [KBMouse/CopyPaste/drop/src/main/java/com/commonsware/android/dragdrop/MainActivity.java](#))

A more sophisticated app might check to see if the MIME type associated with the `Uri` made sense, using either `ContentResolver` or `DocumentFile`. That way, we could offer a custom error message if the user attempted to copy something else.

However, we *do* have crude logic to handle:

- an empty clipboard
- a `ClipData` with no items
- a `ClipData` without a `Uri` (e.g., plain text copied to the clipboard)

## Physical Keyboards and Focusing

In [an article complaining about Android's tablet support](#), Ars Technica's Ron Amodeo pointed out an interesting problem for devices with physical keyboards: setting the focus properly when an activity starts up. This can be addressed in a number of ways; this section shows how you can use [a custom `BindingAdapter` and the data binding framework](#) to help manage this problem.

### The Problem

Suppose that you have a form that has a mix of widgets in it, including one or more `EditText` widgets. In particular, suppose that one of the `EditText` widgets is near the beginning of the activity's layout.

If you allow that widget to get the focus when the activity starts up, and the device does not have a physical keyboard, the input method editor (IME, a.k.a., "soft keyboard") appears immediately. This can be annoying to users, as perhaps they do not want to type anything into that `EditText`. Depending on the orientation of the phone and other settings, either the IME ties up a bunch of screen space that could be used for other things, or the user cannot see anything other than the full-screen landscape IME.

To save the user having to keep dismissing the IME, you might elect to give some other widget the focus at the outset.

However, for devices *with* a physical keyboard, no IME will appear. And, for users who *do* want to start typing right away, having the focus lie elsewhere is aggravating.

It would be cool if Android offered a `android:requestFocus` attribute that took a few possible values:

- `true`, meaning this widget always got the focus (replacing the `[requestFocus/]` child element used for this today)
- `false`, the default

## KEYBOARD AND MOUSE INPUT

---

- `ifHardKeyboard`, meaning this widget should get the focus for devices with a physical keyboard
- `ifNoHardKeyboard`, meaning this widget should get the focus for devices without a physical keyboard

Layouts might then use `android:requestFocus` on two widgets, one with `ifHardKeyboard` and one with `ifNoHardKeyboard`, to designate which widget should get the focus in either case.

Alas, this attribute does not exist. However, with a bit of work, and the assistance of [the data binding framework](#), we can implement something fairly close to it, as is demonstrated in the [DataBinding/Focus](#) sample project.

### A requestFocus BindingAdapter

To invent new View attributes, like the proposed `requestFocus` attribute, we need a `BindingAdapter`. The `@BindingAdapter` annotation can be applied to a static method that takes a `View` (or some subclass, if it only applies to certain view types) and a parameter indicating what sort of attribute value it expects. Then, it is up to the method to actually update the `View` as needed.

So, the `RequestFocusActivity` that demonstrates this feature has a `bindRequestFocus() @BindingAdapter` method:

```
@BindingAdapter("app:requestFocus")
public static void bindRequestFocus(View v, String focusMode) {
    Configuration cfg=v.getResources().getConfiguration();
    boolean hasNoKeyboard=
        cfg.keyboard==Configuration.KEYBOARD_NOKEYS;
    boolean keyboardHidden=
        cfg.hardKeyboardHidden==Configuration.HARDKEYBOARDHIDDEN_YES;
    boolean result=false;

    if (TRUE.equals(focusMode)) {
        result=true;
    }
    else if (IF_HARD_KEYBOARD.equals(focusMode)) {
        if (!hasNoKeyboard && !keyboardHidden) {
            result=true;
        }
    }
    else if (IF_NO_HARD_KEYBOARD.equals(focusMode)) {
        if (hasNoKeyboard || keyboardHidden) {
            result=true;
            if (hasNoKeyboard) v.setFocusableInTouchMode(true);
        }
    }
    else {
        throw new IllegalArgumentException("Unexpected focusMode value: "+focusMode);
    }
}
```

## KEYBOARD AND MOUSE INPUT

---

```
}  
  
if (result) {  
    v.setFocusable(true);  
    v.requestFocus();  
}  
}
```

(from [DataBinding/Focus/app/src/main/java/com/commonsware/android/focusbinding/RequestFocusActivity.java](#))

Unfortunately, there is no obvious way to constrain a `BindingAdapter` to some custom enumerated roster of values. So, we have `bindRequestFocus()` accept a `String`, and we throw an `IllegalArgumentException` if the attribute value is not `true`, if the attribute is not one of three recognized values:

```
private static final String TRUE="true";  
private static final String IF_HARD_KEYBOARD="ifHardKeyboard";  
private static final String IF_NO_HARD_KEYBOARD="ifNoHardKeyboard";
```

(from [DataBinding/Focus/app/src/main/java/com/commonsware/android/focusbinding/RequestFocusActivity.java](#))

(`false` is skipped as a potential value, but you could easily extend this to accept and ignore that value)

The key portion of this method is determining whether or not the user has access to a physical keyboard. This has two components:

1. Does the device have a physical keyboard?
2. Is the physical keyboard presently available?

The latter might be “no” for devices with a sliding keyboard, where the keyboard exists but is not presently exposed.

Using a `Configuration` object, we set up `hasNoKeyboard` and `keyboardHidden` boolean values for those two components. Then, we will call `setFocusable(true)` and `requestFocus()` on the `View` if:

- the attribute value is `true`, or
- the attribute value is `ifHardKeyboard` *and* the device has a physical keyboard *and* the keyboard is not hidden, or
- the attribute value is `ifNoHardKeyboard` *and* either the device lacks a physical keyboard or the physical keyboard is hidden

We also call `setFocusableInTouchMode(true)` if the device has no physical keyboard, to ensure that the widget in question can be focused in touch mode

before we try setting its focus.

### Using the BindingAdapter

The syntax for our attributes is a bit different than what we aimed for:

- We use the app prefix rather than android
- The value has to be a binding expression, otherwise the data binding framework ignores it, so we cannot just use a simple string, but instead have to wrap it in an expression (e.g., `@{"ifNoHardKeyboard"}`)

But, we can use `app:requestFocus` as needed, such as in this layout:

```
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="match_parent">

        <Button
            android:id="@+id/button1"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/a_button"
            app:requestFocus="@{"ifNoHardKeyboard"}" />

        <EditText
            android:id="@+id/editText1"
            android:layout_width="0dp"
            android:layout_height="wrap_content"
            android:layout_weight="1"
            android:hint="@string/str_1st_field"
            android:inputType="text"
            app:requestFocus="@{"ifHardKeyboard"}" />

        <EditText
            android:id="@+id/editText2"
            android:layout_width="0dp"
            android:layout_height="wrap_content"
            android:layout_weight="1"
            android:hint="@string/str_2nd_field"
            android:inputType="text" />

    </LinearLayout>
```

```
</layout>
```

(from [DataBinding/Focus/app/src/main/res/layout/request\\_focus.xml](#))

Here, if the device has an available physical keyboard, we put the focus on the first `EditText` widget, so that the user can start typing right away. But, if the device lacks an available physical keyboard, we put the focus on the `Button`, to avoid the IME appearing right away.

## Offering Mouse Context Menus

One thing that users of mice and trackpads are used to having are context menus, typically displayed as the result of a right-mouse click. More specifically, they are used to a popup menu appearing adjacent to the mouse pointer when they click the right-mouse button.

Android has had its own context menu system since API Level 1. However, it does not look a lot like what desktop users are used to. We can create such a menu ourselves, but it takes a little work, due to bugs and limitations in Android.

Ideally, we would use `PopupMenu`. This does pretty much what the class name implies: displays a popup window containing a menu, driven by a menu resource. However, that popup window will appear to drop down from some anchor `View` that we specify, and there is no way in the public API to adjust its position to be closer to the mouse pointer. Hence, for larger widgets — such as rows in a `ListView` or `RecyclerView` — `PopupMenu` will result in a menu that can appear fairly far away from the mouse pointer, which will be aggravating.

`PopupWindow` and `ListPopupWindow` both allow for fine-grained positioning, which make them better candidates for our purposes. Of the two, `ListPopupWindow` handles the notion of a scrolling list, which may be useful for longer menus. And, we can populate its contents from a simple `ListAdapter`, like an `ArrayAdapter`. The [KBMouse/Context](#) sample project is a clone of the `KBMouse/Hotkeys` sample app that adds in a `ListPopupWindow` for a mouse-driven context menu... but it takes a bit of work.

First, we need to define what goes in the list of the `ListPopupWindow`. A simple solution for that is to use a string-array resource:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <string-array name="popup">
```

## KEYBOARD AND MOUSE INPUT

---

```
<item>@string/menu_video</item>
<item>@string/menu_thumbnail</item>
</string-array>
</resources>
```

(from [KBMouse/Context/app/src/main/res/values/arrays.xml](#))

Here, the two items are references to string resources, for internationalization purposes (in theory, at least).

All of our business logic for adding the context menu lies in the `RowController` — just as it handles clicks (to play the video in a standalone player) and long-clicks (to initiate a drag-and-drop), it can now handle context menus.

First, in the `RowController` constructor, we register the `RowController` as handling touch events for the row, via `setOnTouchListener()`:

```
RowController(View row, ChoiceCapableAdapter<?> adapter) {
    super(row);
    this.adapter=adapter;

    title=(TextView)row.findViewById(android.R.id.text1);
    thumbnail=(ImageView)row.findViewById(R.id.thumbnail);

    row.setOnClickListener(this);
    row.setOnLongClickListener(this);
    row.setOnTouchListener(this);
}
```

(from [KBMouse/Context/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/RowController.java](#))

That requires `RowController` to implement the `View.OnTouchListener` interface, and therefore requires `RowController` to override `onTouch()`:

```
@Override
public boolean onTouch(View v, MotionEvent event) {
    if ((event.getButtonState() & MotionEvent.BUTTON_SECONDARY)!=0 &&
        event.getAction()==MotionEvent.ACTION_DOWN) {
        adapter.onChecked(position, true, true);

        String[] items=
            itemView
                .getContext()
                .getResources()
                .getStringArray(R.array.popup);
        ArrayAdapter<String> adapter=
```

## KEYBOARD AND MOUSE INPUT

---

```
new ArrayAdapter<>(itemView.getContext(),
    android.R.layout.simple_list_item_1,
    items);
final ListPopupWindow popup=
    new ListPopupWindow(itemView.getContext());

popup.setAnchorView(itemView);
popup.setHorizontalOffset((int)event.getX());
popup.setVerticalOffset((int)event.getY()-itemView.getHeight());
popup.setAdapter(adapter);
popup.setWidth(measureContentWidth(itemView.getContext(), adapter));

popup.setOnItemClickListener(
    new AdapterView.OnItemClickListener() {
        @Override
        public void onItemClick(AdapterView<?> parent, View view,
            int position, long id) {
            if (position==0) {
                ((MainActivity)itemView.getContext())
                    .playVideo(videoUri);
            }
            else {
                ((MainActivity)itemView.getContext())
                    .showLargeThumbnail(videoUri);
            }

            popup.dismiss();
        }
    });

popup.show();

return(true);
}

return(false);
}
```

(from [KBMouse/Context/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/RowController.java](#))

To determine if a given `MotionEvent` is a trigger for the context menu, we check two things:

1. Is the `BUTTON_SECONDARY` pressed?
2. Is this a “down” event (`ACTION_DOWN`)?

If yes, we tell our `ChoiceCapableAdapter` to check this row, so it is clear to the user

what they have right-clicked over.

Then, we load in the string array from the resources and wrap that in a standard `ArrayAdapter`. At that point, we can begin configuring the `ListPopupWindow`.

The constructor for the `ListPopupWindow` takes a `Context`. We grab the `Context` from the `itemView` field of this `ViewHolder`, which represents our row.

We then call five configuration methods to set up the look-and-feel of the `ListPopupWindow`. The first four are fairly straightforward:

- `setAnchorView()` specifies the `View` that this popup is anchored to. In this case, we use the row itself (`itemView`).
- `setHorizontalOffset()` and `setVerticalOffset()` indicate, from the upper-left corner of the anchor view, where to place the upper-left corner of the `ListPopupView`. We want the `ListPopupView` to be adjacent to the mouse pointer, and the `getX()` and `getY()` values of the `MotionEvent` tell us where inside the `itemView` the user clicked. However, the *default* position of the `ListPopupWindow` is to be anchored to the *lower left corner* of the anchor view, not the upper left corner. To adjust the horizontal position, we can simply use `getX()`, since both `getX()` and the default horizontal position of the `ListPopupWindow` are on the left. However, the offset for the vertical position needs to be a negative value, as we want to raise the `ListPopupWindow` to where the mouse pointer is. That value is the difference between the `Y` coordinate of the mouse pointer (`getY()`) and the height of the row (`itemView.getHeight()`).
- `setAdapter()` provides the `ArrayAdapter` to populate the list in the `ListPopupWindow`.

The fifth method — `setWidth()` — is more complex than it should be, due to a bug. Ideally, we would call `setWidth(ListPopupWindow.WRAP_CONTENT)`. According to the documentation, this will set the width of the `ListPopupWindow` to be the width of the content of the adapter. Unfortunately, [this does not work](#). And, since that bug has been outstanding since 2013, it is unlikely that it will ever work.

The workaround — as documented in [Stack Overflow](#) — is to calculate the maximum width of our adapter rows ourselves, then call `setWidth()` with that pixel value. This is isolated in a `measureContentWidth()` method:

```
// based on http://stackoverflow.com/a/26814964/115145
```

## KEYBOARD AND MOUSE INPUT

---

```
private int measureContentWidth(Context ctxt, ListAdapter listAdapter) {
    ViewGroup mMeasureParent = null;
    int maxWidth = 0;
    View itemView = null;
    int itemType = 0;

    final ListAdapter adapter = listAdapter;
    final int widthMeasureSpec =
        View.MeasureSpec.makeMeasureSpec(0, View.MeasureSpec.UNSPECIFIED);
    final int heightMeasureSpec =
        View.MeasureSpec.makeMeasureSpec(0, View.MeasureSpec.UNSPECIFIED);
    final int count = adapter.getCount();
    for (int i = 0; i < count; i++) {
        final int positionType = adapter.getItemViewType(i);
        if (positionType != itemType) {
            itemType = positionType;
            itemView = null;
        }

        if (mMeasureParent == null) {
            mMeasureParent = new FrameLayout(ctxt);
        }

        itemView = adapter.getView(i, itemView, mMeasureParent);
        itemView.measure(widthMeasureSpec, heightMeasureSpec);

        final int itemWidth = itemView.getMeasuredWidth();

        if (itemWidth > maxWidth) {
            maxWidth = itemWidth;
        }
    }

    return maxWidth;
}
```

(from [KBMouse/Context/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/RowController.java](#))

This implementation iterates over the items in the adapter, has the adapter create row views for each row (using a bit of light caching to try to recycle row views in simple adapters), then determines the measured width of those rows. The longest measured width is then used as the result. This works for simple rows and short lists, which is all we really need here anyway.

Then, we call `setOnItemClickListener()` to register a listener to find out when rows in the list in the `ListPopupWindow` are clicked. This works the same as with a

## KEYBOARD AND MOUSE INPUT

---

`ListView`. In our case, we look at the passed-in position, and route to the activity's `playVideo()` or `showLargeThumbnail()` methods according to which list item the user clicked upon. We then `dismiss()` the `ListPopupWindow`, so it goes away after the user clicked on one of the list items.

Finally, we can `show()` the `ListPopupWindow`, so it displays its list to the user.

From the user's perspective, right-clicking over one of the videos in the list offers the context menu:

What is missing is the ability for the user to dismiss the context menu. If the user clicks outside the `ListPopupWindow`, it goes away as expected. However, the underlying click event is still processed. So, if the user clicks over the `VideoView` or large thumbnail `ImageView`, everything looks fine. If the user clicks over one of the `RecyclerView` rows... the clicked-upon video starts playing back in a standalone video player, rather than just dismissing the `ListPopupWindow`. This will be addressed in a future edition of this sample app.

Also note that API Level 23 offers `setOnContextClickListener()` on `View`. This works like `setOnClickListener()` and `setOnLongClickListener()`, letting you know via an `OnContextClickListener` that the view was “context-clicked”. However, you do not get details of the touch event, and so you have no good means of positioning the popup to be near where it should go.

## Offering Tooltips

Users of desktop operating systems, and even Web apps, are used to having tooltips available on key UI elements (e.g., buttons). In a mouse-driven environment, these usually appear after the mouse has hovered over the UI element for a short while.

Touchscreens can also offer similar contextual help. For example, if the user long-presses on an action bar item's icon, a Toast will appear with the item's title.

So, there are two pieces to the puzzle of offering tooltips:

1. How do you decide when to show a tooltip?
2. What is the UI for the tooltip itself?

As with many things in Android, there are two options, depending on what version of Android you are running on.

### Android 7.1 and Older

This section will focus on the first piece — how you decide when to show a tooltip — using a simple Toast for the tooltip UI. There are [many Android libraries for tooltip UIs](#), which you may wish to investigate.

### Hover Events

API Level 14 added `setOnHoverListener()` to `View`. This, and the corresponding `OnHoverListener` interface, allow developers to find out when the user is “hovering” over a widget. This can be triggered by a mouse or by some styluses.

The `onHover()` method of your `OnHoverListener` will be called when a change in the state of hovering occurs. You are given the affected `View`, along with the `MotionEvent` that triggered the state change. The `MotionEvent` should have one of three actions:

- `ACTION_HOVER_ENTER`, meaning that the user has begun hovering over the view
- `ACTION_HOVER_MOVE`, meaning that the user was already hovering over the view, but has moved the mouse pointer, so the hover position within the view bounds has changed
- `ACTION_HOVER_EXIT`, meaning that the user is no longer hovering over the view

## KEYBOARD AND MOUSE INPUT

---

The [KBMouse/Tooltip](#) sample project is a clone of the KBMouse/Hotkeys sample app that adds in tooltip support for long-clicks and hovers. MainActivity now implements the `OnLongClickListener` and `OnHoverListener` interfaces, so we can register those listeners on our `VideoView` and large thumbnail `ImageView`:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);

    player=findViewById(R.id.player);

    if (player!=null) {
        player.setOnDragListener(this);
        player.setOnHoverListener(this);
        player.setOnLongClickListener(this);
    }

    thumbnailLarge=findViewById(R.id.thumbnail_large);

    if (thumbnailLarge!=null) {
        thumbnailLarge.setOnDragListener(this);
        thumbnailLarge.setOnHoverListener(this);
        thumbnailLarge.setOnLongClickListener(this);
    }

    setLayoutManager(new LinearLayoutManager(this));
    adapter=new VideoAdapter(getRecyclerView());
    setAdapter(adapter);
    getRecyclerView().requestFocus();

    if (state!=null) {
        isInPermission=
            state.getBoolean(STATE_IN_PERMISSION, false);
    }

    if (hasFilesPermission()) {
        loadVideos();
    }
    else if (!isInPermission) {
        isInPermission=true;

        ActivityCompat.requestPermissions(this,
            new String[] {Manifest.permission.READ_EXTERNAL_STORAGE},
            REQUEST_PERMS);
    }
}
```

## KEYBOARD AND MOUSE INPUT

---

(from [KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

We will see why we are not registering for events on the RecyclerView [a bit later in this chapter](#).

The `onLongClick()` method for the `OnLongClickListener` forwards the event to a `showTooltip()` method, providing a string resource with the particular message to show:

```
@Override
public boolean onLongClick(View v) {
    if (v==thumbnailLarge) {
        showTooltip(R.string.tooltip_thumbnail);
    }
    else if (v==player) {
        showTooltip(R.string.tooltip_player);
    }
    else {
        return(false);
    }

    return(true);
}
```

(from [KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

`showTooltip()` shows a Toast... with a slight wrinkle:

```
private void showTooltip(@StringRes int message) {
    if (tooltip!=null) {
        tooltip.cancel();
    }

    tooltip=Toast.makeText(this, message, Toast.LENGTH_LONG);
    tooltip.show();
}
```

(from [KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

If, while a tooltip Toast is showing, the user long-clicks on a *different* widget, we want to show that tooltip immediately. By default, we would have to wait until the first Toast completed its duration. Toast has a `cancel()` method that does one of three things:

1. If the Toast has not yet been shown, it removes the Toast from the roster of pending Toasts

## KEYBOARD AND MOUSE INPUT

---

2. If the Toast is presently showing, it gets rid of the Toast
3. If the Toast was shown previously, it does nothing, as nothing is needed

So, we hold onto the most-recent tooltip Toast in a field named `tooltip`, and we `cancel()` it before showing the next tooltip.

The `onHover()` method for the `OnHoverListener` forwards the event to a private `onHover()`, where we supply the string resource of the tooltip message:

```
@Override
public boolean onHover(View v, MotionEvent event) {
    if (v==player) {
        onHover(event, R.string.tooltip_player, player);
    }
    else if (v==thumbnailLarge) {
        onHover(event, R.string.tooltip_thumbnail, thumbnailLarge);
    }
    else {
        return(false);
    }

    return(true);
}
```

(from [KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

And that is where things start to get complicated.

### Detecting a Long-Enough Hover

The problem is that while we can find out when the user starts and stops hovering over a view, we need additional code to determine when some time has elapsed between those two events. So, for example, if you want to show a tooltip one second after the user begins hovering over a view, you need to:

- Arrange to find out when one second has elapsed after the user starts hovering over the view
- Cancel that work if the user stops hovering over that view, either preventing the tooltip from appearing (if it has not done so yet) or perhaps causing the tooltip to vanish immediately (if it is presently being displayed)

`postDelayed()` provides a nice cheap way of handling this. We can schedule a `Runnable` to be invoked after our one-second delay, and we can use

## KEYBOARD AND MOUSE INPUT

---

`removeCallbacks()` to cancel the `Runnable` if the user stops hovering over that widget.

However, we do not know the exact sequence of hover events. It may be that we are given an `ACTION_HOVER_ENTER` event for a new widget prior to `ACTION_HOVER_EXIT` of the previous widget. Hence, we need to track per-widget state.

In this case, the sample app holds onto a `Runnable` per widget for which we are displaying tooltips, in a `SparseArray` object:

```
private SparseArray<Runnable> hoverTimers=  
    new SparseArray<>();
```

(from [KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

A `SparseArray` is a data structure that allows `ArrayList`-style indexed access to objects, but it does not assume that the index values are consecutive. Basically, it replaces a `HashMap` of `Integer` objects. The `SparseArray` allows us to use widget IDs as the index values, so as long as each of our tooltip-enabled widgets have unique IDs, we can track their state in the `SparseArray`.

Our private edition of `onHover()` uses this `SparseArray`:

```
private void onHover(MotionEvent event, @StringRes final int message,  
                    final View anchor) {  
    Runnable hover=hoverTimers.get(anchor.getId());  
  
    if (hover==null &&  
        (event.getAction()==MotionEvent.ACTION_HOVER_ENTER ||  
         event.getAction()==MotionEvent.ACTION_HOVER_MOVE)) {  
  
        hover=new Runnable() {  
            @Override  
            public void run() {  
                showTooltip(message);  
            }  
        };  
  
        hoverTimers.put(anchor.getId(), hover);  
        thumbnailLarge.postDelayed(hover, TOOLTIP_DELAY);  
    }  
    else if (hover!=null &&  
             event.getAction()==MotionEvent.ACTION_HOVER_EXIT) {  
        thumbnailLarge.removeCallbacks(hover);  
        hoverTimers.remove(anchor.getId());  
    }  
}
```

## KEYBOARD AND MOUSE INPUT

---

```
}  
}
```

(from [KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

There are two scenarios that we care about:

1. The user starts hovering over a widget, and we have not yet set up the timer `Runnable`, as it does not exist in the `SparseArray`. So, we create the `Runnable` to show our tooltip (via `showTooltip()`), stuff it in the `SparseArray`, and use `postDelayed()` to trigger the `Runnable` after a second.
2. The user stops hovering over a widget, and we already have the timer `Runnable`. In this case, we call `removeCallbacks()` to ensure that this `Runnable` is not run (if it has not run already), plus remove it from the `SparseArray`.

The net effect is that our `Runnable` will be invoked if one second elapses after the user starts hovering over a widget and the user has not stopped hovering over that same widget.

`showTooltip()` raises a `Toast` to serve as a crude tooltip:

```
private void showTooltip(@StringRes int message) {  
    if (tooltip!=null) {  
        tooltip.cancel();  
    }  
  
    tooltip=Toast.makeText(this, message, Toast.LENGTH_LONG);  
    tooltip.show();  
}
```

(from [KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java](#))

However, it is possible that the user displays one tooltip, then quickly hovers over another widget, and that our one-second delay is shorter than the `Toast` display duration. So, we hold onto each `Toast` that we display, and we `cancel()` it before showing the next one. That way, if one `Toast` is outstanding when we need to show a different `Toast`, we can make the switch immediately, rather than having to wait for the rest of the first `Toast` display duration to elapse before showing the next one.

### What We Are Missing

However, the tooltip for the `VideoView` will not display. `VideoView` is an odd widget,

consuming a lot of touch events for no really good reason. Most likely, for a sophisticated Android app, you will want to skip `VideoView` and use something else, such as a `MediaPlayer` tied to your own `SurfaceView` or `TextureView`.

This sample app does not attempt to provide tooltips for the rows in the `RecyclerView`. Even though we are set up to show a tooltip for the `RecyclerView` overall, the hover events are for the rows, not the `RecyclerView`, as the `RecyclerView` itself is not visible. If you wanted tooltips here, your choices are:

- Have the tooltip for the whole `RecyclerView`, forwarding hover events from rows up to your tooltip-management logic
- Have tooltips per row, using some different system than our `SparseArray`, as the row widget IDs will all be the same by default

### Android 8.0+

Android has had the occasional tooltip-like feature, such as the tooltip that you get on action bar items when long-pressing them. Android 8.0 extends this to all widgets. Simply provide the desired text via `android:tooltipText` or `setTooltipText()`. A tooltip will then appear when either the user long-presses the widget or if the user hovers over the widget. In both cases, though, if the long-press or hover event is consumed by something else, the tooltip is not shown.

The [KBMouse/Tooltip0](#) sample project is a clone of the preceding sample app, where we switch to using the tooltip implementation in Android 8.0+.

Specifically, our large-screen layout has tooltips for the `VideoView` and `ImageView` widgets, using `android:tooltipText`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal">

    <android.support.v7.widget.RecyclerView android:id="@+id/video_list"
        xmlns:android="http://schemas.android.com/apk/res/android"
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="1" />

    <LinearLayout
        android:layout_width="0dp"
```

## KEYBOARD AND MOUSE INPUT

---

```
android:layout_height="match_parent"
android:layout_weight="1"
android:orientation="vertical">

<FrameLayout
    android:id="@+id/video_frame"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_marginBottom="4dp"
    android:layout_weight="1"
    android:padding="4dp">

    <VideoView
        android:id="@+id/player"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_gravity="center"
        android:tooltipText="@string/tooltip_player" />
</FrameLayout>

<FrameLayout
    android:id="@+id/thumbnail_frame"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="1"
    android:padding="4dp">

    <ImageView
        android:id="@+id/thumbnail_large"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:scaleType="centerInside"
        android:tooltipText="@string/tooltip_thumbnail" />
</FrameLayout>
</LinearLayout>
</LinearLayout>
```

(from [KBMouse/TooltipO/app/src/main/res/layout-w800dp/main.xml](#))

The result are tooltips reminiscent of those from the original sample:

Hovering over either widget, or long-pressing either widget, will bring up the tooltip.

## Pointer Capture

On a desktop operating system, the “pointer” refers to the mouse cursor. This feature is normally handled by the operating system. “Pointer capture” refers to when a widget blocks the normal mouse cursor, typically because it is going to use the mouse in some way for which the normal pointer would be inappropriate.

In Android 8.0+, you can call `requestPointerCapture()` and `releasePointerCapture()` to have a widget operate in pointer-capture mode or not.

The vast majority of Android apps should not need this.

# Viewing PDFs

---

The Portable Document Format — better known as PDF — has been around for over two decades, and it is still going strong today. As a result, we often have a need to show PDF files to users, whether those files are:

- Shipped with the app, such as documentation
- Downloaded by the app, such as email attachments for the mail client that you are writing
- Otherwise managed by the app, such as with PDF files held in cloud storage that your app is managing on behalf of the user
- And so on

This is another one of those topics that seems fairly simple on the surface, but can get complicated based on your requirements. In particular, if you want to try to present the PDF to the user *in your app*, as opposed to launching some external PDF viewing app, while you have a few options, they all have their issues.

In this chapter, we will review several ways of displaying a PDF to the user, so you can choose what approach (or approaches) are the best fit for your requirements.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## The Criteria

If there are several ways of displaying a PDF, we need some criteria by which to

evaluate those options and make our choice. Here are some likely criteria to use, though you may have others that are more specific to your app's requirements.

### Where is the PDF?

Most of the PDF-viewing options assume that the PDF is on the device already. However, even within that, there are a few possibilities as to where the PDF might be:

- Internal storage (e.g., `getFilesDir()`) of your app
- External storage (e.g., `getExternalFilesDir()`) associated with your app
- Common locations on external storage, such as the standard Documents directory
- Some `Uri` that you obtained via `ACTION_GET_CONTENT` or `ACTION_OPEN_DOCUMENT`
- An asset or raw resource within your app

And, occasionally, developers get boxed into a corner, with a requirement to show a PDF without downloading the PDF.

### Does It Work Offline?

The opposite problem is the offline viewing experience. If the PDF is on the device already, ideally, the PDF-viewing technology can show that PDF without having to have an active Internet connection. After all, many users do not have continuous Internet access.

### How Complex is the PDF?

While the PDF file format has been around for years and years, it has expanded over that time. In the beginning, PDF did not offer things like form fields, annotations, and the like. The more feature-rich your PDF is, the more likely it is that some PDF viewers may be incapable of handling all of those features.

This is not restricted to in-app viewing solutions. PDF viewing apps vary in capability, and there will be some that either do not support your desired features (e.g., allow the user to fill in forms) or only will if the user unlocks the feature through some purchase.

### How Stable is the Solution?

Many PDF-viewing apps are continuously updated. If the user happens to choose one that is not, that is the user's fault, not yours.

However, when you build in PDF viewing into your app, now *you* need to ensure that your solution is up to date and likely to stay stable for the duration of your app's use.

### How Private is the PDF?

The big one, in terms of the major options for viewing the PDF, is the degree of privacy that is tied to that PDF.

If the document comes from the user — for example, it came in an email attachment to the user's inbox that you are managing — you should assume a modest level of privacy. Do not ship that PDF to other servers without the user's approval. However, if the user wants to view the PDF, you should not be afraid of allowing the user to do so using the user's chosen PDF viewing app.

If the document is more tightly controlled by your app — for example, it came as an attachment to some secure messaging client that you are writing — you may be nervous about granting other apps access to that PDF. After all, you do not necessarily know what those other apps might do with the PDF.

Where things get very messy is when the developers think that *they* “own” the PDF, and therefore are trying to restrict that PDF's access, much as how a DRM solution tries to restrict access to videos. Many PDF-viewing apps offer printing, sharing, and other things that the *user* might want, but that the *developers* do not want. In truth, it is rather likely that the user can get to the PDF anyway, whether the developers like it or not, by various means (e.g., extracting PDFs packaged in the APK using an ordinary ZIP file utility). But, this seems to be the #1 reason why some developers are trying to view PDF files within their own app: treating the user as the enemy.

## The Classic Solution: ACTION\_VIEW

The quintessential solution — and the one that you should focus on first — is to use `startActivity()` with an `ACTION_VIEW` Intent, where the `Uri` in that Intent points to your PDF file:

```
startActivity(new Intent(Intent.ACTION_VIEW, uriToThePdf));
```

## VIEWING PDFs

---

This is quick, easy, and gives the user control over how the PDF is rendered, as they can (usually) choose the PDF viewer to use.

However, this is not a universal solution:

- Android itself does not ship with a PDF viewer app, and therefore some devices will not ship with a PDF viewer app. You wind up with an `ActivityNotFoundException` from your `startActivity()` call, and then you need to guide the user to install a PDF viewer app.
- The user may not be able to install such an app, due to limitations imposed by device owner APIs or because the user is using the device on a secondary user account that lacks app-installation capability.
- For maximum compatibility, you will need to set up a `FileProvider` (or the equivalent) and serve your PDF through it, particularly on Android 7.0+ devices, where the `file` scheme for `Uri` values is banned, in effect.

If you are concerned that the user might choose a PDF viewer app that is malware, or is one that has features that you dislike, you could use `PackageManager` and `queryIntentActivities()` to find all activities that support `ACTION_VIEW` for your PDF file. From there, you can find out the apps associated with those activities, and filter that based on a whitelist (or blacklist) of PDF viewer apps. Then, present your own “chooser”-style UI to allow the user to choose from among the valid options.

## The Really Bad Idea: Google Docs

Some developers, though, try desperately to avoid using external PDF viewer apps.

The approach that many of those developers try is the worst available option: have Google Docs render the PDF in a `WebView`, using code reminiscent of:

```
WebView webview=(WebView)findViewById(R.id.webview);
webview.getSettings().setJavaScriptEnabled(true);
webview.loadUrl("http://drive.google.com/viewerng/
viewer?embedded=true&url=" + urlToYourPdf);
```

This has many poor characteristics:

- It requires that the PDF be available publicly on the Web, for Google Docs to be able to access it. From a security standpoint, many more attackers can

- access the PDF online than can on an Android device.
- If the PDF is not already available publicly on the Web, you would need to run a server, or employ some cloud storage or similar service, to host that PDF, adding to your complexity.
- If the PDF needs to be uploaded, now you are consuming lots of extra bandwidth. Not only did you (probably) download the PDF from somewhere, but now you have to re-upload it somewhere, then download whatever bits and bytes the `WebView` winds up using to display it, as served from Google Docs.
- There is no requirement that Google keep this Google Drive view-arbitrary-PDF URL working. As soon as they change it, your app breaks. As soon as they discontinue it, this approach has to be replaced anyway.
- This approach requires a live Internet connection. There is no offline option.

Pretty much anything else will be better than this solution.

## The Built-In Option: PdfRenderer

Routinely, developers are astonished that Android does not ship with some sort of PDF-viewing app, the way that desktop operating systems do.

The closest thing that Android has to a built-in PDF viewer is `PdfRenderer`. This class was added in API Level 21 (Android 5.0), and it allows you to render pages of a PDF to `Bitmap` objects. In turn, you can then use those `Bitmap` objects to present the pages to the user, by one means or another.

This solution has severe limitations:

- As noted, it requires Android 5.0, leaving out older devices.
- It requires a seekable stream on the content, in the form of a `ParcelFileDescriptor`. The net effect of this is that you can only reliably render something backed by a file. Conversely, you cannot render something backed by a pipe. This means that you cannot render assets, raw resources, a PDF that you decrypt into a memory buffer, and so on.
- It chokes on complex PDF files. For example, the author of this book started testing it with [this short research paper](#), only to determine (eventually) that `PdfRenderer` simply cannot render that PDF. `PdfRenderer` was added with an eye towards print preview, and so its implementation may be focused on the sorts of PDFs that you can generate for printing, as opposed to arbitrary PDFs.

---

## VIEWING PDFS

---

- It only gives you Bitmap objects. You still have to implement a UI to present those Bitmap objects to the user.

The [PDF/PdfRenderer](#) sample project illustrates the use of PdfRenderer.

### The RecyclerView

We need to present pages to the user. In a typical PDF viewer, the user can scroll or swipe to move between pages. One could use a ViewPager for that role. However, large Bitmap objects really should be reused, and ViewPager does not make it easy to reuse objects. A RecyclerView would be a better choice.

The [chapter on advanced RecyclerView uses](#) demonstrates setting up a RecyclerView as a replacement for ViewPager for page-at-a-time presentations. The PdfRenderer sample app uses one of those techniques, [involving SnapHelper](#), for presenting the pages to the user.

Hence, our UI is a RecyclerView with a light gray background:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.RecyclerView android:id="@+id/pager"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="#CCCCCC"
    android:clipToPadding="false" />
```

(from [PDF/PdfRenderer/app/src/main/res/layout/main.xml](#))

In onCreate(), our MainActivity sets up that RecyclerView with a LinearLayoutManager, along with a PagerSnapHelper named snapperCarr:

```
pager.setLayoutManager(new LinearLayoutManager(this,
    LinearLayoutManager.HORIZONTAL, false));
snapperCarr.attachToRecyclerView(pager);
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

Eventually, we will tie in a RecyclerView.Adapter and RecyclerView.ViewHolder classes, named PageAdapter and PageController. However, there is nothing to render at the outset, as we do not have a PDF to use.

### Getting the PDF

Later samples in this chapter happen to use PDF rendering technologies that can work with ordinary streams. In those cases, we can package some PDFs as assets, to provide sample behavior without the user having to rummage around and find a PDF.

Alas, that is not an option with PdfRenderer. So, we need to let the user find a PDF on external or removable storage.

To do that, we have an action bar item named “Open” that leads to an `open()` method on MainActivity:

```
Intent i=new Intent()
    .setType("application/pdf")
    .setAction(Intent.ACTION_OPEN_DOCUMENT)
    .addCategory(Intent.CATEGORY_OPENABLE);

startActivityForResult(i, REQUEST_OPEN);
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

Here, we use [the Storage Access Framework](#), invoking an `ACTION_OPEN_DOCUMENT` Intent, requesting PDF files.

We get control again in `onActivityResult()`:

```
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (resultCode==Activity.RESULT_OK) {
        pickedDocument=data.getData();
        show(pickedDocument);
    }
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

If the user chose a PDF, we stuff its `Uri` into a `pickedDocument` field, plus call a private `show()` method:

```
try {
    adapter=new PageAdapter(getLayoutInflater(),
```

## VIEWING PDFs

---

```
        getResolver().openFileDescriptor(uri, "r");
        pager.setAdapter(adapter);
    }
    catch (java.io.IOException e) {
        Log.e("PdfRenderer", getString(R.string.toast_open), e);
        Toast.makeText(this, R.string.toast_open, Toast.LENGTH_LONG).show();
    }
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

show() creates a PageAdapter, giving it a LayoutInflater and a ParcelFileDescriptor on the Uri, obtained by calling openFileDescriptor() on a ContentResolver. We then attach PageAdapter to our pager-style RecyclerView.

To handle configuration changes, we hold onto pickedDocument in the saved instance state Bundle:

```
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putParcelable(STATE_PICKED, pickedDocument);
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

...and restore it in onCreate():

```
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    pager=(RecyclerView)findViewById(R.id.pager);
    pager.setLayoutManager(new LinearLayoutManager(this,
        LinearLayoutManager.HORIZONTAL, false));
    snapperCarr.attachToRecyclerView(pager);

    if (savedInstanceState!=null) {
        pickedDocument=savedInstanceState.getParcelable(STATE_PICKED);

        if (pickedDocument!=null) {
            show(pickedDocument);
        }
    }
}
```

## VIEWING PDFs

---

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

In `onDestroy()`, we call a `close()` method on `PageAdapter` — we will see the role of `close()` shortly:

```
protected void onDestroy() {
    if (adapter!=null) {
        adapter.close();
    }

    super.onDestroy();
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java](#))

## Adding the PdfRenderer

`PageAdapter` is surprisingly short and mostly is focused on implementing the `RecyclerView.Adapter` API:

```
package com.commonsware.android.pdfrenderer;

import android.graphics.pdf.PdfRenderer;
import android.os.ParcelFileDescriptor;
import android.support.v7.widget.RecyclerView;
import android.view.LayoutInflater;
import android.view.ViewGroup;
import java.io.IOException;

class PageAdapter extends RecyclerView.Adapter<PageController> {
    private final LayoutInflater inflater;
    private final PdfRenderer renderer;

    PageAdapter(LayoutInflater inflater, ParcelFileDescriptor pfd)
        throws IOException {
        this.inflater=inflater;
        renderer=new PdfRenderer(pfd);
    }

    @Override
    public PageController onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new PageController(inflater.inflate(R.layout.page, parent, false)));
    }

    @Override
    public void onBindViewHolder(PageController holder, int position) {
```

## VIEWING PDFs

---

```
PdfRenderer.Page page=renderer.openPage(position);

holder.setPage(page);
page.close();
}

@Override
public int getItemCount() {
    return(renderer.getPageCount());
}

void close() {
    renderer.close();
}
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/PageAdapter.java](#))

In the constructor, we create an instance of a PdfRenderer, passing in the ParcelFileDescriptor on our PDF file.

In onCreateViewHolder(), we create an instance of a PageController, passing it an inflated layout representing the page contents — we will examine this in greater detail shortly.

In onBindViewHolder(), we ask the PdfRenderer to give us a PdfRenderer.Page for the page identified by our position, via an openPage() method. We then pass that to the PageController via a setPage() method, before we close() the Page. It is the responsibility of PageController to ensure that it does everything that it needs to do with that page before returning from setPage().

getItemCount() returns the number of pages in the PDF, as determined by getPageCount().

Finally, close() calls close() on the PdfRenderer, to let it release any resources that it is holding onto, such as that ParcelFileDescriptor.

### Showing the Pages

The real fun, of course, is in PageController, for rendering a page of the PDF into a Bitmap to be shown in a page of our pager-style RecyclerView.

To allow for pinch-to-zoom functionality, the PdfRenderer sample app uses [Dave Morrissey's SubsamplingScaleImageView](#):

## VIEWING PDFS

---

```
<com.davemorrissey.labs.subscaleview.SubsamplingScaleImageView
  android:id="@+id/page"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:layout_margin="16dp" />
```

(from [PDF/PdfRenderer/app/src/main/res/layout/page.xml](#))

This has a 16dp margin on all four sides, causing each page of the PDF to appear to be floating over the light gray background of the RecyclerView itself. Android's PdfRenderer does not put any frame around its rendered page, leaving that up to you.

PageController grabs the SubsamplingScaleImageView in the constructor, then uses PdfRenderer .Page and a Bitmap to populate it in setPage():

```
package com.commonware.android.pdfrenderer;

import android.graphics.Bitmap;
import android.graphics.pdf.PdfRenderer;
import android.os.Environment;
import android.support.v7.widget.RecyclerView;
import android.view.View;
import android.widget.ImageView;
import com.davemorrissey.labs.subscaleview.ImageSource;
import com.davemorrissey.labs.subscaleview.SubsamplingScaleImageView;
import java.io.File;
import java.io.FileNotFoundException;
import java.io.FileOutputStream;

class PageController extends RecyclerView.ViewHolder {
  private final SubsamplingScaleImageView iv;
  private Bitmap bitmap;

  PageController(View itemView) {
    super(itemView);

    iv=(SubsamplingScaleImageView)itemView.findViewById(R.id.page);
  }

  void setPage(PdfRenderer.Page page) {
    if (bitmap==null) {
      int height=2000;
      int width=height * page.getWidth() / page.getHeight();

      bitmap=Bitmap.createBitmap(width, height, Bitmap.Config.ARGB_8888);
```

## VIEWING PDFs

---

```
    }  
  
    bitmap.eraseColor(0xFFFFFFFF);  
    page.render(bitmap, null, null, PdfRenderer.Page.RENDER_MODE_FOR_DISPLAY);  
    iv.resetScaleAndCenter();  
    iv.setImage(ImageSource.cachedBitmap(bitmap));  
    }  
}
```

(from [PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/PageController.java](https://github.com/CommunityToolkit/AndroidPdfRenderer/blob/master/AndroidPdfRenderer/src/main/java/com/commonsware/android/pdfrenderer/PageController.java))

In `setPage()`, we lazy-create a `Bitmap`, set to 2000 pixels high and whatever width would be appropriate based on the aspect ratio of the page. This is a simple implementation, suitable for a PDF where all pages have the same aspect ratio. A more sophisticated sample would use some form of object pool for `Bitmap` objects based on aspect ratio.

Note that the `Bitmap` needs to be `ARGB_8888`, exacerbating its memory usage. Attempts to use `RGB_565` — thereby cutting memory usage in half per page — fail with an error from `PdfRenderer`.

Actually rendering the page to the `Bitmap` is performed by the `render()` method on the `Page`. It takes the `Bitmap`, an optional `Rect` indicating a subset of the page to be rendered, an optional `Matrix` to be applied to transform the rendering, and a “render mode” to indicate if this is for use on a screen or (somehow) on a printed page.

However, `render()` does not do anything to the `Bitmap` other than render the page’s contents. In particular, it does not clear the `Bitmap` ahead of time. Since we are reusing the `Bitmap` objects, by default, as those `Bitmap` objects get reused, they would accumulate page contents, which is not what we want. Also, `render()` does not assume any particular background color for pages, if such a color was not specified in the PDF. Instead, it just renders the “ink” on top of the `Bitmap`, with everything else left alone. So, we use `eraseColor()` to reset the `Bitmap` to white before we call `render()`, so we clear out any previous page’s content, and so we have a solid white background for our pages.

Not only are we reusing the `Bitmap`, but we are reusing the `SubsamplingScaleImageView`. If the user used pinch-to-zoom and panned around a previous page, the `SubsamplingScaleImageView` will retain those settings. So, we call `resetScaleAndCenter()` to switch back to the starting point, then call `setImage()` to hand the `SubsamplingScaleImageView` the page to render. `setImage()` takes an `ImageSource`, and in this case we need to use `cachedBitmap()`, to indicate both that the image is in the form of an existing `Bitmap` and that we are caching the `Bitmap`

## VIEWING PDFs

---

ourselves (so the `SubsamplingScaleImageView` should not attempt to `recycle()` the `Bitmap`).

The result is a PDF viewer, where we can pick a PDF from the “Open” action bar item, then swipe through the pages:

## The Thunder Lizard Choice: PDF.js

PdfRenderer has many limitations, none bigger than the fact that it fails to render complex PDFs.

If you have used the Firefox Web browser on your desktop or notebook in the past few years, you may have noticed that its built-in PDF viewer is actually written in JavaScript, in the form of [PDF.js](#). This is designed to handle more complex PDF files, and so it is a more complete solution than is PdfRenderer.

However, PDF.js requires a fairly robust Web rendering engine to work. On Android, that means we are limited to Android 4.4+, when the original `WebView` was replaced by the “Android System `WebView`” app’s implementation, which shares more of its

## VIEWING PDFs

---

guts with Chromium.

The [PDF/PdfJS](#) sample project demonstrates the use of PDF.js.

PDF.js needs a WebView, so we put one in our layout file:

```
<?xml version="1.0" encoding="utf-8"?>
<WebView android:id="@+id/webview"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent" />
```

(from [PDF/PdfJS/app/src/main/res/layout/activity\\_main.xml](#))

Not surprisingly, it needs JavaScript to be enabled for that WebView. However, we also need to give JavaScript the ability to read from arbitrary URLs when we load the JavaScript itself from a file URL, as our PDF might come from somewhere else (e.g., content scheme for a document opened via ACTION\_OPEN\_DOCUMENT):

```
wv=(WebView)findViewById(R.id.webview);
wv.getSettings().setJavaScriptEnabled(true);
wv.getSettings().setAllowUniversalAccessFromFileURLs(true);
```

(from [PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java](#))

PDF.js itself is stored in `assets/pdfjs/` in our main source set. This consists of the JavaScript library (`build/` directory) and the stock Web-based viewer wrapped around that library (`web/` directory). Combined, these two directories represent 4.6MB of material. While some of that could be stripped out or tweaked for mobile use, this highlights one of the problems with the PDF.js solution: it is large. Those assets will compress somewhat — expect about 2MB added to your APK file.

This sample app now gives the “Open” action bar item a submenu, where the user can choose from two pre-packaged PDFs as assets (a set of presentation slides and the infamous 1040(A) tax form from the United States Internal Revenue Service) or to pick one from the filesystem:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/pdfs"
        android:icon="@drawable/ic_folder_open_white_24dp"
        android:showAsAction="always"
        android:title="@string/menu_pdf_files">
    </item>
</menu>
```

## VIEWING PDFs

---

```
<item android:id="@+id/preso" android:title="@string/menu_presentation"/>
<item android:id="@+id/taxes" android:title="@string/menu_taxes" />
<item android:id="@+id/open" android:title="@string/menu_open" />
</menu>
</item>
</menu>
```

(from [PDF/PdfJS/app/src/main/res/menu/pdf.xml](#))

In `onOptionsItemSelected()` of `MainActivity`, we route to `loadPdf()` methods for the two assets and the `open()` method for the “Pick” option:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.preso) {
        loadPdf("MultiWindowAndYourApp.pdf");
        return(true);
    }
    else if (item.getItemId()==R.id.taxes) {
        loadPdf("f1040a.pdf");
        return(true);
    }
    else if (item.getItemId()==R.id.open) {
        open();
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java](#))

`open()` still uses `ACTION_OPEN_DOCUMENT` to allow the user to pick a PDF file. `onActivityResult()` still saves the `Uri` in the `pickedDocument` field but then calls a `loadPdfUri()` method with the string representation of that `Uri`:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (resultCode==Activity.RESULT_OK) {
        pickedDocument=data.getData();
        loadPdfUri(pickedDocument.toString());
    }
}
```

(from [PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java](#))

Similarly, the `loadPdf()` method used by `onOptionsItemSelected()` for the assets

## VIEWING PDFs

---

stores the chosen asset name in a `chosenAsset` field, then calls `loadPdfUri()` with the proper `file:///android_asset/` URL:

```
private void loadPdf(String name) {
    chosenAsset=name;
    loadPdfUri("file:///android_asset/"+name);
}
```

(from [PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java](#))

`loadPdfUri()` then uses `loadUrl()` to load up the Web-based PDF viewer in assets, supplying the URL to the PDF in the file query parameter:

```
private void loadPdfUri(String uri) {
    try {
        ww.loadUrl("file:///android_asset/pdfjs/web/viewer.html?file="+
            URLEncoder.encode(uri, "UTF-8"));
    }
    catch (UnsupportedEncodingException e) {
        e.printStackTrace();
    }
}
```

(from [PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java](#))

This works “out of the box” for the assets, as both the Web viewer and the PDFs come from file URLs. To get the content scheme to work, you have to add `file://` to `HOSTED_VIEWER_ORIGINS` in `web/viewer.js`, to tell the Web viewer that `file://` is a valid origin for the viewer and that any reachable URL should be tried:

```
var HOSTED_VIEWER_ORIGINS = [
    'null',
    'http://mozilla.github.io',
    'https://mozilla.github.io',
    'file://'
];
```

(from [PDF/PdfJS/app/src/main/assets/pdfjs/web/viewer.js](#))

We also need to hold onto `chosenAsset` in our saved instance state:

```
@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putString(STATE_ASSET, chosenAsset);
}
```

## VIEWING PDFs

---

```
outState.putParcelable(STATE_PICKED, pickedDocument);
}
```

(from [PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java](#))

And we restore the PDF in onCreate():

```
@SuppressWarnings("SetJavaScriptEnabled")
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    ww=(WebView)findViewById(R.id.webview);
    ww.getSettings().setJavaScriptEnabled(true);
    ww.getSettings().setAllowUniversalAccessFromFileURLs(true);

    if (savedInstanceState!=null) {
        chosenAsset=savedInstanceState.getString(STATE_ASSET);

        if (chosenAsset==null) {
            pickedDocument=savedInstanceState.getParcelable(STATE_PICKED);

            if (pickedDocument!=null) {
                loadPdfUri(pickedDocument.toString());
            }
        }
        else {
            loadPdf(chosenAsset);
        }
    }
}
```

(from [PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java](#))

## VIEWING PDFs

The result is PDF.js's stock PDF viewer, in our WebView, where the user can scroll vertically to browse all the pages in the PDF:

Figure 694: PDF.js Rendering IRS 1040 Form

## The Native Approach: Pdfium

The major downside to both PdfRenderer and PDF.js as in-process PDF viewing solutions is the required API level. Both work with Android 5.0+, and PDF.js works with Android 4.4. However, you may have a `minSdkVersion` below 19. One approach would be to use an external PDF viewer for those older devices, but if that were an option, you may be better off using that for *all* Android versions, not just older ones.

Your remaining options involve using some C/C++ code for rendering PDFs.

One popular native code base for PDF rendering is [Pdfium](#), from Google, used in Chromium and Chrome. Roughly speaking, it fills the same role there as PDF.js does with Firefox.

Bartosz Schiller's [AndroidPdfViewer](#) library wraps Pdfium in a View that handles rendering and standard gestures (e.g., horizontal swipes to move between pages).

## VIEWING PDFs

---

On the plus side, Pdfium works well on older Android versions. The author of this book tested it back to Android 4.1 (API Level 16) and had no problems, and the library itself claims to support back to API Level 11.

However, there is a cost: APK size. By default, AndroidPdfViewer gives you NDK binaries that support the major CPU architectures: 32- and 64-bit ARM and x86, plus MIPS. As a result, the native binaries take up 30MB of space in your APK. Dropping support for CPU architectures that are less important to you (e.g., ARM) can help, and you can drop the per-APK cost to ~5MB if you use [ABI splits](#) and ship separate APKs per supported CPU architecture (on distribution channels where that is an option).

The [PDF/Pdfium](#) sample project demonstrates the use of AndroidPdfViewer and Pdfium. It is very similar to the PDF.js sample.

However, we need to pull in the AndroidPdfViewer library:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'

    defaultConfig {
        applicationId "com.commonware.android.pdfium"
        minSdkVersion 16
        targetSdkVersion 25
        versionCode 1
        versionName "1.0"
    }
}

dependencies {
    implementation 'com.github.barteksc:android-pdf-viewer:2.3.0'
}
```

(from [PDF/Pdfium/app/build.gradle](#))

Our layout now uses a PDFView widget, instead of a RecyclerView or WebView:

```
<?xml version="1.0" encoding="utf-8"?>
<com.github.barteksc.pdfviewer.PDFView android:id="@+id/viewer"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent" />
```

## VIEWING PDFs

---

(from [PDF/Pdfium/app/src/main/res/layout/activity\\_main.xml](#))

We also need `open()` to support `ACTION_GET_CONTENT`, since `ACTION_OPEN_DOCUMENT` is not supported prior to API Level 19:

```
private void open() {
    if (Build.VERSION.SDK_INT < Build.VERSION_CODES.KITKAT) {
        Intent i =
            new Intent()
                .setType("application/pdf")
                .setAction(Intent.ACTION_GET_CONTENT)
                .addCategory(Intent.CATEGORY_OPENABLE);

        startActivityForResult(i, REQUEST_GET);
    }
    else {
        Intent i =
            new Intent()
                .setType("application/pdf")
                .setAction(Intent.ACTION_OPEN_DOCUMENT)
                .addCategory(Intent.CATEGORY_OPENABLE);

        startActivityForResult(i, REQUEST_OPEN);
    }
}
```

(from [PDF/Pdfium/app/src/main/java/com/commonsware/android/pdfium/MainActivity.java](#))

Then, instead of `loadPdf()` or `loadPdfUri()` methods, we use a `configureViewer()` method. That method takes a `PDFView.Configurator` object, which we get by calling `fromUri()` on the `PDFView` itself, such as from our `onActivityResult()` method:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (resultCode == Activity.RESULT_OK) {
        pickedDocument = data.getData();
        chosenAsset = null;
        configureViewer(viewer.fromUri(pickedDocument));
    }
}
```

(from [PDF/Pdfium/app/src/main/java/com/commonsware/android/pdfium/MainActivity.java](#))

`configureViewer()` then teaches the `PDFView` how we want to render this document:

```
private void configureViewer(PDFView.Configurator configurator) {
```

## VIEWING PDFs

```
configurator
    .enableSwipe(true)
    .swipeHorizontal(true)
    .enableDoubletap(true)
    .scrollHandle(new DefaultScrollHandle(this))
    .load();
}
```

(from [PDF/Pdfium/app/src/main/java/com/commonsware/android/pdfium/MainActivity.java](#))

Here, we:

- Enable horizontal swiping to move between pages
- Enable a scroll handle as an alternative for moving between pages
- Enable a double-tap gesture for toggling between a few different zoom levels

The result is similar to the PDF.js result, since Pdfium can handle similarly-complex PDF files:

Figure 695: Pdfium Sample App Showing IRS 1040 Form

## What To Choose?

So, what do you choose?

Option	Location Flexibility	Offline-Capable	PDF Complexity	Stability	Privacy	APK Size	minSdkVersion
External Viewer	good	good	varies	varies	poor	great	1
Google Docs	poor	poor	good	poor	poor	great	1
PdfRenderer	good	good	poor	good	great	great	21
PDF.js	good	good	good	good	great	meh	19
Pdfium	good	good	good	good	great	poor	11

For most apps, for most situations, using an external PDF viewer is the simplest solution. Use one that already exists, and be in position to suggest one to the user if there is no PDF viewer app available.

If you are certain that you need to keep the PDFs within your own app, and your `minSdkVersion` is 19 or higher, PDF.js offers the best rendering with a modest increase in app size. If, however, you need to support older devices than that, Pdfium will be a solid choice... but be prepared for some distribution complexity as you deal with the ABI splits to keep your APK size down to a reasonable level.

---

## **Trail: Home Screen Effects**

---

# Home Screen App Widgets

---

App widgets are live elements that the user can add to her home screen. Android ships with a variety of app widgets, such as a music player, and device manufacturers frequently add more. However, developers can add their own — in this chapter, we will see how this is done.

For the purposes of this book, “app widgets” will refer to these items that go on the home screen. Other uses of the term “widget” will be reserved for the UI widgets, subclasses of `View`, usually found in the `android.widget` Java package.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapters on:

- [basic widgets](#)
- [broadcast Intents](#)
- [services](#)

## App Widgets and Security

Creating app widgets looks little like creating an activity. That is because the home screen is showing your app widget, whereas your own app shows your own activities. Having a third-party app (a home screen) show a UI from your app has some security ramifications.

Android’s security model is based heavily on Linux user, file, and process security. Each application is (normally) associated with a unique user ID. All of its files are

owned by that user, and its process(es) run as that user. This prevents one application from modifying the files of another or otherwise injecting their own code into another running process. It would be dangerous for the home screen to run arbitrary code itself or somehow allow its UI to be directly manipulated by another process.

The app widget architecture, therefore, is set up to keep the home screen application independent from any code that puts app widgets on that home screen, so bugs in one cannot harm the other.

### The Big Picture for a Small App Widget

The way Android pulls off this bit of security is through the use of RemoteViews.

The application component that supplies the UI for an app widget is not an Activity, but rather a BroadcastReceiver (often in tandem with a Service). The BroadcastReceiver, in turn, does not inflate a normal View hierarchy, like an Activity would, but instead inflates a layout into a RemoteViews object.

RemoteViews encapsulates a limited edition of normal widgets, in such a fashion that the RemoteViews can be “easily” transported across process boundaries. You configure the RemoteViews via your BroadcastReceiver and make those RemoteViews available to Android. Android in turn delivers the RemoteViews to the app widget host (usually the home screen), which renders them to the screen itself.

This architectural choice has many impacts:

- You do not have access to the full range of widgets and containers. You can use `FrameLayout`, `LinearLayout`, and `RelativeLayout` for containers, and `AnalogClock`, `Button`, `Chronometer`, `ImageButton`, `ImageView`, `ProgressBar`, and `TextView` for widgets. And, on API Level 11 and higher, you can use some AdapterView-based widgets, like `ListView`, as we will examine [in the next chapter](#). And, as of API Level 16 (Android 4.1), you can use `GridLayout`... but not its backport on earlier devices.
- The only user input you can get is clicks of the `Button` and `ImageButton` widgets. In particular, there is no `EditText` for text input.
- Because the app widgets are rendered in another process, you cannot simply register an `OnClickListener` to get button clicks; rather, you tell RemoteViews a `PendingIntent` to invoke when a given button is clicked.
- You do not hold onto the RemoteViews and reuse them yourself. Rather, you

create and send out a brand-new RemoteViews whenever you want to change the contents of the app widget. This, coupled with having to transport the RemoteViews across process boundaries, means that updating the app widget is expensive in terms of CPU time, memory, and battery life, when compared to equivalent UI updates of one of your own activities.

- Because the component handling the updates is a BroadcastReceiver, you have to be quick (lest you take too long and Android consider you to have timed out), you cannot use background threads, and your component itself is lost once the request has been completed. Hence, if your update might take a while, you will probably want to have the BroadcastReceiver start a Service and have the Service do the long-running task and eventual app widget update.

## Crafting App Widgets

This will become somewhat easier to understand in the context of some sample code. In the [AppWidget/PairOfDice](#) project, you will find an app widget that displays a roll of a pair of dice. Clicking on the app widget re-rolls, in case you want a better result.

## The Manifest

First, we need to register our BroadcastReceiver implementation in our AndroidManifest.xml file, along with a few extra features:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.appwidget.dice"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"/>

    <uses-feature
        android:name="android.software.app_widgets"
        android:required="true"/>

    <application
        android:allowBackup="false"
        android:icon="@drawable/ic_launcher"
```

## HOME SCREEN APP WIDGETS

---

```
android:label="@string/app_name">
<receiver
  android:name=".AppWidget"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name">
  <intent-filter>
    <action android:name="android.appwidget.action.APPWIDGET_UPDATE"/>
  </intent-filter>

  <meta-data
    android:name="android.appwidget.provider"
    android:resource="@xml/widget_provider"/>
</receiver>

<activity
  android:name="PairOfDiceActivity"
  android:theme="@android:style/Theme.Translucent.NoTitleBar">
  <intent-filter>
    <action android:name="android.intent.action.MAIN"/>

    <category android:name="android.intent.category.LAUNCHER"/>
  </intent-filter>
</activity>
</application>
</manifest>
```

(from [AppWidget/PairOfDice/app/src/main/AndroidManifest.xml](#))

Here, along with a do-nothing activity, we have a `<receiver>`. Of note:

1. Our `<receiver>` has `android:label` and `android:icon` attributes, which are not normally needed on `BroadcastReceiver` declarations. However, in this case, those are used for the entry that goes in the roster of available widgets to add to the home screen. Hence, you will probably want to supply values for both of those, and use appropriate resources in case you want translations for other languages.
2. Our `<receiver>` has an `<intent-filter>` for the `android.appwidget.action.APPWIDGET_UPDATE` action. This means we will get control whenever Android wants us to update the content of our app widget. There may be other actions we want to monitor — more on this in a [later section](#).
3. Our `<receiver>` also has a `<meta-data>` element, indicating that its `android.appwidget.provider` details can be found in the `res/xml/widget_provider.xml` file. This metadata is described in greater detail

shortly.

### The uses-feature Element

If the central point of your application is to provide an app widget, you should strongly consider adding a `<uses-feature>` element to advertise this fact to markets like the Play Store:

```
<uses-feature android:name="android.software.app_widgets" android:required="true" />
```

In principle, having this element means that markets should block the installation of your app on devices where there is no app-widget-capable home screen or other known places for supporting app widgets.

If, however, your app has an app widget, but it is an adjunct to other forms of UI (typically a launcher activity), then you may wish to leave off this `<uses-feature>` element, or set it to `android:required="false"`.

### The Metadata

Next, we need to define the app widget provider metadata. This has to reside at the location indicated in the manifest — in this case, in `res/xml/widget_provider.xml`:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="144dip"
    android:minHeight="72dip"
    android:updatePeriodMillis="900000"
    android:initialLayout="@layout/widget"
/>
```

(from [AppWidget/PairOfDice/app/src/main/res/xml/widget\\_provider.xml](#))

Here, we provide a few pieces of information:

1. The minimum width and height of the app widget (`android:minWidth` and `android:minHeight`). These are approximate — the app widget host (e.g., home screen) will tend to convert these values into “cells” based upon the overall layout of the UI where the app widgets will reside. However, they should be no smaller than the minimums cited here. Also, ideally, you use `dip` instead of `px` for the dimensions, so the number of cells will remain constant regardless of screen density.
2. The frequency in which Android should request an update of the widget’s

## HOME SCREEN APP WIDGETS

---

- contents (android:updatePeriodMillis). This is expressed in terms of milliseconds, so a value of 3600000 is a 60-minute update cycle. Note that the minimum value for this attribute is 30 minutes — values less than that will be “rounded up” to 30 minutes. Hence our 15-minute (900000 millisecond) request will actually result in an update every 30 minutes.
3. The initial layout to use for the app widget, for the time between when the user requests the app widget and when onUpdate() of our AppWidgetProvider gets control.

Note that the calculations for determining the number of cells for an app widget varies. The dip dimension value for an N-cell dimension was  $(74 * N) - 2$  (e.g., a 2x3 cell app widget would request a width of 146dip and a height of 220dip). The value as of API Level 14 (a.k.a., Ice Cream Sandwich) is now  $(70 * N) - 30$  (e.g., a 2x3 cell app widget would request a width of 110dip and a height of 180dip). To have your app widgets maintain a consistent number of cells, you will need two versions of your app widget metadata XML, one in res/xml-v14/ (with the API Level 14 calculation) and one in res/xml/ (for prior versions of Android).

### The Layout

Eventually, you are going to need a layout that describes what the app widget looks like. You need to stick to the widget and container classes noted above; otherwise, this layout works like any other layout in your project.

For example, here is the layout for the PairOfDice app widget:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
    >
    <ImageView android:id="@+id/left_die"
        android:layout_centerVertical="true"
        android:layout_alignParentLeft="true"
        android:src="@drawable/die_5"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginLeft="7dip"
    />
    <ImageView android:id="@+id/right_die"
```

## HOME SCREEN APP WIDGETS

---

```
        android:layout_centerVertical="true"
        android:layout_alignParentRight="true"
        android:src="@drawable/die_2"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginRight="7dip"
    />
</RelativeLayout>
```

(from [AppWidget/PairOfDice/app/src/main/res/layout/widget.xml](#))

All we have is a pair of `ImageView` widgets (one for each die), inside of a `RelativeLayout`. The `RelativeLayout` has a background, specified as a [nine-patch PNG file](#). This allows the `RelativeLayout` to have guaranteed contrast with whatever wallpaper is behind it, so the user can tell the actual app widget bounds.

## The BroadcastReceiver

Next, we need a `BroadcastReceiver` that can get control when Android wants us to update our `RemoteViews` for our app widget. To simplify this, Android supplies an `AppWidgetProvider` class we can extend, instead of the normal `BroadcastReceiver`. This simply looks at the received `Intent` and calls out to an appropriate lifecycle method based on the requested action.

The one method that frequently needs to be implemented on the provider is `onUpdate()`. Other lifecycle methods may be of interest and are discussed [later](#) in this chapter.

For example, here is the implementation of the `AppWidgetProvider` for `PairOfDice`:

```
package com.commonware.android.appwidget.dice;

import android.app.PendingIntent;
import android.appwidget.AppWidgetManager;
import android.appwidget.AppWidgetProvider;
import android.content.ComponentName;
import android.content.Context;
import android.content.Intent;
import android.widget.RemoteViews;

public class AppWidget extends AppWidgetProvider {
    private static final int[] IMAGES={R.drawable.die_1,R.drawable.die_2,
                                        R.drawable.die_3,R.drawable.die_4,
                                        R.drawable.die_5,R.drawable.die_6};

    @Override
    public void onUpdate(Context ctxt, AppWidgetManager mgr,
                        int[] appWidgetIds) {
        ComponentName me=new ComponentName(ctxt, AppWidget.class);
```

## HOME SCREEN APP WIDGETS

---

```
mgr.updateAppWidget(me, buildUpdate(ctxt, appWidgetIds));
}

private RemoteViews buildUpdate(Context ctxt, int[] appWidgetIds) {
    RemoteViews updateViews=new RemoteViews(ctxt.getPackageName(),
                                           R.layout.widget);

    Intent i=new Intent(ctxt, AppWidget.class);

    i.setAction(AppWidgetManager.ACTION_APPWIDGET_UPDATE);
    i.putExtra(AppWidgetManager.EXTRA_APPWIDGET_IDS, appWidgetIds);

    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i,
                                                PendingIntent.FLAG_UPDATE_CURRENT);

    updateViews.setImageResource(R.id.left_die,
                                IMAGES[(int)(Math.random()*6)]);
    updateViews.setOnClickPendingIntent(R.id.left_die, pi);
    updateViews.setImageResource(R.id.right_die,
                                IMAGES[(int)(Math.random()*6)]);
    updateViews.setOnClickPendingIntent(R.id.right_die, pi);
    updateViews.setOnClickPendingIntent(R.id.background, pi);

    return updateViews;
}
}
```

(from [AppWidget/PairOfDice/app/src/main/java/com/commonsware/android/appwidget/dice/AppWidget.java](#))

To update the RemoteViews for our app widget, we need to build those RemoteViews (delegated to a buildUpdate() helper method) and tell an AppWidgetManager to update the widget via updateAppWidget(). In this case, we use a version of updateAppWidget() that takes a ComponentName as the identifier of the widget to be updated. Note that this means that we will update all instances of this app widget presently in use — the concept of multiple app widget instances is covered in greater detail [later in this chapter](#).

Working with RemoteViews is a bit like trying to tie your shoes while wearing mittens — it may be possible, but it is a bit clumsy. In this case, rather than using methods like findViewById() and then calling methods on individual widgets, we need to call methods on RemoteViews itself, providing the identifier of the widget we wish to modify. This is so our requests for changes can be serialized for transport to the home screen process. It does, however, mean that our view-updating code looks a fair bit different than it would if this were the main View of an activity or row of a ListView.

To create the RemoteViews, we use a constructor that takes our package name and the identifier of our layout. This gives us a RemoteViews that contains all of the widgets we declared in that layout, just as if we inflated the layout using a

## HOME SCREEN APP WIDGETS

---

LayoutInflater. The difference, of course, is that we have a RemoteViews object, not a View, as the result.

We then use methods like:

1. `setImageViewResource()` to set the image for each of our ImageView widgets, in this case a randomly chosen die face (using graphics created from a set of SVG files from the [OpenClipArt site](#))
2. `setOnClickPendingIntent()` to provide a PendingIntent that should get fired off when a die, or the overall app widget background, is clicked

We then supply that RemoteViews to the AppWidgetManager, which pushes the RemoteViews structure to the home screen, which renders our new app widget UI.

### The Result

If you compile and install all of this, you will have a new app widget entry available. How you add app widgets to the home screen varies based upon Android version and the home screen implementation, and there are too many possibilities to try to list here.

No matter how you add the Pair of Dice, the app widget will appear on the home screen:

*Figure 696: Pair of Dice, In Action*

## Another and Another

As indicated above, you can have multiple instances of the same app widget outstanding at any one time. For example, one might have multiple picture frames, or multiple “show-me-the-latest-RSS-entry” app widgets, one per feed. You will distinguish between these in your code via the identifier supplied in the relevant `AppWidgetProvider` callbacks (e.g., `onUpdate()`).

If you want to support separate app widget instances, you will need to store your state on a per-app-widget-identifier basis. You will also need to use an appropriate version of `updateAppWidget()` on `AppWidgetManager` when you update the app widgets, one that takes app widget identifiers as the first parameter, so you update the proper app widget instances.

Conversely, there is nothing requiring you to support multiple instances as independent entities. For example, if you add more than one `PairOfDice` app widget

to your home screen, nothing blows up – they just show the same roll. That is because `PairOfDice` uses a version of `updateAppWidget()` that does not take any app widget IDs, and therefore updates all app widgets simultaneously.

## App Widgets: Their Life and Times

There are three other lifecycle methods that `AppWidgetProvider` offers that you may be interested in:

1. `onEnabled()` will be called when the first widget instance is created for this particular widget provider, so if there is anything you need to do once for all supported widgets, you can implement that logic here
2. `onDeleted()` will be called when a widget instance is removed from the home screen, in case there is any data you need to clean up specific to that instance
3. `onDisabled()` will be called when the last widget instance for this provider is removed from the home screen, so you can clean up anything related to all such widgets

You will need to add appropriate action strings to your `<intent-filter>` for each of these events, such as `ACTION_APPWIDGET_ENABLED` to be notified about enabled events via `onEnabled()`.

## Controlling Your (App Widget's) Destiny

As `PairOfDice` illustrates, you are not limited to updating your app widget only based on the timetable specified in your metadata. That timetable is useful if you can get by with a fixed schedule. However, there are cases in which that will not work very well:

1. If you want the user to be able to configure the polling period (the metadata is baked into your APK and therefore cannot be modified at runtime)
2. If you want the app widget to be updated based on external factors, such as a change in location

The recipe shown in `PairOfDice` will let you use `AlarmManager` (described in [another chapter](#)) or proximity alerts or whatever to trigger updates. All you need to do is:

1. Arrange for something to broadcast an Intent that will be picked up by the `BroadcastReceiver` you are using for your app widget provider

2. Have the provider process that Intent directly or pass it along to a Service (such as an IntentService)

Also, note that the `updatePeriodMillis` setting not only tells the app widget to update every so often, it will even *wake up the phone* if it is asleep so the widget can perform its update. On the plus side, this means you can easily keep your widgets up to date regardless of the state of the device. On the minus side, this will tend to drain the battery, particularly if the period is too fast. If you want to avoid this wakeup behavior, set `updatePeriodMillis` to 0 and use `AlarmManager` to control the timing and behavior of your widget updates.

Note that if there are multiple instances of your app widget on the user's home screen, they will all update approximately simultaneously if you are using `updatePeriodMillis`. If you elect to set up your own update schedule, you can control which app widgets get updated when, if you choose.

## One Size May Not Fit All

It may be that you want to offer multiple app widget sizes to your users. Some might only want a small app widget. Some might really like what you have to offer and want to give you more home screen space to work in.

### Android 1.x/2.x

The good news: this is easy to do.

The bad news: it requires you, in effect, to have one app widget per size.

The size of an app widget is determined by the app widget metadata XML file. That XML file is tied to a `<receiver>` element in the manifest representing one app widget. Hence, to have multiple sizes, you need multiple metadata files and multiple `<receiver>` elements.

This also means your app widgets will show up multiple times in the app widget selection list, when the user goes to add an app widget to their home screen. Hence, supporting many sizes will become annoying to the user, if they perceive you are “spamming” the app widget list. Try to keep the number of app widget sizes to a reasonable number (say, one or two sizes).

### Android 3.0+

As of API Level 11, it is possible to have a resizable app widget. To do this, you can have an `android:resizeMode` attribute in your widget metadata, with a value of `horizontal`, `vertical`, or `both` (e.g., `horizontal|vertical`). When the user long-taps on an existing widget, they should see handles to allow the widget to be resized:

*Figure 697: API Demos App Widget, Resizing*

You can also have `android:minResizeWidth` and `android:minResizeHeight` attributes, measured in dp, that indicate the approximate smallest size that your app widget can support. These values will be interpreted in terms of “cells”, as with the `android:minWidth` and `android:minHeight` attributes, and so the dp values you supply will not be used precisely.

However, for Android 3.x and 4.0 (API Level 11-15), your code would not be informed about being resized. You had to simply ensure that your layout would intelligently use any extra space automatically. Hence, resizing tended to be used primarily with adapter-driven app widgets, as will be discussed [in the next chapter](#).

Starting with API Level 16, though, you can find out when the user resizes your app widget, so you can perhaps use a different layout for a different size, or otherwise

## HOME SCREEN APP WIDGETS

---

adapt to the available space. Finding out about resize events takes a bit more work, as is illustrated in the [AppWidget/Resize](#) sample project.

This app widget project is similar to `PairOfDice`, described earlier in this chapter. However, our layout skips the dice, replacing them with a `TextView` widget in the `RelativeLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
    android:orientation="horizontal">

    <TextView
        android:id="@+id/size"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerInParent="true"
        android:textColor="@android:color/white"
        android:textAppearance="?android:attr/textAppearanceMedium">

    </TextView>
</RelativeLayout>
```

(from [AppWidget/Resize/app/src/main/res/layout/widget.xml](#))

Our `widget_provider.xml` resource stipulates our desired `android:resizeMode` and minimum resize dimensions:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="180dip"
    android:minHeight="110dip"
    android:minResizeWidth="110dip"
    android:minResizeHeight="40dip"
    android:initialLayout="@layout/widget"
    android:resizeMode="horizontal|vertical"
/>
```

(from [AppWidget/Resize/app/src/main/res/xml/widget\\_provider.xml](#))

Finding out about app widget resizing is a different event than finding out about app widget updates. Hence, we need to add a new `<action>` element to the `<intent-filter>` of our `<receiver>` in the manifest, indicating that we want

---

## HOME SCREEN APP WIDGETS

---

APPWIDGET\_OPTIONS\_CHANGED as well as ACTION\_UPDATE:

```
<receiver
    android:name="AppWidget"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <intent-filter>
        <action android:name="android.appwidget.action.APPWIDGET_UPDATE"/>
        <action android:name="android.appwidget.action.APPWIDGET_OPTIONS_CHANGED"/>
    </intent-filter>

    <meta-data
        android:name="android.appwidget.provider"
        android:resource="@xml/widget_provider"/>
</receiver>
```

(from [AppWidget/Resize/app/src/main/AndroidManifest.xml](#))

Then, our app widget implementation can override an `onAppWidgetOptionsChanged()` method:

```
@Override
public void onAppWidgetOptionsChanged(Context ctxt,
    AppWidgetManager mgr,
    int appWidgetId,
    Bundle newOptions) {
    RemoteViews updateViews=
        new RemoteViews(ctxt.getPackageName(), R.layout.widget);
    String msg=
        String.format(Locale.getDefault(),
            "[%d-%d] x [%d-%d]",
            newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MIN_WIDTH),
            newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MAX_WIDTH),
            newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MIN_HEIGHT),
            newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MAX_HEIGHT));

    updateViews.setTextViewText(R.id.size, msg);

    mgr.updateAppWidget(appWidgetId, updateViews);
}
```

(from [AppWidget/Resize/app/src/main/java/com/commonsware/android/appwidget/resize/AppWidget.java](#))

You will notice that we skip `onUpdate()`. We will be called with `onAppWidgetOptionsChanged()` when the app widget is added and resized. Hence, in the case of this app widget, we can define what the app widget looks like from `onAppWidgetOptionsChanged()`, avoiding `onUpdate()`. That being said, more typical app widgets will wind up implementing both methods, especially if they are supporting lower API levels than 16, where `onAppWidgetOptionsChanged()` will not be called.

## HOME SCREEN APP WIDGETS

---

Also remember that your process may well be terminated in between calls to app widget lifecycle methods like `onUpdate()` and `onAppWidgetOptionsChanged()`. Hence, if there is data from one method that you want in the other, be sure to persist that data somewhere.

In the `AppWidget` implementation of `onAppWidgetOptionsChanged()`, we can find out about our new app widget size by means of the `Bundle` supplied to our method. What we *cannot* find out is our exact size. Rather, we are provided minimum and maximum dimensions of our app widget via four values in the `Bundle`:

- `AppWidgetManager.OPTION_APPWIDGET_MIN_WIDTH`
- `AppWidgetManager.OPTION_APPWIDGET_MAX_WIDTH`
- `AppWidgetManager.OPTION_APPWIDGET_MIN_HEIGHT`
- `AppWidgetManager.OPTION_APPWIDGET_MAX_HEIGHT`

In our case, we grab these `int` values and pour them into a `String` template, using that to fill in the `TextView` of the app widget's contents.

When our app widget is initially launched, we show our initial size ranges:

*Figure 698: Resize Widget, As Initially Added*

## HOME SCREEN APP WIDGETS

---

When the user resizes our app widget, we show the new size ranges:

*Figure 699: Resize Widget, During Resize Operation*

However, not all home screen implementations will necessarily send the `APPWIDGET_OPTIONS_CHANGED` when an app widget is added to the home screen, only when the user resizes it later. For example, while the emulator's home screen for Android 4.1 broadcasts `APPWIDGET_OPTIONS_CHANGED`, it does not for 4.2 or 4.3. Hence, you may want to also examine the size information in `onUpdate()` as well, so that you react to the initial size as well as any future sizes. One way to do this is to simply iterate over the supplied app widget IDs and invoke your own `onAppWidgetOptionsChanged()` method:

```
// based on http://stackoverflow.com/a/18552461/115145

@Override
public void onUpdate(Context context,
                    AppWidgetManager appWidgetManager,
                    int[] appWidgetIds) {
    super.onUpdate(context, appWidgetManager, appWidgetIds);

    for (int appWidgetId : appWidgetIds) {
        Bundle options=appWidgetManager.getAppWidgetOptions(appWidgetId);
    }
}
```

```
onAppWidgetOptionsChanged(context, appWidgetManager, appWidgetId,  
                           options);  
    }  
}
```

(from [AppWidget/Resize/app/src/main/java/com/commonsware/android/appwidget/resize/AppWidget.java](#))

## Lockscreen Widgets

Android's lockscreen (a.k.a., the keyguard) had long been unmodifiable by developers. This led to a number of developers creating so-called "replacement lockscreens", which generally reduce device security, as they can be readily bypassed. However, on Android 4.2 through 4.4, developers can create app widgets that the user can deploy to the lockscreen, helping to eliminate the need for "replacement lockscreens".

However, note that this capability was dropped with Android 5.0. As a result, this particular app widget feature may not be something that you want to worry about. That being said, it is available for those versions, and you are welcome to support it for those versions.

Declaring that an app widget supports being on the lockscreen instead of (or in addition to) the home screen is very easy. All you must do is add an `android:widgetCategory` attribute to your app widget metadata resource. That attribute should have a value of either `keyguard` (for the lockscreen), `home_screen`, or both (e.g., `keyguard|home_screen`), depending upon where you want the app widget to be eligible. By default, if this attribute is missing, Android assumes a default value of `home_screen`.

Users cannot resize the lockscreen widgets at this time. However, you still will want to specify an `android:resizeMode` attribute in your app widget metadata, as whether or not you include vertical resizing will affect the height of your app widget. Lockscreen widgets without `vertical` will have a fixed small height on tablets, while lockscreen widgets with `vertical` will fill the available height. Lockscreen widgets on phones will always be small (to fit above the PIN/password entry area), and lockscreen widgets on all devices will stretch to fill available space horizontally.

You can also specify a different starting layout to use when your app is added to the lockscreen, as opposed to being added to the home screen. To do this, just add an `android:initialKeyguardLayout` attribute to your app widget metadata, pointing to the lockscreen-specific layout to use.

## HOME SCREEN APP WIDGETS

---

To see this in action, take a look at the [AppWidget/TwoOrThreeDice](#) sample project. This is a revised clone of the `PairOfDice` sample, allowing the dice to be added to the lockscreen, and showing three dice on the lockscreen instead of the two on the home screen.

Our app widget metadata now contains the lockscreen-related attributes: `android:widgetCategory` and `android:initialKeyguardLayout`:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="144dip"
    android:minHeight="72dip"
    android:updatePeriodMillis="900000"
    android:initialLayout="@layout/widget"
    android:initialKeyguardLayout="@layout/lockscreen"
    android:widgetCategory="keyguard|home_screen"
/>
```

(from [AppWidget/TwoOrThreeDice/app/src/main/res/xml/widget\\_provider.xml](#))

Our lockscreen layout simply adds a third die, `middle_die`:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
    >
    <ImageView android:id="@+id/left_die"
        android:layout_centerVertical="true"
        android:layout_alignParentLeft="true"
        android:src="@drawable/die_3"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginLeft="7dip"
    />
    <ImageView android:id="@+id/middle_die"
        android:layout_centerInParent="true"
        android:src="@drawable/die_2"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginLeft="7dip"
        android:layout_marginRight="7dip"
    />
    <ImageView android:id="@+id/right_die"
```

## HOME SCREEN APP WIDGETS

---

```
    android:layout_centerVertical="true"
    android:layout_alignParentRight="true"
    android:src="@drawable/die_2"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_marginRight="7dip"
  />
</RelativeLayout>
```

(from [AppWidget/TwoOrThreeDice/app/src/main/res/layout/lockscreen.xml](#))

However, by specifying a different layout for the lockscreen widget, we have a problem. We need to know, in our Java code, what layout to use for the RemoteViews and how many dice need to be updated. And, ideally, we would handle this in a backwards-compatible fashion, so our app widget will have its original functionality on older Android devices. Plus, supporting the lockscreen makes it that much more likely that the user will have more than one instance of our app widget (e.g., one on the lockscreen and one on the homescreen), so we should do a better job than `PairOfDice` did about handling multiple app widget instances.

To deal with the latter point, our new `onUpdate()` method iterates over each of the app widget IDs supplied to it and calls a private `updateWidget()` method for each, so we can better support multiple instances:

```
@Override
public void onUpdate(Context ctxt, AppWidgetManager mgr,
                    int[] appWidgetIds) {
    for (int appWidgetId : appWidgetIds) {
        updateWidget(ctxt, mgr, appWidgetId);
    }
}
```

(from [AppWidget/TwoOrThreeDice/app/src/main/java/com/commonsware/android/appwidget/dice/AppWidget.java](#))

The `updateWidget()` method is a bit more complicated than the `PairOfDice` equivalent code:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private void updateWidget(Context ctxt, AppWidgetManager mgr,
                          int appWidgetId) {
    int layout=R.layout.widget;

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        int category=
            mgr.getAppWidgetOptions(appWidgetId)
                .getInt(AppWidgetManager.OPTION_APPWIDGET_HOST_CATEGORY,
```

## HOME SCREEN APP WIDGETS

---

```
        -1);

    layout=
        (category == AppWidgetProviderInfo.WIDGET_CATEGORY_KEYGUARD)
            ? R.layout.lockscreen : R.layout.widget;
    }

    RemoteViews updateViews=
        new RemoteViews(ctxt.getPackageName(), layout);
    Intent i=new Intent(ctxt, AppWidget.class);

    i.putExtra(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetId);

    PendingIntent pi=
        PendingIntent.getBroadcast(ctxt, appWidgetId, i,
            PendingIntent.FLAG_UPDATE_CURRENT);

    updateViews.setImageResource(R.id.left_die,
        IMAGES[(int)(Math.random() * 6)]);
    updateViews.setOnClickPendingIntent(R.id.left_die, pi);
    updateViews.setImageResource(R.id.right_die,
        IMAGES[(int)(Math.random() * 6)]);
    updateViews.setOnClickPendingIntent(R.id.right_die, pi);
    updateViews.setOnClickPendingIntent(R.id.background, pi);

    if (layout == R.layout.lockscreen) {
        updateViews.setImageResource(R.id.middle_die,
            IMAGES[(int)(Math.random() * 6)]);
        updateViews.setOnClickPendingIntent(R.id.middle_die, pi);
    }

    mgr.updateAppWidget(appWidgetId, updateViews);
}
```

(from [AppWidget/TwoOrThreeDice/app/src/main/java/com/commonsware/android/appwidget/dice/AppWidget.java](#))

First, we need to choose which layout we are working with. We assume that we are to use the original `R.layout.widget` resource by default. But, if we are on API Level 17 or higher, we can call `getAppWidgetOptions()` on the `AppWidgetManager`, to get the `Bundle` of options — the same options that we could be delivered in `onAppWidgetOptionsUpdate()` as described [in the previous section](#). One value that will be in this `Bundle` is `AppWidgetManager.OPTION_APPWIDGET_HOST_CATEGORY`, which will be an `int` with a value of `AppWidgetProviderInfo.WIDGET_CATEGORY_KEYGUARD` if our app widget is on the lockscreen. In that case, we switch to using `R.layout.lockscreen`. In addition, we know then we need to update the `middle_die` when we are updating the other dice.

## HOME SCREEN APP WIDGETS

---

There is also a subtle change in our `getBroadcast()` call to `PendingIntent`: we pass in the app widget ID as the second parameter, whereas in `PairOfDice` we passed 0. `PendingIntent` objects are cached in our process, and by default we will get the same `PendingIntent` when we call `getBroadcast()` for the same `Intent`. However, in our case, we may *want* two or more different `PendingIntent` objects for the same `Intent`, with differing extras (`EXTRA_APPWIDGET_ID`). Since extras are not considered when evaluating equivalence of `Intent` objects, just having different extras is insufficient to get different `PendingIntent` objects for those `Intent` objects. The second parameter to `getBroadcast()` (and `getActivity()` and `getService()`) on `PendingIntent` is a unique identifier, to differentiate between two otherwise equivalent `Intent` objects, forcing `PendingIntent` to give us distinct `PendingIntent` objects. This way, we can support two or more app widget instances, each having their own `PendingIntent` objects for their click events.

On an Android 4.2+ lockscreen, you should be able to swipe to one side (e.g., a bezel swipe from left to right), to expose an option to add an app widget:

*Figure 700: Lockscreen Add-A-Widget Panel, On a 4.2 Emulator*

## HOME SCREEN APP WIDGETS

---

Tapping the “+” indicator (and, if needed, entering your device PIN or password), brings up an app widget chooser:

*Figure 701: Lockscreen Widget Selection List, On a 4.2 Emulator*

## HOME SCREEN APP WIDGETS

---

Choosing TwoOrThreeDice will then add the app widget to the lockscreen, with three dice, not two:

*Figure 702: Lockscreen with TwoOrThreeDice, On a 4.2 Emulator*

### Preview Images

App widgets can have preview images attached. Preview images are drawable resources representing a preview of what the app widget might look like on the screen. On tablets, this will be used as part of an app widget gallery, replacing the simple context menu presentation you used to see on Android 1.x and 2.x phones:

*Figure 703: App Widget Gallery, on Android 5.0*

## HOME SCREEN APP WIDGETS

---

To create the preview image itself, the Android 3.0+ emulator images contain a Widget Preview application that lets you run an app widget in its own container, outside of the home screen:

*Figure 704: The Widget Preview application, showing a preview of the Analog Clock app widget*

From here, you can take a snapshot and save it to external storage, copy it to your project's `res/drawable-nodpi/` directory (indicating that there is no intrinsic density assumed for this image), and reference it in your app widget metadata via an `android:previewImage` attribute. We will see an example of such an attribute in [the chapter on advanced app widgets](#).

## Being a Good Host

In addition to creating your own app widgets, it is possible to host app widgets. This is mostly aimed for those creating alternative home screen applications, so they can take advantage of the same app widget framework and all the app widgets being built for it.

This is not very well documented, but it involves the `AppWidgetHost` and

## HOME SCREEN APP WIDGETS

---

AppWidgetHostView classes. The latter is a View and so should be able to reside in an app widget host's UI like any other ordinary widget.

# Adapter-Based App Widgets

---

API Level 11 introduced a few new capabilities for app widgets, to make them more interactive and more powerful than before. The documentation lags a bit, though, so determining how to use these features takes a bit of exploring. Fortunately for you, the author did some of that exploring on your behalf, to save you some trouble.

## Prerequisites

Understanding this chapter requires that you have read [the preceding chapter](#) and all of its prerequisites.

## AdapterViews for App Widgets

In addition to the classic widgets available for use in app widgets and RemoteViews, five more were added for API Level 11:

1. GridView
2. ListView
3. StackView
4. ViewFlipper
5. AdapterViewFlipper

Three of these (GridView, ListView, ViewPager) are widgets that existed in Android since the outset. StackView was added in API Level 11 to provide a “stack of cards” UI:

*Figure 705: The Google Books app widget, showing a StackView*

AdapterViewFlipper works like a ViewPager, allowing you to toggle between various children with only one visible at a time. However, whereas with ViewPager all children are fully-instantiated View objects held by the ViewPager parent, AdapterViewFlipper uses the Adapter model, so only a small number of actual View objects are held in memory, no matter how many potential children there are.

With the exception of ViewPager, the other four all require the use of an Adapter. This might seem odd, as there is no way to provide an Adapter to a RemoteViews. That is true, but API Level 11 added new ways for Adapter-like communication between the app widget host (e.g., home screen) and your application. We will take an in-depth look at that in [an upcoming section](#).

## Building Adapter-Based App Widgets

In an activity, if you put a ListView or GridView into your layout, you will also need to hand it an Adapter, providing the actual row or cell View objects that make up the contents of those selection widgets.

In an app widget, this becomes a bit more complicated. The host of the app widget does not have any Adapter class of yours. Hence, just as we have to send the

## ADAPTER-BASED APP WIDGETS

---

contents of the app widget's UI via a RemoteViews, we will need to provide the rows or cells via RemoteViews as well. Android, starting with API Level 11, has a RemoteViewsService and RemoteViewsFactory that you can use for this purpose. Let's take a look, in the form of the [AppWidget/LoremWidget](#) sample project, which will put a ListView of 25 Latin words into an app widget.

### The AppWidgetProvider

At its core, our AppWidgetProvider (named WidgetProvider, in a stunning display of creativity) still needs to create and configure a RemoteViews object with the app widget UI, then use updateAppWidget() to push that RemoteViews to the host via the AppWidgetManager. However, for an app widget that involves an AdapterView, like ListView, there are two more key steps:

- You have to tell the RemoteViews the identity of a RemoteViewsService that will help fill the role that the Adapter would in an activity
- You have to provide the RemoteViews with a “template” PendingIntent to be used when the user taps on a row or cell in the AdapterView, to replace the onItemClick() or similar method you might have used in an activity

For example, here is WidgetProvider for our Latin-word app widget:

```
package com.commonware.android.appwidget.lorem;

import android.app.PendingIntent;
import android.appwidget.AppWidgetManager;
import android.appwidget.AppWidgetProvider;
import android.content.Context;
import android.content.Intent;
import android.net.Uri;
import android.widget.RemoteViews;

public class WidgetProvider extends AppWidgetProvider {
    public static String EXTRA_WORD=
        "com.commonware.android.appwidget.lorem.WORD";

    @Override
    public void onUpdate(Context ctxt, AppWidgetManager appWidgetManager,
        int[] appWidgetIds) {
        for (int i=0; i<appWidgetIds.length; i++) {
            Intent svcIntent=new Intent(ctxt, WidgetService.class);

            svcIntent.putExtra(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetIds[i]);
            svcIntent.setData(Uri.parse(svcIntent.toUri(Intent.URI_INTENT_SCHEME)));
```

## ADAPTER-BASED APP WIDGETS

---

```
RemoteViews widget=new RemoteViews(ctxt.getPackageName(),
                                   R.layout.widget);

widget.setRemoteAdapter(R.id.words, svcIntent);

Intent clickIntent=new Intent(ctxt, LoremActivity.class);
PendingIntent clickPI=PendingIntent
    .getActivity(ctxt, 0,
                clickIntent,
                PendingIntent.FLAG_UPDATE_CURRENT);

widget.setPendingIntentTemplate(R.id.words, clickPI);

appWidgetManager.updateAppWidget(appWidgetIds[i], widget);
}

super.onUpdate(ctxt, appWidgetManager, appWidgetIds);
}
}
```

(from [AppWidget/LoremWidget/app/src/main/java/com/commonsware/android/appwidget/lorem/WidgetProvider.java](#))

The call to `setRemoteAdapter()` is where we point the `RemoteViews` to our `RemoteViewsService` for our `AdapterView` widget. The main rules for the `Intent` used to identify the `RemoteViewsService` are:

1. The service must be identified by its data (`Uri`), so even if you create the `Intent` via the `Context-and-Class` constructor, you will need to convert that into a `Uri` via `toUri(Intent.URI_INTENT_SCHEME)` and set that as the `Uri` for the `Intent`. Why? While your application has access to your `RemoteViewsService` Class object, the app widget host will not, and so we need something that will work across process boundaries. You could elect to add your own `<intent-filter>` to the `RemoteViewsService` and use an `Intent` based on that, but that would make your service more publicly visible than you might want.
2. Any extras that you package on the `Intent` — such as the app widget ID in this case — will be on the `Intent` that is delivered to the `RemoteViewsService` when it is invoked by the app widget host.

Note that there are two flavors of `setRemoteAdapter()`. An older deprecated one takes the app widget ID as the first parameter. The current one does not. The current one, though, is only available on API Level 14 and higher.

---

## ADAPTER-BASED APP WIDGETS

---

The call to `setPendingIntentTemplate()` is where we provide a `PendingIntent` that will be used as the template for all row or cell clicks. As we will see in a bit, the underlying `Intent` in the `PendingIntent` will have more data added to it by our `RemoteViewsFactory`.

In all other respects, our `WidgetProvider` is unremarkable compared to other app widgets. It will need to be registered in the manifest as a `<receiver>`, as with any other app widget.

### The `RemoteViewsService`

Android supplies a `RemoteViewsService` class that you will need to extend, and this class is the one you must register with the `RemoteViews` for an `AdapterView` widget. For example, here is `WidgetService` (once again, a highly creative name) from the `LoremWidget` project:

```
package com.commonware.android.appwidget.lorem;

import android.content.Intent;
import android.widget.RemoteViewsService;

public class WidgetService extends RemoteViewsService {
    @Override
    public RemoteViewsFactory onGetViewFactory(Intent intent) {
        return(new LoremViewsFactory(this.getApplicationContext(),
                                     intent));
    }
}
```

(from [AppWidget/LoremWidget/app/src/main/java/com/commonware/android/appwidget/lorem/WidgetService.java](#))

As you can see, this service is practically trivial. You have to override one method, `onGetViewFactory()`, which will return the `RemoteViewsFactory` to use for supplying rows or cells for the `AdapterView`. You are passed in an `Intent`, the one used in the `setRemoteAdapter()` call. Hence, if you have more than one `AdapterView` widget in your app widget, you could elect to have two `RemoteViewsService` implementations, or one that discriminates between the two widgets via something in the `Intent` (e.g., custom action string). In our case, we only have one `AdapterView`, so we create an instance of a `LoremViewFactory` and return it. Google has suggested using `getApplicationContext()` here to supply the `Context` object to `RemoteViewsFactory`, instead of using the `Service` as a `Context`, though it is unclear why this is.

## ADAPTER-BASED APP WIDGETS

---

Another thing different about the RemoteViewsService is how it is registered in the manifest:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.appwidget.lorem"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-feature
        android:name="android.software.app_widgets"
        android:required="true"/>

    <application
        android:allowBackup="false"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name="LoremActivity"
            android:label="@string/app_name"
            android:theme="@android:style/Theme.Translucent.NoTitleBar">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>

        <receiver
            android:name="WidgetProvider"
            android:icon="@drawable/ic_launcher"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.appwidget.action.APPWIDGET_UPDATE"/>
            </intent-filter>

            <meta-data
                android:name="android.appwidget.provider"
                android:resource="@xml/widget_provider"/>
        </receiver>

        <service
            android:name="WidgetService"
            android:permission="android.permission.BIND_REMOTEVIEWS"/>
    </application>
</manifest>
```

---

## ADAPTER-BASED APP WIDGETS

---

(from [AppWidget/LoremWidget/app/src/main/AndroidManifest.xml](#))

Note the use of `android:permission`, specifying that whoever sends an Intent to `WidgetService` must hold the `BIND_REMOTEVIEWS` permission. This can only be held by the operating system. This is a security measure, so arbitrary applications cannot find out about your service and attempt to spoof being the OS and cause you to supply them with `RemoteViews` for the rows, as this might leak private data.

### The RemoteViewsFactory

A `RemoteViewsFactory` interface implementation looks and feels a lot like an `Adapter`. In fact, one could imagine that the Android developer community might create `CursorRemoteViewsFactory` and `ArrayRemoteViewsFactory` and such to further simplify writing these classes.

For example, here is `LoremViewsFactory`, the one used by the `LoremWidget` project:

```
package com.commonware.android.appwidget.lorem;

import android.appwidget.AppWidgetManager;
import android.content.Context;
import android.content.Intent;
import android.os.Bundle;
import android.widget.RemoteViews;
import android.widget.RemoteViewsService;

public class LoremViewsFactory implements
    RemoteViewsService.RemoteViewsFactory {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
    private Context ctxt=null;
    private int appWidgetId;

    public LoremViewsFactory(Context ctxt, Intent intent) {
        this.ctxt=ctxt;
        appWidgetId=
            intent.getIntExtra(AppWidgetManager.EXTRA_APPWIDGET_ID,
                AppWidgetManager.INVALID_APPWIDGET_ID);
    }

    @Override
    public void onCreate() {
```

## ADAPTER-BASED APP WIDGETS

---

```
// no-op
}

@Override
public void onDestroy() {
    // no-op
}

@Override
public int getCount() {
    return(items.length);
}

@Override
public RemoteViews getViewAt(int position) {
    RemoteViews row=
        new RemoteViews(ctxt.getPackageName(), R.layout.row);

    row.setTextViewText(android.R.id.text1, items[position]);

    Intent i=new Intent();
    Bundle extras=new Bundle();

    extras.putString(WidgetProvider.EXTRA_WORD, items[position]);
    extras.putInt(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetId);
    i.putExtras(extras);
    row.setOnClickFillInIntent(android.R.id.text1, i);

    return(row);
}

@Override
public RemoteViews getLoadingView() {
    return(null);
}

@Override
public int getViewTypeCount() {
    return(1);
}

@Override
public long getItemId(int position) {
    return(position);
}

@Override
public boolean hasStableIds() {
```

## ADAPTER-BASED APP WIDGETS

---

```
    return(true);
}

@Override
public void onDataChange() {
    // no-op
}
}
```

(from [AppWidget/LoremWidget/app/src/main/java/com/commonsware/android/appwidget/lorem/LoremViewsFactory.java](#))

You need to implement a handful of methods that have the same roles in a `RemoteViewsFactory` as they do in an `Adapter`, including:

1. `getCount()`
2. `getViewTypeCount()`
3. `getItemId()`
4. `hasStableIds()`

In addition, you have `onCreate()` and `onDestroy()` methods that you must implement, even if they do nothing, to satisfy the interface.

You will need to implement `getLoadingView()`, which will return a `RemoteViews` to use as a placeholder while the app widget host is getting the real contents for the app widget. If you return `null`, Android will use a default placeholder.

The bulk of your work will go in `getViewAt()`. This serves the same role as `getView()` does for an `Adapter`, in that it returns the row or cell `View` for a given position in your data set. However:

1. You have to return a `RemoteViews`, instead of a `View`, just as you have to use `RemoteViews` for the main content of the app widget in your `AppWidgetProvider`
2. There is no recycling, so you do not get a `View` (or `RemoteViews`) back to somehow repopulate, meaning you will create a new `RemoteViews` every time

The impact of the latter is that you do not want to put large data sets into an app widget, as scrolling may get sluggish, just as you do not want to implement an `Adapter` without recycling unused `View` objects.

In `LoremViewsFactory`, the `getViewAt()` implementation creates a `RemoteViews` for a custom row layout, cribbed from one in the Android SDK:

## ADAPTER-BASED APP WIDGETS

---

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2006 The Android Open Source Project

limitations under the License.
-->

<TextView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@android:id/text1"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:textAppearance="?android:attr/textAppearanceLarge"
    android:gravity="center_vertical"
    android:paddingLeft="8dp"
    android:paddingStart="8dp"
    android:textColor="@android:color/white"
    android:minHeight="?android:attr/listPreferredItemHeight"
/>
```

(from [AppWidget/LoremWidget/app/src/main/res/layout/row.xml](#))

Then, `getViewAt()` pours in a word from the static `String` array of Latin words into that `RemoteViews` for the `TextView` inside it. It also creates an `Intent` and puts the Latin word in as an `EXTRA_WORD` extra, then provides that `Intent` to `setOnClickFillInIntent()`. In addition, it adds the app widget instance ID as an extra, reusing the framework's own `AppWidgetManager.EXTRA_APPWIDGET_ID` as the key. The contents of the "fill-in" `Intent` are merged into the "template" `PendingIntent` from `setPendingIntentTemplate()`, and the resulting `PendingIntent` is what is invoked when the user taps on an item in the `AdapterView`. The fully-configured `RemoteViews` is then returned.

### The Rest of the Story

The app widget metadata needs no changes related to Adapter-based app widget contents. However, `LoremWidget` does add the `android:previewImage` attribute:

## ADAPTER-BASED APP WIDGETS

---

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="146dip"
    android:minHeight="146dip"
    android:updatePeriodMillis="0"
    android:initialLayout="@layout/widget"
    android:autoAdvanceViewId="@+id/words"
    android:previewImage="@drawable/preview"
    android:resizeMode="vertical"
/>
```

(from [AppWidget/LoremWidget/app/src/main/res/xml/widget\\_provider.xml](#))

This points to the `res/drawable-nodpi/preview.png` file that represents a “widgetshot” of the app widget in isolation, obtained from the Widget Preview application:

*Figure 706: The preview of LoremWidget*

Also, the metadata specifies `android:resizeMode="vertical"`. This attribute is new to Android 3.1, and allows the app widget to be resized by the user (in this case, only in the vertical direction, to show more rows). Older versions of Android will ignore this attribute, and the app widget will remain in your requested size. You can use `vertical`, `horizontal`, or `both` (via the pipe operator) as values for `android:resizeMode`.

## ADAPTER-BASED APP WIDGETS

---

When the user taps on an item in the list, our `PendingIntent` is set to bring up `LoremActivity`. This activity has `android:theme="@android:style/Theme.Translucent.NoTitleBar"` set in the manifest, meaning that [it will not have its own user interface](#). Rather, it will extract our `EXTRA_WORD` — and the app widget ID — out of the `Intent` used to launch the activity and displays it in a `Toast` before finishing:

```
package com.commonware.android.appwidget.lorem;

import android.app.Activity;
import android.appwidget.AppWidgetManager;
import android.os.Bundle;
import android.widget.Toast;

public class LoremActivity extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        String word=getIntent().getStringExtra(WidgetProvider.EXTRA_WORD);

        if (word == null) {
            word="We did not get a word!";
        }

        Toast.makeText(this,
            String.format("#%d: %s",
                getIntent().getIntExtra(AppWidgetManager.EXTRA_APPWIDGET_ID,
                    AppWidgetManager.INVALID_APPWIDGET_ID),
                word), Toast.LENGTH_LONG).show();

        finish();
    }
}
```

(from [AppWidget/LoremWidget/app/src/main/java/com/commonware/android/appwidget/lorem/LoremActivity.java](#))

## The Results

When you compile and install the application, nothing new shows up in the home screen launcher, because we have no activity defined to respond to `ACTION_MAIN` and `CATEGORY_HOME`. This would be unusual for an application distributed through the Play Store, as users often get confused if they install something and then do not know how to start it. However, for the purposes of this example, we should be fine, as readers of programming books never get confused about such things.

## ADAPTER-BASED APP WIDGETS

---

However, if you bring up the app widget gallery (e.g., long-tap on the home screen of an Android 6.0 device or emulator), you will see LoremWidget there, complete with preview image. You can drag it into one of the home screen panes and position it. When done, the app widget appears as expected:

*Figure 707: LoremWidget on Android Home Screen*

The `ListView` is live and can be scrolled. Tapping an entry brings up the corresponding `Toast`.

## ADAPTER-BASED APP WIDGETS

---

If the user long-taps on the app widget, they will be able to reposition it. On Android 3.1 and beyond, when they lift their finger after the long-tap, the app widget will show resize handles on the sides designated by your `android:resizeMode` attribute:

*Figure 708: LoremWidget on Android Home Screen, with Resize Handles*

## ADAPTER-BASED APP WIDGETS

---

The user can then drag those handles to expand or shrink the app widget in the specified dimensions:

*Figure 709: Resized LoremWidget on Android Home Screen*

# Publishing Slices

---

In 2018, Google introduced the concept of slices, as a way for apps to publish information to be embedded in the UI of other apps. Google is expected to make a major push for apps to publish slices. This chapter explores how this is done.

## What's a Slice?

What a slice actually is depends on your perspective.

From the user's standpoint, when they are in another app — such as Google Assistant — as part of their use of that app, they see data and UI elements that are tied to your app. So, for example, if your app helps users book hotel rooms, and the user asks the Assistant about a particular city, the Assistant might ask your app for a slice, to show the user hotel options in that city.

From the standpoint of your app, a slice is structured data, roughly analogous to publishing JSON from a Web service. While you get to specify text and images, and while you get to suggest particular types of user interactions (e.g., “allow the user to toggle this value between on and off”), the actual UI is rendered by another app. In some respects, this is reminiscent of [app widgets](#), but RemoteViews give you much more direct control over the actual UI than do slices.

## What Slices Contain

The data that makes up a slice is a combination of a generic UI structure and the user-facing elements (e.g., text, images) that should go into that UI structure. So, for example, you can create a list or grid, by saying that you want a series of rows and providing the text and images to go into those rows.

Elements in that UI structure can also be associated with `PendingIntent` objects to let you know when the user interacts with them, from simple clicks on image buttons, to being notified when the user changes values of toggles and sliders.

However, while you indicate in your code that you want a grid, the actual details of what that grid really looks like (margins, padding, colors, etc.) is up to the app that displays your slice. You do not get a vote.

### Where Slices Get Used

In many respects, this is the big mystery at the moment.

Google has indicated that some of their products — Search and Assistant — will support slices. Google has also published code to allow other apps to display slices. However, as with Google’s code for allowing apps to host app widgets, the code is largely undocumented. It remains to be seen how widespread slices become. They could be huge, or they could be a little-used feature — only time will tell.

### A Tale of Two Slices

There are two implementations of the slice API: the one that you will use, and the other one.

The one that you will use is in the `AndroidX` family of libraries. This works back to API Level 19 (Android 4.4), covering the vast majority of Android devices in use today.

The other one is native to Android 9.0. It is not completely clear why this exists, given that there is a library version, and given that Google has been trending away from having duplicate implementations of things (see the deprecated native implementations of fragments and loaders). Regardless, until your `minSdkVersion` rises to 28 or higher, you will want to use the `AndroidX` slice API.

As a result, this chapter focuses on the `AndroidX` slice API.

### Slice Sizes

When another app (the “hosting app”) elects to show a slice from your app, in principle, that slice will show up in one of three sizes.

It could show up in what amounts to a shortcut-style icon:

*Figure 710: Slice, “Shortcut” Rendering*

It could show up as a single “row”:

Header Title

This is the summary

*Figure 711: Slice, “Small” Rendering*

It could show up as a list of rows:

You do not really have control over which size the hosting app uses. You simply provide the data for the slice, and the hosting app decides how to render it. As a result, the slice API is designed to allow you to define the “large” rendering with a series of built-in fallbacks for how that is displayed in the “small” or “shortcut” sizes.

In theory, all hosting apps will render slices the same way. In practice, you should [make no assumptions](#) about how your slices will be rendered.

## Setting Up a Slice

In theory, Android Studio 3.2 offers a wizard for setting up the code to allow your app to publish slices. In practice, as of Android Studio 3.2 Canary 15, that wizard is rather buggy, and it will be better if you avoid it for now.

What you need are:

- The dependencies and other Gradle settings to allow you to use the

AndroidX slice API

- A `SliceProvider` implementation
- The `<provider>` element for that `SliceProvider`

### The Gradle Settings

The AndroidX slice API has dependencies on some things that are only a part of Android 9.0. As a result, you need to have `compileSdkVersion 28` at the moment in order to be able to use *either* slice API (native or AndroidX).

Also, the AndroidX family of libraries does not play nicely with the previous set of artifacts from the Android Support Library and related areas (e.g., the Architecture Components). You will need to:

- Use the `androidx` artifacts yourself
- Avoid any third-party libraries that depend upon the Android Support Library artifacts (until such time as the promised Jetifier tool starts to work)

For example, the [Slices/SamplerX](#) sample project has this `app/build.gradle` file:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 'android-P'

    defaultConfig {
        applicationId "com.commonware.android.slice.sampler"
        minSdkVersion 21
        targetSdkVersion 27
        versionCode 1
        versionName "1.0"
    }
}

dependencies {
    implementation 'androidx.appcompat:appcompat:1.0.0-beta01'
    implementation 'androidx.slice:slice-builders:1.0.0-beta01'
}
```

(from [Slices/SamplerX/app/build.gradle](#))

Here, in addition to `compileSdkVersion 28`, we have two `androidx` dependencies:

- `androidx.slice:slice-builders`, which will be your typical dependency for

using the AndroidX slice API

- `androidx.appcompat:appcompat`, which is the AndroidX edition of `appcompat-v7`, which your app will need to use, for reasons that will become clearer later in this chapter

## The SliceProvider

Your code that defines the slice will go in a subclass of `SliceProvider`. `SliceProvider` is supplied by the slice API. As its name suggests, it is a subclass of `ContentProvider`, but one where the API that you implement is tied to slices.

The method that you will almost always implement is `onBindSlice()`, where your job is to return the `Slice` to be shown:

```
@Override
public Slice onBindSlice(Uri sliceUri) {
    Context ctxt=getContext();

    if (ctxt==null) {
        return null;
    }

    ListBuilder builder=new ListBuilder(ctxt, sliceUri, ListBuilder.INFINITY)
        .setAccentColor(ctxt.getResources().getColor(R.color.colorAccent))
        .addAction(buildIconAction(ctxt, "Top-level Action",
            R.drawable.ic_looks_two_black_24dp));

    builder
        .setHeader(buildHeader(ctxt))
        .addRow(buildSimpleRow(ctxt))
        .addInputRange(buildRangeRow(ctxt));

    return builder.build();
}
```

(from [Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java](#))

We will explore this code in greater detail [shortly](#).

The other required method is `onCreateSliceProvider()`, where you can perform any up-front one-time initialization that you might need. Return true when this work — if any — is done:

```
@Override
public boolean onCreateSliceProvider() {
```

```
return true;
}
```

(from [Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java](#))

### The Manifest Entry

Since a `SliceProvider` is a `ContentProvider`, you will need a corresponding `<provider>` element in the manifest:

```
<provider
    android:name=".SamplerSliceProvider"
    android:authorities="${applicationId}.provider"
    android:exported="true" />
```

(from [Slices/SamplerX/app/src/main/AndroidManifest.xml](#))

As with every `<provider>`, the `android:authorities` must hold one or more unique values. Here, we use [manifest merging placeholders](#) to base our authority string off of the `applicationId` that we are defining in Gradle.

The `<provider>` must also be exported, via `android:exported="true"` and *not* have any permission-related attributes (e.g., `android:permission`). Normally, from a security standpoint, this is really bad, as it means that any app at any time can work with this provider, without user involvement. As it turns out, the slice API has its own permission system “baked into” the `SliceProvider` implementation.

## The Activity That You Didn't Write

Part of that permission system comes in the form of an activity that is automatically added to your manifest. If you open the manifest for your slice-enabled project and look at the “Merged Manifest” tab, you will see an `<activity>` element for an activity that you did not write, named `androidx.slice.compat.SlicePermissionActivity`:

```

▼ <provider
  android:authorities="com.commonware.android.slice.sampler.provider"
  android:exported="true"
  android:name="com.commonware.android.slice.sampler.SamplerSliceProvider"
▼ <receiver
  android:enabled="true"
  android:name="com.commonware.android.slice.sampler.SliceActionReceiver"
▼ <activity
  android:name="androidx.slice.compat.SlicePermissionActivity" >

```

Text Merged Manifest

Figure 713: Manifest Merger Tab, Showing Added Activity

By default, this activity will use the theme that you have established in your `<application>` element. Since `SlicePermissionActivity` uses `appcompat`, your theme would need to be based on `Theme.AppCompat`, or else this activity will crash when started. If the rest of your app is not using `appcompat`, you will need to use [the manifest merger process](#) to override the `android:theme` attribute for this added `<activity>`, pointing to a theme that *does* inherit from `Theme.AppCompat`:

```

<activity
  android:name="androidx.slice.compat.SlicePermissionActivity"
  android:theme="@style/YourAppCompatTheme" />

```

We will see where this activity gets used [later in this chapter](#).

## Binding a Slice

The bulk of your business logic for your slice will either be in your `onBindSlice()` method or called from that method:

```

@Override
public Slice onBindSlice(Uri sliceUri) {

```

## PUBLISHING SLICES

---

```
Context ctxt=getContext();

if (ctxt==null) {
    return null;
}

ListBuilder builder=new ListBuilder(ctxt, sliceUri, ListBuilder.INFINITY)
    .setAccentColor(ctxt.getResources().getColor(R.color.colorAccent))
    .addAction(buildIconAction(ctxt, "Top-level Action",
        R.drawable.ic_looks_two_black_24dp));

builder
    .setHeader(buildHeader(ctxt))
    .addRow(buildSimpleRow(ctxt))
    .addInputRange(buildRangeRow(ctxt));

return builder.build();
}
```

(from [Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java](#))

The first thing that all of Google’s examples do is check to see if `getContext()` returns null. In theory, this should never happen in a `ContentProvider`, and so it is unclear why they are doing this check. However, the check is cheap, and there is a chance that there is something odd about `SliceProvider` and `onBindSlice()` that causes `getContext()` to return null in some scenarios. So, just check it, and return null from `onBindSlice()` if `getContext()` returns null.

For simple providers, you can then start building your slice. Complex providers, though, might want to return different slices in different scenarios. A slice for showing the weather might want to show different results based on a location (e.g., weather in New York City versus weather in Chennai). You can examine the path portion of the `Uri` that is supplied to `onBindSlice()`, examine its path segments, and create different slices for different values (e.g., `/weather/cities/newyork` might return a different slice than does `/weather/cities/chennai`). In this case, though, you will need to decide what you are going to do if you get a `Uri` that is unexpected (e.g., no path segments, unrecognized city name).

Most slices will be constructed based on a `ListBuilder`. The `ListBuilder` allows you to build a list of rows that form the “large” representation of your slice. One of those rows will be designated the “header”, and that will be what forms the “small” representation of your slice. Also, you can associate an action with the `ListBuilder` itself, and that action’s icon will be what shows up for the “shortcut” representation of your slice.

## PUBLISHING SLICES

---

To create a `ListBuilder`, use the three-parameter constructor that takes:

- a `Context`, which you get from `getContext()` in your `SliceProvider`
- the `Uri` associated with this slice
- the “time to live” for the data in this slice, expressed in milliseconds

The “time to live” would appear to be used to trigger automatic refreshes of your slice, though it is unclear how this will be handled in hosting apps. If your slice data is not particularly time-sensitive, pass `ListBuilder.INFINITY` for the third parameter to the `ListBuilder` constructor.

The two methods that you will want to call for your initial `ListBuilder` setup are:

- `setAccentColor()`, to teach the `ListBuilder` how to tint the icons and widgets when your slice is rendered, and
- `addAction()`, to supply a `SliceAction`

This particular `SliceAction` is made up of three things:

- A message to be displayed, when relevant (e.g., as a content description for accessibility)
- An icon, using `IconCompat`, which usually comes from a bitmap or resource
- A `PendingIntent` to identify what should happen if the user triggers this action (e.g., taps on the shortcut icon)

Here, we use our own `buildIconAction()` method to create the `SliceAction`:

```
SliceAction buildIconAction(Context ctxt, String msg, @DrawableRes int iconRes) {
    return SliceAction.create(buildActionPI(ctxt, msg, iconRes),
        buildIcon(ctxt, iconRes), ListBuilder.ICON_IMAGE, msg);
}
```

(from [Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java](#))

That, in turn, uses `buildActionPI()` and `buildIcon()` methods:

```
PendingIntent buildActionPI(Context ctxt, String msg, int id) {
    Intent i=new Intent(ctxt, SliceActionReceiver.class)
        .putExtra(SliceActionReceiver.EXTRA_MSG, msg);

    return PendingIntent.getBroadcast(ctxt, id, i, PendingIntent.FLAG_UPDATE_CURRENT);
}
```

(from [Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java](#))

We use a broadcast `PendingIntent`, pointing to a `SliceActionReceiver`, which will

## PUBLISHING SLICES

---

just display a Toast with the text of our message, packaged into the Intent as EXTRA\_MSG:

```
package com.commonware.android.slice.sampler;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.widget.Toast;

public class SliceActionReceiver extends BroadcastReceiver {
    static final String EXTRA_MSG="msg";

    @Override
    public void onReceive(Context context, Intent intent) {
        Toast
            .makeText(context, intent.getStringExtra(EXTRA_MSG), Toast.LENGTH_LONG)
            .show();
    }
}
```

(from [Slices/SamplerX/app/src/main/java/com/commonware/android/slice/sampler/SliceActionReceiver.java](#))

A SliceAction can be configured in a few different ways — we will examine the details [later in the chapter](#).

In truth, our ListBuilder does have rows, which we add via `setHeader()`, `addRow()`, and `addInputRange()` methods. We will examine those [later in the chapter](#). For the moment, take it on faith that they add three rows to our list of rows, the first of which is our header.

## Trying a Slice

A slice is a data structure. What a hosting app will show is a rendered edition of that data structure. However, the rendering code is not in your slice-publishing app — that is in the hosting app. You have no built-in means of showing your slice.

To that end, Google has an [open source Slice Viewer utility](#) that you can use for testing your slice.

## Installing the Slice Viewer

Visit [the Releases area of the Slice Viewer GitHub repo](#) and find the latest release.

## PUBLISHING SLICES

There should be an APK file associated with that release. Download it and install it on your test device or emulator. For example, you could download the APK with your development machine's Web browser, then install the app via adb:

```
adb install /path/to/slice-viewer.apk
```

### Running Your Slice in the Viewer

The simplest way to get your slice into the Slice Viewer is by setting up a custom run configuration in Android Studio. To do this:

1. Choose Run > Edit Configurations from the Android Studio main menu
2. Click the + icon and choose to add an Android App run configuration
3. Give the run configuration an obvious name (e.g., run-slice)
4. Choose the appropriate module from the “Module” drop-down (e.g., app)
5. Change the “Launch” drop-down in the “Launch Options” group to be “URL”
6. Fill in `slice-content://...` in the “URL” field in the “Launch Options” group, where the ... is replaced by your provider's authority string and, if applicable, any path that you wish to receive in your Uri

Figure 714: Run Configuration for Use with the Slice Viewer

## PUBLISHING SLICES

---

1. Change anything else in the run configuration that you might normally change, if anything
2. Click “OK” to save the run configuration
3. Run that run configuration on a device or emulator that already has the Slice Viewer app installed

This will cause the Slice Viewer to display your slice... or, at least, display a permission request:

*Figure 715: Slice Viewer, Showing Permission Note*

## The User Flow

When the user is first presented with a slice from your app, the slice will not show any actual information. Instead, for “small” and “large” representations, it will show a message indicating that the hosting app wants to show a slice from your app. In the “shortcut” representation, the user just sees the icon.

When the user taps on the slice's UI, the `SlicePermissionActivity` will be displayed, asking the user to grant permission for the hosting app to show slices from your app:

If the user clicks “Allow”, then the user will be taken back to the hosting app, which should now show the actual slice, instead of the permission-request placeholder.

Hence, if the slice system works as designed, the hosting app should not have access to any data from your app unless the user allows such access via that permission request.

However, bear in mind that this is not a system-level permission grant. While the dialog is styled to look a bit like system security dialogs, it is really coming from your app, by way of the slice API.

## The SliceAction

The rows in your slice can contain `SliceAction` objects. We saw an example of this earlier, defining a `SliceAction` to be attached to the `ListBuilder`.

Many row types (“templates”) can have a primary action. This usually will control what happens when the user taps on the body of the row... [though that is not always the case](#).

Some row types take additional actions that will appear in the rows themselves. These actions come in one of two forms:

- Actions with an associated icon, where tapping the icon triggers the `PendingIntent`
- Actions that are tied to a `Switch` widget (or similar sort of “toggle”), where toggling the `Switch` on or off triggers the `PendingIntent`

In the latter case, the `Intent` inside of your `PendingIntent` will be augmented with a `Slice.EXTRA_TOGGLE_STATE` boolean extra, containing the checked state of the `Switch`. So, for example, if your `PendingIntent` is a broadcast, your `BroadcastReceiver` will receive an `Intent` that is set up as you have it in the `PendingIntent`, plus it will contain the `Slice.EXTRA_TOGGLE_STATE` extra.

## The Slice Item Templates

The bulk of the content of a slice comes in the form of rows that you hand to the `ListBuilder`.

Those rows are defined using a fixed roster of “templates”. You describe the basic type of row (e.g., a simple row, a row showing a series of grid cells) and the data that should go into that row. The hosting app — typically in conjunction with some Google-supplied rendering code — will use that information to render your slice in the hosting app’s UI. As a result, you do not have pixel-level control over what the rows look like. You control some icons, the accent color, and the text to be displayed, and perhaps some actions, and that’s about it.

There are five row templates: “simple rows”, headers, range rows, input range rows, and grid rows.

### Simple Rows

A simple row is defined using a `ListBuilder.RowBuilder` and added to a `ListBuilder` via its `addRow()` method.

Simple rows offer:

## PUBLISHING SLICES

---

- A title and subtitle, as simple text
- A primary action, in the form of a `SliceAction`
- A start (“title”) item and one or more end items, each of which is either an icon, a `SliceAction`, or a timestamp

All of these are optional, though if you supply none of them, your row does not show up in the rendered output.

In the sample app, we are setting the title, subtitle, and primary action, along with one end item:

```
RowBuilder buildSimpleRow(Context ctxt) {
    return new RowBuilder()
        .setTitle("Simple Row Title")
        .setSubtitle("This is the subtitle")
        .setPrimaryAction(buildIconAction(ctxt, "Simple Row Primary Action",
            R.drawable.ic_looks_4_black_24dp))
        .addEndItem(buildToggleAction(ctxt, "Simple Row End Item", R.id.toggle));
}
```

(from [Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java](#))

The end item is a Switch, created via `SliceAction.createToggle()`:

```
SliceAction buildToggleAction(Context ctxt, String msg, int id) {
    return SliceAction.createToggle(buildActionPI(ctxt, msg, id), msg, false);
}
```

(from [Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java](#))

In principle, our `PendingIntent` could point to something that will use the `Slice.EXTRA_TOGGLE_STATE` extra to react to the now-current Switch state; in this app, that extra is ignored.

## Headers

A header row is created using a `ListBuilder.HeaderBuilder` and is attached to the `ListBuilder` via its `setHeader()` method. As the name suggests, a list-based slice has only one header, whereas it can have several of the other row templates.

In addition to the same sort of title and subtitle support as is seen in simple rows, `HeaderBuilder` has a `setSummary()` method, which provides text that may be used in circumstances where the entire list is not displayed:

```
ListBuilder.HeaderBuilder buildHeader(Context ctxt) {
    return new ListBuilder.HeaderBuilder()
        .setTitle("Header Title")
        .setSubtitle("This is the subtitle")
        .setSummary("This is the summary", false)
        .setPrimaryAction(buildIconAction(ctxt, "Header Primary Action",
            R.drawable.ic_looks_one_black_24dp));
}
```

(from [Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java](#))

In “small” mode, the summary is shown in place of the subtitle.

Headers can have actions. Those added via `addAction()` are simply shown in the header. The “primary action” behaves differently [depending on circumstances](#), as was the case with simple rows. All actions on headers will appear at the end, after the title and subtitle.

### Range Rows and Input Range Rows

“Range rows” show value on a numerical scale, by default using a `ProgressBar` or similar widget. An “input range row” uses a `SeekBar` or similar widget, to allow the user to choose something within the numerical range.

Despite the similar names, these are independent constructs:

- Use a `ListBuilder.RangeBuilder` to add a range row to a `ListBuilder`, via its `addRange()` method
- Use a `ListBuilder.InputRangeBuilder` to add an input range row to a `ListBuilder`, via its `addInputRange()` method

The builders have a similar API:

- `setTitle()`, `setSubtitle()`, and `setPrimaryAction()` akin to simple rows
- `setValue()` and `setMax()` to set the current value and the maximum value for the range (where the minimum is 0)

`ListBuilder.InputRangeBuilder` additionally has an [oddly-named](#) `setInputAction()` method, where you supply a `PendingIntent` to be sent when the user changes the `SeekBar` position. Your component responding to the `PendingIntent` will have access to a `Slice.EXTRA_RANGE_VALUE` extra with the new value of the `SeekBar`. Note that `setInputAction()` is required; you will crash at runtime if you fail to supply a `PendingIntent` via this method.

The SamplerX sample app offers an input range row:

```
ListBuilder.InputRangeBuilder buildRangeRow(Context ctxt) {
    return new ListBuilder.InputRangeBuilder()
        .setTitle("Range Title")
        .setSubtitle("This is the subtitle")
        .setMax(10)
        .setValue(5)
        .setPrimaryAction(buildIconAction(ctxt, "Range Primary Action",
            R.drawable.ic_looks_5_black_24dp))
        .setInputAction(buildActionPI(ctxt, "Range Selection Changed", R.id.range));
}
```

(from [Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java](#))

We will see an example of a range row [later in this chapter](#).

## Grid Rows

A slice can also have a “grid row”. This template uses a series of cells for the content. Each cell is created by a `ListBuilder.GridRowBuilder.CellBuilder`, where the row overall is created by a `ListBuilder.GridRowBuilder`. The resulting row is added to the `ListBuilder` via its `addGridRow()` method.

Unlike the other row types, a grid row has no title, subtitle, or actions (other than a primary action). It simply has cells. Each cell can have some mix of:

- “title text” (which might be rendered in bold)
- text
- images

You can have up to two pieces of text and one image, but they can appear in whatever order you want. They will be vertically stacked within the cell, with the roster of cells laid out horizontally within the row.

The row might be horizontally scrollable. If there is not enough room to show all of your cells, your “see more” data (`setSeeMoreAction()` or `setSeeMoreCell()`) will be used to allow the user to do something to see the rest of the data, such as launch one of your activities.

We will see a grid row [later in this chapter](#).

## Hey, What About...?

You cannot invent your own row templates, insofar as the slice API does not have an

---

extensible API for this. Bear in mind that any custom templates would have to be honored both by slice publishers and slice hosting apps, which limits the utility of any “home-grown” row templates.

However, it is likely that Google will add more row templates to the slice API over time. There are already hints that they will allow for text input, akin to how that is offered in notifications.

## Actions and Sizes

Given those templates, plus the API of `ListBuilder`, it would seem that the rules for actions would be simple:

- Actions defined on the rows are used on those rows
- Actions defined on the `ListBuilder` would be used in other situations, such as shortcut mode, where there are no rows

Unfortunately, [that is not how it works](#).

## Shortcut Mode

When your slice is rendered as a shortcut, the primary action *of the first row* is used for the shortcut. It is that primary action’s icon that is displayed, and it is that primary action’s `PendingIntent` that is invoked when the user taps on that shortcut.

Actions defined on the `ListBuilder`, elsewhere on the first row, or on other rows, are ignored in this mode.

## Small and Large Modes

When your slice is rendered in “small” mode, the first row of your list is what is shown. Typically, that will be the header row, but a header row is optional – whatever the first row is that you hand to the `ListBuilder` will be used.

When your slice is rendered in “large” mode, more of your rows are shown, though the exact number may depend on the amount of screen space allocated to the slice.

Actions that you define on the `ListBuilder` will show up as “end items” on the first row. The row’s primary action controls what happens if the user clicks on the body of the row itself, but the primary action’s icon is not used.

The primary action on the second and subsequent rows in “large” mode is simply used for handling the clicks on the row body. The icon for such actions is ignored.

## Asynchronous Slices

The `SamplerX` project demonstrates the basics of showing a slice and illustrates how to use some common row templates. However, on the whole, it is not very realistic. Usually, there will be some application data that you wish to display in the slice, whether from a database, file, Web service, or other source.

In an ideal world, getting this data would be instantaneous. As Android developers know all too well, any form of I/O is slow, some slower than others.

In a nice-if-not-ideal world, the slice API would have a built-in system for allowing us to load data asynchronously, in a reliable fashion. Alas, it does not. In fact, `onBuildSlice()` is a blocking call — we need to return from it very quickly, or else the slice hosting app may freeze up or otherwise offer a poor user experience.

While we might offer an optimized path in `onBuildSlice()` for creating the “real” slice using data that is cached, we cannot assume that the data that we need will be cached in memory. It is likely that we have no process at all prior to the request for our slice leading to the `onBuildSlice()` call. As a result, we need to handle both the “we have the data” case and the “we need to load the data” case, which gets a bit complicated.

If you want to include images that come from the network, things get even more complicated. For privacy and security reasons — plus simplicity, most likely — you cannot put a URL to some hosted image in a slice. Instead, you need to create an `IconCompat` based on the `Bitmap` that you get from downloading the image identified by the URL. That, in turn, gets a bit interesting, because most of the popular image-loading libraries are designed for asynchronous use. Here, asynchronous APIs are not an option: we need the `Bitmap` to load into the slice, before `onBindSlice()` returns.

The [Slices/WeatherSlice](#) sample project will attempt to demonstrate all of this, though the details of asynchronously loading your app’s data will vary widely by app. This particular app will show the weather forecast for New York City, pulled from the US National Weather Service’s Web service API.

## Dealing with No Data

If you have no data, you need to still return a slice from `onBindSlice()`. However, there is no requirement that the slice resemble the “real” slice that you would return when you do have your data. You are welcome to use whatever sort of row structure that you want to let the user know that you are busily fetching the data for their slice.

In `WeatherSliceProvider` - the `WeatherSlice` sample’s `SliceProvider` subclass – when we have no data, we return a slice with a range bar that theoretically shows download progress:

```
package com.commonware.android.slice.weather;

import android.app.PendingIntent;
import android.content.Context;
import android.content.Intent;
import android.net.Uri;
import org.threeten.bp.OffsetDateTime;
import org.threeten.bp.format.DateTimeFormatter;
import org.threeten.bp.format.FormatStyle;
import androidx.annotation.DrawableRes;
import androidx.core.graphics.drawable.IconCompat;
import androidx.slice.Slice;
import androidx.slice.SliceProvider;
import androidx.slice.builders.GridRowBuilder;
import androidx.slice.builders.ListBuilder;
import androidx.slice.builders.SliceAction;
import static androidx.slice.builders.ListBuilder.LARGE_IMAGE;

public class WeatherSliceProvider extends SliceProvider {
    static final Uri NYC_FORECAST=
        Uri.parse(
            "https://forecast.weather.gov/MapClick.php?lat=40.7146&lon=-74.0071");
    static final DateTimeFormatter FORMATTER=
        DateTimeFormatter.ofLocalizedDateTime(FormatStyle.SHORT);
    static final Uri ME=new Uri.Builder()
        .scheme("content")
        .authority(BuildConfig.APPLICATION_ID+".provider")
        .build();

    @Override
    public boolean onCreateSliceProvider() {
        return true;
    }

    public Slice onBindSlice(Uri sliceUri) {
        Context ctxt=getContext();

        if (ctxt==null) {
            return null;
        }

        ListBuilder builder=new ListBuilder(ctxt, sliceUri, ListBuilder.INFINITY)
```

## PUBLISHING SLICES

---

```
        .setAccentColor(ctxt.getResources().getColor(R.color.colorAccent));

builder.setHeader(buildHeader(ctxt));

WeatherResponse weather=Forecaster.LATEST;

if (weather==null) {
    Forecaster.enqueueWork(getContext());

    builder.addRange(new ListBuilder.RangeBuilder()
        .setTitle(ctxt.getString(R.string.downloading)));
}
else {
    builder.addGridRow(buildGridRow());
}

return builder.build();
}

ListBuilder.HeaderBuilder buildHeader(Context ctxt) {
return new ListBuilder.HeaderBuilder()
    .setTitle(ctxt.getString(R.string.header_title))
    .setPrimaryAction(
        buildIconAction(ctxt, ctxt.getString(R.string.msg_forecast),
            R.drawable.ic_wb_sunny_black_24dp));
}

GridRowBuilder buildGridRow() {
GridRowBuilder row=new GridRowBuilder();

for (int i=0; i<Forecaster.COUNT; i++) {
WeatherResponse.Period period=Forecaster.LATEST.properties.periods.get(i);
OffsetDateTime odt=OffsetDateTime.parse(period.startTime);

row.addCell(new GridRowBuilder.CellBuilder()
    .addTitleText(odt.format(FORMATTER))
    .addImage(IconCompat.createWithBitmap(period.iconBitmap), LARGE_IMAGE)
    .addText(
        String.format("%d%s", period.temperature, period.temperatureUnit)));
}

return row;
}

SliceAction buildIconAction(Context ctxt, String msg,
    @DrawableRes int iconRes) {
return SliceAction.create(buildActionPI(ctxt, iconRes),
    buildIcon(ctxt, iconRes), ListBuilder.ICON_IMAGE, msg);
}

PendingIntent buildActionPI(Context ctxt, int id) {
Intent i=new Intent(Intent.ACTION_VIEW, NYC_FORECAST);

return PendingIntent.getActivity(ctxt, id, i,
    PendingIntent.FLAG_UPDATE_CURRENT);
}

IconCompat buildIcon(Context ctxt, @DrawableRes int iconRes) {
return IconCompat.createWithResource(ctxt, iconRes);
}
}
```

## PUBLISHING SLICES

---

```
}
```

(from [Slices/WeatherSlice/app/src/main/java/com/commonsware/android/slice/weather/WeatherSliceProvider.java](#))

We will explore what a `WeatherResponse` is and what a `Forecaster` is later. For the moment, we are focusing on the case where `Forecaster.LATEST` is `null`, in which case our slice has a header row plus the range row. When the slice is first run, we have not had a chance to download a weather forecast, so the range bar shows up:

*Figure 717: Slice Viewer App, Showing WeatherSlice, Without a Forecast*

### Loading the Data

We cannot load our data in `onBindSlice()`, because it may take a while. In this sample, we offload that work to a `Forecaster` class. `Forecaster` is a `JobIntentService`, and its responsibility is to use `Retrofit` to download the weather forecast.

`WeatherResponse` and some related classes contain the forecast itself:

```
package com.commonsware.android.slice.weather;  
  
import android.graphics.Bitmap;  
import java.util.List;
```

## PUBLISHING SLICES

---

```
public class WeatherResponse {
    public final Properties properties=null;

    public static class Properties {
        public final List<Period> periods=null;
    }

    public static class Period {
        public final String startTime=null;
        public final int temperature;
        public final String temperatureUnit=null;
        public final String icon=null;
        public Bitmap iconBitmap;

        public Period() {
            temperature=0;
        }
    }
}
```

(from [Slices/WeatherSlice/app/src/main/java/com/commonsware/android/slice/weather/WeatherResponse.java](#))

This is structured as the National Weather Service Web API returns it... with one slight difference. The Web service API returns a URL to an icon representing a forecast in the `icon` field of the `Period` class. However, for our slice, we need the actual image itself.

Hence, the `onHandleWork()` method of `Forecaster` not only uses `Retrofit` to retrieve the Web service response, but it also uses `OkHttp` to download the image for a given forecast `Period` and uses `BitmapFactory` to decode that image into a `Bitmap`:

```
package com.commonsware.android.slice.weather;

import android.content.Context;
import android.content.Intent;
import android.graphics.BitmapFactory;
import android.util.Log;
import androidx.annotation.NonNull;
import androidx.core.app.JobIntentService;
import okhttp3.OkHttpClient;
import okhttp3.Request;
import okhttp3.ResponseBody;
import retrofit2.Retrofit;
import retrofit2.converter.gson.GsonConverterFactory;

public class Forecaster extends JobIntentService {
```

## PUBLISHING SLICES

---

```
static WeatherResponse LATEST=null;
static final int COUNT=4;
private static final double NYC_LATITUDE=40.730610;
private static final double NYC_LONGITUDE=-73.935242;
private static final int UNIQUE_JOB_ID=1337;

static void enqueueWork(Context ctxt) {
    enqueueWork(ctxt, Forecaster.class, UNIQUE_JOB_ID,
        new Intent(ctxt, Forecaster.class));
}

@Override
public void onHandleWork(@NonNull Intent intent) {
    OkHttpClient ok=new OkHttpClient.Builder().build();
    Retrofit retrofit=
        new Retrofit.Builder()
            .client(ok)
            .baseUrl("https://api.weather.gov")
            .addConverterFactory(GsonConverterFactory.create())
            .build();
    NWSInterface nws=retrofit.create(NWSInterface.class);
    double roundedLat=(double)Math.round(NYC_LATITUDE*10000d)/10000d;
    double roundedLon=(double)Math.round(NYC_LONGITUDE*10000d)/10000d;

    try {
        WeatherResponse response=
            nws.getForecast(roundedLat, roundedLon).execute().body();

        for (int i=0;i<COUNT;i++) {
            WeatherResponse.Period period=response.properties.periods.get(i);
            ResponseBody body=ok
                .newCall(new Request.Builder().url(period.icon).build())
                .execute()
                .body();

            period.iconBitmap=BitmapFactory.decodeStream(body.byteStream());
        }

        LATEST=response;
        getContentResolver().notifyChange(WeatherSliceProvider.ME, null);
    }
    catch (Throwable t) {
        Log.e(getClass().getSimpleName(),
            "Exception from Retrofit request to National Weather Service", t);
    }
}
```

---

## PUBLISHING SLICES

---

(from [Slices/WeatherSlice/app/src/main/java/com/commonsware/android/slice/weather/Forecaster.java](#))

Once we have our data, we need to let the slice hosting app know to reload the slice. To do that, we use `notifyChange()` on a `ContentResolver`, telling it that the data at our provider's `Uri` has changed. Through either a `ContentObserver` or `JobScheduler`, the slice hosting app will find out about our data change and will reload our slice, triggering a fresh call to `onBindSlice()` in `WeatherSliceProvider`.

### Using the Data

This time, `onBindSlice()` will see that `Forecaster.LATEST` has data, and it builds a slice with two rows: a header and a grid row:

```
ListBuilder.HeaderBuilder buildHeader(Context ctxt) {
    return new ListBuilder.HeaderBuilder()
        .setTitle(ctxt.getString(R.string.header_title))
        .setPrimaryAction(
            buildIconAction(ctxt, ctxt.getString(R.string.msg_forecast),
                R.drawable.ic_wb_sunny_black_24dp));
}

GridRowBuilder buildGridRow() {
    GridRowBuilder row=new GridRowBuilder();

    for (int i=0; i<Forecaster.COUNT; i++) {
        WeatherResponse.Period period=Forecaster.LATEST.properties.periods.get(i);
        OffsetDateTime odt=OffsetDateTime.parse(period.startTime);

        row.addCell(new GridRowBuilder.CellBuilder()
            .addTitleText(odt.format(FORMATTER))
            .addImage(IconCompat.createWithBitmap(period.iconBitmap), LARGE_IMAGE)
            .addText(
                String.format("%d%s", period.temperature, period.temperatureUnit)));
    }

    return row;
}
```

(from [Slices/WeatherSlice/app/src/main/java/com/commonsware/android/slice/weather/WeatherSliceProvider.java](#))

We have one cell per forecast period, where `Forecaster` is only downloading the icons for `COUNT` periods (defined as 4 in the current code). Each cell contains:

- the date and time for the forecast period,
- the image of the forecast, from the downloaded `Bitmap`, and
- the forecasted temperature

The date and time come from the National Weather Service API in ISO-8601 format. This app uses [Jake Wharton's ThreeTenABP library](#), which offers a set of Java classes that mimic the Java 8 `java.time` classes. We use `OffsetDateTime` to parse the

ISO-8601 string, then use a static `DateTimeFormatter` to create a better-formatted bit of text to show the user.

For each cell, we use a `GridRowBuilder.CellBuilder` to create the cell, add it to the row via `addCell()`, and add the overall `GridRowBuilder` to the `ListBuilder` via `addGridRow()`.

For the image portion of the cells, we pass in `LARGE_IMAGE` as a flag, indicating that we want the image to be as large as possible. Alternatives are `ICON_IMAGE` (rendered small and tinted with your accent color) and `SMALL_IMAGE` (rendered small but not tinted).

Note that we add a primary action to the header. Slices require a primary action; otherwise the slice-building code will crash:

```
java.lang.IllegalStateException: A slice requires a primary action; ensure one of
your builders has called #setPrimaryAction with a valid SliceAction.
    at
androidx.slice.builders.impl.ListBuilderV1Impl.build(ListBuilderV1Impl.java:142)
    at androidx.slice.builders.ListBuilder.build(ListBuilder.java:235)
    at
com.commonware.android.slice.weather.WeatherSliceProvider.onBindSlice(WeatherSliceProvider.java:73)
    at
androidx.slice.compat.SliceProviderWrapperContainer$SliceProviderWrapper.onBindSlice(SliceProviderWrapp
    at android.app.slice.SliceProvider.onBindSliceStrict(SliceProvider.java:545)
    at android.app.slice.SliceProvider.handleBindSlice(SliceProvider.java:459)
    at android.app.slice.SliceProvider.call(SliceProvider.java:365)
    at android.content.ContentProvider$Transport.call(ContentProvider.java:401)
    at
android.content.ContentProviderNative.onTransact(ContentProviderNative.java:272)
    at android.os.Binder.execTransact(Binder.java:731)
```

In this case, the primary action brings up a Web browser to view a weather forecast for New York City.

## Warning: Make No Rendering Assumptions

With an Android app's own UI, given sufficient work, you can have pixel-perfect control. When an Android app contributes to other UI — such as a Notification — you lose that level of control. Slices work the same way, in that you provide the data to be displayed but do not have absolute control over the way it looks.

That lack of control will be visible in most, if not all, slice hosting apps. In part, this

## PUBLISHING SLICES

---

is due to screen space, as the host gets to decide how much space to allocate to the slice, which in turn steers the design towards a particular rendering mode (e.g., “small” or “shortcut” for smaller areas).

However, while many slice hosts will just use the rendered output from Google’s supplied slice rendering code, other slice hosts will make changes to that View hierarchy or even process the slices themselves. In these cases, the look of your slice may vary radically from the normal output that you see in apps like the Slice Viewer.

All that you get to do is supply the data and related hints as to how you want things to be rendered, and the slice host decides what to do. So, for example, if your slice has lots of rows, the rendered slice may or may not support scrolling to view all of those rows. You can, if you wish, call `setSeeMoreAction()` to supply a `SliceAction` that the slice host can attach to some form of “see more” button. Or, you can call `setSeeMoreRow()` to provide a simple row that will be displayed when scrolling is disabled, where you can have actions that help the user to get to an activity or something that will show them all of the data.

For example, here is the output from the `WeatherSlice` sample, showing a forecast:

*Figure 718: WeatherSlice, As Rendered by Slice Viewer App*

## PUBLISHING SLICES

---

We supplied the text and image. However, we do not control the actual formatting, such as:

- How many cells to show (we supplied 4, but only 3 are rendered)
- What size font is used for the text
- How large the ImageView is for the forecast
- What aspect ratio is used for the ImageView
- How the vertical whitespace is allocated
- And so on

## Other Slice Viewer Features

On the screen that appears in the Slice Viewer when you run your slice via your custom run configuration, an action bar item will allow you to switch between the three rendering modes (shortcut, small, large), so you can see what your slice looks like in all three modes.

If you launch the Slice Viewer directly from the home screen or other launcher, you will be presented with a list of all slices that you have run previously:

Figure 719: Slice Viewer Launcher Activity, Showing Two Slices

## PUBLISHING SLICES

---

This screen has the same action bar option for switching between the three rendering modes. The action bar also has a SearchView (or something similar) where you can type in the ContentProvider Uri for a slice (e.g., `content://com.commonware.android.slice.sampler.provider`), to load a slice that way. The arrow icons next to each Uri take you to the same screen that is displayed when you run your slice via the run configuration, showing just that one slice.

# Hosting Slices

---

For a `SliceProvider` to be useful, something need to be able to request and display a slice served by that provider. In this chapter, we will explore what it takes to do just that: display in your app a slice obtained from some other app's `SliceProvider`.

## What You Need to Know

Hosting slices is tied very closely to `LiveData` from the Architecture Components. In a nutshell, `LiveData` is a way for you to subscribe to updates to some source of data, akin to subscribing to an RxJava `Observable`. `LiveData` has the added benefit of being aware of the Android lifecycle, so it can cleanly unsubscribe from the data source when the hosting activity or fragment is destroyed. You can learn more about `LiveData` from CommonsWare's book, [Android's Architecture Components](#).

The [Slices/Inspector](#) sample project shown in this chapter happens to be written in Kotlin. If you are not familiar with Kotlin, focus less on the syntax shown in the examples and more on the concepts outlined in the prose.

## Why?

Just because *somebody* needs to host slices does not mean that *you* have to host slices in your app. So, why would you bother writing code to display other apps' slices?

- Perhaps you are not interested in hosting slices from *arbitrary* apps, but instead wish to host slices from other apps in your app suite, as a form of integration.
- Perhaps you are interested in integrating slices from specific slice providers,

## HOSTING SLICES

---

if they happen to be installed on the device. For example, someday, the Wikipedia app might offer slices tied to search terms, where the slice might have a sentence about the topic and perhaps an image. That slice could lead users over to the Wikipedia app to learn more. You might be interested in displaying their slices, rather than hooking up to some Wikipedia-specific API, to help users learn more about specific terms that they encounter in your app.

- Perhaps you maintain a home screen/launcher app, and you want to offer slices as another form of interactive content, alongside classic Android [app widgets](#).
- Perhaps a firm like Amazon might offer slices based on products, where your request for their slice can include a referral code. Users who purchase products from your app (and your hosted Amazon slices) trigger you to earn referral fees, as another income source.

Depending on how the slice ecosystem evolves, there could be many good reasons to host slices. And, the good news is that for simple scenarios, hosting slices is not very difficult.

## How?

You have two main approaches for hosting a slice. Most developers will take the simple approach, using some Google-supplied library code to display and update the slice. If needed, though, you can get at the raw information about the slice and build your own custom rendered edition of that information.

In both cases, for the moment, we will assume that we know the `Uri` of the `SliceProvider`. In the Inspector sample app, to keep it simple, this value is hard-coded in `gradle.properties` to be the `SamplerX` example from [the chapter on publishing slices](#):

```
SLICE_URI=content://com.commonware.android.slice.dice.provider
```

(from [Slices/Inspector/gradle.properties](#))

You can test using the Inspector with any other slice provider simply by changing that line to provide the `Uri` that you wish to test. That `Uri` is then hoisted into `BuildConfig` via a `buildConfigField` statement in `app/build.gradle`:

```
buildConfigField "String", "SLICE_URI", "' ' + SLICE_URI + ' ' "
```

(from [Slices/Inspector/app/build.gradle](#))

So, the app's code can identify our SliceProvider via `BuildConfig.SLICE_URI`.

### The Simple Way: SliceView

Only two classes are really needed to render a slice given the Uri:

- `SliceView`, which is a widget that knows how to display a slice, and
- `SliceLiveData`, which is a `LiveData` that knows how to communicate with a `SliceProvider`, given its Uri, and push slice data to a `SliceView`

The sample app has a `ViewPager` with four tabs. The first three tabs each show a slice from the provider identified by `SLICE_URI`. Those tabs each use a `SliceView`, centered inside of a `ConstraintLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<androidx.constraintlayout.widget.ConstraintLayout xmlns:android="http://schemas.android.com/apk/res/
android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@android:color/darker_gray">

    <androidx.slice.widget.SliceView
        android:id="@+id/slice"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_margin="8dp"
        android:background="@android:color/white"
        app:layout_constraintBottom_toBottomOf="parent"
        app:layout_constraintEnd_toEndOf="parent"
        app:layout_constraintStart_toStartOf="parent"
        app:layout_constraintTop_toTopOf="parent" />
</androidx.constraintlayout.widget.ConstraintLayout>
```

(from [Slices/Inspector/app/src/main/res/layout/fragment\\_slice.xml](#))

A `SliceView` has no intrinsic background. If you do nothing else, it will render text and images with no background. In this layout, we set the `ConstraintLayout` to have a gray background and the `SliceView` to have a white background, so you can see the bounds the `SliceView`.

The sample app has a `TabAdapter` serving as our `PagerAdapter` for the `ViewPager`. For those first three tabs, it creates instances of a `SliceFragment`:

```
package com.commonware.android.slice.inspector

import androidx.fragment.app.Fragment
import androidx.fragment.app.FragmentManager
import androidx.fragment.app.FragmentPagerAdapter
import androidx.slice.widget.SliceView
```

## HOSTING SLICES

---

```
class TabAdapter(fm: FragmentManager, private val titles: Array<String>) : FragmentPagerAdapter(fm) {
    override fun getCount() = 4

    override fun getPageTitle(position: Int) = titles[position]

    override fun getItem(position: Int): Fragment =
        when (position) {
            0 -> SliceFragment.newInstance(SliceView.MODE_SHORTCUT)
            1 -> SliceFragment.newInstance(SliceView.MODE_SMALL)
            2 -> SliceFragment.newInstance(SliceView.MODE_LARGE)
            else -> InspectorFragment()
        }
}
```

(from [Slices/Inspector/app/src/main/java/com/commonsware/android/slice/inspector/TabAdapter.kt](#))

The `newInstance()` factory method on `SliceFragment` takes a `SliceView` “mode” value, indicating whether we want a shortcut, a small view, or a large view. These modes were describe in [the chapter on publishing slices](#).

In `onCreateView()`, the `SliceFragment` fills the mode into the `SliceView` via `setMode()` (via the mode property syntax in Kotlin), defaulting to large mode if for some reason we did not get a mode provided to us:

```
package com.commonsware.android.slice.inspector

import android.net.Uri
import android.os.Bundle
import android.view.LayoutInflater
import android.view.View
import android.view.ViewGroup
import androidx.fragment.app.Fragment
import androidx.slice.widget.SliceLiveData
import androidx.slice.widget.SliceView

private const val ARG_MODE = "mode"

class SliceFragment : Fragment() {
    companion object {
        fun newInstance(mode: Int) =
            SliceFragment().apply {
                arguments = Bundle().apply { putInt(ARG_MODE, mode) }
            }
    }

    override fun onCreateView(inflater: LayoutInflater, container: ViewGroup?, state: Bundle?): View? {
        val result = inflater.inflate(R.layout.fragment_slice, container, false)
        val sliceView = result.findViewById<SliceView>(R.id.slice)

        sliceView.mode = arguments?.getInt(ARG_MODE, SliceView.MODE_LARGE) ?: SliceView.MODE_LARGE

        SliceLiveData
            .fromUri(activity!!, Uri.parse(BuildConfig.SLICE_URI))
            .observe(this, sliceView)
    }
}
```

## HOSTING SLICES

---

```
return result
}
}
```

(from [Slices/Inspector/app/src/main/java/com/commonsware/android/slice/inspector/SliceFragment.kt](#))

Then, we:

- Parse SLICE\_URI into an actual Uri
- Pass that, along with our activity, to `SliceLiveData.fromUri()`, to get a `SliceLiveData` that is configured to pull slice data from the identified provider
- `observe()` that `SliceLiveData`, having its slice data be fed into the `SliceView`

And... that's it.

## HOSTING SLICES

---

At this point, SliceLiveData and SliceView take over to render the slice in the requested mode:

*Figure 720: Slice Inspector, Showing Shortcut Mode*

## HOSTING SLICES

Figure 721: Slice Inspector, Showing Small Mode

Figure 722: Slice Inspector, Showing Large Mode

All of the actions included in the slice are handled by `SliceView`. In this case, all of

## HOSTING SLICES

the `SamplerX` actions work, each showing a `Toast` with the appropriate message.

Also, so long as your `SliceLiveData` has an active observer, it will receive updates to the slice content if the `SliceProvider` publishes updates. So, for example, if you inspect a slice that needs to perform network I/O — such as the weather slice profiled in [the chapter on publishing slices](#) — you will first get whatever the “loading” slice content is, then you will get the real content. `SliceLiveData` simply pushes new slices to the `SliceView`, which updates its content accordingly.

### The Fully-Custom Way: Slice

You do not need a `SliceView` to display the contents of a slice, if you want to decide how to display those contents yourself. Instead, have the `SliceLiveData` route to your own code. It will hand you `Slice` objects, which you can inspect and use for setting up your own UI.

Unfortunately, this is largely undocumented.

The fourth tab in the `Slice Inspector` brings up a graph showing the various pieces of a slice:

This is handled by a separate `InspectorFragment`, using a `TreeView` from [this library](#).

A `Slice` is a tree structure, created using the various builders inside of the `SliceProvider`. The root `Slice` will contain one or more `SliceItem` objects, obtained via the `getItems()` method (or the `items` property in Kotlin). Each `SliceItem` has a `getFormat()` method indicating what sort of item it is and what it contains:

- `FORMAT_TEXT` contains some text to render, which you can get via `getText()` on the `SliceItem`
- `FORMAT_IMAGE` contains an image to render, which you can get via `getIcon()` on the `SliceItem`
- `FORMAT_SLICE` contains a nested `Slice` in the tree, which you can get via `getSlice()` and can then traverse as desired
- And so on

The sample app's graph simply puts the format value into each of the nodes, since formats happen to be human-readable strings. A app that wanted to do its own rendering of a slice — such as a screen reader wanting to use text-to-speech — would need to make sense of what is all in these slices and how to use them.

Most such apps will leverage `SliceMetadata` to help. You can wrap a `Slice` in a `SliceMetadata` via the `SliceMetadata.from()` method. `SliceMetadata` will give you higher-order information about an individual slice, such as:

- The actions, toggles, and similar elements that may be a part of the slice
- The title, subtitle, summary, and other text that is part of the slice
- `isPermissionSlice()`, which attempts to tell you if this slice is really a request for the user to grant permissions, instead of containing actual content
- And so on

## The Catch: Discovering Slices

The `Slice Inspector` sample app cheats. It already knows the `Uri` of the slice provider, courtesy of that `SLICE_URI` value in `gradle.properties`.

In some cases, your app will be able to cheat as well. If you want to show slices from some particular app, you can “bake” the `Uri` to its provider into your code by one

means or another. You can use `PackageManager` and `queryContentProviders()` to determine if that provider exists, and if it does, you can arrange to display its slices.

But what if you do not know what slice providers to use?

Eventually, the slice ecosystem will work out options for discovering slice providers. There is already a partial mechanism in place, involving `Intent` objects, but it is largely undocumented as of July 2018. Plus, it is fairly abstract, moving the discovery question from “how do I get the `Uri`?” to “how do I create the correct `Intent`?”

### Slices... from the Web?

Most of the focus on slices assume that the `Uri` in question is tied to a `SliceProvider`.

However, there is code in [Google’s Slice Viewer app](#) that supports slice `Uri` values having `http` or `https` as a scheme, instead of `content`. This implies that slices might come directly from Web servers, in addition to from local slice providers.

A slice host will not really care about the difference, other than perhaps needing the `INTERNET` permission where it might not be required otherwise. `SliceLiveData` is already asynchronous, so whether the slice data is coming from another app on the device or is coming from a server is an implementation detail for `SliceLiveData`, not for the hosting app.

Right now, there is no documentation for how one would do this. It is entirely possible that this bit of code was from some experiments that will never be fully supported by the slice libraries. However, if you are implementing a slice host, you may wish to watch for any signs that slices are being served by Web sites — if nothing else, they would represent additional scenarios for your app’s test suite.

# Advanced Permissions

---

Adding basic permissions to your app to allow it to, say, access the Internet, is fairly easy. However, the full permissions system has many capabilities beyond simply asking the user to let you do something. This chapter explores other uses of permissions, from securing your own components to using signature-level permissions (your own or Android's).

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the chapter on permissions](#) and the chapter on [signing your app](#).

One of the sample apps uses [RxJava and RxAndroid](#), which are introduced elsewhere in the book.

## Securing Yourself

Principally, at least initially, permissions are there to allow the user to secure their device. They have to agree to allow you to do certain things, such as reading contacts, that they might not appreciate.

The other side of the coin, of course, is to secure your own application. If your application is mostly activities, security may be just an “outbound” thing, where you request the right to use resources of other applications. If, on the other hand, you put content providers or services in your application, you will want to implement “inbound” security to control which applications can do what with the data.

Note that the issue here is less about whether other applications might “mess up”

## ADVANCED PERMISSIONS

---

your data, but rather about privacy of the user's information or use of services that might incur expense. That is where the stock permissions for built-in Android applications are focused – can you read or modify contacts, can you send SMS, etc. If your application does not store information that might be considered private, security is less an issue. If, on the other hand, your application stores private data, such as medical information, security is much more important.

The first step to securing your own application using permissions is to declare said permissions, once again in the `AndroidManifest.xml` file. In this case, instead of `uses-permission`, you add `permission` elements. Once again, you can have zero or more `permission` elements, all as direct children of the root `manifest` element.

Declaring a permission is slightly more complicated than using a permission. There are three pieces of information you need to supply:

- The symbolic name of the permission. To keep your permissions from colliding with those from other applications, you should use your application's Java namespace as a prefix
- A label for the permission: something short that would be understandable by users
- A description for the permission: something a wee bit longer that is understandable by your users

```
<permission
  android:name="vnd.tlagency.sekritis.SEE_SEKRITS"
  android:label="@string/see_sekritis_label"
  android:description="@string/see_sekritis_description" />
```

This does not enforce the permission. Rather, it indicates that it is a possible permission; your application must still flag security violations as they occur.

### Enforcing Permissions via the Manifest

There are two ways for your application to enforce permissions, dictating where and under what circumstances they are required. The easier one is to indicate in the manifest where permissions are required.

Activities, services, and receivers can all declare an attribute named `android:permission`, whose value is the name of the permission that is required to access those items:

```
<activity
```

## ADVANCED PERMISSIONS

---

```
android:name=".SekritApp"
android:label="Top Sekrit"
android:permission="vnd.tlagency.sekrits.SEE_SEKRITS">
<intent-filter>
  <action android:name="android.intent.action.MAIN" />
  <category
    android:name="android.intent.category.LAUNCHER"
  />
</intent-filter>
</activity>
```

Only applications that have requested your indicated permission will be able to access the secured component. In this case, “access” means:

1. Activities cannot be started without the permission
2. Services cannot be started, stopped, or bound to an activity without the permission
3. Intent receivers ignore messages sent via `sendBroadcast()` unless the sender has the permission

### Enforcing Permissions Elsewhere

In your code, you have two additional ways to enforce permissions.

Your services can check permissions on a per-call basis via `checkCallingPermission()`. This returns `PERMISSION_GRANTED` or `PERMISSION_DENIED` depending on whether the caller has the permission you specified. For example, if your service implements separate read and write methods, you could require separate read versus write permissions in code by checking those methods for the permissions you need from Java.

Also, you can include a permission when you call `sendBroadcast()`. This means that eligible broadcast receivers must hold that permission; those without the permission are ineligible to receive it. We will examine `sendBroadcast()` in greater detail elsewhere in this book.

### Requiring Standard System Permissions

While normally you require your own custom permissions using the techniques described above, there is nothing stopping you from reusing a standard system permission, if it would fit your needs.

---

## ADVANCED PERMISSIONS

---

For example, suppose that you are writing YATC (Yet Another Twitter Client). You decide that in addition to YATC having its own UI, you will design YATC to be a “Twitter engine” for use by third party apps:

- Send timeline updates via broadcast Intents
- Publish the timeline, the user’s own tweets, @-mentions, and the like via a `ContentProvider`
- Offer a command-based service interface for posting updates to the timeline
- And so on

You could, and perhaps should, implement your own custom permission. However, since any app can get to Twitter just by having the `INTERNET` permission, one could argue that a third-party app should just need that same `INTERNET` permission to use your API (rather than integrating JTwitter or another third-party JAR).

## Signature Permissions

Each permission in Android is assigned a protection level, via an `android:protectionLevel` attribute on the `<permission>` element. By default, permissions are at a normal level, but they can also be flagged as dangerous, `signatureOrSystem`, or `signature`. In the latter two cases, “signature” means that the app requesting the permission and the app requiring the permission should have been signed by the same signing key. In the case of `signatureOrSystem` — only used by the firmware — the app requesting the permission either needs to be signed by the firmware’s signing key or reside on the system partition (e.g., come pre-installed with the device).

## Firmware-Only Permissions

Most of Android’s permissions mentioned in this book are ones that any SDK application can hold, if they ask for them and the user grants them. `INTERNET`, `READ_CONTACTS`, `ACCESS_FINE_LOCATION`, and `kin` all are normal permissions.

`BRICK` is not.

There was a permission in Android, named `BRICK`, that, in theory, allows an application to render a phone inoperable (a.k.a., “brick” the phone). While there is no `brickMe()` method in the Android SDK tied to this permission, presumably there might be something deep in the firmware that was protected by this permission. Though, since Android 6.0 removed the `BRICK` permission from the SDK, it is clearly

not something Google expects us to use.

The BRICK permission could not be held by ordinary Android SDK applications. You could request it all you want, and it will not be granted.

However, applications that are signed with the same signing key that signed the firmware *could* hold the BRICK permission.

That is because [the system's own manifest](#) used to have the following `<permission>` element:

```
<permission android:name="android.permission.BRICK"
            android:label="@string/permlab_brick"
            android:description="@string/permdesc_brick"
            android:protectionLevel="signature" />
```

### Your Own Signature Permissions

You too can require signature-level permissions. That will restrict the holders of that permission to be other apps signed by your signing key. This is particularly useful for inter-process communication between apps in a suite — by using signature permissions, you ensure that only your apps will be able to participate in those communications.

One nice thing about these sorts of signature-level permissions is that the user is not bothered with them. It is assumed that the user will agree to the communication between the apps signed by the same signing key. Hence, the user will not see signature-level permissions at install or upgrade time.

Since in some cases, you may not be sure which app will be installed first, it is best to have all apps in the suite include the *same* `<permission>` element, in addition to the corresponding `<uses-permission>` element. That way, no matter which app is installed first, it can declare the permission that all will share.

Though, that has its own problems, as you will see in the next section.

### The Custom Permission Vulnerability

(NOTE: Some of the material in this section originally appeared in material hosted in [the CWAC-Security project repository](#). In addition, the author would like to thank Mark Carter and “Justin Case” for their contributions in this topic area).

---

## ADVANCED PERMISSIONS

---

Unfortunately, custom permissions have some undocumented limitations that make them intrinsically risky. Specifically, custom permissions can be defined by anyone, at any time, and “first one in wins”, which opens up the possibility of unexpected behavior.

Here, we will walk through some scenarios and show where the problems arise, plus discuss how to mitigate them as best we can.

### Scenarios

All of the following scenarios focus on three major app profiles.

App A is an app that defines a custom permission in its manifest, such as:

```
<permission
  android:name="com.commonware.cwac.security.demo.OMG"
  android:description="@string/perm_desc"
  android:label="@string/perm_label"
  android:protectionLevel="normal"/>
```

App A also defends a component using the `android:permission` attribute, referencing the custom permission:

```
<provider
  android:name="FileProvider"
  android:authorities="com.commonware.cwac.security.demo.files"
  android:exported="true"
  android:grantUriPermissions="false"
  android:permission="com.commonware.cwac.security.demo.OMG">
  <grant-uri-permission android:path="/test.pdf"/>
</provider>
```

App B has a `<uses-permission>` element to declare to the user that it wishes to access components defended by that permission:

```
<uses-permission android:name="com.commonware.cwac.security.demo.OMG"/>
```

App C has the same `<uses-permission>` element. The difference is that App B *also* has the `<permission>` element, just as App A does, albeit with different descriptive information (e.g., `android:description`) and, at times, a different protection level.

All three apps are signed with different signing keys, because in the real world they would be from different developers.

So, to recap:

- A defines a permission and uses it for defense
- B defines the same permission and requests to hold it
- C just requests to hold this permission

With all that in mind, let's walk through some possible scenarios, focusing on two questions:

1. What is the user told, when the app is installed through normal methods (i.e., not via adb), regarding this permission?
2. What access, if any, does App B or App C have to the ContentProvider from App A?

### The Application SDK Case (A, Then C)

Suppose the reason why App A has defined a custom permission is because it wants third-party apps to have the ability to access its secured components... but only with user approval. By defining a custom permission, and having third-party apps request that permission, the user should be informed about the requested permission and can make an informed decision.

Conversely, if an app tries to access a secured component but has not requested the permission, the access attempt should fail.

App C has requested the custom permission via the `<uses-permission>` element. If the permission — defined by App A — has an `android:protectionLevel` of `normal` or `dangerous`, the user will be informed about the requested permission at install time. If the user continues with the installation, App C can access the secured component.

If, however, the `android:protectionLevel` is `signature`, the user is not informed about the requested permission at install time, as the system can determine on its own whether or not the permission should be granted. In this case, App A and App C are signed with different signing keys, so Android silently ignores the permission request. If the user continues with installation, then App C tries to access App A's secured component, App C crashes with a `SecurityException`.

In other words, this all works as expected.

### **The Application SDK Problem Case (C, Then A)**

However, in many cases, there is nothing forcing the user to install App A before App C. This is particularly true for publicly-distributed apps on common markets, like the Play Store.

When the user installs App C, the user is not informed about the request for the custom permission, presumably because that permission has not yet been defined. If the user later installs App A, App C is not retroactively granted the permission, and so App C's attempts to use the secured component fail.

This works as expected, though it puts a bit of a damper on custom permissions. One way to work around this would be for the user to uninstall App C, then install it again (with App A already installed). This returns us to the original scenario from the preceding section. However, if the user has data in App C, losing that data may be a problem (as in a "let's give App C, or perhaps App A, one-star ratings on the Play Store" sort of problem).

### **The Peer Apps Case, Part One (A, Then B)**

Suppose now we augment our SDK-consuming app (formerly App C) to declare the same permission that App A does, in an attempt to allow the two apps to be installed in either order. That is what App B is: the same app as App C, but where it has the same `<permission>` element as does App A in its manifest.

This scenario is particularly important where both apps could be of roughly equal importance to the user. In cases where App C is some sort of plugin for App A, it is not unreasonable for the author of App A to require App A to be installed first. But, if Twitter and Facebook wanted to access components of each others' apps, it would be unreasonable for either of those firms to mandate that their app must be installed first. After all, if Twitter wants to be installed first, and Facebook wants to be installed first, one will be disappointed.

If the user installs App A (the app defending a component with the custom permission) before App B, the user will be notified at install time about App B's request for this permission. Notably, the information shown on the installation security screen will contain App A's description of the permission. And, if the user goes ahead and installs App B, App B can indeed access App A's secured component, since it was granted permission by the user.

Once again, everything is working as expected. Going back to the two questions:

1. The user is informed when App B or App C requests the permission defined by App A.
2. App B and App C can hold that permission if and only if they meet the requirements of the protection level

### **The Peer Apps Case, Part Two (B, Then A)**

What happens if we reverse the order of installation? After all, if App A and App B are peers, from the standpoint of the user, there is roughly a 50% chance that the user will install App B before App A.

Here is where things go off the rails.

#### **The user is not informed about App B's request for the custom permission.**

The user will be informed about any platform permissions that the app requests via other `<uses-permission>` elements. If there are none, the user is told that App B requests no permissions... despite the fact that it does.

When the user installs App A, the same thing occurs. Of course, since App A does not have a `<uses-permission>` element, this is not all that surprising.

However, at this point, **even though the user was not informed**, App B holds the custom permission and can access the secured component.

This is bad enough when both parties are ethical. App B could be a piece of malware, though, designed to copy the data from App A, ideally without the user's knowledge. And, if App B is installed before App A, that would happen.

So, going to the two questions:

1. The user is **not** informed about App B's request for the permission...
2. ...but App B gets it anyway and can access the secured component

### **The Downgraded-Level Malware Case (B, Then A, Again)**

You might think that the preceding problem would only be for normal or dangerous protection levels. If App A defines a permission as requiring a matching signature, and App A marks a component as being defended by that permission, Android must require the signature match, right?

Wrong.

The behavior is identical to the preceding case. Android does not use the *defender's* protection level. It uses the *definer's* protection level, meaning the protection level of whoever was installed first and had the <permission> element.

So, if App A has the custom permission defined as signature, and App B has the custom permission defined as normal, if App B is installed first, the behavior is as shown in the preceding section:

1. The user is **not** informed about App B's request for the permission...
2. ...but App B gets it anyway and can access the secured component, despite the signatures not matching

### The Peer Apps Case With a Side Order of C

What happens if we add App C back into the mix? Specifically, what if App B is installed first, then App A, then App C?

When App C eventually gets installed, the user is prompted for the custom permission that App C requests via <uses-permission>. However, the description that the user sees is from App B, the one that first defined the custom <permission>. Moreover, the protection level is whatever App B defined it to be. So if App B downgraded the protection level from App A's intended signature to be normal, App C can hold that permission and access the secured App A component, even if it is signed by another signing key.

Not surprisingly, the same results occur if you install App B, then App C, then App A.

### Behavior Analysis

The behavior exhibited in these scenarios is consistent with two presumed implementation "features" of Android's permission system:

1. First one in wins. In other words, the first app (or framework, in the case of the OS's platform permissions) that defines a <permission> for a given android:name gets to determine what the description is and what the protection level is.
2. The user is only prompted to confirm a permission if the app being installed has a <uses-permission> element, the permission was already defined by

some other app, and the protection level is not signature.

### Risk Assessment

The “first one in wins” rule is a blessing and a curse. It is a curse, insofar as it opens up the possibility for malware to hold a custom permission without the user’s awareness of that, and even to downgrade a signature-level permission to normal. However, it is a blessing, in that the malware would have to be installed first; if it is installed second, either its request to hold the permission will be seen by the user (normal or dangerous) or the request to hold the permission will be rejected (signature).

This makes it somewhat unlikely for a piece of malware to try to sneakily make off with data. Eventually, if enough users start to ask publicly why App B needs access to App A’s data (for cases where App A was installed first and the user knows about the permission request), somebody in authority may eventually realize that this is a malware attack. Of course, “eventually” may be a rather long time.

However, there are some situations where Android’s custom permission behavior presents risk even greater than that. If the attacker has a means of being *sure* that their app was installed first, they can hold any permission from any third-party app they want to that was known at install time.

For example:

- Somebody could sell a used Android device, and the buyer could neglect to factory-reset it, and the malware could be installed by the seller
- Somebody could sell a used Android device with a ROM mod preinstalled, based on a normal ROM mod (e.g., CyanogenMod), but with an additional bit of malware installed, to prevent a factory reset from foiling the attack’
- Somebody could distribute devices to users who might think the device is “factory clean” and not laden with malware (e.g., devices given as gifts)
- Somebody could distribute devices to users who might think that the pre-installed malware is actually a legitimate app (e.g., devices given to employees by an employer wishing to monitor usage by examining protected data from third-party apps)

### Android 5.0’s “Fix”

Android 5.0 now prevents two apps from defining the same <permission> (“same” based on android:name) unless they are signed by the same signing key. First one in

## ADVANCED PERMISSIONS

---

wins; the second app installation will fail.

On the plus side:

- This solves the security problem, as an attacker (B) cannot get at a defender's (A's) data by virtue of having been installed first, as A simply cannot be installed in this case.
- This has no impact on developers using signature-level `<permission>` elements for their own app suite.

However, it does pose significant limitations on legitimate public uses of custom `<permission>` elements. Only the defender should have the `<permission>` element now. Some client of the defender's app (C) should not have the `<permission>` element and should simply rely upon the fact that the defender should be installed first. If the client were to define the `<permission>`, then either the client *or* the defender cannot be installed, which is pointless.

This has usability issues:

- A client should check, on first run of their app, if an expected defender (and its `<permission>` element) exists. If not, the client should alert the user to this fact and perhaps stop the app from proceeding further. The user would have to uninstall the client, install the defender, then reinstall the client, to get everything working properly, and the more the user uses the client app, the more painful the uninstall might be.
- It is impossible for two apps to be clients of each other. By definition, one app has to be installed first and the other second, which means only the first-to-be-installed app can have a custom `<permission>`. If Facebook wanted to hold a custom Twitter permission, and Twitter wanted to hold a custom Facebook permission, one of them is out of luck — if Facebook is installed first, it cannot request Twitter's permission (as it does not yet exist) nor can it define Twitter's permission (as if it does, Twitter cannot be installed). This *might* be able to be overcome for apps that are pre-loaded as part of a ROM mod or other custom Android build.

And, of course, this fix is only for Android 5.0 and above.

### Mitigation Using PermissionUtils

The “first one in wins” rule also leads us to a mitigation strategy: On first run of our app, see if any other app has defined permissions that we have defined. If that has

happened, then we are at risk, and take appropriate steps. If, however, no other app has defined our custom permissions, then the Android permission system should work for us, and we can proceed as normal.

[The CWAC-Security library](#) provides some helper code, in the form of the `PermissionUtils` class, to detect other apps defining the same custom permissions that you define.

The idea is that you call `checkCustomPermissions()` — a static method on `PermissionUtils` — on the first run of your app. It will return details about what other apps have already defined custom permissions that your app defines. If `checkCustomPermissions()` returns nothing, you know that everything is fine, and you can move ahead. Otherwise, you can:

- Check to see if the offending app is on some whitelist, or otherwise meets criteria that suggests that it is OK
- Alert the user, indicating that these already-installed apps will have access to your app secured components
- Upload details about the offending apps to your server, so you can try to track down whether they are legitimate users of some API that you are exposing or are malware
- Whatever else you feel is necessary

## Custom Dangerous Permissions, and Android 6.0

Android 6.0 introduced the concept of runtime permissions, where dangerous permissions need to be requested at runtime in addition to being requested in the manifest. This is covered back in [the introductory chapter on permissions](#).

However, what happens if you define a custom dangerous permission?

The good news is that it works. However, you will want to test it, in part to see what it looks like to users, so you can get the phrasing of your permission-related string resources correct.

The [Permissions/CustomDangerous](#) sample project contains two application modules:

- `app` is an app that defends an activity using a custom dangerous permission
- `client` is an app that wishes to request that permission and start that

## ADVANCED PERMISSIONS

---

protected activity

The `<permission>` element is unremarkable, other than the `protectionLevel` being set to `dangerous`:

```
<permission
  android:name="com.commonware.android.perm.custdanger.SOMETHING"
  android:description="@string/perm_desc"
  android:label="@string/perm_label"
  android:protectionLevel="dangerous" />
```

(from [Permissions/CustomDangerous/app/src/main/AndroidManifest.xml](#))

The label and description come from string resources:

```
<string name="perm_label">Custom Dangerous Permission</string>
<string name="perm_desc">This is a description. No, really.</string>
```

(from [Permissions/CustomDangerous/app/src/main/res/values/strings.xml](#))

The client module uses the same `AbstractPermissionActivity` seen elsewhere in this book to request that `com.commonware.android.perm.custdanger.SOMETHING` permission at runtime.

## ADVANCED PERMISSIONS

---

If you install the app application, then install and run the client application, what you see is the *description*, not the label, appear in the runtime permission dialog:

*Figure 724: Custom Dangerous Permission, As Shown In Runtime Permission Dialog, on Android 6.0.1*

## ADVANCED PERMISSIONS

---

If you go into Settings > Apps > Custom Dangerous Client > Permissions, the custom dangerous permission does not show up immediately, due to a poorly-designed UI:

*Figure 725: App Permissions in Settings, Showing Nothing Useful*

---

## ADVANCED PERMISSIONS

---

Instead, the user needs to tap on the “Additional permissions” row to have that be replaced by the custom dangerous permission:

*Figure 726: App Permissions in Settings, Showing Custom Dangerous Permission*

Here, the *label* is what shows up, not the description.

Hence, you will want to tailor your phrasing of these string resources to make sense in their respective use cases.

## Finding the Available Permissions

On the one hand, developers should try to stick to documented permissions.

On the other hand, documentation is sometimes lacking. This is particularly true for permissions other than those defined by the OS itself, ones that come from other apps that change more frequently, including the Play Services SDK and framework.

You might find that you need to determine what permissions have been defined on a given device. Perhaps that need is at runtime — if you request a permission that does not exist, you cannot actually get it, and that may lead to problems in the

## ADVANCED PERMISSIONS

---

future. Perhaps that need is just during development itself, to inspect some device and determine what it does and does not have in terms of permissions.

PackageManager offers methods to allow you to examine the device's permissions and permission groups. The [Permissions/PermissionReporter](#) sample app uses these methods to build up a tabbed UI listing the defined permissions, broken down by protection level.

`getAllPermissionGroups()` on PackageManager will return a list of `PermissionGroupInfo` objects. This method takes an `int` value; 0 generally will be fine for your use cases.

On its own, `PermissionGroupInfo` is not especially useful. However, you can turn around and call `queryPermissionsByGroup()` on PackageManager, passing in the name from the `PermissionGroupInfo`, to get all of the permissions in that group. This method also takes an `int` value as the second parameter, where once again 0 will be fine.

`queryPermissionsByGroup()` returns a List of `PermissionInfo` objects. `PermissionInfo` has a few interesting values:

- `name`, which is the fully-qualified name of the permission
- `descriptionRes`, which is the string resource ID from the permission's `android:description` attribute
- `protectionLevel`, which is a set of flags indicating the nature of the permission's security

Note that to get the actual text of the description, there is a `loadDescription()` method on `PermissionInfo` that will do all the work to find the actual string for the description, based upon the app that defined the permission and the current locale.

To get the details of all the permissions defined on a device, we will have to call `queryPermissionsByGroup()` for each permission group. Each of those calls will involve IPC, and so this *might* be slow enough to warrant its own thread.

With that in mind, `MainActivity` in the `PermissionReporter` sample app has a `PermissionSource` that collects information about the permissions on the system. That information is aggregated in a `PermissionRoster`, which the data emitted by this `Observable`:

```
private static class PermissionSource implements ObservableOnSubscribe<PermissionRoster> {  
    private Context ctx;
```

## ADVANCED PERMISSIONS

---

```
private PermissionSource(Context ctxt) {
    this.ctxt=ctxt.getApplicationContext();
}

@Override
public void subscribe(ObservableEmitter<PermissionRoster> emitter)
    throws Exception {
    PackageManager pm=ctxt.getPackageManager();
    final PermissionRoster result=new PermissionRoster();

    addPermissionsFromGroup(pm, null, result);

    for (PermissionGroupInfo group :
        pm.getAllPermissionGroups(0)) {
        addPermissionsFromGroup(pm, group.name, result);
    }

    emitter.onNext(result);
    emitter.onComplete();
}

private void addPermissionsFromGroup(PackageManager pm,
    String groupName,
    PermissionRoster result)
    throws PackageManager.NameNotFoundException {
    for (PermissionInfo info :
        pm.queryPermissionsByGroup(groupName, 0)) {
        int coreBits=
            info.protectionLevel &
            PermissionInfo.PROTECTION_MASK_BASE;

        switch (coreBits) {
            case PermissionInfo.PROTECTION_NORMAL:
                result.add(PermissionType.NORMAL, info);
                break;

            case PermissionInfo.PROTECTION_DANGEROUS:
                result.add(PermissionType.DANGEROUS, info);
                break;

            case PermissionInfo.PROTECTION_SIGNATURE:
                result.add(PermissionType.SIGNATURE, info);
                break;

            default:
                result.add(PermissionType.OTHER, info);
                break;
        }
    }
}
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/MainActivity.java](#))

The `subscribe()` method loops over the permission groups:

```
for (PermissionGroupInfo group :
```

---

## ADVANCED PERMISSIONS

---

```
pm.getAllPermissionGroups(0)) {
    addPermissionsFromGroup(pm, group.name, result);
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/MainActivity.java](#))

As it turns out, not all permissions are part of a group. To find out the details of these un-grouped permissions, you need to call `queryPermissionsByGroup()` with a null permission group name.

For each permission group (plus the magic null group), we call a private `addPermissionsFromGroup()` method (shown above) to collect the details of the permissions in that group.

The `protectionLevel` field on a `PermissionInfo` contains a number of different sorts of flags. The `PROTECTION_MASK_BASE` is a bitmask that restricts the bits we are looking at to the ones for basic protections. We then divide the permissions into four groups based on protection level:

- normal
- dangerous
- signature
- other (which, on older devices, will include system or signatureOrSystem permissions)

Those `PermissionInfo` objects are then poured into the `PermissionRoster` object:

```
package com.commonsware.android.permreporter;

import android.content.pm.PermissionInfo;
import android.os.Parcel;
import android.os.Parcelable;
import java.util.ArrayList;
import java.util.HashMap;

class PermissionRoster {
    private HashMap<PermissionType, ArrayList<PermissionInfo>> roster=
        new HashMap<PermissionType, ArrayList<PermissionInfo>>();

    void add(PermissionType type, PermissionInfo info) {
        ArrayList<PermissionInfo> list=roster.get(type);

        if (list==null) {
            list=new ArrayList<>();
            roster.put(type, list);
        }
    }
}
```

## ADVANCED PERMISSIONS

---

```
    }  
  
    list.add(info);  
  }  
  
  ArrayList<PermissionInfo> getListForType(PermissionType type) {  
    return(roster.get(type));  
  }  
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/PermissionRoster.java](#))

PermissionType is an enum defined by this project for the four groups and includes some Java shenanigans for being able to convert back and forth between integer values and the enum values:

```
package com.commonsware.android.permreporter;  
  
import android.util.SparseArray;  
  
enum PermissionType {  
  NORMAL(0),  
  DANGEROUS(1),  
  SIGNATURE(2),  
  OTHER(3);  
  
  private static final SparseArray<PermissionType> BY_VALUE=  
    new SparseArray<PermissionType>(4);  
  
  static {  
    for (PermissionType type : PermissionType.values()) {  
      BY_VALUE.put(type.value, type);  
    }  
  }  
  
  private final int value;  
  
  PermissionType(int value) {  
    this.value=value;  
  }  
  
  static PermissionType forValue(int value) {  
    return(BY_VALUE.get(value));  
  }  
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/PermissionType.java](#))

# **Restricted Profiles and UserManager**

---

Android 4.2 introduced the concept of having multiple distinct users of a tablet. Each user would get their own portion of internal and external storage, as if they each had their own tablet.

Android 4.3 extends this a bit further, with the notion of setting up restricted profiles. As the name suggests, a restricted profile is restricted, in terms of what it can do on the device. Some restrictions will be device-wide (e.g., can the user install apps?), and some restrictions will be per-app. You can elect to allow your app to be restricted, where you define the possible ways in which your app can be restricted, and the one setting up the restricted profile can then configure the desired options for some specific profile.

This chapter will explain how users set up these restricted profiles, what you can learn about the device-wide restrictions, and how you can offer your own restrictions for your own app.

## **Prerequisites**

Understanding this chapter requires that you have read the core chapters of this book, particularly [the chapter on files](#) and its [section on multiple user accounts](#).

## **Android Tablets and Multiple User Accounts**

The theory is that tablets are likely to be shared, whether among family members, among team members in a business, or similar sorts of group settings. There are three levels of “user” in an Android 4.3+ tablet that we will need to consider.

### Primary User

The primary user is whoever first set up the tablet after initial purchase. In a family, this is probably a parent; in a corporate setting, this might be an IT administrator.

Prior to Android 4.2, there was only one user per device, and that user could (generally) do anything. In Android 4.2+, the primary user holds this role.

One thing that the primary user can do is set up other users, via the Users option in the Settings app:

*Figure 727: Users Screen in Settings*

## RESTRICTED PROFILES AND USERMANAGER

---

Tapping the “Add user or profile” entry allows the primary user to set up another user or restricted profile:

*Figure 728: Add Dialog in Users Screen in Settings*

### Secondary User

Choosing “User” from the Add dialog will define a secondary user of the device. This user has much of the same control as the primary user, in terms of being able to install and run whatever apps are desired.

*Figure 729: Add New User Warning Dialog in Users Screen in Settings*

### Restricted Profile

A restricted profile is akin to a secondary user, in that it gets its own separate portion of internal and external storage. Beyond that, though, the primary user can further configure what the restricted profile can access:

*Figure 730: Restricted Profile Configuration Screen in Settings*

The bulk of the restricted profile configuration screen is a list of apps, with Switch widgets to allow the primary user to allow or deny access to each app.

## RESTRICTED PROFILES AND USERMANAGER

---

Some apps will have the “settings” icon to the left of the Switch. Tapping that will either bring up a dedicated activity for restricting operations within that app, or it will add new rows to the list with individual restriction options for that app. For example, tapping the settings icon for the Settings app adds a row where the primary user can block location sharing:

*Figure 731: Location Sharing Restrictions*

The “settings” icon in the first row, for the profile itself, will allow the primary user to control things for the entire profile, notably its name.

## RESTRICTED PROFILES AND USERMANAGER

---

Switching to the restricted profile (e.g., via the lockscreen) will show the constrained set of available apps:

## Determining What the User Can Do

Your app can find out what device-level restrictions were placed on the current user by means of the UserManager system service. Specifically, as you can see in MainActivity of the [RestrictedProfiles/Device](#) sample project, all you need to do is:

- Acquire an instance of a UserManager by calling `getSystemService()` on a Context, passing in `USER_SERVICE` as the service's name
- Calling `getUserRestrictions()` on the UserManager:

```
package com.commonware.android.profile.device;

import android.support.v4.app.FragmentActivity;
import android.os.Bundle;
import android.os.UserManager;
import android.widget.Toast;

public class MainActivity extends FragmentActivity {
```

## RESTRICTED PROFILES AND USERMANAGER

---

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    UserManager mgr=(UserManager)getSystemService(USER_SERVICE);
    Bundle restrictions=mgr.getUserRestrictions();

    if (restrictions.keySet().size() > 0) {
        setContentView(R.layout.activity_main);

        RestrictionsFragment f=
            (RestrictionsFragment)getSupportFragmentManager().findFragmentById(R.id.contents);

        f.showRestrictions(restrictions);
    }
    else {
        Toast.makeText(this, R.string.no_restrictions, Toast.LENGTH_LONG)
            .show();
        finish();
    }
}
```

(from [RestrictedProfiles/Device/app/src/main/java/com/commonsware/android/profile/device/MainActivity.java](#))

`getUserRestrictions()` returns a `Bundle`, whose keys are documented on `UserManager` for various device-level restrictions that theoretically can be placed on the user. Here, “theoretically” means that while `UserManager` documents several `DISALLOW_*` constants, only two seem to be directly accessible to the primary user for configuration via `Settings`:

- `DISALLOW_MODIFY_ACCOUNTS`, to prevent a restricted profile from, among other things, modifying restricted profiles
- `DISALLOW_SHARE_LOCATION`, to prevent the apps run in this restricted profile from gathering location data

`MainActivity` examines the `Bundle` and, if it is empty, just displays a `Toast` and exits via `finish()`. This is the behavior you will see if you run this sample app on a non-restricted profile, such as the primary user. If, however, the `Bundle` has one or more keys, we inflate an `activity_main` layout that contains a `RestrictionsFragment` in a `<fragment>` element:

```
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/contents"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    class="com.commonsware.android.profile.device.RestrictionsFragment"/>
```

(from [RestrictedProfiles/Device/app/src/main/res/layout/activity\\_main.xml](#))

## RESTRICTED PROFILES AND USERMANAGER

---

We then retrieve the `RestrictionsFragment` from the `FragmentManager` and call `showRestrictions()` on it, passing in the `Bundle`.

`RestrictionsFragment` is a `ListFragment` employing a custom `RestrictionsAdapter`. The `RestrictionsAdapter` wraps around the `Bundle` and an `ArrayList` of its keys. The `RestrictionsAdapter` constructor creates the `ArrayList` by sorting the `keySet()` of the `Bundle`. `getView()` on `RestrictionsAdapter` lets the superclass handle inflating the row (`android.R.layout.simple_list_item_1`), then puts an icon on the right side by using `setCompoundDrawablesWithIntrinsicBounds()`, which can tuck a drawable resource onto any of the four sides of a `TextView`.

The resulting list will show green icons for keys where the `Bundle` has stored a true Boolean value, and a red icon for false:

*Figure 733: Default Device Restrictions, on a Nexus 7 (2013)*

Since the keys are negative in tone (e.g., `DISALLOW_MODIFY_ACCOUNTS`), true means that the restriction is enforced and the underlying operation (e.g., modifying accounts) *cannot* be done.

## Impacts of Device-Level Restrictions

Your app's functionality may be limited by these device-level restrictions. This section outlines some of the results you should expect from a restricted profile.

### Restricting Location Access

If a restricted profile is prevented from sharing the device's location with apps, those apps simply will not receive location updates. There is no good way to detect this via the location API (e.g., `isProviderEnabled()` returns `true`), so you will have to detect this via `getUserRestrictions()` on `UserManager` as noted above.

### Uninstalling Apps

Even without specific configuration, the restricted profile can only uninstall apps that they are available to that profile. However, since apps are really shared between profiles, this only removes that app from the restricted profile; it does not actually uninstall the app from the device as a whole.

## Enabling Custom Restrictions

As noted earlier, the list of apps that is shown on the restricted profile configuration screen in Settings can have “settings” icons. The Settings app itself will have a settings icon, to allow the primary user to configure device-level restrictions.

But, what if you want *your* app to have such a settings icon? Maybe it makes sense for your app to allow the primary user to restrain restricted profiles from doing certain things within your app:

- Block in-app purchases
- Only show certain categories of content, not the full roster
- Only allow operation during certain times of the day

The means by which the Settings app restricts profiles is also available to you. You can declare to Android what aspects of your app can be restricted. Android will then collect that restriction data for you. Your app, at runtime, can then determine what restrictions are in place (if any) and take appropriate steps.

All of this will be illustrated using the [RestrictedProfiles/App](#) sample project.

### Stating Your Restrictions

The biggest thing that you need to do to restrict your app is teach Android how to collect restrictions. In other words, you need to tell Android what to do when the user taps that settings icon in the restricted profile entry for your app.

You have two major options:

- Provide a list of the restrictions that Android should render and collect itself, or
- Provide an Intent that can be used to start up an activity of your own design where you collect those restrictions

Either approach will require you to set up a manifest-registered BroadcastReceiver, set to respond to the `android.intent.action.GET_RESTRICTION_ENTRIES` action:

```
<receiver android:name="RestrictionEntriesReceiver">
  <intent-filter>
    <action android:name="android.intent.action.GET_RESTRICTION_ENTRIES"/>
  </intent-filter>
</receiver>
```

(from [RestrictedProfiles/App/app/src/main/AndroidManifest.xml](#))

That BroadcastReceiver will be called with `sendOrderedBroadcast()`, not so much to affect ordering, but to allow the BroadcastReceiver to send back a result via its `setResultExtras()` method. This provides a Bundle that the broadcaster can eventually retrieve, in this case providing details of what restrictions we wish to collect from the primary user to restrict the profile.

#### Option #1: RestrictionEntry List

To collect restrictions the way the Settings app does — with restriction rows appearing below your app in the restricted profile screen in Settings — your BroadcastReceiver will need to put an entry into the return Bundle, under the key of `EXTRA_RESTRICTIONS_LIST` (a constant defined on the Intent class). The value needs to be an ArrayList of RestrictionEntry objects, with each RestrictionEntry describing one restriction to collect.

Another thing that the RestrictionEntry objects contain is their current value. Android itself retains these values and supplies them to your BroadcastReceiver via an `EXTRA_RESTRICTIONS_BUNDLE` extra on the incoming Intent. Your app needs to

## RESTRICTED PROFILES AND USERMANAGER

---

use those current values when constructing its list of `RestrictionEntry` objects to return.

So, let's take a look at `RestrictionEntriesReceiver`, the receiver we have set up to handle the `android.intent.action.GET_RESTRICTION_ENTRIES` action for this sample app.

The entry point for `RestrictionEntriesReceiver` is `onReceive()`, as it is for any basic `BroadcastReceiver`:

```
@Override
public void onReceive(Context ctxt, Intent intent) {
    Bundle current=
        (Bundle)intent.getParcelableExtra(Intent.EXTRA_RESTRICTIONS_BUNDLE);
    ArrayList<RestrictionEntry> restrictions=
        new ArrayList<RestrictionEntry>();

    restrictions.add(buildBooleanRestriction(ctxt, current));
    restrictions.add(buildChoiceRestriction(ctxt, current));
    restrictions.add(buildMultiSelectRestriction(ctxt, current));

    Bundle result=new Bundle();

    result.putParcelableArrayList(Intent.EXTRA_RESTRICTIONS_LIST,
        restrictions);

    setResultExtras(result);
}
```

(from [RestrictedProfiles/App/app/src/main/java/com/commonsware/android/profile/app/RestrictionEntriesReceiver.java](#))

In `onReceive()`, `RestrictionEntriesReceiver` pulls out the `Bundle` of current restrictions, by retrieving the `EXTRA_RESTRICTIONS_BUNDLE` extra from the `Intent` passed into `onReceive()`. Note that this `Bundle` could very well be empty, if this is the first time we are being asked for restrictions.

`RestrictionEntriesReceiver` creates an empty `ArrayList` of `RestrictionEntry` objects, then calls a series of builder methods to create a total of three such `RestrictionEntry` objects, adding each to the list. `onReceive()` goes on to create a `Bundle` representing the results to be returned, packages the `ArrayList` in that `Bundle` under the `EXTRA_RESTRICTIONS_LIST` key, and returns that `Bundle` to the caller by means of `setResultExtras()`.

The three builder methods are each responsible for defining a single

## RESTRICTED PROFILES AND USERMANAGER

---

RestrictionEntry, including populating it with the current value from the current Bundle.

There are three types of RestrictionEntry, for boolean, single-selection lists (“choice”), and multi-selection lists. The RestrictionEntry constructor takes two parameters:

- The String key under which we will later retrieve this restriction value
- The current value of the restriction

The current value is:

- A boolean for boolean restrictions
- A String for choice restrictions
- A String array for multi-select restrictions

Our first builder, buildBooleanRestriction(), populates and returns a RestrictionEntry designed to collect a boolean value from the primary user, via a CheckBox:

```
private RestrictionEntry buildBooleanRestriction(Context ctxt,
                                                Bundle current) {
    RestrictionEntry entry=
        new RestrictionEntry(RESTRICTION_BOOLEAN,
                            current.getBoolean(RESTRICTION_BOOLEAN,
                                                false));

    entry.setTitle(ctxt.getString(R.string.boolean_restriction_title));
    entry.setDescription(ctxt.getString(R.string.boolean_restriction_desc));

    return(entry);
}
```

(from [RestrictedProfiles/App/app/src/main/java/com/commonsware/android/profile/app/RestrictionEntriesReceiver.java](#))

buildBooleanRestriction() retrieves the current value from current Bundle to use with the RestrictionEntry constructor. In this case, if there is no such entry in the Bundle, the overall default value is false.

Each RestrictionEntry can have a title (setTitle()), supplying a string which will be displayed to describe what this restriction is. A boolean restriction can also have a description (setDescription()), containing another string with a bit more text. Note that, at the present time, the other two types of restrictions will ignore any

## RESTRICTED PROFILES AND USERMANAGER

---

description that you include. Also note that the values supplied to `setTitle()` and `setDescription()` need to be strings, and so if you wish to use a string resource, you will need to get the actual string value yourself via `getString()`.

The remaining two builder methods have a similar structure:

```
private RestrictionEntry buildChoiceRestriction(Context ctxt,
                                                Bundle current) {
    RestrictionEntry entry=
        new RestrictionEntry(RESTRICTION_CHOICE,
                             current.getString(RESTRICTION_CHOICE));

    entry.setTitle(ctxt.getString(R.string.choice_restriction_title));
    entry.setChoiceEntries(ctxt, R.array.display_values);
    entry.setChoiceValues(ctxt, R.array.restriction_values);

    return(entry);
}

private RestrictionEntry buildMultiSelectRestriction(Context ctxt,
                                                      Bundle current) {

    RestrictionEntry entry=
        new RestrictionEntry(RESTRICTION_MULTI,
                             current.getStringArray(RESTRICTION_MULTI));

    entry.setTitle("A Multi-Select Restriction");
    entry.setChoiceEntries(ctxt, R.array.display_values);
    entry.setChoiceValues(ctxt, R.array.restriction_values);

    return(entry);
}
```

(from [RestrictedProfiles/App/app/src/main/java/com/commonsware/android/profile/app/RestrictionEntriesReceiver.java](#))

As with a `ListPreference`, you provide two string arrays to the `RestrictionEntry`, representing the values the primary user sees (`setChoiceEntries()`) and the corresponding values to be supplied to your app based upon the choice(s) (`setChoiceValues()`). You can supply these either as Java string arrays or as `<string-array>` resources – `RestrictionEntriesReceiver` goes with the latter approach.

### Option #2: Custom Restriction Activity

It may be that what you want to collect, in terms of restrictions, cannot readily be represented in the form of `Switch` widgets and list dialogs. For example, to restrict

## RESTRICTED PROFILES AND USERMANAGER

---

use of your app based on time, it would be nice to use a `TimePickerDialog` or the equivalent.

The alternative to returning an `EXTRA_RESTRICTIONS_LIST` roster of `RestrictionEntry` objects from your `BroadcastReceiver` is to have the result `Bundle` contain `EXTRA_RESTRICTIONS_INTENT`. This key should point to an `Intent` that identifies the activity that you want to start up when the user taps the settings icon. Android will call `startActivityForResult()` on that `Intent` when the user taps on the settings icon.

Your job is to collect the restrictions from the user, using the `EXTRA_RESTRICTIONS_BUNDLE` from the incoming `Intent` to pre-populate your activity, if desired. When the user is done, you should call `setResult()`, passing in an `Intent` that contains another `EXTRA_RESTRICTIONS_BUNDLE` with the revised data, or optionally a `EXTRA_RESTRICTIONS_LIST` (with the `RestrictionEntry` objects containing the values to be used).

### What the Primary User Sees

Given the `RestrictionEntriesReceiver` described above, when the primary user goes to configure a restricted profile, your app will appear with a settings icon next to it:

*Figure 734: Restricted Profile, Showing App Settings Icon*

## RESTRICTED PROFILES AND USERMANAGER

---

Tapping that settings icon will “unfold” and display the restrictions that you configured via the RestrictionEntry objects:

*Figure 735: Restricted Profile, Showing App Restrictions*

## RESTRICTED PROFILES AND USERMANAGER

---

The primary user can then interact with your restrictions, toggling checkboxes and popping up the list dialogs:

*Figure 736: Restricted Profile, Showing Choice Restriction*

## RESTRICTED PROFILES AND USERMANAGER

Figure 737: Restricted Profile, Showing Multi-Select Restriction

### Finding Out the Current Restrictions

Now, the rest of your app needs to find out what restrictions are placed upon it, so behavior can be tailored accordingly. To do this, call `getApplicationRestrictions()` on `UserManager`, passing in your package name, as seen here in `MainActivity`:

```
package com.commonware.android.profile.app;

import android.support.v4.app.FragmentActivity;
import android.os.Bundle;
import android.os.UserManager;
import android.widget.Toast;

public class MainActivity extends FragmentActivity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        UserManager mgr=(UserManager) getSystemService(USER_SERVICE);
        Bundle restrictions=
            mgr.getApplicationRestrictions(getPackageName());

        if (restrictions.keySet().size() > 0) {
            setContentView(R.layout.activity_main);

            RestrictionsFragment f=
```

## RESTRICTED PROFILES AND USERMANAGER

---

```
(RestrictionsFragment)getSupportFragmentManager().findFragmentById(R.id.contents);

    f.showRestrictions(restrictions);
}
else {
    Toast.makeText(this, R.string.no_restrictions, Toast.LENGTH_LONG)
        .show();
    finish();
}
}
```

(from [RestrictedProfiles/App/app/src/main/java/com/commonsware/android/profile/app/MainActivity.java](#))

This Bundle could be empty, or it could have values specified by the primary user to restrict the profile that is running your app.

In the case of this sample, we once again set up a RestrictionsAdapter to show the results, if the Bundle is not empty. However, our adapter is a bit more complicated, as there are more than boolean restrictions now. getView() has been updated to handle all three possible restrictions, showing the icon for the boolean restriction, and showing the value(s) from the lists in the other restrictions:

```
package com.commonsware.android.profile.app;

import android.support.v4.app.ListFragment;
import android.os.Bundle;
import android.text.TextUtils;
import android.view.View;
import android.view.ViewGroup;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.AdapterView.OnItemSelectedListener;
import android.widget.TextView;
import java.util.ArrayList;
import java.util.Collections;

public class RestrictionsFragment extends ListFragment {
    public void showRestrictions(Bundle restrictions) {
        setListAdapter(new RestrictionsAdapter(restrictions));
    }
}

class RestrictionsAdapter extends ArrayAdapter<String> {
    Bundle restrictions;

    RestrictionsAdapter(Bundle restrictions) {
        super(getActivity(), android.R.layout.simple_list_item_1,
            new ArrayList<String>());
    }

    ArrayList<String> keys=
        new ArrayList<String>(restrictions.keySet());
```

## RESTRICTED PROFILES AND USERMANAGER

---

```
    Collections.sort(keys);
    addAll(keys);

    this.restrictions=restrictions;
}

@Override
public View getView(int position, View convertView, ViewGroup parent) {
    TextView row=
        (TextView)super.getView(position, convertView, parent);
    String key=getItem(position);

    if (RestrictionEntriesReceiver.RESTRICTION_BOOLEAN.equals(key)) {
        int icon=
            restrictions.getBoolean(key) ? R.drawable.ic_true
            : R.drawable.ic_false;

        row.setCompoundDrawablesWithIntrinsicBounds(0, 0, icon, 0);
    }
    else if (RestrictionEntriesReceiver.RESTRICTION_CHOICE.equals(key)) {
        row.setText(String.format("%s (%s)", key,
            restrictions.getString(key)));
    }
    else {
        String value=
            TextUtils.join(" | ", restrictions.getStringArray(key));

        row.setText(String.format("%s (%s)", key, value));
    }

    return(row);
}
}
```

(from [RestrictedProfiles/App/app/src/main/java/com/commonsware/android/profile/app/RestrictionsFragment.java](#))

The result, when run on a restricted profile with restrictions placed upon our app, is to show those restrictions:

*Figure 738: App Restrictions Demo, on a Restricted Profile*

## Implicit Intents May Go “Boom”

The primary user of a tablet, when setting up a restricted profile, can control what apps are available to that profile. In many cases, if the user is setting up a restricted profile in the first place, the list of apps available to that profile will be fairly limited, such as only allowing a young child to access a few games and educational apps.

`startActivity()` always has the chance of throwing an `ActivityNotFoundException`. However, for certain Intent actions, we often ignore this possibility, because we are certain that there will be an app that can handle our request:

- All Android devices have Web browsers, right?
- All Android devices have some sort of mapping application, right?
- All Android devices let you pick a contact, right?

## RESTRICTED PROFILES AND USERMANAGER

---

Now, with restricted profiles, you will need to deal with the `ActivityNotFoundException` case all of the time. You have three basic approaches for this:

1. Wrap all `startActivity()` and `startActivityForResult()` calls in a try/catch block that catches `ActivityNotFoundException` and intelligently handle the problem
2. Use `PackageManager` and `resolveActivity()` *before* trying to start the activity, where if `resolveActivity()` returns null, you know that there is no activity available to handle your desired operation
3. Switch out some of your `startActivity()` and `startActivityForResult()` calls for implementations in your app (e.g., embed [Maps V2](#) rather than try to launch a potentially-nonexistent activity)

You might consider implementing a `safeStartActivity()` utility method that wraps up your particular plan, so you can debug it once.

# Device Authentication

---

Android devices have supported device authentication since the beginning. Users could lock their devices with a PIN, passphrase, or “pattern”, to help deter unauthorized use. Nowadays, fingerprint sensors are available on some Android devices as another authentication option.

For the vast majority of apps, none of this matters.

Some apps have sensitive content (e.g., password manager) or offer sensitive services (e.g., banking app). These apps may want to tie more tightly into the device authentication options, to ensure that the person working with the app right now is the device’s authorized user.

In this chapter, we will look at how to perform this sort of integration.

## Prerequisites

One of the examples in this chapter makes use of [RxJava](#).

## Is the Device Secure?

You cannot validate the identity of the user on a device that is not secured by something (PIN, passphrase, pattern, fingerprint, etc.). So, one of the first things you may wish to determine is whether or not such a lock has been applied to the device.

Android has two separate ways of accomplishing this, with slightly different feature sets.

### The DevicePolicyManager Approach

In [the chapter on device administration](#), we cover a number of APIs for managing the lock quality. In particular, DevicePolicyManager has the concept of “password quality”. Any app — not just designated device admin apps — can call getPasswordQuality() on a DevicePolicyManager instance to find out the designated minimum required quality. A value of PASSWORD\_QUALITY\_UNSPECIFIED indicates that “anything goes”. PASSWORD\_QUALITY\_SOMETHING indicates that the device needs some form of authentication, but does not establish any criteria beyond that. Other values start to put restrictions on the authentication option, such as PASSWORD\_QUALITY\_ALPHABETIC, indicating that the authentication cannot be in the form of a simple PIN.

Other methods let you get minimum required password lengths, minimum required characters of certain classes (e.g., symbols), and so forth.

It is fairly likely that the current authentication option in force adheres to the password criteria exposed by those methods.

### The KeyguardManager Approach

The KeyguardManager system service has a simpler API... with a couple of wrinkles.

- isDeviceSecure() returns true if the device is secured with a PIN, pattern, or password. However, this method is new to API Level 23.
- isKeyguardSecure() returns true if the device is secured with a PIN, pattern, password, or SIM card lock. A “SIM card lock” amounts to a PIN associated with the SIM card, one that follows the SIM card around if you move it between devices. Conversely, a device that is secured solely by a SIM card lock can be accessed simply by removing the SIM card. This method is available on API Level 16 and higher devices.

Since SIM card locks do not seem very common, the two methods will tend to return the same result. However, since SIM card lock security is fairly weak, on Android 6.0+, use isDeviceSecure(), so SIM card locks are not taken into account with the result.

The [DeviceAuth/SecureCheck](#) sample application demonstrates the use of these methods (and of a few others that we will see shortly).

Our activity’s UI consists of two big icons with those two KeyguardManager method

## DEVICE AUTHENTICATION

---

names as captions.

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.constraint.ConstraintLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    tools:context="com.commonware.android.auth.check.MainActivity">

    <TextView
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_marginEnd="8dp"
        android:text="@string/label_device"
        android:textAlignment="viewStart"
        android:textAppearance="?android:textAppearanceLarge"
        android:typeface="monospace"
        app:layout_constraintBottom_toBottomOf="@id/device"
        app:layout_constraintLeft_toRightOf="@id/device"
        app:layout_constraintRight_toRightOf="parent"
        app:layout_constraintTop_toTopOf="@id/device" />

    <ImageView
        android:id="@+id/device"
        android:layout_width="64dp"
        android:layout_height="64dp"
        android:layout_marginStart="8dp"
        android:layout_marginTop="8dp"
        app:layout_constraintStart_toStartOf="parent"
        app:layout_constraintTop_toTopOf="parent" />

    <TextView
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_marginEnd="8dp"
        android:text="@string/label_keyguard"
        android:textAlignment="viewStart"
        android:textAppearance="?android:textAppearanceLarge"
        android:typeface="monospace"
        app:layout_constraintBottom_toBottomOf="@id/keyguard"
        app:layout_constraintLeft_toRightOf="@id/keyguard"
        app:layout_constraintRight_toRightOf="parent"
        app:layout_constraintTop_toTopOf="@id/keyguard" />

    <ImageView
        android:id="@+id/keyguard"
        android:layout_width="64dp"
        android:layout_height="64dp"
        android:layout_marginStart="8dp"
        android:layout_marginTop="8dp"
        app:layout_constraintStart_toStartOf="parent"
        app:layout_constraintTop_toBottomOf="@id/device" />

</android.support.constraint.ConstraintLayout>
```

(from [DeviceAuth/SecureCheck/app/src/main/res/layout/activity\\_main.xml](#))

## DEVICE AUTHENTICATION

---

In `onCreate()`, we retrieve a `KeyguardManager` system service and set the images on those icons based on the `KeyguardManager` results:

- If the method returns `true`, we show a locked icon
- If the method returns `false`, we show an unlocked icon
- If the method cannot be called (`isDeviceSecure()` on pre-Android 6.0 devices), we show a question mark icon, indicating that we do not know the result

```
private KeyguardManager mgr;

@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    mgr=(KeyguardManager) getSystemService(KEYGUARD_SERVICE);

    ImageView device=findViewById(R.id.device);
    ImageView keyguard=findViewById(R.id.keyguard);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.M) {
        if (mgr.isDeviceSecure()) {
            device.setImageResource(R.drawable.ic_lock_black_24dp);
        }
        else {
            device.setImageResource(R.drawable.ic_lock_open_black_24dp);
        }
    }
    else {
        device.setImageResource(R.drawable.ic_help_black_24dp);
    }

    if (mgr.isKeyguardSecure()) {
        keyguard.setImageResource(R.drawable.ic_lock_black_24dp);
    }
    else {
        keyguard.setImageResource(R.drawable.ic_lock_open_black_24dp);
    }
}
```

(from [DeviceAuth/SecureCheck/app/src/main/java/com/commonsware/android/auth/check/MainActivity.java](#))

## DEVICE AUTHENTICATION

---

Running the app will show the results of those calls:

*Figure 739: Secure Check, As Run On Secure Android 5.0 Device*

*Figure 740: Secure Check, As Run On Insecure Android 6.0 Device*

## Reconfirming the User

Those methods are interesting, but they do not tell you much about the current user. Obviously, if the device is not secure, you have no idea who the current user is. However, even if the device has a PIN/password/pattern lock, it is possible that the real user unlocked device, but somebody else now has that unlocked device. Some apps will want a way to re-authenticate the user, to confirm that the person working with the device right now is the real user, not somebody else who has their hands on the unlocked device.

KeyguardManager has a `createConfirmDeviceCredentialIntent()` method that helps with this. This method returns an Intent that can be used with `startActivityForResult()`. What then appears is a system-supplied activity that requires the user to re-authenticate the device. In `onActivityResult()`, a `RESULT_OK` result means that the user successfully re-authenticated. Anything else means that the user failed to re-authenticate and eventually pressed BACK to return to your app.

The SecureCheck sample app has an action bar icon that, when tapped, invokes an `authenticate()` method, one that uses `createConfirmDeviceCredentialIntent()`:

## DEVICE AUTHENTICATION

---

```
@TargetApi(Build.VERSION_CODES.LOLLIPOP)
private void authenticate() {
    Intent i=mgr.createConfirmDeviceCredentialIntent("title", "description");

    if (i==null) {
        Toast.makeText(this, "No authentication required!", Toast.LENGTH_SHORT).show();
    }
    else {
        startActivityForResult(i, REQUEST_CODE);
    }
}
```

(from [DeviceAuth/SecureCheck/app/src/main/java/com/commonsware/android/auth/check/MainActivity.java](#))

`createConfirmDeviceCredentialIntent()` takes two parameters: a title and a description. In principle, these should appear on the authentication activity, to provide context to the user as to why this screen appeared. In reality, the description may or may not appear, so do not assume that the user will be able to see whatever you put there.

Since this Intent is designed for use with `startActivityForResult()`, we cannot directly put it into a `PendingIntent` or anything. If for some reason you needed to re-authenticate from a Notification or app widget or something, you can use a `Theme.Translucent.NoTitleBar`-themed activity for the `PendingIntent`, as such activities are effectively invisible. That activity, in turn, can call `startActivityForResult()` with the Intent from `createConfirmDeviceCredentialIntent()`.

Here, we just call `startActivityForResult()` directly, showing a Toast in `onActivityResult()` based upon the user's response:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (requestCode==REQUEST_CODE) {
        if (resultCode==RESULT_OK) {
            Toast.makeText(this, "Authenticated!", Toast.LENGTH_SHORT).show();
        }
        else {
            Toast.makeText(this, "WE ARE UNDER ATTACK!", Toast.LENGTH_SHORT).show();
        }
    }
}
```

(from [DeviceAuth/SecureCheck/app/src/main/java/com/commonsware/android/auth/check/MainActivity.java](#))

## DEVICE AUTHENTICATION

---

On some devices (e.g., Nexus 5X running Android 8.1), the authentication activity uses `FLAG_SECURE` and cannot be captured in a screenshot. Other devices have no such restriction:

*Figure 741: Re-Authentication Activity on a Samsung Galaxy Note 3*

Note that only the title appears here; on the Nexus 5X with Android 8.1, both the title and the description appear.

`createConfirmDeviceCredentialIntent()` has a significant limitation: the Intent that you create always triggers authentication when started. Sometimes, this is a feature, if you absolutely want to ensure that the user is authenticated before proceeding. Sometimes, this is a bug, if your flow keeps forcing the user to re-authenticate. There is a way to use `createConfirmDeviceCredentialIntent()` to have an authentication timeout, so a successful authentication skips future authentication for some amount of time. This is a bit complex to set up, as it requires custom use of the keystore, and so we will explore it in greater detail in [the next chapter](#).

### Fingerprints

Android 6.0 added APIs for fingerprint sensors. For most users, and for most apps, fingerprints are just another aspect of unlocking a device. However, apps can more deeply integrate with the fingerprint sensor if desired.

Note that the libraries and classes related to fingerprints are only supported on API Level 23 and higher.

### Authenticating the User

One obvious use of the fingerprint sensor is to authenticate the current user, ensuring that the person holding the device is who we think it is.

There are a few options for doing this, with varying levels of complexity.

#### Via KeyguardManager

The simplest solution is to not worry about fingerprints, but instead to use the techniques shown earlier in this chapter to authenticate the user.

When a user sets up a fingerprint to use for unlocking a device, that is an adjunct to a more traditional PIN or passphrase. When you start the activity identified by the Intent returned by `createConfirmDeviceCredentialIntent()`, you are requesting that the user authenticate by whatever means is appropriate. If a fingerprint is an option, the user will be able to use a fingerprint to authenticate.

This is cheap and easy, but it does not *require* that the user use a fingerprint. The user could type in their PIN or passphrase instead.

#### Using RxFingerprint

It is possible that you will want to use a fingerprint specifically. For example, perhaps you are using fingerprints as part of a multi-factor authentication system, where the user needs to provide some sort of passphrase for your app *and* authenticate with a fingerprint.

The simplest way to do this is to use one of the [many third-party libraries that exist to simplify Android's fingerprint API](#). For example, the [DeviceAuth/FingerCheck](#) sample application uses [RxFingerprint](#), which offers an RxJava-compatible API for

## DEVICE AUTHENTICATION

---

authenticating a user via a registered fingerprint.

The first requirement for working with fingerprints explicitly is to request the `USE_FINGERPRINT` permission:

```
<uses-permission android:name="android.permission.USE_FINGERPRINT" />
```

(from [DeviceAuth/FingerCheck/app/src/main/AndroidManifest.xml](#))

This is not a dangerous permission, so you do not need to request it at runtime using `requestPermissions()`. But, you have to have it, so that users that investigate the full slate of permissions requested by your app will know that you wish to work with fingerprints.

Android 9.0 introduced a new permission, `USE_BIOMETRIC`, to better reflect the migration from simple fingerprints to more biometric authentication options (e.g., iris scan). You may wish to request both `USE_FINGERPRINT` and `USE_BIOMETRIC`, knowing that the latter will be ignored on pre-Android 9.0 devices.

`RxFingerprint` itself is just another artifact to request as part of your dependencies:

```
dependencies {
    implementation 'com.android.support:support-vector-drawable:27.0.2'
    implementation 'com.android.support.constraint:constraint-layout:1.0.2'
    implementation 'io.reactivex.rxjava2:rxjava:2.1.7'
    implementation 'io.reactivex.rxjava2:rxandroid:2.0.1'
    implementation 'com.mtramin:rxfingerprint:2.2.1'
}
```

(from [DeviceAuth/FingerCheck/app/build.gradle](#))

When you want to authenticate the user, you can use `isAvailable()` and `authenticate()` static methods on the `RxFingerprint` class:

```
if (RxFingerprint.isAvailable(this)) {
    disposable=RxFingerprint.authenticate(this)
    .subscribe(this::onAuthResult,
        t -> {
            Log.e(getClass().getSimpleName(), "Exception authenticating", t);
        });
}
else {
    Toast.makeText(this, R.string.msg_not_available, Toast.LENGTH_LONG).show();
}
```

## DEVICE AUTHENTICATION

---

You need to call `isAvailable()` first. If this returns `false`, you cannot authenticate using a fingerprint, for any number of reasons, including:

- The device is running on less than API Level 23, which you can validate yourself using `Build.VERSION.SDK_INT`
- The device does not have a fingerprint sensor — you can also check this by calling `hasSystemFeature(PackageManager.FEATURE_FINGERPRINT)` on a `PackageManager` and seeing if it returns `true` or `false`
- The user has not registered a fingerprint

Assuming that there is a fingerprint eligible for authentication, `authenticate()` turns on the fingerprint sensor. There is no visible indication of this, and so you will need to do something in your app to let the user know that it is time for them to scan their fingerprint.

There are four possible outcomes. The unexpected one is some sort of crash. In that case, your RxJava stream will contain a `Throwable` representing the crash. In the code shown above, `subscribe()` routes that `Throwable` to some code that logs the message to `LogCat` (and, ideally, should do other things as well, to let the user know that something went wrong).

Everything else routes through a `FingerprintAuthenticationResult` object that is the output of the RxJava stream set up by `isAvailable()`. You can call `getResult()` on that to get an enum value that indicates what happened:

```
private void onAuthResult(FingerprintAuthenticationResult authResult) {
    String msg=getString(R.string.msg_not_possible);

    switch (authResult.getResult()) {
        case FAILED:
            msg=getString(R.string.msg_failed);
            button.setImageDrawable(off);
            unsub();
            break;
        case HELP:
            msg=authResult.getMessage();
            break;
        case AUTHENTICATED:
            msg=getString(R.string.msg_authenticated);
            button.setImageDrawable(off);
            unsub();
            break;
    }
}
```

## DEVICE AUTHENTICATION

---

```
Toast.makeText(this, msg, Toast.LENGTH_LONG).show();
}
```

(from [DeviceAuth/FingerCheck/app/src/main/java/com/commonsware/android/auth/finger/MainActivity.java](#))

If we get a HELP event, the user can try to scan their fingerprint again. The `getMessage()` method on the `FingerprintAuthenticationResult` provides a message to show the user to hint at what they might do to get a better scan. Otherwise, `AUTHENTICATED` means that the user successfully authenticated using a fingerprint, and `FAILED` means that the user failed authentication.

In all three cases, the fingerprint sensor is still active, and will remain so until we `dispose()` of the `Disposable` representing this RxJava subscription, handled here by the `unsub()` method:

```
private void unsub() {
    if (disposable!=null) {
        disposable.dispose();
        disposable=null;
    }
}
```

(from [DeviceAuth/FingerCheck/app/src/main/java/com/commonsware/android/auth/finger/MainActivity.java](#))

In this sample app, the layout consists of a single `ImageButton`, showing a vector drawable of a stylized fingerprint. That fingerprint will show up in one of two colors: black normally, but blue when the fingerprint sensor is active. In `onCreate()`, we set up tinted editions of the vector drawable, plus hook up an `authenticate()` method to the button:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    off=DrawableCompat.wrap(VectorDrawableCompat.create(getResources(),
        R.drawable.ic_fingerprint_black_24dp, null));
    off.setTint(getResources().getColor(android.R.color.black, null));

    on=DrawableCompat.wrap(VectorDrawableCompat.create(getResources(),
        R.drawable.ic_fingerprint_black_24dp, null));
    on.setTint(getResources().getColor(R.color.primary, null));

    button=findViewById(R.id.fingerprint);
    button.setImageDrawable(off);
    button.setOnClickListener(view -> authenticate());
}
```

## DEVICE AUTHENTICATION

---

```
}
```

(from [DeviceAuth/FingerCheck/app/src/main/java/com/commonsware/android/auth/finger/MainActivity.java](#))

authenticate() contains the RxFingerprint calls from earlier, but with some additional manipulation of the button drawable, to toggle it blue while the scan is going on and toggle it black if an exception occurs:

```
private void authenticate() {
    unsub();

    if (RxFingerprint.isAvailable(this)) {
        button.setImageDrawable(on);
        disposable=RxFingerprint.authenticate(this)
            .subscribe(this::onAuthResult,
                t -> {
                    Log.e(getClass().getSimpleName(), "Exception authenticating", t);
                    button.setImageDrawable(off);
                });
    }
    else {
        Toast.makeText(this, R.string.msg_not_available, Toast.LENGTH_LONG).show();
    }
}
```

(from [DeviceAuth/FingerCheck/app/src/main/java/com/commonsware/android/auth/finger/MainActivity.java](#))

## DEVICE AUTHENTICATION

---

The layout sets the ImageButton to be approximately one inch square:

*Figure 742: Finger Check Sample, As Initially Launched*

## DEVICE AUTHENTICATION

---

When you tap that button, the fingerprint turns blue:

*Figure 743: Finger Check Sample, As Initially Launched*

## DEVICE AUTHENTICATION

---

From there, what happens depends on the user, but ideally involves a successful authentication:

*Figure 744: Finger Check Sample, As Initially Launched*

### Directly

The `FingerprintManager` system service is the Android gateway to the fingerprint-specific APIs. It has only three methods, at least as of Android 8.1.

Two of these simply indicate whether or not you can bother using the third method:

- `isHardwareDetected()` returns `true` if the device has a fingerprint sensor that is set up for use by the Android SDK, `false` otherwise
- `hasEnrolledFingerprints()` returns `true` if the user has set up one or more fingerprints in Settings, `false` otherwise

If either of those methods return `false`, you cannot authenticate the user by fingerprint.

If they both return `true`, though, you can use the third method — `authenticate()` — to authenticate the user with a fingerprint.

`authenticate()` takes five parameters:

- A `CryptoObject`, which for simple authentication can be `null`
- A `CancellationSignal` object that you can use to cancel the attempt to authenticate
- Some currently-unused flags (pass in 0 for now)
- A callback object, to find out what is happening with the authentication attempt
- A `Handler`, if you want the callback methods to be called on some other thread (otherwise, pass `null` to be called back on the main application thread)

Your `AuthenticationCallback` implementation can be called with four methods:

- `onAuthenticationSucceeded()`, if the user did indeed pass the authentication
- `onAuthenticationFailed()`, if the sensor detected a fingerprint, but it was not one of the registered fingerprints (e.g., from some other person)
- `onAuthenticationHelp()`, when there was a problem in scanning the fingerprint, but the user can try again (e.g., the finger moved too much)
- `onAuthenticationError()`, when something goes wrong that does not represent a failure (i.e., mismatched fingerprint) and is not recoverable

`RxFingerprint` simply wraps all of this in an RxJava-friendly API.

### Encrypting Data Using Fingerprints and Libraries

The `CryptoObject` that you can pass into `authenticate()` is tied to the device [keystore](#) for use with digitally signing and encrypting data securely. You do not have to use `FingerprintManager` to work with the keystore, but it is one option. However, as we will see in [the chapter on the keystore](#), working with the keystore is a bit complex.

#### RxFingerprint

`RxFingerprint` offers simple `encrypt()` and `decrypt()` methods. Each return an `Observable` for you to be able to react to the results of the cryptography.

Both methods have three parameters in common:

1. An `EncryptionMethod` enum value, which is either `AES` (for `AES-256`)

## DEVICE AUTHENTICATION

---

- symmetric key encryption) or RSA (for public-key encryption)
2. The Activity requesting this work
  3. A “key name”, which must be unique within your app, to identify the encryption key(s) that are generated and securely stored as part of this work

The advantage of RSA is that the user only needs to scan their fingerprint when data is decrypted. Encryption can occur at any time without a fingerprint. With AES, a fingerprint is needed for both encryption and decryption. However, AES should be a bit faster, particularly for larger amounts of data.

The `encrypt()` method takes a fourth parameter, which is a `String` representing the data to be encrypted. It is your job to marshal your data into a `String` by one means or another. What you get, reactively, from the `encrypt()` process is another `String`, representing the encrypted value. It is your job to save this somewhere, such as in a file.

The `decrypt()` method then works in reverse:

- Its fourth parameter is the encrypted `String`
- The result of the decryption is the original “plaintext” value that you supplied to `encrypt()` originally

the [DeviceAuth/FingerKey](#) sample application illustrates the use of these two methods.

The value that we are saving is a randomly-generated passphrase, for reasons that will become clearer [later in this chapter](#). Specifically, it is 128 characters of random alphanumeric values, generated via a `SecureRandom` instance:

```
private char[] generatePassphrase() {
    char[] result=new char[128];

    for (int i=0; i<result.length; i++) {
        result[i]=BASE36_SYMBOLS.charAt(rng.nextInt(BASE36_SYMBOLS.length()));
    }

    return result;
}
```

(from [DeviceAuth/FingerKey/app/src/main/java/com/commonsware/android/key/MainActivity.java](#))

Here, `BASE36_SYMBOLS` is simply a `String` of the candidate characters to use in the random passphrase:

---

## DEVICE AUTHENTICATION

---

```
private static final String BASE36_SYMBOLS="abcdefghijklmnopqrstuvwxyz0123456789";
```

(from [DeviceAuth/FingerKey/app/src/main/java/com/commonsware/android/key/MainActivity.java](#))

rng is a SecureRandom instance:

```
private final SecureRandom rng=new SecureRandom();
```

(from [DeviceAuth/FingerKey/app/src/main/java/com/commonsware/android/key/MainActivity.java](#))

That passphrase is generated as part of starting up the activity and is held onto in a passphrase field.

The UI is the same as in the FingerAuth sample shown above, with a large fingerprint button. This time, when the user taps the button, we will encrypt the passphrase using RSA encryption, then turn around and decrypt the value. The decryption will require the user to scan their fingerprint.

The button is now tied to a doTheWork method, which confirms that we have fingerprint access, then calls encrypt() on the RxFingerprint instance:

```
private void doTheWork() {
    unsub();

    if (RxFingerprint.isAvailable(this)) {
        disposable=RxFingerprint.encrypt(EncryptionMethod.RSA, this, KEY_NAME,
            new String(passphrase))
            .subscribe(this::onEncResult,
                t -> {
                    Log.e(getClass().getSimpleName(), "Exception authenticating", t);
                    button.setImageDrawable(off);
                });
    }
    else {
        Toast.makeText(this, R.string.msg_not_available, Toast.LENGTH_LONG).show();
    }
}
```

(from [DeviceAuth/FingerKey/app/src/main/java/com/commonsware/android/key/MainActivity.java](#))

Here, KEY\_NAME is just a simple constant. The passphrase is held onto as a char array, so we need to convert that to a String before passing it to encrypt() as the value to be encrypted.

The subscribe() call on the Observable routes control to an onEncResult() method in normal cases, or logs an Exception to LogCat in case of a serious failure.

There are three possible outcomes from onEncResult()... in theory. In reality, it will depend on the encryption algorithm. AES requires fingerprint authentication for

## DEVICE AUTHENTICATION

---

both encryption and decryption, and so there is a chance that the user fails the fingerprint authentication step. RSA — which this sample app uses — does not require fingerprint authentication for encryption. This means that everything should succeed (a result of AUTHENTICATED, or we should get a Throwable).

So, if we are AUTHENTICATED, our data has been encrypted, and so we can get that encrypted value via `getEncrypted()` on the `FingerprintEncryptionResult`. In a real app, you would save this somewhere for long-term use. Here, we just turn right around and:

- Show the “on” state for the `ImageButton`, with a blue fingerprint
- Clean up the previous subscription via `unsub()`
- Pass the `getEncrypted()` value to `RxFingerprint.decrypt()` to decrypt this value

```
private void onEncResult(FingerprintEncryptionResult encResult) {
    if (encResult.getResult()==FingerprintResult.AUTHENTICATED) {
        button.setImageDrawable(on);
        unsub();

        String encryptedValue=encResult.getEncrypted();

        disposable=RxFingerprint.decrypt(EncryptionMethod.RSA, this, KEY_NAME,
            encryptedValue)
            .subscribe(this::onDecResult,
                t -> {
                    Log.e(getClass().getSimpleName(), "Exception decrypting", t);
                    button.setImageDrawable(off);
                });
    }
    else {
        Toast.makeText(this, "This was unexpected...", Toast.LENGTH_LONG).show();
    }
}
```

(from [DeviceAuth/FingerKey/app/src/main/java/com/commonsware/android/key/MainActivity.java](#))

`decrypt()` takes the same first three parameters as does `encrypt()`:

1. The `EncryptionMethod` enum value corresponding with how you encrypted the value
2. The `Activity` requesting this work
3. The same “key name” that you used with `encrypt()`

## DEVICE AUTHENTICATION

---

The fourth parameter is the encrypted data to be decrypted.

`decrypt()` returns an `Observable` of `FingerprintDecryptionResult`. We use the same pattern as before, routing the normal case to an `onDecResult()` method and logging any exceptions to `LogCat`.

`onDecResult()` will need to deal with all three possible fingerprint scan outcomes (FAILED, HELP, and AUTHENTICATED), since any decryption requires a fingerprint scan. The first two of those scenarios we handle the same as in `FingerAuth`; the third one just confirms that our decrypted data matches the plaintext that we supplied to `encrypt()` back in the beginning:

```
private void onDecResult(FingerprintDecryptionResult decResult) {
    String msg=getString(R.string.msg_not_possible);

    switch (decResult.getResult()) {
        case FAILED:
            msg=getString(R.string.msg_failed);
            button.setImageDrawable(off);
            unsub();
            break;
        case HELP:
            msg=decResult.getMessage();
            break;
        case AUTHENTICATED:
            button.setImageDrawable(off);
            unsub();

            if (decResult.getDecrypted().equals(new String(passphrase))) {
                msg=getString(R.string.msg_match);
            }
            else {
                msg=getString(R.string.msg_mismatch);
            }

            break;
    }

    Toast.makeText(this, msg, Toast.LENGTH_LONG).show();
}
```

(from [DeviceAuth/FingerKey/app/src/main/java/com/commonsware/android/key/MainActivity.java](#))

In a real app, of course, you would use this decrypted data for something useful.

### Whorlwind

Square — authors of a seemingly-infinite number of open source Android libraries — has their take on fingerprints and encryption, in [the Whorlwind library](#).

This is simpler to use than RxFingerprint, if you do not need control over the encryption algorithm that is used or the storage location for the encrypted data. That is handled for you by Whorlwind. It uses the RSA algorithm, which avoids the need for fingerprint authentication for encrypting the data. And, it provides a Storage abstraction for persisting the encrypted data in a key-value store. Whorlwind ships with a SharedPreferencesStorage, or you can create another implementation of the Storage interface that meets your needs.

### OK, So What Was *That* All About?

Encrypting a random string seems to be a bit esoteric. Developers are used to encrypting things of value, and a random string would not appear to be of value.

On its own, a random string is useless.

However, there are encrypted data stores for Android that rely on a passphrase, such as [SQLCipher for Android](#). Those data stores have no means of integrating with a fingerprint scanner directly.

The encrypted random string, therefore, serves as a bridge between the fingerprint authentication — or, as we will see, [the keystore](#) — and the passphrase-based data store:

- We generate the long random string
- We use that string as the passphrase with the data store
- We encrypt that string using RxFingerprint, Whorlwind, etc.
- We save that encrypted string somewhere (inside a Whorlwind Storage, in a file, in SharedPreferences, etc.)

Later on, to access the passphrase-based data store, we:

- Load the encrypted string
- Decrypt it, which will involve user authentication
- Use the decrypted random string as our passphrase

The net result is an encrypted data store (e.g., SQLCipher for Android) with device-

based authentication, instead of (or in addition to) a user-entered passphrase.

We will explore this pattern in greater detail in [the next chapter](#).

### **Limitations of Fingerprint-Based Encryption**

Under the covers, all of this winds up using [the keystore](#) for handling the encryption securely. Using the keystore has many benefits, but it also has some limitations, particularly when it comes to changes to the lockscreen. The next chapter has [a section that reviews these limitations](#).

# Keys and the Keystore

---

The Java Cryptography Architecture (JCA) has been available in Java since Java 1.1, though it has expanded over the years. It gives us `KeyStore` objects that can manage cryptographic keys for a variety of symmetric and asymmetric ciphers. You can create keys, then use those keys to encrypt, decrypt, sign, and validate data. The actual algorithms that implement the cryptography come from service provider implementations (SPIs) that plug into the JCA. You do not need to know all of the details of the cryptography – you treat the algorithms mostly as a black box.

Android extends JCA by offering a `KeyStore` that is integrated into the Android architecture. In particular, on some Android 7.0+ devices, the keys can be tied to hardware, as part of the so-called Trusted Execution Environment (TEE, presumably named by a golfer). This dramatically reduces the likelihood of your keys somehow getting leaked to some malicious actor. The Android-supplied `KeyStore` also offers hooks to tie keys to device authentication, where you can require the user to authenticate the device before you can use the key to decrypt the data.

In this chapter, we will explore the basics of using this Android-specific `KeyStore`. The important word in the preceding sentence is “basics”, as this is *not* a complete treatment of how to use the JCA. The JCA is part of standard Java; other educational resources can show you how to implement effective cryptography using the JCA.

Also note that many of the Android-specific APIs shown in this chapter have a `minSdkVersion` of 23.

## Prerequisites

To understand this chapter, please read [the preceding chapter on device authentication](#) first. Also, the examples in this chapter make extensive use of [RxJava](#).

### Terminology

First, let's review some...ummmm... “key” terms that will be used in this chapter.

#### Keys

To encrypt, decrypt, sign, or validate some data, you need a key and a corresponding algorithm.

From a `javax.crypto` standpoint, the Java class that we use to represent keys is `SecretKey`. Whether this is the “real” key, or is merely an identifier to “key material” held elsewhere (e.g., in hardware), depends on the SPI and `KeyStore` implementation.

#### KeyStore

A `KeyStore`, as the name suggests, is a storage location for keys. There are several implementations of `KeyStore`, based on the storage location and format of the keys in the store.

In Android, we are particularly interested in one known as `AndroidKeyStore`. It offers two benefits:

1. The “key material” — the actual bytes representing the key — never make it into our application process. Instead, the cryptography is performed by a system process. The APIs that we use make it appear that everything is local, but in reality IPC is occurring under the covers to pass our data and key identifier to this system process. The benefit here is that even if our process gets attacked, the attacker cannot get the “key material” to be able to decrypt encrypted data away from this device.
2. On supported devices, and for supported key/algorithm combinations, the key material may “bound” to the device itself. This means that even the system process that normally does the cryptography does not have the bytes representing the key itself. Instead, the cryptography is performed by dedicated hardware, as part of the TEE. The key material held in the `AndroidKeyStore` needs to be blended with secure data held in hardware to get the *real* key to use with the cryptography. As a result, even if an attacker is able to hack core system processes, the attacker will not be able to retrieve a key that can be used outside of this device.

### KeyChain

If you rummage around the Android SDK, you will also see a separate `KeyChain` class. This offers a stripped down system similar to the `KeyStore`. However, the `KeyChain` is for device-wide keys, and as such is usually not what developers of an individual app need.

### Getting a KeyStore

The `AndroidKeyStore` is merely the name of a JCA `KeyStore` that you obtain using standard `javax.crypto` APIs:

```
ks=KeyStore.getInstance("AndroidKeyStore");
ks.load(null);
```

The static `getInstance()` method returns an instance of the `KeyStore`, and `load()` is used to populate it. With traditional JCA `KeyStore` implementations, `load()` is used to load the keys from a file. The `AndroidKeyStore` does not need this, and so we can pass `null` into the `load()` method.

Note that these methods throw a variety of checked exceptions, and so you will need to be in position to catch those and do something useful. In practice, nothing should go wrong, as those checked exceptions are mostly for cases where:

- You provide an invalid `KeyStore` type name (e.g., `KeyStore.getInstance("this does not exist")`)
- There are problems loading the keys from a file (file not found, file corrupt, etc.)

### Creating a Key

Android has a dedicated `KeyGenParameterSpec` class, with a corresponding `Builder`, that is used to create secret keys for symmetric encryption, stored in the `AndroidKeyStore`:

```
KeyGenParameterSpec spec=
    new KeyGenParameterSpec.Builder("thisIsMyKey",
        KeyProperties.PURPOSE_ENCRYPT | KeyProperties.PURPOSE_DECRYPT)
        .setBlockModes(KeyProperties.BLOCK_MODE_CBC)
        .setEncryptionPaddings(KeyProperties.ENCRYPTION_PADDING_PKCS7)
        .build();
```

```
KeyGenerator keygen=  
    KeyGenerator.getInstance(KeyProperties.KEY_ALGORITHM_AES, "AndroidKeyStore");  
  
keygen.init(spec);  
SecretKey secretKey=keygen.generateKey();
```

Grafting the Android-specific `AndroidKeyStore` onto the JCA base results in a few oddities. For example, we do not need to do anything to save this key in the `AndroidKeyStore` — saving it is a side effect of creating the key using a `KeyGenerator` backed by the `AndroidKeyStore` (via the `getInstance()` static method).

Each of your app's keys has a name ("thisIsMyKey" in the above example). You will use this name to reference the key later on. This name needs to be unique for your app, though it does not need to be unique for the entire device.

Most of the methods on the `KeyGenParameterSpec.Builder` are tied to the JCA, such as the block modes, encryption paddings, and so forth. The above configuration — when coupled with `KEY_ALGORITHM_AES` when creating the `KeyGenerator` — is for `AES/CBC/PKCS7Padding`, which is a fairly typical symmetric key setup. Most of the details of setting up the `Builder`, therefore, are tied to the specific form of encrypting or digital signature that you wish to employ. The details of this are well out of scope for this book and are best left to educational resources dedicated to Java cryptography.

The JCA `KeyStore` is designed around symmetric keys (e.g., `SecretKey`) classes, though asymmetric encryption has been grafted onto the original `KeyStore` API, so RSA-style public-key encryption can also be performed using the `AndroidKeyStore`.

## Tying the Key to Device Authentication

Part of the reason for an Android-specific `KeyGenParameterSpec` class is to be able to offer Android-specific features to extend the JCA. A prominent example of this is tying a generated key to [device authentication](#), such that your app can only use the key if the user is currently authenticated.

The two primary `Builder` methods for this are:

- `setUserAuthenticationRequired(true)`, to indicate that the key being generated requires user authentication

## KEYS AND THE KEYSTORE

---

- `setUserAuthenticationValidityDurationSeconds()`, to indicate how long we have, after user authentication, to be able to use the key, before the user needs to re-authenticate

The default validity period is, in effect, zero seconds. Every use of the key requires an immediately-preceding authentication. This may be excessive, and you will want to consider whether setting a longer validity period (e.g., one minute) is more appropriate for your situation.

So, in this sample, we generate a key with user authentication required, with a 60-second timeout:

```
KeyGenParameterSpec spec=
    new KeyGenParameterSpec.Builder("thisIsMyKey",
        KeyProperties.PURPOSE_ENCRYPT | KeyProperties.PURPOSE_DECRYPT)
        .setBlockModes(KeyProperties.BLOCK_MODE_CBC)
        .setEncryptionPaddings(KeyProperties.ENCRYPTION_PADDING_PKCS7)
        .setUserAuthenticationRequired(true)
        .setUserAuthenticationValidityDurationSeconds(60)
        .build();

KeyGenerator keygen=
    KeyGenerator.getInstance(KeyProperties.KEY_ALGORITHM_AES, "AndroidKeyStore");

keygen.init(spec);
SecretKey secretKey=keygen.generateKey();
```

Later on, when we try to use the key for encryption, decryption, etc., we may get a `UserNotAuthenticatedException`. This means that the user has not authenticated against the device within the timeout period, and so we need to re-authenticate the user (e.g., `createConfirmDeviceCredentialIntent()`) before trying the cryptographic operation again. [The preceding chapter](#) outlines how to use `createConfirmDeviceCredentialIntent()` to authenticate the user.

## Learning More About Your Key

For keys created in the `AndroidKeyStore`, you can use a somewhat clunky set of APIs to find out more details about the key, in particular whether the key is backed by any sort of hardware security (e.g., the TEE). This information is available through an Android-specific `KeyInfo` class. Unfortunately, you have to get one of those by means of a `SecretKeyFactory` and a cast, as shown below:

```
SecretKey key=(SecretKey)ks.getKey(keyName, null);
```

---

## KEYS AND THE KEYSTORE

---

```
KeyInfo info=
    (KeyInfo)SecretKeyFactory.getInstance(key.getAlgorithm(), "AndroidKeyStore")
        .getKeySpec(key, KeyInfo.class);

if (info.isInsideSecureHardware()) {
    Toast.makeText(this, "Key is inside secure hardware", Toast.LENGTH_LONG).show();
}
else {
    Toast.makeText(this, "Key is only secured by software", Toast.LENGTH_LONG).show();
}
```

Given the `SecretKey`, you can get the associated `SecretKeyFactory`, based on the algorithm and keystore name. That `SecretKeyFactory` has a `getKeySpec()` method, which takes the `SecretKey` and the spec class (`KeyInfo.class` in this case). That needs to be cast to a `KeyInfo`, this JCA code probably pre-dates Java's support for generics.

The sample code shown above checks one specific characteristic of the key: does the key reside inside of secure hardware. You get that from a call to `isInsideSecureHardware()`.

## Encrypting Data

So, with all of that as background, let's look at actually encrypting some data using all of this stuff.

The [DeviceAuth/SecureNote](#) sample application has a single activity with a really big `EditText` widget, for you to type in a note. We will store that note in an encrypted form, using a key that requires device authentication.

And to do that, we will spend some time in a [bodega](#).

## Introducing RxKeyBodega

The `RxKeyBodega` class in this project implements a small RxJava-based API wrapped around the relevant `javax.crypto` and `android.security.keystore` classes. The idea is to isolate most of the "hard core" encryption logic in this class, but allow for composability, so that the calling app can control things like:

- Where the encrypted data comes from, and what happens to it after it is decrypted
- Where the encrypted data goes, after it is encrypted

---

## KEYS AND THE KEYSTORE

---

- What thread is used for all of this

The only aspect that RxKeyBodega cannot handle itself is device authentication, since that involves a UI.

(this is far smaller than a key “store”; hence, a key “bodega”)

### Encrypting the Note

First, let’s look at the encryption path. Our MainActivity not only has the really big EditText, but it has a “save” action bar item that, when clicked, will save the contents of the EditText in an encrypted form.

### RxKeyBodega Client

That action bar item is tied to a save() method on MainActivity, which uses RxKeyBodega to set up an RxJava chain to process our encryption:

```
private void save() {
    final Context app=getApplicationContext();
    byte[] toEncrypt=note.getText().toString().getBytes(UTF8);

    RxKeyBodega.encrypt(toEncrypt, KEY_NAME, TIMEOUT_SECONDS)
        .subscribeOn(Schedulers.io())
        .map(result -> {
            File f=new File(app.getFilesDir(), FILENAME);

            RxKeyBodega.save(f, result);

            return f;
        })
        .observeOn(AndroidSchedulers.mainThread())
        .subscribe(
            file -> Toast.makeText(MainActivity.this, R.string.saved, Toast.LENGTH_SHORT).show(),
            t -> {
                if (t instanceof UserNotAuthenticatedException) {
                    requestAuth(REQUEST_SAVE);
                }
                else {
                    Toast.makeText(MainActivity.this, t.getMessage(), Toast.LENGTH_LONG).show();
                    Log.e(getString(R.string.app_name), "Exception saving encrypted file", t);
                }
            }
        );
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonware/android/auth/note/MainActivity.java](#))

We will take a look at RxKeyBodega.encrypt() in the next section, but it returns an Observable of an EncryptionResult object, which itself is part of RxKeyBodega. We

## KEYS AND THE KEYSTORE

---

supply the data to be encrypted as a byte array, which we encode using UTF8 from the `Editable` returned by the `EditText` and its `getText()` method. We pass that, along with a unique name for the encryption key to use and how long the device authentication timeout should be. That encryption key will be lazy-created if it does not already exist.

After routing this work to the `io()` thread, we use `map()` to process the `EncryptionResult`. We create a `File` pointing to where we want the encrypted data to be stored on internal storage, then call `RxKeyBodega.save()` to save the `EncryptionResult` to that file. This `File` is then supplied downstream to our subscriber lambda, which:

- Shows a `Toast` if everything seems OK
- Calls `requestAuth()` if we got a `UserNotAuthenticatedException`, indicating that we need the user to re-authenticate with the device before we can encrypt
- Shows an error `Toast` if something else went wrong

`requestAuth()` takes a request code as a parameter and kicks off device authentication using `createConfirmDeviceCredentialIntent()`:

```
private void requestAuth(int requestCode) {
    Intent i=
        mgr.createConfirmDeviceCredentialIntent("title", "description");

    if (i==null) {
        Toast.makeText(this, "No authentication required?!?",
            Toast.LENGTH_SHORT).show();
    }
    else {
        startActivityForResult(i, requestCode);
    }
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/MainActivity.java](#))

In `onActivityResult()`, if the user authenticated, we try `save()` again:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
    Intent data) {
    if (resultCode==RESULT_OK) {
        if (requestCode==REQUEST_SAVE) {
            save();
        }
    }
}
```

```
    }
    else if (requestCode==REQUEST_LOAD) {
        load();
    }
}
else {
    Toast.makeText(this, R.string.sorry, Toast.LENGTH_SHORT).show();
    finish();
}
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/MainActivity.java](#))

If the user declined to authenticate, we show a Toast and `finish()` the activity, since there is nothing useful that we can do.

### RxKeyBodega Implementation

Overall, RxKeyBodega follows the implementation approach used by RxFingerprint, profiled in [the previous chapter](#). So, for example, the `encrypt()` method on RxKeyBodega does not encrypt anything itself, but rather creates an Observable — named `EncryptObservable` — that will handle the encryption work itself:

```
static Observable<EncryptionResult> encrypt(byte[] toEncrypt, String keyName,
                                           int timeout) {
    return Observable.create(new EncryptObservable(keyName, timeout, toEncrypt));
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/RxKeyBodega.java](#))

This way, the consumer of RxKeyBodega can control the thread on which the encryption work is performed.

`EncryptObservable` extends a `BodegaObservable` class. It lazy-initializes a `KeyStore`, where `KEYSTORE` is "AndroidKeyStore", so we get access to the (potentially) hardware-backed keystore:

```
private abstract static class BodegaObservable {
    KeyStore ks;
    Exception initException;

    BodegaObservable() {
        try {
            ks=KeyStore.getInstance(KEYSTORE);
            ks.load(null);
        }
    }
}
```

## KEYS AND THE KEYSTORE

---

```
        catch (Exception e) {
            initException=e;
        }
    }
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/RxKeyBodega.java](#))

Nothing should go wrong in that initialization, but `getInstance()` and `load()` throw some checked exceptions. If one occurs, it is held onto in an `initException` field.

`EncryptObservable` implements the `ObservableOnSubscribe` interface, so the bulk of its logic goes into the `subscribe()` method, called when something eventually subscribes to this `Observable`:

```
@Override
public void subscribe(ObservableEmitter<EncryptionResult> emitter)
    throws Exception {
    if (initException==null) {
        createKey(keyName, timeout);

        SecretKey secretKey=(SecretKey)ks.getKey(keyName, null);
        Cipher cipher=Cipher.getInstance("AES/CBC/PKCS7Padding");
        SecureRandom rand=new SecureRandom();
        byte[] iv=new byte[BLOCK_SIZE];

        rand.nextBytes(iv);

        IvParameterSpec ivParams=new IvParameterSpec(iv);

        cipher.init(Cipher.ENCRYPT_MODE, secretKey, ivParams);
        emitter.onNext(new EncryptionResult(ivParams.getIV(), cipher.doFinal(toEncrypt)));
    }
    else {
        throw initException;
    }
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/RxKeyBodega.java](#))

If `initException` is not null, we throw it here, so that the exception works its way through the RxJava chain and can be picked up by a `Throwable` handler in `MainActivity`.

If `initException` is null, though, we start off by lazy-creating our key, in a `createKey()` method:

```
private void createKey(String keyName, int timeout) throws Exception {
    KeyStore.Entry entry=ks.getEntry(keyName, null);
```

## KEYS AND THE KEYSTORE

---

```
if (entry==null) {
    KeyGenParameterSpec spec=
        new KeyGenParameterSpec.Builder(keyName,
            KeyProperties.PURPOSE_ENCRYPT | KeyProperties.PURPOSE_DECRYPT)
            .setBlockModes(KeyProperties.BLOCK_MODE_CBC)
            .setEncryptionPaddings(KeyProperties.ENCRYPTION_PADDING_PKCS7)
            .setUserAuthenticationRequired(true)
            .setUserAuthenticationValidityDurationSeconds(timeout)
            .setRandomizedEncryptionRequired(false)
            .build();

    KeyGenerator keygen=
        KeyGenerator.getInstance(KeyProperties.KEY_ALGORITHM_AES, KEYSTORE);

    keygen.init(spec);
    keygen.generateKey();
}
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/RxKeyBodega.java](#))

This uses the approach outlined earlier in this chapter, creating an AES/CBC/PKCS7Padding key. In particular, it is tied to device authentication, so the user will have had to entered their PIN, passcode, fingerprint, etc. within the timeout period, or else the encryption cannot be performed.

Once we are sure that we have a key, `subscribe()` creates a Cipher for that key, uses `doFinal()` to pass along the data to be encrypted, and passes that `doFinal()` response, along with an “initialization vector”, to an `EncryptionResult` constructor. The `EncryptionResult` is what gets emitted by this `Observable` and is what is picked up by `MainActivity` in the first step of its RxJava chain.

The `save()` utility method on `RxKeyBodega`, used by `MainActivity`, writes the initialization vector data and the encrypted data to the supplied file:

```
static void save(File f, EncryptionResult result)
    throws IOException {
    BufferedSink sink=Okio.buffer(Okio.sink(f));

    sink.write(result.iv);
    sink.write(result.encrypted);
    sink.close();
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/RxKeyBodega.java](#))

### Some Quick Initialization Vector Notes

Some encryption schemes use an initialization vector (IV). This is a series of random bytes that serves as the initial input into the encryption algorithm. The bytes do not have to be secret, which is why it is safe for us to save them as part of the encrypted data, as we did in the `subscribe()` method of `EncryptObservable` above.

However, the bytes *do* have to be random. This has been a problem with Android.

Early versions of Android had a hard-coded default IV value, rather than randomly generating a value. This is bad, and it forced developers to have to create their own IV using `SecureRandom`.

Google apparently has fixed the default IV behavior. In fact, to use your own IV, you have to call `setRandomizedEncryptionRequired()` on the `KeyGenParameterSpec.Builder`, as part of creating your key in the `AndroidKeyStore`. If you fail to do this, when you go to supply your own IV bytes for encryption, you crash, with an exception whose message reads: “Caller-provided IV not permitted when encrypting”.

So, as of API Level 23, Google wants you to use their random IV implementation, rather than supply your own IV bytes. But, on older Android devices, you cannot rely on Google’s implementation.

So, now what?

The safest course of action is to do what we are doing in the `SecureNote` sample: provide a random IV and tell Android that we intend to do this, via the `setRandomizedEncryptionRequired()`. This way, even if some device manufacturer screws something up and their device winds up with non-random default IV values, you are covered.

### Escaping If Device Is Insecure

Lazy-creating that key — in fact, this entire app — only makes sense if the device has a secure keyguard. Otherwise, we cannot have the key be tied to device authentication.

So, part of what we do in `onCreate()` is get a `KeyguardManager` and see if the

keyguard is secure, using the techniques outlined in [the preceding chapter](#):

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    mgr=(KeyguardManager) getSystemService(KEYGUARD_SERVICE);

    if (mgr.isKeyguardSecure()) {
        note=findViewById(R.id.note);
        load();
    }
    else {
        Toast.makeText(this, R.string.insecure, Toast.LENGTH_LONG).show();
        finish();
    }
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/MainActivity.java](#))

If it is not secure, we show a Toast and finish() our activity to leave the app.

### Starting Decryption in onCreate()

If we do have a secure keyguard, we call a load() method, which will kick off loading the encrypted data and decrypting it.

You might wonder why we do not take a similar approach for encrypting and saving the note. Rather than force the user to click a “save” action bar item, we could call save() from onDestroy(), or perhaps from onStop().

The problem is that we may need the user to re-authenticate, if they have not authenticated since before the timeout window. That requires us to start an activity and get a result. However, that is not safe to do once our activity is destroyed. So what happens is that the user presses BACK to exit the app, we determine that we need to authenticate the user, and then:

- We have to fail to save the note, possibly with an error message, or
- We can try to show the authentication activity, get a result, and then save the note, but that is quite likely to fail, given that our activity will be destroyed along the way

As a result, while we can automatically decrypt the note, we cannot automatically

encrypt it.

### Decrypting the Note

Now, let's turn our attention to the `load()` method.

#### RxKeyBodega Client

`load()` implements another RxJava Observable chain, to take what we wrote to the file, decrypt it, and show the results in the `EditText` for possible changes by the user:

```
private void load() {
    Observable.just(new File(getFilesDir(), FILENAME))
        .subscribeOn(Schedulers.io())
        .observeOn(AndroidSchedulers.mainThread())
        .filter(File::exists)
        .map(RxKeyBodega::load)
        .flatMap(toDecrypt -> RxKeyBodega.decrypt(toDecrypt, KEY_NAME))
        .subscribe(bytes -> note.setText(new String(bytes, UTF8)),
            t -> {
                if (t instanceof UserNotAuthenticatedException) {
                    requestAuth(REQUEST_LOAD);
                }
                else {
                    Toast.makeText(MainActivity.this, t.getMessage(), Toast.LENGTH_LONG).show();
                    Log.e(getString(R.string.app_name), "Exception loading encrypted file", t);
                }
            });
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/MainActivity.java](#))

The Observable starts out with a `File` pointing to where the note is saved on internal storage. We then use the `filter()` operator to only continue if the file exists — if it doesn't, that means we have no notes to load, and so the empty `EditText` is a fine starting point.

We then use a static `load()` method on `RxKeyBodega` to do the file I/O to read in the file. We pass the result from `load()` to the `RxKeyBodega.decrypt()` method, supplying the same `KEY_NAME` that we will want to use for encryption.

At that point, there are three possibilities:

1. Everything succeeds, in which case we get the decrypted bytes, so we can turn them into a `String` (using the UTF8 charset) and apply that to the `EditText`

---

## KEYS AND THE KEYSTORE

---

2. We get a `UserNotAuthenticatedException`, in which case we request that the user authenticate, and if that succeeds, `onActivityResult()` will try the `load()` again
3. We get some other exception, in which case we just show a Toast and log the exception

### RxKeyBodega Implementation

The `load()` method on `RxKeyBodega` simply reads in the data that we wrote out:

```
static EncryptionResult load(File f) throws Exception {
    BufferedSource source=Okio.buffer(Okio.source(f));
    byte[] iv=source.readByteArray(BLOCK_SIZE);
    byte[] encrypted=source.readByteArray();

    source.close();

    return new EncryptionResult(iv, encrypted);
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/RxKeyBodega.java](#))

To read in the initialization vector, we need to know how many bytes it should be. That is based on the choice of encryption cipher, but the value is a constant for any given cipher. So, we get that in a static initialization block, and pray to the high heavens that JCA does not throw an unexpected exception:

```
private static final int BLOCK_SIZE;

static {
    int blockSize=-1;

    try {
        blockSize=Cipher.getInstance("AES/CBC/PKCS7Padding").getBlockSize();
    }
    catch (Exception e) {
        Log.e("RxKeyBodega", "Could not get AES/CBC/PKCS7Padding cipher", e);
    }

    BLOCK_SIZE=blockSize;
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/RxKeyBodega.java](#))

(a production-grade app would do something with the exception besides logging it

to LogCat)

load() then wraps the initialization vector and encrypted data in an EncryptionResult, which becomes input for the decrypt() method, which turns around and hands it to a DecryptObservable:

```
static Observable<byte[]> decrypt(EncryptionResult toDecrypt, String keyName) {
    return Observable.create(new DecryptObservable(keyName, toDecrypt));
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/RxKeyBodega.java](#))

DecryptObservable then uses JCA to decrypt the encrypted data, using the chosen Cipher and initialization vector, emitting the decrypted data:

```
private static class DecryptObservable extends BodegaObservable implements
ObservableOnSubscribe<byte[]> {
    final private String keyName;
    final private EncryptionResult toDecrypt;

    private DecryptObservable(String keyName, EncryptionResult toDecrypt) {
        this.keyName=keyName;
        this.toDecrypt=toDecrypt;
    }

    @Override
    public void subscribe(ObserverEmitter<byte[]> emitter)
        throws Exception {
        if (initException==null) {
            SecretKey secretKey=(SecretKey)ks.getKey(keyName, null);
            Cipher cipher=Cipher.getInstance("AES/CBC/PKCS7Padding");

            cipher.init(Cipher.DECRYPT_MODE, secretKey, new IvParameterSpec(toDecrypt.iv));
            emitter.onNext(cipher.doFinal(toDecrypt.encrypted));
        }
        else {
            throw initException;
        }
    }
}
```

(from [DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/RxKeyBodega.java](#))

## Time-Limited Device Authentication

In [the previous chapter](#), we saw the use of createConfirmDeviceCredentialIntent() to force the user to re-authenticate before proceeding with something in your app. As noted then, the problem is that createConfirmDeviceCredentialIntent() always forces re-authentication, even if the user authenticated just moments ago (e.g., just unlocked their device).

## KEYS AND THE KEYSTORE

---

However, for working with `AndroidKeyStore`-backed keys, we can require device authentication... but with a timeout. That way, the user only needs to re-authenticate if they have not authenticated recently, for whatever value of “recently” we want when setting up the key.

So, if you want to use `createConfirmDeviceCredentialIntent()`, but you want a timeout, one solution is silly, but works: encrypt something with a timeout-enabled, authenticated key. What you encrypt does not matter — you can throw away the results of the encryption. You are simply leveraging the timeout facility to let you know whether authentication is really needed or not.

The [DeviceAuth/SecureTimeout](#) sample application demonstrates this. It is based on the `SecureCheck` sample from the preceding chapter, but now uses the encryption technique outlined above.

In `onCreate()`, we set up the `AndroidKeyStore`:

```
try {
    ks=KeyStore.getInstance(KEYSTORE);
    ks.load(null);
}
catch (Exception e) {
    Toast.makeText(this, "Ummm... this shouldn't happen", Toast.LENGTH_LONG).show();
    Log.e(getClass().getSimpleName(), "Exception initializing keystore", e);
}
```

(from [DeviceAuth/SecureTimeout/app/src/main/java/com/commonsware/android/auth/check/MainActivity.java](#))

We only enable the authentication action bar item if we have a secure keyguard, as otherwise we cannot set up the key that we want to use:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
    menu.findItem(R.id.auth).setEnabled(mgr.isKeyguardSecure());

    return super.onCreateOptionsMenu(menu);
}
```

(from [DeviceAuth/SecureTimeout/app/src/main/java/com/commonsware/android/auth/check/MainActivity.java](#))

As before, tapping that action bar item invokes an `authenticate()` method. Before, that just blindly called `createConfirmDeviceCredentialIntent()` and forced authentication. Now... it's a bit different:

```
private void authenticate() {
    try {
```

## KEYS AND THE KEYSTORE

---

```
        createKeyForTimeout();
    }
    catch (Exception e) {
        Toast.makeText(this, "Could not create the key", Toast.LENGTH_LONG).show();
        Log.e(getClass().getSimpleName(), "Exception creating key", e);
        return;
    }

    if (needsAuth(false)) {
        Intent i=
            mgr.createConfirmDeviceCredentialIntent("title", "description");

        if (i==null) {
            Toast.makeText(this, "No authentication required!",
                Toast.LENGTH_SHORT).show();
        }
        else {
            startActivityForResult(i, REQUEST_CODE);
        }
    }
}
```

(from [DeviceAuth/SecureTimeout/app/src/main/java/com/commonsware/android/auth/check/MainActivity.java](#))

We start by invoking the same sort of lazy-create-the-key logic that we used in SecureNote, this time in a `createKeyForTimeout()` method:

```
private void createKeyForTimeout() throws Exception {
    KeyStore.Entry entry=ks.getEntry(KEY_NAME, null);

    if (entry==null) {
        KeyGenParameterSpec spec=
            new KeyGenParameterSpec.Builder(KEY_NAME,
                KeyProperties.PURPOSE_ENCRYPT | KeyProperties.PURPOSE_DECRYPT)
                .setBlockModes(KeyProperties.BLOCK_MODE_CBC)
                .setEncryptionPaddings(KeyProperties.ENCRYPTION_PADDING_PKCS7)
                .setUserAuthenticationRequired(true)
                .setUserAuthenticationValidityDurationSeconds(TIMEOUT_SECONDS)
                .build();

        KeyGenerator keygen=
            KeyGenerator.getInstance(KeyProperties.KEY_ALGORITHM_AES, KEYSTORE);

        keygen.init(spec);
        keygen.generateKey();
    }
}
```

(from [DeviceAuth/SecureTimeout/app/src/main/java/com/commonsware/android/auth/check/MainActivity.java](#))

If that works, we call a `needsAuth()` method to see if we need authentication or not:

## KEYS AND THE KEYSTORE

---

```
private boolean needsAuth(boolean isRecheck) {
    boolean result=false;

    try {
        SecretKey secretKey=(SecretKey)ks.getKey(KEY_NAME, null);
        Cipher cipher=Cipher.getInstance("AES/CBC/PKCS7Padding");

        cipher.init(Cipher.ENCRYPT_MODE, secretKey);
        cipher.doFinal(POINTLESS_DATA);

        if (!isRecheck) {
            Toast.makeText(this, "Already authenticated!", Toast.LENGTH_LONG).show();
        }
    }
    catch (UserNotAuthenticatedException e) {
        result=true;
    }
    catch (KeyPermanentlyInvalidatedException e) {
        Toast.makeText(this, "You reset the lock screen!",
            Toast.LENGTH_LONG).show();
    }
    catch (Exception e) {
        Toast.makeText(this, "Could not validate the key", Toast.LENGTH_LONG).show();
        Log.e(getClass().getSimpleName(), "Exception validating key", e);
    }

    return result;
}
```

(from [DeviceAuth/SecureTimeout/app/src/main/java/com/commonsware/android/auth/check/MainActivity.java](#))

This just encrypts a pointless bit of data:

```
private static final byte[] POINTLESS_DATA=new byte[] {1, 2, 3};
```

(from [DeviceAuth/SecureTimeout/app/src/main/java/com/commonsware/android/auth/check/MainActivity.java](#))

There are several possible outcomes of this. The biggest one is that we could catch a `UserNotAuthenticatedException`, meaning that the user has not authenticated within our timeout. In that case, `needsAuth()` returns `true`, and `authenticate()` uses `createConfirmDeviceCredentialIntent()` to trigger authentication. `onActivityResult()` then calls `needsAuth()` again, to confirm that we did successfully authenticate the user:

```
protected void onActivityResult(int requestCode, int resultCode,
    Intent data) {
    if (requestCode==REQUEST_CODE) {
        if (resultCode==RESULT_OK) {
            if (needsAuth(true)) {
                Toast.makeText(this, "Good authentication... but still needs auth?",
                    Toast.LENGTH_SHORT).show();
            }
            else {
                Toast.makeText(this, "Authenticated!", Toast.LENGTH_SHORT).show();
            }
        }
    }
}
```

```
    }  
    else {  
        Toast.makeText(this, "WE ARE UNDER ATTACK!", Toast.LENGTH_SHORT).show();  
    }  
}
```

(from [DeviceAuth/SecureTimeout/app/src/main/java/com/commonsware/android/auth/check/MainActivity.java](#))

The boolean parameter to `needsAuth()` simply indicates whether we are checking on the first or second pass. If we can successfully encrypt the pointless data, we know that the user has authenticated within our timeout period. If it's the first pass through `needsAuth()`, we show a Toast here, otherwise we show it in `onActivityResult()`.

This sample specifically checks for `KeyPermanentlyInvalidatedException`. This will be thrown if we *had* a key from before, but the user reset their lock screen, and that key is now no longer valid. If there was data encrypted using that key... the user is now in big trouble. From a JCA standpoint, you should be able to use `deleteEntry()` on the `KeyStore` to remove the old key under your key name and create a new one, if desired.

## Encrypting Passphrases

The `AndroidKeyStore` is good for some scenarios, such as your own encrypted files. However, other things will need passphrases and do not integrate with the JCA. A prominent example is `SQLCipher` for Android. `SQLCipher` is an extension to `SQLite`, and `SQLite` is not tied to Android. Hence, `SQLCipher` is not tied to Android, and the `SQLCipher` for Android distribution is focused more on providing a near-clone of the Android `SQLite` classes (e.g., `SQLiteDatabase`).

However, you can integrate anything that takes a passphrase with the `AndroidKeyStore` – and, by extension, with fingerprint-based device authentication — by generating the passphrase and encrypting it. This works akin to encrypting notes, as seen in the earlier example, in that you are encrypting and decrypting from files. However, rather than the files being the actual data, they are merely the keys with which to access that actual data, which has its own security solution.

The [DeviceAuth/CipherNote](#) sample application is a clone of the `SecureNote` sample. There, the note was encrypted and saved as a file. In this sample, the note is saved in `SQLCipher` for Android, with a generated passphrase being encrypted and saved as a file. In this case, this approach is overkill. However, there are plenty of scenarios where you need a `SQLite`-like solution for querying and such, but you also

---

## KEYS AND THE KEYSTORE

---

want to give the user the option of tying their security to device authentication, instead of having to type in a passphrase themselves.

From a UI standpoint, CipherNote works the same as SecureNote:

- The existing content is decrypted when the activity starts up, if that content exists, and possibly involving device authentication if needed
- When the user taps the “save” action bar item, the content is saved in an encrypted form

### A NoteRepository

We start off with a simple SQLiteOpenHelper subclass named DatabaseHelper:

```
package com.commonware.android.auth.note;

import android.content.Context;
import net.sqlcipher.database.SQLiteDatabase;
import net.sqlcipher.database.SQLiteOpenHelper;

public class DatabaseHelper extends SQLiteOpenHelper {
    private static final String DATABASE_NAME="note.db";
    private static final int SCHEMA=1;

    DatabaseHelper(Context context) {
        super(context, DATABASE_NAME, null, SCHEMA);

        SQLiteDatabase.loadLibs(context);
    }

    @Override
    public void onCreate(SQLiteDatabase db) {
        db.execSQL("CREATE TABLE note (_id INTEGER PRIMARY KEY AUTOINCREMENT, content TEXT);");
    }

    @Override
    public void onUpgrade(SQLiteDatabase db, int oldVersion, int newVersion) {
        throw new RuntimeException("How did we get here?");
    }
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonware/android/auth/note/DatabaseHelper.java](https://github.com/CommonWare/device-auth/blob/master/app/src/main/java/com/commonware/android/auth/note/DatabaseHelper.java))

This sets up a trivial table (note) with a primary key and the content. It also initializes SQLCipher for Android, by means of `SQLiteDatabase.loadLibs(context)`.

That is then wrapped in a NoteRepository, which provides us with an RxJava-based API for loading and saving notes from the encrypted database, given a passphrase. As with many repository-style classes — and as with many things that work with

## KEYS AND THE KEYSTORE

---

SQLite or SQLCipher for Android — NoteRepository is a singleton. Its sole instance is lazy-created, as it needs a Context for use with DatabaseHelper:

```
private static volatile NoteRepository INSTANCE;
private SQLiteDatabase db;

private synchronized static NoteRepository init(Context ctxt, char[] passphrase) {
    if (INSTANCE==null) {
        INSTANCE=new NoteRepository(ctxt.getApplicationContext(), passphrase);
    }

    return INSTANCE;
}

private synchronized static NoteRepository get() {
    return INSTANCE;
}

private NoteRepository(Context ctxt, char[] passphrase) {
    DatabaseHelper helper=new DatabaseHelper(ctxt);

    db=helper.getWritableDatabase(passphrase);
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/NoteRepository.java](#))

The NoteRepository holds onto the SQLiteDatabase opened from the DatabaseHelper. More importantly, it does *not* hold onto the passphrase. Ideally, that passphrase should be cleared out of memory after the database is opened, as SQLCipher for Android no longer needs it, and the longer the passphrase is in memory, the more likely it is that somebody is going to find a way to extract it.

Our model object representing the note is named Note:

```
static class Note {
    final long id;
    final String content;

    private Note(long id, String content) {
        this.id=id;
        this.content=content;
    }
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/NoteRepository.java](#))

Loading the Note is reactive. We have a static load() method that returns an Observable based on a LoadObservable:

```
static Observable<Note> load(Context ctxt, char[] passphrase) {
```

## KEYS AND THE KEYSTORE

---

```
return Observable.create(new LoadObservable(ctxt, passphrase));
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/NoteRepository.java](#))

LoadObservable does as its name suggests: it loads the note from the database:

```
private static class LoadObservable implements ObservableOnSubscribe<Note> {
    private final Context app;
    private final char[] passphrase;

    LoadObservable(Context ctxt, char[] passphrase) {
        this.app=ctxt.getApplicationContext();
        this.passphrase=passphrase;
    }

    @Override
    public void subscribe(ObservableEmitter<Note> e) throws Exception {
        Cursor c=NoteRepository.init(app, passphrase).db
            .rawQuery("SELECT _id, content FROM note", null);

        if (c.isAfterLast()) {
            e.onNext(EMPTY);
        }
        else {
            c.moveToFirst();
            e.onNext(new Note(c.getLong(0), c.getString(1)));
            Arrays.fill(passphrase, '\u0000');
        }

        c.close();
    }
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/NoteRepository.java](#))

While LoadObservable holds onto the passphrase, it does not make its own copy. Instead, it uses `Arrays.fill()` to clear out that char array as part of loading the note.

If there are no rows in the database, that means this was the first run of the app (or the user cleared the app's data). RxJava does not like an `ObservableEmitter` emitting a null value, so we have a magic `EMPTY` constant `Note` to use that signifies that we had no note:

```
private static final Note EMPTY=new Note(-1, null);
```

---

## KEYS AND THE KEYSTORE

---

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/NoteRepository.java](#))

Otherwise, this code is unremarkable: it queries the database, gets the values out of the Cursor to create a Note, and emits the Note.

There is a corresponding `save()` method. It is not reactive, but instead is designed to be added to some external RxJava chain. It takes the existing Note and the revised content from the `EditText`, either inserts or updates the database with the content, and returns a fresh Note instance:

```
static Note save(Note note, String content) {
    ContentValues cv=new ContentValues(1);

    cv.put("content", content);

    if (note==EMPTY) {
        long id=NoteRepository.get().db.insert("note", null, cv);

        return new Note(id, content);
    }
    else {
        NoteRepository.get().db.update("note", cv, "_id=?",
            new String[]{String.valueOf(note.id)});

        return new Note(note.id, content);
    }
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/NoteRepository.java](#))

This way, clients can blindly request a `save()`, and the repository can determine if that requires an insert or an update, based on whether we are starting with the `EMPTY` note or not.

## RxPassphrase

This sample modifies `RxKeyBodega` from earlier into `RxPassphrase`. Here, we have a reactive API to get our passphrase for use with our `SQLCipher for Android` database... including lazy-creating (and encrypting) that passphrase if it does not already exist.

The public API is a simple static `get()` method. It takes the file to use for storing the passphrase, the key name for our key in the `AndroidKeyStore`, and our desired authentication timeout as parameters. It just creates a `PassphraseObservable` to do

## KEYS AND THE KEYSTORE

---

the real work:

```
static Observable<char[]> get(File encryptedFile, String keyName, int timeout) {
    return Observable.create(new RxPassphrase.PassphraseObservable(encryptedFile, keyName, timeout));
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/RxPassphrase.java](#))

subscribe() initializes our KeyStore, then sees if the encrypted passphrase file exists, branching to load() or create() methods accordingly:

```
@Override
public void subscribe(ObservableEmitter<char[]> emitter) throws Exception {
    KeyStore ks=KeyStore.getInstance(KEYSTORE);

    ks.load(null);

    if (encryptedFile.exists()) {
        load(ks, emitter);
    }
    else {
        create(ks, emitter);
    }
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/RxPassphrase.java](#))

create() first creates a 128-character passphrase, using the same base36 algorithm used in an example from [the preceding chapter](#):

```
private void create(KeyStore ks, ObservableEmitter<char[]> emitter)
    throws Exception {
    SecureRandom rand=new SecureRandom();
    char[] passphrase=new char[128];

    for (int i=0; i<passphrase.length; i++) {
        passphrase[i]=BASE36_SYMBOLS.charAt(rand.nextInt(BASE36_SYMBOLS.length()));
    }

    createKey(ks, keyName, timeout);

    SecretKey secretKey=(SecretKey)ks.getKey(keyName, null);
    Cipher cipher=Cipher.getInstance("AES/CBC/PKCS7Padding");
    byte[] iv=new byte[BLOCK_SIZE];

    rand.nextBytes(iv);

    IvParameterSpec ivParams=new IvParameterSpec(iv);

    cipher.init(Cipher.ENCRYPT_MODE, secretKey, ivParams);

    byte[] toEncrypt=toBytes(passphrase);
```

## KEYS AND THE KEYSTORE

---

```
byte[] encrypted=cipher.doFinal(toEncrypt);

BufferedSink sink=Okio.buffer(Okio.sink(encryptedFile));

sink.write(iv);
sink.write(encrypted);
sink.close();

emitter.onNext(passphrase);
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/RxPassphrase.java](#))

create() then lazy-creates our key in our KeyStore, using the same createKey() method as was used previously:

```
private void createKey(KeyStore ks, String keyName, int timeout)
    throws Exception {
    KeyStore.Entry entry=ks.getEntry(keyName, null);

    if (entry==null) {
        KeyGenParameterSpec spec=
            new KeyGenParameterSpec.Builder(keyName,
                KeyProperties.PURPOSE_ENCRYPT | KeyProperties.PURPOSE_DECRYPT)
                .setBlockModes(KeyProperties.BLOCK_MODE_CBC)
                .setEncryptionPaddings(KeyProperties.ENCRYPTION_PADDING_PKCS7)
                .setUserAuthenticationRequired(true)
                .setUserAuthenticationValidityDurationSeconds(timeout)
                .setRandomizedEncryptionRequired(false)
                .build();

        KeyGenerator keygen=
            KeyGenerator.getInstance(KeyProperties.KEY_ALGORITHM_AES, KEYSTORE);

        keygen.init(spec);
        keygen.generateKey();
    }
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/RxPassphrase.java](#))

We then create a random initialization vector, and use that to help create our Cipher for encryption. We encrypt the passphrase and IV bytes, writing the results to the designated file, before returning the cleartext passphrase. That passphrase can then be passed to the NoteRepository for the purposes of creating our encrypted database.

Note that encryption might throw a UserNotAuthenticatedException, which the client needs to catch and route through the

## KEYS AND THE KEYSTORE

---

createConfirmDeviceCredentialIntent()-based UI for authenticating the user.

If our encrypted passphrase file already exists, we can just open and decrypt it:

```
private void load(KeyStore ks, ObservableEmitter<char[]> emitter)
    throws Exception {
    BufferedSource source=Okio.buffer(Okio.source(encryptedFile));
    byte[] iv=source.readByteArray(BLOCK_SIZE);
    byte[] encrypted=source.readByteArray();

    source.close();

    SecretKey secretKey=(SecretKey)ks.getKey(keyName, null);
    Cipher cipher=Cipher.getInstance("AES/CBC/PKCS7Padding");

    cipher.init(Cipher.DECRYPT_MODE, secretKey, new IvParameterSpec(iv));

    byte[] decrypted=cipher.doFinal(encrypted);
    char[] passphrase=toChars(decrypted);

    emitter.onNext(passphrase);
}
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/RxPassphrase.java](#))

We do not use createKey() here, as by definition our key should already exist, as we used it to encrypt the file. If for some reason our *key* is lost, then our data is lost, and we have to start over from scratch anyway.

## Using the NoteRepository and RxPassphrase

The overall flow of MainActivity has not changed: we still call load() from onCreate() and still call save() from the action bar item click. Merely their implementations have changed, to blend NoteRepository and RxPassphrase.

load() starts an RxJava chain by asking RxPassphrase to get() the passphrase:

```
private void load() {
    final Context app=getApplicationContext();
    File encryptedFile=new File(getFilesDir(), FILENAME);

    RxPassphrase.get(encryptedFile, KEY_NAME, TIMEOUT_SECONDS)
        .subscribeOn(Schedulers.io())
        .observeOn(AndroidSchedulers.mainThread())
        .flatMap(chars -> NoteRepository.load(app, chars))
        .subscribe(this::onNoteReady,
```

## KEYS AND THE KEYSTORE

---

```
t -> {
    if (t instanceof UserNotAuthenticatedException) {
        requestAuth(REQUEST_LOAD);
    }
    else {
        Toast.makeText(MainActivity.this, t.getMessage(), Toast.LENGTH_LONG).show();
        Log.e(getString(R.string.app_name), "Exception loading encrypted file", t);
    }
}
});
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/MainActivity.java](#))

That passphrase is then used with `NoteRepository.load()` to get the note from the encrypted database, using `flatMap()` to attach the `Observable` from `NoteRepository.load()` onto the existing chain. Then, if everything succeeds, we call `onNoteReady()` to hold onto the `Note` object and populate the `EditText`:

```
private void onNoteReady(NoteRepository.Note note) {
    this.note=note;
    textarea.setText(note.content);
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/MainActivity.java](#))

If we get a `UserNotAuthenticatedException`, we go through the same `requestAuth()` as before, triggering authentication. In `onActivityResult()`, we call `load()` again to try to get the `Note`, now that the user has authenticated.

The passphrase is stored on internal storage, in `getFilesDir()` (new `File(getFilesDir(), FILENAME)`). Hence, in principle, it will only get deleted if the database itself gets deleted, such as the user choosing “Clear Data” for our app in Settings. This is important, as our data will be lost if *either* the database or the encrypted passphrase file are lost.

`save()` does not need to use `RxPassphrase`, as `NoteRepository` should already have the open database. So, we can just use `NoteRepository.save()` to persist the note:

```
private void save() {
    Observable.just(textarea.getText().toString())
        .map(content -> NoteRepository.save(note, content))
        .subscribeOn(Schedulers.io())
        .observeOn(AndroidSchedulers.mainThread())
        .subscribe(this::onNoteSaved,
            t -> {
                if (t instanceof UserNotAuthenticatedException) {
                    requestAuth(REQUEST_LOAD);
                }
                else {
                    Toast.makeText(MainActivity.this, t.getMessage(), Toast.LENGTH_LONG).show();
                }
            }
        );
}
```

---

## KEYS AND THE KEYSTORE

---

```
        Log.e(getString(R.string.app_name), "Exception loading encrypted file", t);
    }
    });
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/MainActivity.java](#))

Here, `onNoteSaved()` just shows the “Saved!” Toast, plus calls `onNoteReady()` to ensure that we have the Note for any subsequent `save()` call:

```
private void onNoteSaved(NoteRepository.Note note) {
    Toast.makeText(this, R.string.saved, Toast.LENGTH_LONG).show();
    onNoteReady(note);
}
```

(from [DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/MainActivity.java](#))

## A Key(Store) Limitation

The keys in the `AndroidKeyStore` are tied to a secure keyguard. That is why these samples check for a secure keyguard before proceeding.

But what if the user *had* a secure keyguard, then downgrades to merely swipe-to-unlock?

When they downgrade, they should get a system warning that they will lose some information. In particular, on fingerprint-enabled devices, they should get a note about losing stored fingerprints. However, the system warning may not be a sufficient deterrent, and the user may downgrade their keyguard security anyway.

If that happens, your keys in the `AndroidKeyStore` get wiped out. Even if the user turns right around and sets up a secure keyguard again, whatever had been in the `AndroidKeyStore` is gone, and anything encrypted with one of those keys will be unrecoverable.

Changing between different types of security — such as switching between a PIN and a passphrase — is fine and will not affect the `AndroidKeyStore`.

# Miscellaneous Security Techniques

---

This chapter outlines some additional security measures that you can consider for your applications that do not necessarily warrant a full chapter on their own at this time.

In other words, it's just a pile of interesting security stuff.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. In addition, you should review the [app signing chapter](#) if you are unfamiliar with the signing process.

## Public Key Validation

We sign our apps with signing keys all the time. By default, we are signing with a so-called “debug signing key”, created automatically by the build tools. For production, we sign with a different signing key. The primary use of that signing key is to determine equivalence of authorship:

- Is this APK, representing an upgrade to an already-installed app, signed by the same signing key that signed that app?
- Is this APK, that requests firmware-defined signature-level permissions, signed by the same signing key that signed the firmware?

However, as it turns out, information about the public key that signed an APK is visible to us, for our own APK as well as for any other APK on the device. We can leverage that to help determine whether a given APK was signed by something we

recognize. This goes above and beyond using Android's built-in signature-based defenses (e.g., using a custom signature-level permission).

### Scenarios

There are several scenarios in which we might imagine that we could employ our own public key validation. How well the technique will work, though, depends on what we are checking and the nature of the attack we are defending against.

### Checking Yourself

You might consider checking your own app's public key. After all, if your app is not signed with your production signing key, something very strange is going on, and the natural reaction is that "something strange" is unlikely to be a good thing for you.

However, there are some issues here.

First and foremost, checking your own signing key assumes that whatever caused you to *not* be signed by that key did not also modify your validation algorithm. For example, suppose that you validate your signing key to determine if somebody perhaps reverse-engineered and modified your app, perhaps to remove some license checks. This will only catch an attacker that removed the licensing checks and did not *also* remove your signature validation, or modify the validation to use the attacker's signing key. While it is possible that an attacker will modify one part but not another, it remains unclear how well this defense will work in practice.

Also, bear in mind that you, as a developer, may be opting into services that intentionally change your app's signature. Various providers will "wrap" your app, whether for interstitial ad banners or for quasi-DRM. There are three possible ways that they wrap your app:

1. They sign it with their signing key, which means that your runtime validation of the key will fail, as your app is now signed by their key, not yours. This is also *very* risky, as if for whatever reason you are no longer able to use their service (e.g., they go out of business), you may have difficulty in upgrading your app, as you will not have the right key to use.
2. They sign it with *your* signing key, either one that you upload, or one that they generate for you. In this case, your runtime public key validation logic could still work. On the other hand, now this other firm is perfectly capable

- of upgrading your app, or shipping other apps, signed with your production signing key, and this has its own set of risks.
3. They allow you to download the “wrapped” app and have you sign it yourself with your own signing key. This is the best alternative from a security standpoint, but it is the most tedious, as now you have additional work to do to publish your app.

### Checking Arbitrary Other Apps

What will tend to be more reliable is to check *other* applications’ public keys. While they might have been cracked, it is unlikely that the same attacker also attacked *your* app, and so you can help detect problems in others.

For example, let us consider a specific scenario: a client-side JAR for integration to a third-party app.

This book outlines many forms of IPC, from content providers to remote services to broadcast Intent objects. If you are creating an app that offers such IPC endpoints, you may wish to consider also shipping a JAR to make using those endpoints a bit easier. You might create a library that handles all of the details of sending commands to your remote service, or you might create a library that provides a wrapper around the AIDL-generated Java proxy classes for remote binding.

Another thing such a JAR could do is check the integrity of your app. The JAR’s code is in the client’s app, not yours, and while your app might be cracked, the client’s app might not. You could check the validity of the public key of your own app from the client’s app, and fail if there is a detected problem.

This might be especially important depending upon the nature of the app and the JAR that is providing access to it. If the app is an app offering on-device payments (e.g., a Google Wallet sort of app), and the app offers an API for other apps to do payments, it is fairly important that those other apps can trust the payment app. By checking the public key, your JAR can help provide that level of trust... or at least ensure that nobody else has done something specifically to degrade that trust.

This is particularly important for avoiding device-hosted man-in-the-middle attacks on your IPC from client apps to your app. In an ideal world, you would only allow IPC via signature-level permissions, but that will not work in cases where third parties are writing the clients.

If your IPC is based upon a service (command pattern or binding pattern), if

multiple service implementations all advertise the same `<intent-filter>`, Android needs to decide which service will handle the request. First, it will take into account the `android:priority` value on the `<intent-filter>` (even though this behavior is currently undocumented). For multiple services with the same priority (e.g., no priority specified), the first one that was installed will be the one that is chosen. In either case, the client has no way to know, short of examining the service's public key, whether the service that will respond to the requests for IPC is the legitimate service or something else advertising that it supports the same Intent action. Even with Android 5.0 blocking your ability to bind via an implicit Intent, you wind up with the same sorts of problems when you use `resolveService()` to try to determine the `ComponentName` of the service to make an explicit Intent for it.

### The Easy Solution: SignatureUtils

The author of this book has published [the CWAC-Security library](#). Among other things, this library has a `SignatureUtils` class that makes it relatively easy for you to compare the signature of some Android app to a known good value.

All you need to do is call the static `getSignatureHash()` method, supplying some `Context` (any will do) and the package name of the app that you wish to check. This will return the SHA-256 hash of the signing key of the app, as a set of capitalized, colon-delimited hex values.

You can get the same sort of hash by running the Java 7 version of `keytool`. Hence, if the app you wish to test is another one of yours, perhaps signed with a different signing key, you can use `keytool` to get the value to compare with the result of `getSignatureHash()`. Or, during development, create a little utility app that will dump the `getSignatureHash()` value for the third-party app, and run it on a device containing a known good version of that app (i.e., one that does not appear to have been replaced by malware).

Ideally, over time, we will be able to get app developers to publish their SHA-256 hashes on their Web sites, as another means of getting a known value of the hash to compare at runtime.

If you determine that `getSignatureHash()` does *not* return the right value, this means that the app that is installed on the device is written by somebody other than the app's original author. Often times, this will mean the app has malware in it. It is up to you to determine how you wish to respond to this scenario:

- Alert the user?

- Send data back to your server, or to your analytics collection point, with details of the bad APK?
- Block usage of your app, or usage of features that depend upon the flawed third party?
- Something else?

### Examining Public Keys

Under the covers, `SignatureUtils` uses `PackageManager` and related classes to examine what they somewhat erroneously refer to as “signatures”. The [MiscSecurity/SigDump](#) sample project will allow us to browse the list of installed packages, see a decoded public key on the screen for a package that we select, plus dump the “signature” as a binary file for later comparison using another app.

### The UI Structure

This app has a single activity, whose UI consists of:

- a `RecyclerView` to show the list of packages, and
- a set of labeled `TextView` widgets to show details of the last-clicked-upon package

These are wrapped in a `ConstraintLayout`, which uses `Barrier` objects to organize the `TextView` widgets into a table:

```
<layout>
  <data>
    <variable
      name="model"
      type="com.commonware.android.signature.dump.MainActivity.DetailModel" />
  </data>
  <android.support.constraint.ConstraintLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <android.support.v7.widget.RecyclerView
      android:id="@+id/packages"
      android:layout_width="0dp"
      android:layout_height="0dp"
      android:layout_margin="4dp"
      android:background="#11000000"
      app:layout_constraintBottom_toTopOf="@id/selected"
      app:layout_constraintEnd_toEndOf="parent"
      app:layout_constraintStart_toStartOf="parent">
```

## MISCELLANEOUS SECURITY TECHNIQUES

---

```
app:layout_constraintTop_toTopOf="parent" />

<TextView
    android:id="@+id/selected"
    android:text="@{model.selected}"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    android:textStyle="bold"
    app:layout_constraintBottom_toTopOf="@id/top_row"
    app:layout_constraintStart_toStartOf="parent" />

<android.support.constraint.Barrier
    android:id="@+id/column"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    app:barrierDirection="end"
    app:constraint_referenced_ids="subject_caption,issuer_caption,valid_caption" />

<android.support.constraint.Barrier
    android:id="@+id/top_row"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    app:barrierDirection="top"
    app:constraint_referenced_ids="subject_caption,subject" />

<TextView
    android:id="@+id/subject_caption"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    android:text="@string/subject"
    app:layout_constraintBottom_toTopOf="@id/middle_row"
    app:layout_constraintStart_toStartOf="parent" />

<TextView
    android:id="@+id/subject"
    android:text="@{model.sigModel.subject}"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    app:layout_constraintBottom_toTopOf="@id/middle_row"
    app:layout_constraintStart_toStartOf="@id/column" />

<android.support.constraint.Barrier
    android:id="@+id/middle_row"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    app:barrierDirection="top"
    app:constraint_referenced_ids="issuer_caption,issuer" />

<TextView
    android:id="@+id/issuer_caption"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    android:text="@string/issuer"
    app:layout_constraintBottom_toTopOf="@id/bottom_row"
    app:layout_constraintStart_toStartOf="parent" />
```

## MISCELLANEOUS SECURITY TECHNIQUES

---

```
<TextView
    android:id="@+id/issuer"
    android:text="@{model.sigModel.issuer}"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    app:layout_constraintBottom_toTopOf="@id/bottom_row"
    app:layout_constraintStart_toStartOf="@id/column" />

<android.support.constraint.Barrier
    android:id="@+id/bottom_row"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    app:barrierDirection="top"
    app:constraint_referenced_ids="valid_caption,valid" />

<TextView
    android:id="@+id/valid_caption"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    android:text="@string/valid_between"
    app:layout_constraintBottom_toBottomOf="parent"
    app:layout_constraintStart_toStartOf="parent" />

<TextView
    android:id="@+id/valid"
    android:text="@{model.sigModel.validDates}"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    app:layout_constraintBottom_toBottomOf="parent"
    app:layout_constraintStart_toStartOf="@id/column" />

</android.support.constraint.ConstraintLayout>
</layout>
```

(from [MiscSecurity/SigDump/app/src/main/res/layout/activity\\_main.xml](#))

The TextView contents use data binding expressions to pull information in from a DetailModel, which we will examine shortly.

But, given this structure, the job of the activity is to show the list of packages in the RecyclerView and, when a list item is clicked, update the DetailModel to fill in the remaining widgets.

### Listing the Packages

MainActivity holds a DetailModel object in a field:

```
private final DetailModel detailModel=new DetailModel();
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/MainActivity.java](#))

## MISCELLANEOUS SECURITY TECHNIQUES

---

In `onCreate()` of `MainActivity`, we set up the data binding and bind that data model, plus populate the `RecyclerView`:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    ActivityMainBinding binding=
        DataBindingUtil.setContentView(this, R.layout.activity_main);

    binding.setModel(detailModel);

    binding.packages.setLayoutManager(new LinearLayoutManager(this));
    binding.packages.addItemDecoration(new DividerItemDecoration(this,
        LinearLayoutManager.VERTICAL));
    binding.packages.setAdapter(new PackageAdapter(getLayoutInflater(),
        buildPackageList(), detailModel));
}
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/MainActivity.java](#))

The `RecyclerView` uses a `PackageAdapter` to fill in its contents:

```
private static class PackageAdapter extends RecyclerView.Adapter<ViewHolder> {
    private final LayoutInflater inflater;
    private final List<PackageInfo> packages;
    private final DetailModel detailModel;

    private PackageAdapter(LayoutInflater inflater,
        List<PackageInfo> packages,
        DetailModel detailModel) {
        this.inflater=inflater;
        this.packages=packages;
        this.detailModel=detailModel;
    }

    @NonNull
    @Override
    public ViewHolder onCreateViewHolder(@NonNull ViewGroup parent,
        int viewType) {
        View row=
            inflater.inflate(android.R.layout.simple_list_item_1, parent, false);

        return new ViewHolder(row);
    }

    @Override
```

---

## MISCELLANEOUS SECURITY TECHNIQUES

---

```
public void onBindViewHolder(@NonNull RowHolder holder,
                            int position) {
    holder.bind(packages.get(position), detailModel);
}

@Override
public int getItemCount() {
    return packages.size();
}
}
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/MainActivity.java](#))

This wraps around a List of PackageInfo objects, which we get from PackageManager:

```
public List<PackageInfo> buildPackageList() {
    List<PackageInfo> result=
        getPackageManager().getInstalledPackages(PackageManager.GET_SIGNATURES);

    Collections.sort(result, (a, b) -> (a.packageName.compareTo(b.packageName)));

    return result;
}
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/MainActivity.java](#))

getPackageList() calls getInstalledPackages() on PackageManager, specifically requesting to retrieve signature information via the GET\_SIGNATURES flag. The list we get back from getInstalledPackages() can be in any order, so we sort the results before returning it for display purposes.

### Decoding the Key

We need to fill in those TextView widgets, and to do that, we need to have a DetailModel.

That class just holds onto a pair of ObservableField objects, one for the “selected” package name (whatever the user last clicked on), and one for a separate SigModel class:

```
public static class DetailModel {
    public final ObservableField<String> selected=new ObservableField<>();
    public final ObservableField<SigModel> sigModel=new ObservableField<>();
}
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/MainActivity.java](#))

## MISCELLANEOUS SECURITY TECHNIQUES

---

SigModel holds the formatted data to pour into the TextView widgets, populated from an X509Certificate object:

```
public static class SigModel {
    public final String subject;
    public final String issuer;
    public final String validDates;

    private SigModel(X509Certificate cert) {
        this.subject=cert.getSubjectDN().toString();
        this.issuer=cert.getIssuerDN().toString();
        this.validDates=
            FORMAT.format(cert.getNotBefore())+" to "+
            FORMAT.format(cert.getNotAfter());
    }
}
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/MainActivity.java](#))

We are interested in three items from the X509Certificate. The subject is who the certificate is for and the issuer is who created the certificate. For a self-signed certificate — what we usually use for Android app development – the subject and the issuer usually are the same party. We also want to show the valid date range for the certificate, where we get the getNotBefore() and getNotAfter() dates and format them using a SimpleDateFormat object:

```
private static final DateFormat FORMAT=
    DateFormat.getDateInstance();
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/MainActivity.java](#))

So now we are left with the glue code: when the user clicks on a package in the list, we need to get an X509Certificate representing the contents of the signing key and use that to put a fresh SigModel into the DetailModel, so data binding can update the TextView widgets.

That is all taken care of by RowHolder, which is the ViewHolder for our RecyclerView:

```
private static class RowHolder extends RecyclerView.ViewHolder {
    private final TextView title;
    private final View row;

    RowHolder(View itemView) {
        super(itemView);
    }
}
```

## MISCELLANEOUS SECURITY TECHNIQUES

---

```
row=itemView;
title=itemView.findViewById(android.R.id.text1);
}

void bind(final PackageInfo packageInfo, final DetailModel detailModel) {
    title.setText(packageInfo.packageName);

    row.setOnClickListener(v -> {
        detailModel.selected.set(packageInfo.packageName);
        detailModel.sigModel.set(new SigModel(buildCertificate(packageInfo)));
        SigSaver.enqueueWork(title.getContext(), packageInfo);
    });
}

private X509Certificate buildCertificate(PackageInfo packageInfo) {
    Signature[] signatures=packageInfo.signatures;
    byte[] raw=signatures[0].toByteArray();
    CertificateFactory certFactory;

    try {
        certFactory=CertificateFactory.getInstance("X509");
    }
    catch (CertificateException e) {
        Log.e(getClass().getSimpleName(),
            "Exception getting CertificateFactory", e);
        return null;
    }

    X509Certificate cert;
    ByteArrayInputStream bin=new ByteArrayInputStream(raw);

    try {
        cert=(X509Certificate)certFactory.generateCertificate(bin);
    }
    catch (CertificateException e) {
        Log.e(getClass().getSimpleName(),
            "Exception getting X509Certificate", e);
        return null;
    }

    return cert;
}
}
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/MainActivity.java](#))

When we bind() a PackageInfo into the row, we also set up an click listener for the row itself, to find out when the user taps on it. There, we update the two fields of the

## MISCELLANEOUS SECURITY TECHNIQUES

---

DetailModel, using buildCertificate() to get the X509Certificate for use with SigModel.

The PackageInfo object contains a signatures field with an array of Signature objects. Despite the name, those each are an encoded representation of an X509Certificate. Traditionally, Android apps have been signed with just one key, so we only look at the first element of the array. Then, using Java cryptography classes, we:

- Get the byte array of the encoded certificate, by calling toByteArray() on the Signature
- Get a CertificateFactory for the X509 format
- Wrap the bytes in a ByteArrayInputStream
- And ask the CertificateFactory to decode the certificate

### Dumping the Key

The click listener we applied to the row also has this line:

```
SigSaver.enqueueWork(title.getContext(), packageInfo);
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/MainActivity.java](#))

This invokes a SigSaver implementation of a JobIntentService. Its job is to write this “signature” to a file, so it could be transferred off of the device and perhaps examined using tools like openssl.

SigSaver uses getPackageInfo() on PackageManager to get the PackageInfo object for a specific package, then gets the same byte array that buildCertificate() does and writes it to a file on external storage:

```
package com.commonsware.android.signature.dump;

import android.content.Context;
import android.content.Intent;
import android.content.pm.PackageInfo;
import android.content.pm.PackageManager;
import android.content.pm.Signature;
import android.support.annotation.NonNull;
import android.support.v4.app.JobIntentService;
import android.util.Log;
import java.io.File;
import java.io.FileOutputStream;
```

## MISCELLANEOUS SECURITY TECHNIQUES

---

```
public class SigSaver extends JobIntentService {
    private static final int UNIQUE_JOB_ID=1337;
    private static final String EXTRA_PACKAGE="package";

    static void enqueueWork(Context ctxt, PackageInfo packageInfo) {
        Intent i=new Intent(ctxt, SigSaver.class)
            .putExtra(EXTRA_PACKAGE, packageInfo.packageName);

        enqueueWork(ctxt, SigSaver.class, UNIQUE_JOB_ID, i);
    }

    @Override
    protected void onHandleWork(@NonNull Intent intent) {
        String packageName=intent.getStringExtra(EXTRA_PACKAGE);

        try {
            PackageInfo packageInfo=getPackageManager().getPackageInfo(packageName,
                PackageManager.GET_SIGNATURES);
            File output=
                new File(getExternalFilesDir(null),
                    packageName.replace('.', '_')+".bin");

            if (output.exists()) {
                output.delete();
            }

            Signature[] signatures=packageInfo.signatures;
            byte[] raw=signatures[0].toByteArray();

            try {
                FileOutputStream fos=new FileOutputStream(output.getPath());

                fos.write(raw);
                fos.close();
            }
            catch (java.io.IOException e) {
                Log.e(getClass().getSimpleName(),
                    "Exception in writing signature file", e);
            }
        }
        catch (PackageManager.NameNotFoundException e) {
            Log.e(getClass().getSimpleName(),
                "Exception loading package info: "+packageName, e);
        }
    }
}
```

## MISCELLANEOUS SECURITY TECHNIQUES

---

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/SigSaver.java](#))

### The Result

When you run the app, you will get a list of all of the installed packages, which will include system packages that have no activities (and, therefore, nothing in the app drawer of your launcher):

*Figure 745: SigDump App, As Initially Launched*

Scrolling to and clicking on a package will populate the bottom panel with the details of that package's signature:

*Figure 746: SigDump App, After Clicking on the SigDump Entry*

Also, a copy of the public signing key — as an encoded X.509 certificate — is written out to a file on external storage.

## Choosing Your Signing Keysize

[The documentation for app signing](#) contains a small side note about the `-keysize` parameter to `keytool`, the utility used to generate our signing keys:

The size of each generated key (bits). If not supplied, Keytool uses a default key size of 1024 bits. In general, we recommend using a key size of 2048 bits or higher.

The reason for the 2,048-bit key size recommendation is that 1,024-bit RSA (the `keytool` default) has been considered at risk for a few years.

The recent revelations about state-sponsored decryption research should be

## MISCELLANEOUS SECURITY TECHNIQUES

---

hammering this home. Even if today, forging a 1,024-bit digital signature is still impractical for all but the largest security agencies, it is well within reason that this will fall within the reach of large botnets in the not-too-distant future. Once signing keys can be cracked, apps will be able to be replaced with hacked editions, without tripping up the signature check, or signature-level permission checks might start passing due to forged signatures.

Switching to a larger keysize is not that hard... for new apps. Just specify `-keysize 4096` when creating your production signing key, and you should be good for a long time, barring a major decryption breakthrough for RSA signatures.

For existing apps with existing signing keys, though, you cannot change the key without breaking your ability to update the app.

Create a new, stronger production signing key, as a separate key from whatever you are using for production. Make note to use that new signing key for any new apps you create. And, if you have other reasons why you are migrating an existing user base to a new app (e.g., free app for which you are now offering a paid-app option), consider using the new signing key.

If you are a consultant, and you create unique signing keys per project, just cut over to using a stronger key for new clients and projects.

And if you are [creating apps for which security is paramount](#), you might consider whether it is worthwhile to move your user base to a new version of the app with a new signing key at some point, just for the added protection.

## Avoiding Accidental APIs

One place where developers create their own security problems is with “accidental APIs”.

An API, of course, is where one code base exposes some interface that another code base can use. An accidental API is when one code base does not intend to expose an interface, but does anyway, possibly to the app’s detriment.

Bear in mind that if your app becomes popular, other developers will poke and prod at it, to see if they can connect to your app by one means or another. Perhaps they want to offer features that you have not gotten to yet. Perhaps they have more nefarious aims. Regardless, making sure that other code can only work with your

app the way that *you* intend for such code to work with your app.

### Export Only What's Necessary

A component of your app is only reachable by a third-party app if it is exported. Otherwise, it is inaccessible to third-party apps.

(Admittedly, content providers have an exception to this rule, which we will get to shortly)

You normally do not think about exporting components, except when it comes to content providers. However, your choices for how you implement your app may lead you to accidentally export things that you did not realize were exported.

### Export Defaults

The official way to declare whether or not a component is exported is to have an `android:exported` attribute for that component in the manifest (e.g., on an `<activity>` element). However, many times, we do not have such an attribute, but instead rely on the default export behavior.

Activities, services, and broadcast receivers have a simple rule for the default: if the component has an `<intent-filter>`, it is exported by default. Otherwise, it is not exported by default.

This, in turn, leads to a fairly simple development rule: only use an `<intent-filter>` and implicit Intent objects for working with your components if you *also* want third party apps to work with those components. Otherwise, do not use `<intent-filter>`, and instead communicate with your components using explicit Intent objects (e.g., the kind that take a Java class as the second constructor parameter).

For example, the classic MAIN/LAUNCHER `<intent-filter>` on your launcher activity is specifically there because you *want* a third party app — the launcher — to be able to start your activity. Most, if not all, of your other activities probably do not need an `<intent-filter>`, as they are likely to be private to your app.

### The Chooser Bug

Some developers choose to still use an `<intent-filter>` and implicit Intent objects for their own private activities, yet then use `android:exported` to enforce the

privacy.

This is not a good plan.

The rest of the system, notably PackageManager, does not pay much attention to `android:exported` *until the time when the component is to be used*, such as when the activity is to be started. Then, and only then, does Android realize that the component is not exported, and it fails the request, usually with a cryptic `SecurityException`.

A classic example of where this can cause problem came to light in 2012, with the UPS Mobile app. The rest of this section is an excerpt from [the author's blog post on this incident](#):

The [UPS Mobile app](#) allows you to track packages and do a handful of other things that you might ordinarily do via the UPS Web site. It generally seems to be well-regarded, but it has an annoying flaw:

It claims to be Barcode Scanner, and does a lousy job at it.

[Barcode Scanner](#), from [ZXing](#), is a favorite among Android developers for its integration possibilities. However, some people do not like having a dependence upon the Barcode Scanner app, so they grab the open source code and attempt to blend it into their own apps. This is neither endorsed nor supported by the ZXing team, but since it is open source, it is also perfectly legitimate.

However, UPS (or whoever they hired to build the app) screwed up. They not only copied the source code, but they copied the manifest entry for the scanning activity. And, their activity has:

```
<intent-filter>  
  <action android:name="com.google.zxing.client.android.SCAN" />  
  <category android:name="android.intent.category.DEFAULT" />  
</intent-filter>
```

This means that on any device that has UPS Mobile installed, they will be an option for handling Barcode Scanner Intent objects. What happened was that the person asking the question was manually invoking `startActivityForResult()` to bring up Barcode Scanner, was getting a chooser with UPS Mobile in it, and then was crashing upon choosing UPS Mobile... because UPS Mobile declared this activity to be not exported.

## MISCELLANEOUS SECURITY TECHNIQUES

---

There was [a bug](#), in which Android would display non-exported activities in a chooser, despite the fact that they could never be successfully used by the user. This appears to have been fixed as of Android 4.2, despite the issue being declined.

So, what should we learn from this?

First, UPS Mobile should not have used that `<intent-filter>`. As Dianne Hackborn has pointed out, your `<intent-filter>` mix [is effectively part of your app's API](#), and so you need to think long and hard about every `<intent-filter>` you publish. UPS Mobile is not Barcode Scanner and should not be advertising that they handle such Intent objects, despite the activity being not exported.

Second, UPS Mobile probably should not have had *any* `<intent-filter>` elements for this activity, if they intend to use it purely internally. They could just as easily use an explicit Intent to identify the activity and avoid all of this nonsense.

Third, the person who filed the SO question ideally would have been using ZXing's IntentIntegrator. As Sean Owen of the ZXing project noted in a comment on my answer, IntentIntegrator ensures that only Barcode Scanner or official brethren will handle any scan requests, so this problem would not have appeared.

Fourth, Android really should not be showing non-exported activities in a chooser, which means probably that PackageManager should be filtering out non-exported activities from methods like `queryIntentActivities()`, which I presume lies at the heart of the chooser.

In summary, if your component is truly private, do not have an `<intent-filter>` on it, lest you cause yourself, and your users, problems with other apps.

### The ContentProvider Behavior Change

Content providers are a little different... in lots of ways. In the specific scenarios being covered here, there are two primary differences.

First, third-party apps *can* still access a provider that has `android:exported="false"`. However, they can only do so in response to some operation initiated by your application, using `android:grantUriPermissions` and flags like `FLAG_GRANT_READ_URI_PERMISSION`. A third-party app will have no *independent* access to your non-exported provider.

Second, the default value for `android:exported` not only does not depend upon

<intent-filter> (since few providers use one), but it has changed over the years:

- For apps with `android:minSdkVersion` *and* `android:targetSdkVersion` set to 16 or lower, the provider is exported by default
- All other apps, the provider is *not* exported by default

Lint will complain about your manifest having a <provider> without an `android:exported` attribute.

### Sanitize Your Input Extras

If you do expose one or more of your components to third-party apps, and you are supporting certain Intent extras on any Intent objects used to talk to those components, make sure that the extras' values make sense.

Even Google makes this error, as was seen in [the PreferenceActivity bug](#). PreferenceActivity supports an extra, named `:android:show_fragment`, to indicate that the activity should immediately jump to a specific fragment, rather than start at the top level of the preference navigation. The problem is that PreferenceActivity did not — and, at the time, could not — validate that the fragment to be loaded is a fragment that is *supposed* to be loaded. This would allow attackers to force apps, like Settings, to load arbitrary fragments, including those not normally accessible to the current user. This is the reason why we now need to override `isValidFragment()` in our PreferenceActivity implementations, so we can declare whether or not a particular requested fragment is a legitimate choice or not.

The equivalent behavior for a ContentProvider is to sanitize the inputs to methods like `query()`, `update()`, `openFile()`, and so on, to make sure that you do not expose something that you should not. For example, blindly accepting paths to `openFile()` could get you in trouble, if the `Uri` contains relative paths (e.g., `content://your.authority.here/./databases/your-private.db`), perhaps allowing third parties to get at files that you did not intend for them to access.

### Secure Your Output Extras

Similarly, if you send broadcasts or otherwise use IPC to talk to third-party apps, bear in mind that others might be able to see some of that interaction, depending on the IPC in question.

The obvious case is with a broadcast Intent for an implicit Intent. Any app with a registered receiver will be able to “tune into” that broadcast and get whatever data is

inside the Intent. In cases where you cannot use permissions to limit the scope of the broadcast, you need to make sure that there is nothing in the Intent that is private to the user.

Sometimes, though, non-obvious cases will emerge. For a few years, Intent extras on activities might be viewed by third-party apps that held the `GET_TASKS` permission, courtesy of the recent-tasks list. The Intent used to launch the task is available via `ActivityManager` and `getRecentTasks()`. While this specific problem was resolved in Android 4.1.1, there may be other similar scenarios lurking about.

## Other Ways to Expose Data

Sometimes, we expose data to third-party apps by using standard Android APIs. We focus on the normal publisher and consumer of data using those APIs and forget about other apps that might be monitoring those communications. Or, we might not realize that one party in those communications may not have the user's best interests at heart. This section outlines some examples.

### App Widgets

Any data that is put into the widgets inside of your `RemoteViews` for an app widget is visible to the home screen, lockscreen, or other app widget host. Those apps are the ones actually converting the `RemoteViews` into a view hierarchy, and they can inspect those views, reading the text in your `TextViews`, and so forth.

As a result, be careful about exposing potentially sensitive data via an app widget.

### Notifications

Custom notifications also use `RemoteViews` and therefore could suffer from the same problem.

On the surface, you might not be worried quite so much about this, because the `Notification` object goes to the `NotificationManager`, for display by the OS itself.

However, as of Android 4.3 (API Level 18), apps can register to listen to added and removed notifications via a `NotificationListenerService`. Not only can such a service read the text from your `Notification`, but it can also access your `RemoteViews`. This includes any `RemoteViews` that may be generated for you by the expanded notification classes (e.g., `BigPictureStyle`).

As a result, be careful about exposing potentially sensitive data via a Notification.

### Clipboard

Any app can retrieve text off of the clipboard. After all, that's the point behind a clipboard.

However, this does mean that you need to be careful what you put on the clipboard in the first place. The quintessential problem case is a password manager: putting a password on the clipboard for easy pasting into an app's `EditText` password field will be popular, but it allows that password to be retrieved by other apps.

You can attempt to help reduce the window of risk by clearing the clipboard after a period of time. However, bear in mind that your process might be terminated before that occurs. Also, only clear the clipboard if the clipboard text is still yours — do not clear the clipboard if another app has already put its own contents there, lest you confuse and irritate the user in the middle of some other paste operation.

### ServerSocket and Kin

If you open up any sort of server-style socket connection — TCP/IP, Bluetooth, etc. — bear in mind that the Android security framework may not be able to help you much. You cannot secure a `ServerSocket` with an `android.permission` attribute, for example. It is up to you to validate whether a particular request is expected and allowed, or not.

### Jacking Attacks

Jacking attacks, in general, refer to cases where what the user *thinks* they are interacting with on-screen is not *actually* what they are interacting with. Instead, something else has interposed itself between the user and the activity that the user is trying to use. That “something else” might be trying to intercept user input (tapjacking, activity jacking) or confuse the user about what is actually being interacted with (window jacking).

### Classic Tapjacking

Tapjacking refers to another program intercepting and inspecting touch events that are delivered to your foreground activity (or related artifacts, such as the input method editor). At its worst, tapjackers could intercept passwords, PINs, and other

private data.

The term “tapjacking” seems to have been coined by Lookout Mobile Security, in a [blog post](#) that originally demonstrated this issue.

### The Problem

You may recall that there are three axes to consider with Android user interfaces. The X and Y axes are the ones you typically think about, as they control the horizontal and vertical positioning of widgets in an activity. The Z axis — effectively “coming out the screen towards the user’s eyes” — can be used in applications for sophisticated techniques, such as a pop-up panel.

Normally, you think of the Z axis within the scope of your activity and its widgets. However, there are ways to display “system alerts” – widgets that can float over the top of any activity. A Toast is the one you are familiar with, most likely. A Toast displays something on the screen, yet touch events on the Toast itself will be passed through to the underlying activity. Lookout demonstrated that it is possible to create a fully-transparent Toast. However, the lifetime of a Toast is limited (3.5 seconds maximum), which would limit how long it can try to grab touch events.

However, any application holding the `SYSTEM_ALERT_WINDOW` permission can display their own “system alerts” with custom look and custom duration. By making one that is fully transparent and lives as long as possible, a tapjacker can obtain touch events for any application in the system, including lock screens, home screens, and any standard activity.

On the surface, this might not seem terribly useful, since the View cannot see what is being tapped upon.

However, a savvy malware author would identify what activity is in the foreground and log that information along with the tap details and the screen size, periodically dumping that information to some server. The malware author can then scan the touch event dumps to see what interesting applications are showing up. With a minor investment – and possibly collaboration with other malware authors — the author can know what touch events correspond to what keys on various input method editors, including the stock keyboards used by a variety of devices. Loading a pirated version of the APK on an emulator can indicate which activity has the password, PIN, or other secure data. Then, it is merely a matter of identifying the touch events applied to that activity and matching them up with the soft keyboard to determine what the user has entered. Over time, the malware author can perhaps

develop a script to help automate this conversion.

Hence, the on-device tapjacker does not have to be very sophisticated, other than trying to avoid detection by the user. All of the real work to leverage the intercepted touch events can be handled offline.

### How to Address This

In principle, Android 4.0.3 fixed this, by preventing touch events from being delivered to two separate applications. Either the tapjacking View gets the touch event (and consumes it), or the tapjacking View does not get the touch event (and therefore does not know about it).

For Android 2.2 and 2.3 devices, you also have the option of `setFilterTouchesWhenObscured()`, which will be examined [later in this chapter](#).

### Activity Jacking

In August 2014, a number of media outlets [reported](#) on a [research paper](#) and [USENIX conference presentation](#) describing a way by which your users could be tricked into providing confidential information — passwords, credit card information, and such — to a piece of malware, rather than to your app. This flew in the face of conventional wisdom, which said that the tapjacking fixes from Android 4.0.3 cleared up this sort of problem.

The paper points out that there are ways of writing malware such that:

- the malware can pop an *activity* in front of yours, and
- do so at just the right time, to mimic one of your activities, such that the user thinks that the malware’s activity is actually yours and enters the confidential data into the malware activity

The authors describe it as a UI inference attack; to keep with the theme of this chapter, this section refers to it as “activity jacking”.

### The Problem

The details of how to execute the attack are rather esoteric, using lots of curious approaches to find out when an activity comes onto the screen and, more specifically, *which* activity of an app being attacked it is. Readers are encouraged to

[review the paper](#) if you want details of exactly how to execute this sort of attack their way.

However, one simpler way of knowing this stuff is to implement an `AccessibilityService`. Officially, such services are supposed to help with accessibility, such as providing TalkBack-style audio announcements as the user navigates the UI by touch alone. In practice, a lot of apps use `AccessibilityService` to be able to monitor user inputs across the device and, in some cases, modify those inputs. Some password managers, for example, implement an `AccessibilityService` to help them auto-fill login dialogs. As a result, many users install and enable an `AccessibilityService` without really thinking about whether they can trust that service.

Given that you know when a particular activity appears on the screen, the attack is simple: launch your own activity that looks much like the original. The user might miss the fact that two activities just appeared, then go ahead and interact with your activity, thinking that it is from the real app. For example, you might interpose your own authentication dialog in front of the one for the banking app, thereby getting the user's PIN or passcode.

You can further take steps to try to “cover your tracks” and deal with the fact that the real activity is waiting for user input:

- If you are using an `AccessibilityService`, you can use `performGlobalAction()` to initiate a BACK button press, right after dismissing your own activity, to dismiss the original activity.
- Otherwise, you can pretend that the user input is flawed and needs to be re-entered. In the case of an authentication dialog, you can pop up a regular `AlertDialog` that says that their password was not recognized. When the user dismisses that dialog, you also `finish()` your intercepting activity, returning the user to the real activity, where they can complete the real authentication.

### How to Address This

An activity jack attack has two key weaknesses:

1. The attacker cannot see the screen, because on non-buggy devices, the attacker has no means of silently capturing a screenshot of our activity as it comes into the foreground. Hence, while the attacker can create an activity that tries to mimic ours, they can only do so statically, analyzing our

## MISCELLANEOUS SECURITY TECHNIQUES

---

- activity's UI on their development machine and creating their own lookalike.
2. We know that our activity has left the foreground, as we are called with `onPause()` (and perhaps other lifecycle methods, depending upon the nature of the attacker).

Hence, one defense can be to include in our activity a **secure element** that cannot be mimicked ahead of time, then **hide that element** (or our whole UI) when we are no longer in the foreground.

This concept of a secure element is not new. Some financial services Web sites have taken this approach. As part of the user setting up their online banking account, the user chooses an image from a collection of clipart. On the Web page that collects the user's passphrase, the page also shows this secure element. The user is taught that if they do not see their chosen image, then the Web page they are looking at is not really from their bank, and therefore they should not type in their passphrase.

This is not that hard to implement in Android. You too would allow the user to choose a piece of clipart, displaying that in an `ImageView` on your secure activity in `onResume()`. In `onPause()` you would hide that `ImageView` via `setVisibility(View.INVISIBLE)`. That way:

- Since the image is chosen by the user, the attacker is unlikely to mimic the same image
- Since you are hiding the image when you are not in the foreground, the attacker cannot use a transparent region in their activity to have your image "peek through" their attacking activity

As a result, if the user is paying attention, the user should see either the wrong image or no image at all, and the user should realize that they are being activity jacked and therefore fail to proceed.

You might be tempted to do something else in response to your secure activity being replaced in the foreground by another app's activity, such as pop up a warning dialog. However, there are plenty of valid scenarios when this would occur, such as an incoming phone call, and you have no reliable means of whitelisting all possible valid scenarios. There will be a high incidence of false positives, and that may not help the user. Having this as an user-selectable option is fine, but I would not go this route by default.

## Window Jacking

Sometimes, the objective of the attacker is not to prevent the user from entering in information, or even to see what the user enters. Sometimes, the objective is to confuse the user, tricking them into clicking on things that they might not want to click on.

### The Problem

A great example of this comes from Android 6.0's runtime permission system.

Apps with `targetSdkVersion` of 23 or higher will need to call `requestPermissions()` at various points, to ask the user to grant runtime permissions not previously granted (or granted but later revoked). That brings up a system-supplied dialog-themed activity:

Figure 747: Runtime Permission System Dialog

Perhaps the attacker wants the user to agree to the permission but fears that the user might deny it instead. The attacker could use `SYSTEM_ALERT_WINDOW` to put a *View on top of the system dialog*, replacing the real permission explanation with something seemingly benign. The user — who may not have a lot of Android experience — clicks “Allow”, where if the user were presented with the *real* message,

the user might have clicked “Deny”.

### How to Address This

Quoting [the Android documentation](#):

Sometimes it is essential that an application be able to verify that an action is being performed with the full knowledge and consent of the user, such as granting a permission request, making a purchase or clicking on an advertisement. Unfortunately, a malicious application could try to spoof the user into performing these actions, unaware, by concealing the intended purpose of the view. As a remedy, the framework offers a touch filtering mechanism that can be used to improve the security of views that provide access to sensitive functionality.

To enable touch filtering, call `setFilterTouchesWhenObscured(boolean)` or set the `android:filterTouchesWhenObscured` layout attribute to `true`. When enabled, the framework will discard touches that are received whenever the view’s window is obscured by another visible window. As a result, the view will not receive touches whenever a toast, dialog or other window appears above the view’s window.

For the runtime permission window jacking, using `setFilterTouchesWhenObscured()` would prevent the user from clicking on either the “Allow” or the “Deny” buttons. The alternative message would be in its own window, floating over the dialog. Hence, that should cause `FLAG_WINDOW_IS_OBSCURED` to be set on any `MotionEvent`s delivered to the dialog, and those touch events would be dropped.

For example, take a look at the `res/layout/main.xml` file in the [Tapjacking/RelativeSecure](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:filterTouchesWhenObscured="true">
    <TextView android:id="@+id/label"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="URL:"
```

```
        android:layout_alignBaseline="@+id/entry"
        android:layout_alignParentLeft="true" />
<EditText
    android:id="@+id/entry"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_toRightOf="@id/label"
    android:layout_alignParentTop="true" />
<Button
    android:id="@+id/ok"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_below="@id/entry"
    android:layout_alignRight="@id/entry"
    android:text="OK" />
<Button
    android:id="@+id/cancel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_toLeftOf="@id/ok"
    android:layout_alignTop="@id/ok"
    android:text="Cancel" />
</RelativeLayout>
```

(from [Tapjacking/RelativeSecure/app/src/main/res/layout/main.xml](#))

Here, we have `android:filterTouchesWhenObscured="true"` on the `RelativeLayout` at the root of the layout resource. This property cascades to a container's children, and so if a tapjacker (or `Toast` or whatever) is above any of the widgets in the `RelativeLayout`, none of the touch events will be processed.

More fine-grained control can be achieved in custom widgets by overriding `onFilterTouchEventForSecurity()`, which gets control before the regular touch event methods. You can determine if a touch event had been intercepted by looking for the `FLAG_WINDOW_IS_OBSCURED` flag in the `MotionEvent` passed to `onFilterTouchEventForSecurity()`, and you can make the decision of how to handle this on an event-by-event basis.

### The Problem with the Solution

According to Iwo Banaś, this approach [may not actually work](#) due to bugs in Android's implementation. The filter-when-obscured logic depends upon a `FLAG_WINDOW_IS_OBSCURED` value being on the `MotionEvent`, and that may be getting lost somewhere along the way.

The author of this book has not yet attempted to replicate Mr. Banaś' findings.

### Google's Line of Defense: Obscuring the Foreground

Google's focus, besides the fixes listed above, is to make it increasingly difficult for one app to find out when another app is in the foreground. This is a key component of jacking attacks, as the jacker needs to know what is behind it. For example, with window jacking, obscuring the permission message only makes sense when the permission dialog appears — having some floating message appear at other points in time will be a giveaway that something is amiss.

As a result, methods on `ActivityManager` that used to provide details of all running processes have been neutered, frequently only providing details about your own process. Similarly, in Android 7.0, attempts by apps to find out about other processes through Linux-isms, like `/proc`, are being locked down.

### Using `FLAG_SECURE`

By default, your activity's UI contents can be captured for any number of things:

- the overview screen (a.k.a., recent-tasks list)
- screenshots and screencasts, whether via the [media projection APIs](#) or some other device-supplied means
- the [Assist API](#), such as Google's "Now On Tap" feature

However, you may have some activities that should not be captured in this fashion, due to potential privacy issues.

For that, you can apply `FLAG_SECURE` to an Activity:

```
public class FlagSecureTestActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        getWindow().setFlags(LayoutParams.FLAG_SECURE,
            LayoutParams.FLAG_SECURE);

        setContentView(R.layout.main);
    }
}
```

## MISCELLANEOUS SECURITY TECHNIQUES

---

Call `setFlags()` before `setContentView()`, in this case setting `FLAG_SECURE`.

In theory, this will prevent any of the aforementioned capture options from working.

Unfortunately, the Android framework sometimes creates its own `Window` instances, such as the drop-down in a `Spinner`. Even if you set `FLAG_SECURE` on the `Window` for an activity, the Android framework does not pass that flag to any other windows created on behalf of that activity, and those windows show up in:

- Screenshots and screencasts taken by the media projection APIs on Android 5.0+
- The Assist API (e.g., Now On Tap) on Android 6.0+
- Android Studio screen recordings on Android 4.4+

This has been demonstrated to affect:

- `AutoCompleteTextView`
- `Spinner` (both dropdown and dialog modes)
- the overflow menu of the framework-supplied action bar
- `ShareActionProvider`
- `Dialog` and subclasses (e.g., `AlertDialog`)
- `Toast`

Of these, only the `Dialog` offers us access to its `Window`, on which we could apply `FLAG_SECURE`, for developers that realize that this is required.

Google has officially stated that [all of this is working as intended](#).

If you are using `FLAG_SECURE`, you should thoroughly exercise your app's UI on Android 4.4+ while recording a screencast — the Android Studio screen recorder would be a simple tool to use. Then, play back that screencast, see what windows show up, and identify those that contain sensitive information that should not appear. Some of the windows that appear will not contain sensitive information — here, the risk is that you might add sensitive information to them in the future but forget about this bug.

Then, you have two main courses of action: rewrite your UI to avoid the UI elements that are leaking this information, or attempt to patch the problem.

---

## **Trail: Data Storage and Retrieval**

---

# Content Provider Theory

---

Android publishes data to you via an abstraction known as a “content provider”. Access to contacts and the call log, for example, are given to you via a set of content providers. In a few places, Android expects you to supply a content provider, such as for integrating your own search suggestions with the Android Quick Search Box. And, content providers are one way for you to supply data to third party applications, or to consume information from third party applications. As such, content providers have the potential to be something you would encounter frequently, even if in practice they do not seem used much.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on [working with local databases](#).

## Using a Content Provider

Any `Uri` in Android that begins with the `content://` scheme represents a resource served up by a content provider. Content providers offer data encapsulation using `Uri` instances as handles – you neither know nor care where the data represented by the `Uri` comes from, so long as it is available to you when needed. The data could be stored in a SQLite database, or in flat files, or retrieved off a device, or be stored on some far-off server accessed over the Internet.

Given a `Uri`, you may be able to perform basic CRUD (create, read, update, delete) operations using a content provider. `Uri` instances can represent either collections or individual pieces of content. Given a collection `Uri`, you may be able to create new pieces of content via insert operations. Given an instance `Uri`, you may be able to

read data represented by the `Uri`, update that data, or delete the instance outright. Or, given a `Uri`, you may be able to open up a handle to what amounts to a file, that you can read and, possibly, write to.

These are all phrased as “may” because the content provider system is a facade. The actual implementation of a content provider dictates what you can and cannot do, and not all content providers will support all capabilities.

### Pieces of a Uri

A `Uri` for a `ContentProvider` is made up of two to four components.

A provider `Uri` always has a content scheme. So, when represented as a string, you will see the `Uri` start with `content://`.

After the scheme, where in an `http://` URL you would find a domain name or IP address, a provider `Uri` always has the authority string. This is unique on the device — only one provider will be tied to a given authority string.

What comes after the authority string is up to the provider. It is structured like the path segments of an `http://` URL, but what those path segments mean is up to the provider implementation. The one approximate rule is that a `Uri` pointing to an individual piece of content — such as a row of a table or view in a database — frequently has the `Uri` end in a number, where the number indicates a unique identifier of that content.

Most of the Android APIs expect these to be `Uri` objects, though in common discussion, it is simpler to think of them as strings. The `Uri.parse()` static method creates a `Uri` out of the string representation.

### Getting a Handle

So, where do these `Uri` instances come from?

Some `Uri` values are part of the framework. For example, `ContactsContract.Contacts.CONTENT_URI` is a `Uri` pointing at the collection of contacts.

You might also get `Uri` instances handed to you from other sources, such as getting `Uri` handles for contacts via activities responding to `ACTION_PICK` or `ACTION_GET_CONTENT` Intent objects.

You can also hard-wire literal `String` objects (e.g., `"content://contacts/people"`) and convert them into `Uri` instances via `Uri.parse()`. This is not an ideal solution, as the base `Uri` values could conceivably change over time. For example, while you *used* to access contacts via a `Uri` like `content://contacts/people`, that is no longer the case. `ContactsContract.Contacts.CONTENT_URI` is a different value and will give you better results.

### The Database-Style API

Of the two flavors of API that a content provider may support, the database-style API is more prevalent. Using a `ContentResolver`, you can perform standard “CRUD” operations (create, read, update, delete) using what looks like a SQL interface.

#### Makin’ Queries

Given a base `Uri`, you can run a query to return data out of the content provider related to that `Uri`. This has much of the feel of SQL: you specify the “columns” to return, the constraints to determine which “rows” to return, a sort order, etc. The difference is that this request is being made of a content provider, not directly of some database (e.g., SQLite).

You have two main options for running a query:

1. Use the `query()` method on `ContentResolver` from some sort of background thread
2. Use a `CursorLoader`, as is discussed [in an upcoming chapter](#)

The standard `query()` method on `ContentResolver` takes five parameters:

- The base `Uri` of the content provider to query, or the instance `Uri` of a specific object to query
- An array of properties (think “columns”) from that content provider that you want returned by the query
- A constraint statement, functioning like a SQL `WHERE` clause
- An optional set of parameters to bind into the constraint clause, replacing any `?` that appear there
- An optional sort statement, functioning like a SQL `ORDER BY` clause

This method returns a `Cursor` object, which you can use to retrieve the data returned by the query.

## CONTENT PROVIDER THEORY

---

This will hopefully make more sense given an example. This chapter shows some sample bits of code from the [ContentProvider/ConstantsPlus](#) sample project. This is the same basic application as was first shown back in the [chapter on database access](#), but rewritten to pull the database logic into a content provider, which is then used by a retained ListFragment.

As before, in `onViewCreated()`, we kick off a `LoadCursorTask` if we do not already have our `Cursor`, such as via a configuration change:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    SimpleCursorAdapter adapter=
        new SimpleCursorAdapter(getActivity(), R.layout.row,
            current, new String[] {
                DatabaseHelper.TITLE,
                DatabaseHelper.VALUE },
            new int[] { R.id.title, R.id.value },
            0);

    setListAdapter(adapter);

    if (current==null) {
        task=new LoadCursorTask(getActivity()).execute();
    }
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

`LoadCursorTask` inherits from a `BaseTask`. `BaseTask` and its subclasses need a `ContentResolver` to be able to work with our `ContentProvider`. So, `BaseTask` takes a `Context` in its constructor and uses that to retrieve a `ContentResolver`:

```
abstract private class BaseTask<T> extends AsyncTask<T, Void, Cursor> {
    final ContentResolver resolver;

    BaseTask(Context ctxt) {
        super();

        resolver=ctxt.getContentResolver();
    }
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

## CONTENT PROVIDER THEORY

---

In `doInBackground()`, `LoadCursorTask` calls a `doQuery()` method inherited from `BaseTask`, which in turn uses our `ContentResolver` to query our `ContentProvider`:

```
protected Cursor doQuery() {
    Cursor result=resolver.query(Provider.Constants.CONTENT_URI,
        PROJECTION, null, null, null);

    result.getCount();

    return(result);
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

In the call to `query()`, we provide:

1. The `Uri` for our provider (`Provider.Constants.CONTENT_URI`), in this case representing the collection of physical constants managed by the provider
2. A list of properties to retrieve
3. Three `null` values, indicating that we do not need a constraint clause (the `Uri` represents the instance we need), nor parameters for the constraint, nor a sort order (we should only get one entry back)

The biggest “magic” here is the list of properties. The lineup of what properties are possible for a given provider should be provided by the documentation (or source code) for the content provider itself. In this case, we define logical values on the `Provider` provider implementation class that represent the various properties (namely, the unique identifier, the display name or title, and the value of the constant), and we refer to them with our `PROJECTION`:

```
private static final String[] PROJECTION=new String[] {
    Provider.Constants._ID, Provider.Constants.TITLE,
    Provider.Constants.VALUE };
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

### Adapting to the Circumstances

Now that we have a `Cursor` via `query()`, we have access to the query results and can do whatever we want with them. You might, for example, manually extract data from the `Cursor` to populate widgets or other objects.

In our case, we are using the `SimpleCursorAdapter`, set up in `onViewCreated()`, to render our `Cursor`. This means that we need to take the `Cursor` that `doQuery()`

## CONTENT PROVIDER THEORY

---

generates and arrange to hand that to the SimpleCursorAdapter. The `onPostExecute()` method on `BaseTask` handles this:

```
@Override
public void onPostExecute(Cursor result) {
    ((CursorAdapter)getListAdapter()).changeCursor(result);
    current=result;
    task=null;
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

### Give and Take

Of course, content providers would be astonishingly weak if you couldn't add or remove data from them, and were instead limited to only update what is there. Fortunately, content providers offer these abilities as well.

To insert data into a content provider, you have two options available on the `ContentProvider` interface (available through `getContentResolver()` to your activity):

- Use `insert()` with a collection `Uri` and a `ContentValues` structure describing the initial set of data to put in the row
- Use `bulkInsert()` with a collection `Uri` and an array of `ContentValues` structures to populate several rows at once

The `insert()` method returns a `Uri` for you to use for future operations on that new object. The `bulkInsert()` method returns the number of created rows; you would need to do a query to get back at the data you just inserted.

For example, if the user chooses our “Add” overflow item, we pop up a dialog to collect a new constant:

```
private void add() {
    LayoutInflater inflater=getActivity().getLayoutInflater();
    View addView=inflater.inflate(R.layout.add_edit, null);
    AlertDialog.Builder builder=new AlertDialog.Builder(getActivity());

    builder.setTitle(R.string.add_title).setView(addView)
        .setPositiveButton(R.string.ok, this)
        .setNegativeButton(R.string.cancel, null).show();
}
```

## CONTENT PROVIDER THEORY

---

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

Then, if the user taps the “OK” button in the dialog, our `onClick()` listener is called, where we collect the entered values from the user, pour them into a `ContentValues` structure, and pass that to an `InsertTask`:

```
@Override
public void onClick(DialogInterface dialog, int which) {
    ContentValues values=new ContentValues(2);
    AlertDialog dlg=(AlertDialog)dialog;
    EditText title=(EditText)dlg.findViewById(R.id.title);
    EditText value=(EditText)dlg.findViewById(R.id.value);

    values.put(DatabaseHelper.TITLE, title.getText().toString());
    values.put(DatabaseHelper.VALUE, value.getText().toString());

    task=new InsertTask(getActivity()).execute(values);
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

`InsertTask`, in its `doInBackground()` method, calls `insert()` on a `ContentResolver` to insert this row:

```
@Override
protected Cursor doInBackground(ContentValues... values) {
    resolver.insert(Provider.Constants.CONTENT_URI, values[0]);

    return(doQuery());
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

Notice that we also call `doQuery()` again. That is because our `Cursor` is now out of date, and we need to obtain a fresh `Cursor` with fresh results. And, as with `LoadTask`, `InsertTask` inherits from `BaseTask`, not only providing us with that `doQuery()` method but also the `onPostExecute()` method that puts the `Cursor` into the `SimpleCursorAdapter`.

To delete one or more rows from the content provider, use the `delete()` method on `ContentResolver`. This works akin to a SQL `DELETE` statement and takes three parameters:

- A `Uri` representing the collection (or instance) from which you wish to delete rows

- A constraint statement, functioning like a SQL WHERE clause, to determine which rows should be deleted
- An optional set of parameters to bind into the constraint clause, replacing any ? that appear there

### The Streaming API

Sometimes, what you are trying to retrieve does not look like a set of rows and columns, but rather looks like a stream. For example, [the MediaStore provider](#) manages the index of all music, video, and image files available on external storage, and you can use MediaStore to open up a stream to read in the contents of one of those files. Here, working with the Uri and the provider is much like working with a URL and a Web server.

Some content providers, like MediaStore, support both the database-style and streaming APIs — you query to find media that matches your criteria, then can open some file that matches. Other content providers might only support the streaming API.

### Working with the Stream

Given a Uri that represents some file managed by the content provider, you can use `openInputStream()` and `openOutputStream()` on a `ContentResolver` to access an `InputStream` or `OutputStream`, respectively. Note, though, that not all content providers may support both modes. For example, if you are working with a content provider that serves files stored inside the application (e.g., assets in the APK file), you will not be able to get an `OutputStream` to modify the content.

Also note that `openInputStream()` and `openOutputStream()` work with both `file://` and `content://` Uri values — you do not need to manually inspect the Uri and handle files separately if you do not want to.

### Retrieving Metadata

You can call `getType()` on a `ContentResolver`, supplying a Uri as a parameter. This will return the MIME type reported by the `ContentProvider` for the data at that Uri. For the streaming API, this will give you results reminiscent of a Web server — some specific MIME type if the provider knows it, otherwise probably some generic MIME type (e.g., `application/octet-stream`).

You can also call `query()` on the `ContentResolver`. Your projection (the list of columns to return) can include:

- `OpenableColumns.SIZE`, which will return the length of the file being streamed to you for that `Uri`, and
- `OpenableColumns.DISPLAY_NAME`, which should be some name for the file that the user might recognize

### The DATA Anti-Pattern

However, the authors of `MediaStore` screwed up developer expectations, due to a legacy convention.

The legacy convention was that a `content://Uri` might not be openable directly using something like `openInputStream()`. Instead, it pointed to a database row, retrievable via `query()`, and you would look in the `DATA` column for how to access the actual data. Some providers no doubt continue to use this pattern, as does `MediaStore`. The rules for what the `DATA` column would be were not well documented, but by convention they tended to be a path to a file. The problem is that this runs afoul of Google's current guidance, as there is no guarantee that other apps can access such a file.

**Do not** blindly assume that if you get a `content://Uri` that it is for the `DATA` pattern. Try to open a stream on the `Uri`, and if that fails, then see if the `DATA` pattern is in play. Or, if you `query()` to get the size and/or display name first, also request the `DATA` column, and if it exists and is not `null`, try that if opening the stream directly does not work.

## Building Content Providers

Building a content provider is a very tedious task. There are many requirements of a content provider, in terms of methods to implement and public data members to supply. And, until you try using it, you have no great way of telling if you did any of it correctly (versus, say, building an activity and getting validation errors from the resource compiler).

That being said, building a content provider is of huge importance if your application wishes to make data available to other applications. If your application is keeping its data solely to itself, you may be able to avoid creating a content provider, just accessing the data directly from your activities. But, if you want your data to

possibly be used by others — for example, you are building a feed reader and you want other programs to be able to access the feeds you are downloading and caching — then a content provider is right for you.

### First, Some Dissection

The content `Uri` is the linchpin behind accessing data inside a content provider. When using a content provider, all you really need to know is the provider's base `Uri`; from there you can run queries as needed, or construct a `Uri` to a specific instance if you know the instance identifier.

When building a content provider, though, you need to know a bit more about the innards of the content `Uri`.

A content `Uri` has two to four pieces, depending on situation:

1. It always has a scheme (`content://`), indicating it is a content `Uri` instead of a `Uri` to a Web resource (`http://`).
2. It always has an authority, which is the first path segment after the scheme. The authority is a unique string identifying the content provider that handles the content associated with this `Uri`.
3. It may have a data type path, which is the list of path segments after the authority and before the instance identifier (if any). The data type path can be empty, if the content provider only handles one type of content. It can be a single path segment (`foo`) or a chain of path segments (`foo/bar/goo`) as needed to handle whatever data access scenarios the content provider requires.
4. It may have an instance identifier, which is an integer identifying a specific piece of content. A content `Uri` without an instance identifier refers to the collection of content represented by the authority (and, where provided, the data path).

For example, a content `Uri` could be as simple as `content://secrets`, which would refer to the collection of content held by whatever content provider was tied to the `secrets` authority (e.g., `SecretsProvider`). Or, it could be as complex as `content://secrets/card/pin/17`, which would refer to a piece of content (identified as 17) managed by the `secrets` content provider that is of the data type `card/pin`.

### Next, Some Typing

Next, you need to come up with some MIME types corresponding with the content your content provider will provide. There are three basic patterns.

For the streaming API, the MIME type that you will use should be the actual MIME type of the stream itself. Perhaps you already know the MIME type (e.g., you got it in an HTTP header when you downloaded the content from a Web server). Perhaps you will use `MimeTypeMap` to try to infer a MIME type based on a file extension. That is up to you, just as it is up to you to ensure that your Web server returns proper MIME types for streams that it serves up.

For the database-style API, even though the MIME type system is not really designed for this sort of thing, we still use MIME types. Each `Uri` will have an associated MIME type, indicating what is represented by that `Uri`. A `Uri` that points to a collection of content (e.g., a database table or view) will use one MIME type structure, while a `Uri` that points to an individual piece of content (e.g., a row in that database table or view) will use a different MIME type structure.

The collection MIME type should be of the form `vnd.X.cursor.dir/Y`, where `X` is the name of your firm, organization, or project, and `Y` is a dot-delimited type name. So, for example, you might use `vnd.tlagency.cursor.dir/sekrits.card.pin` as the MIME type for your collection of secrets.

The instance MIME type, for an individual piece of content, should be of the form `vnd.X.cursor.item/Y`, usually for the same values of `X` and `Y` as you used for the collection MIME type (though that is not strictly required).

### Implementing the Database-Style API

Just as an activity and a receiver are both Java classes, so is a content provider. So, the big step in creating a content provider is crafting its Java class, with a base class of `ContentProvider`.

In your subclass of `ContentProvider`, you are responsible for implementing six methods that, when combined, perform the services that a content provider is supposed to offer to activities wishing to create, read, update, or delete content via the database-style API.

### Implement onCreate()

As with an activity, the main entry point to a content provider is `onCreate()`. Here, you can do whatever initialization you want. In particular, here is where you should lazy-initialize your data store. For example, if you plan on storing your data in such-and-so directory on external storage, with an XML file serving as a “table of contents”, you should check and see if that directory and XML file are there and, if not, create them so the rest of your content provider knows they are out there and available for use.

Similarly, if you have rewritten your content provider sufficiently to cause the data store to shift structure, you should check to see what structure you have now and adjust it if what you have is out of date.

### Implement query()

As one might expect, the `query()` method is where your content provider gets details on a query some activity wants to perform. It is up to you to actually process said query.

The query method gets, as parameters:

1. A `Uri` representing the collection or instance being queried
2. A `String` array representing the list of properties that should be returned
3. A `String` representing what amounts to a SQL `WHERE` clause, constraining which instances should be considered for the query results
4. A `String` array representing values to “pour into” the `WHERE` clause, replacing any `?` found there
5. A `String` representing what amounts to a SQL `ORDER BY` clause

You are responsible for interpreting these parameters however they make sense and returning a `Cursor` that can be used to iterate over and access the data.

As you can imagine, these parameters are aimed towards people using a SQLite database for storage. You are welcome to ignore some of these parameters (e.g., you elect not to try to roll your own SQL `WHERE` clause parser), but you need to document that fact so activities only attempt to query you by instance `Uri` and not by using parameters that you elect to ignore.

### Implement insert()

Your `insert()` method will receive a `Uri` representing the collection and a `ContentValues` structure with the initial data for the new instance. You are responsible for creating the new instance, filling in the supplied data, and returning a `Uri` to the new instance.

### Implement update()

Your `update()` method gets the `Uri` of the instance or collection to change, a `ContentValues` structure with the new values to apply, a `String` for a SQL `WHERE` clause, and a `String` array with parameters to use to replace `?` found in the `WHERE` clause. Your responsibility is to identify the instance(s) to be modified (based on the `Uri` and `WHERE` clause), then replace those instances' current property values with the ones supplied.

This will be annoying, unless you are using SQLite for storage. Then, you can pretty much pass all the parameters you received to the `update()` call to the database, though the `update()` call will vary slightly depending on whether you are updating one instance or several.

### Implement delete()

As with `update()`, `delete()` receives a `Uri` representing the instance or collection to work with and a `WHERE` clause and parameters. If the activity is deleting a single instance, the `Uri` should represent that instance and the `WHERE` clause may be null. But, the activity might be requesting to delete an open-ended set of instances, using the `WHERE` clause to constrain which ones to delete.

As with `update()`, though, this is simple if you are using SQLite for database storage (sense a theme?). You can let it handle the idiosyncrasies of parsing and applying the `WHERE` clause — all you have to do is call `delete()` on the database.

### Implement getType()

The last method you need to implement is `getType()`. This takes a `Uri` and returns the MIME type associated with that `Uri`. The `Uri` could be a collection or an instance `Uri`; you need to determine which was provided and return the corresponding MIME type.

### Update the Manifest

The glue tying the content provider implementation to the rest of your application resides in your `AndroidManifest.xml` file. Simply add a `<provider>` element as a child of the `<application>` element, such as:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.constants"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="18"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <provider
            android:name=".Provider"
            android:authorities="com.commonware.android.constants.Provider"
            android:exported="false"/>

        <activity
            android:name=".ConstantsBrowser"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

(from [ContentProvider/ConstantsPlus/app/src/main/AndroidManifest.xml](#))

The `android:name` property is the name of the content provider class, with a leading dot to indicate it is in the stock namespace for this application's classes (just like you

use with activities).

The `android:authorities` property should be a semicolon-delimited list of the authority values supported by the content provider. Recall, from earlier in this chapter, that each content `Uri` is made up of a scheme, authority, data type path, and instance identifier. Each authority from each `CONTENT_URI` value should be included in the `android:authorities` list. Now, when Android encounters a content `Uri`, it can sift through the providers registered through manifests to find a matching authority. That tells Android which application and class implements the content provider, and from there Android can bridge between the calling activity and the content provider being called.

Several other attributes relate to security:

- `android:exported` indicates whether third-party apps are able to initiate communications with your provider on their own
- `android:readPermission` and `android:writePermission` allow you to defend your provider with permissions; third-party apps have to have `<uses-permission>` elements for those permissions to be able to work with your provider
- `android:grantUriPermissions` indicates whether you are able to selectively “poke pinholes in the firewall” of your provider security, to say that for specific IPC operations (e.g., starting a third-party activity), that third party has limited access to your provider’s content

These will be explored later in this book.

### **Add Notify-On-Change Support**

A feature that your content provider can offer to its clients is notify-on-change support. This means that your content provider will let clients know if the data for a given content `Uri` changes.

For example, suppose you have created a content provider that retrieves RSS and Atom feeds from the Internet based on the user’s feed subscriptions (via OPML, perhaps). The content provider offers read-only access to the contents of the feeds, with an eye towards several applications on the phone using those feeds versus everyone implementing their own feed poll-fetch-and-cache system. You have also implemented a service that will get updates to those feeds asynchronously, updating the underlying data store. Your content provider could alert applications using the feeds that such-and-so feed was updated, so applications using that specific feed can

refresh and get the latest data.

On the content provider side, to do this, call `notifyChange()` on your `ContentResolver` instance (available in your content provider via `getContext().getContentResolver()`). This takes two parameters: the `Uri` of the piece of content that changed and the `ContentObserver` that initiated the change. In many cases, the latter will be `null`; a non-`null` value simply means that the observer that initiated the change will not be notified of its own changes.

On the content consumer side, an activity can call `registerContentObserver()` on its `ContentResolver` (via `getContentResolver()`). This ties a `ContentObserver` instance to a supplied `Uri` — the observer will be notified whenever `notifyChange()` is called for that specific `Uri`. When the consumer is done with the `Uri`, `unregisterContentObserver()` releases the connection.

### Implementing the Streaming API

If you want to have a `ContentProvider` support streaming data via the streaming API, you will still need to set up the `<provider>` element, choose an authority, and create a subclass of `ContentProvider` as with the database-style API. From there, whether you are adding the streaming API to an existing provider or creating a new one, there is some additional work to be done.

#### Serving the Stream

If you want consumers of your `ContentProvider` to be able to call `openInputStream()` or `openOutputStream()` on a `Uri`, the most likely approach is to implement the `openFile()` method. The `openFile()` method returns a curious object called a `ParcelFileDescriptor`. Given that, the `ContentResolver` can obtain the `InputStream` or `OutputStream` that was requested. There are various static methods on `ParcelFileDescriptor` to create instances of it, such as an `open()` method that takes a `File` object as the first parameter. Note that this works for both files on external storage and files within your own project's app-local file storage (e.g., `getFilesDir()`).

`openFile()` also gets a `String` parameter that is the “mode” for opening the file. This can be converted into appropriate flags for use with `ParcelFileDescriptor` and its `open()` method. Mostly, this is for determining whether we are opening the file for read or write operations.

### Serving the Metadata

You should implement the `query()` method in your provider as well. If the `Uri` is pointing to one of your streams, you should create a one-row `MatrixCursor` and supply the `OpenableColumns` as the columns. `OpenableColumns` has two values: `DISPLAY_NAME` (for some human-readable name of the stream) and `SIZE` (the length of the stream in bytes). Based on the projection string array passed into `query()`, you can skip columns that the client is not requesting.

You also need to implement `getType()`. For the database-style API, you pretty much invent your own MIME types. For the streaming API, you should be returning MIME types for the `Uri` values that really represent the contents of that `Uri`. In other words, your `getType()` method should behave like you would expect a Web server to do with respect to the `Content-Type` header. If you know the MIME type for certain (e.g., you got it yourself in an HTTP or IMAP operation and saved it), use that. If you do not know the MIME type for certain, you can try the `MimeTypeMap` class, which knows how to map common file extensions to their MIME type counterparts. Worst-case, return `application/octet-stream`.

### The Rest of the Requirements

You also have to implement the following abstract methods:

- `onCreate()`
- `insert()`
- `update()`
- `delete()`

If you are not supporting the database-style API, you are welcome to have `insert()`, `update()`, and `delete()` throw some `RuntimeException`, to indicate that those operations are not supported.

## Issues with Content Providers

Content providers are not without their issues.

The biggest complaint seems to be the lack of an `onDestroy()` companion to the `onCreate()` method you can implement. Hence, if you open a database in `onCreate()`, you close it... never. Sometimes, you can alleviate this by initializing things on demand and releasing them immediately, such as opening a database as

## CONTENT PROVIDER THEORY

---

part of `insert()` and closing it within the same method. This does not always work, however — for example, you cannot close the database you query in `query()`, since the `Cursor` you return would become invalid. Holding onto an open `SQLiteDatabase` is not a problem, as all of your data changes are written to disk as part of committing transactions. So, many `ContentProvider` implementations settle for simply never closing the database.

The fact that `ContentProvider` is effectively a facade means that a consumer of a `ContentProvider` has no idea what to expect. It is up to documentation to explain what `Uri` values can be used, what columns can be returned, what query syntax is supported, and so on. And, the fact that it is a facade means that much of the richness of the `SQLite` interface is lost, such as `GROUP BY`. To top it off, the API supported by `ContentProvider` is rather limited — if what you want to share does not look like a database and does not look like a file, it may be difficult to force it into the `ContentProvider` API.

Another issue is the client's dependence upon the provider itself. If, for whatever reason, the provider's process is terminated while the client has an open `Cursor` on query results, the client's process is also terminated. It is unclear if the same effect occurs when the client has an open stream from a provider through the streaming API, though it seems likely. Now, in theory, the importance of the provider's process should be raised to the highest importance of any of its clients, though this behavior is not documented and may not occur in practice.

This behavior by Android is rather drastic, more drastic than what happens to HTTP clients when the Web server they are connected to crashes. There, the client winds up with some sort of exception and can move on. The moral of this story is: when working with a `ContentProvider`, it behooves you to use the data quickly, particularly if your app is in the background at the time.

# Content Provider Implementation Patterns

---

[The previous chapter](#) focused on the concepts, classes, and methods behind content providers. This chapter more closely examines some implementations of content providers, organized into simple patterns.

## Prerequisites

Understanding this chapter requires that you have read [the preceding chapter](#), along with [the chapter on permissions](#).

## The Single-Table Database-Backed Content Provider

The simplest database-backed content provider is one that only attempts to expose a single table's worth of data to consumers. The `CallLog` content provider works this way, for example.

### Step #1: Create a Provider Class

We start off with a custom subclass of `ContentProvider`, named, cunningly enough, `Provider`. Here we need the database-style API methods: `query()`, `insert()`, `update()`, `delete()`, and `getType()`.

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

### onCreate()

Here is the onCreate() method for Provider, from the [ContentProvider/ConstantsPlus](#) sample application:

```
@Override
public boolean onCreate() {
    db=new DatabaseHelper(getContext());

    return(true);
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

While that does not seem all that special, the “magic” is in the private DatabaseHelper object, a fairly conventional SQLiteOpenHelper implementation:

```
package com.commonsware.android.constants;

import android.content.ContentValues;
import android.content.Context;
import android.database.Cursor;
import android.database.sqlite.SQLiteOpenHelper;
import android.database.sqlite.SQLiteDatabase;
import android.hardware.SensorManager;

class DatabaseHelper extends SQLiteOpenHelper {
    private static final String DATABASE_NAME="constants.db";
    static final String TITLE="title";
    static final String VALUE="value";

    public DatabaseHelper(Context context) {
        super(context, DATABASE_NAME, null, 1);
    }

    @Override
    public void onCreate(SQLiteDatabase db) {
        Cursor c=db.rawQuery("SELECT name FROM sqlite_master WHERE type='table' AND name='constants'", null);

        try {
            if (c.getCount()==0) {
                db.execSQL("CREATE TABLE constants (_id INTEGER PRIMARY KEY AUTOINCREMENT, title TEXT, value REAL);");

                ContentValues cv=new ContentValues();

                cv.put(Provider.Constants.TITLE, "Gravity, Death Star I");
                cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_DEATH_STAR_I);
                db.insert("constants", Provider.Constants.TITLE, cv);

                cv.put(Provider.Constants.TITLE, "Gravity, Earth");
                cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_EARTH);
                db.insert("constants", Provider.Constants.TITLE, cv);
            }
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
```

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

```
cv.put(Provider.Constants.TITLE, "Gravity, Jupiter");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_JUPITER);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Mars");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MARS);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Mercury");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MERCURY);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Moon");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MOON);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Neptune");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_NEPTUNE);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Pluto");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_PLUTO);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Saturn");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_SATURN);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Sun");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_SUN);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, The Island");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_THE_ISLAND);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Uranus");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_URANUS);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Venus");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_VENUS);
db.insert("constants", Provider.Constants.TITLE, cv);
    }
}
finally {
    c.close();
}
}

@Override
public void onUpgrade(SQLiteDatabase db, int oldVersion, int newVersion) {
    android.util.Log.w("Constants", "Upgrading database, which will destroy all old data");
    db.execSQL("DROP TABLE IF EXISTS constants");
    onCreate(db);
}
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/DatabaseHelper.java](#))

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

Note that we are creating the DatabaseHelper in onCreate() and are never closing it. That is because there is no onDestroy() (or equivalent) method in a ContentProvider. While we might be tempted to open and close the database on every operation, that will not work, as we cannot close the database and still hand back a live Cursor from the database. Hence, we leave it open and assume that SQLite's transactional nature will ensure that our database is not corrupted when Android shuts down the ContentProvider.

### query()

For SQLite-backed storage providers like this one, the query() method implementation should be largely boilerplate. Use a SQLiteQueryBuilder to convert the various parameters into a single SQL statement, then use query() on the builder to actually invoke the query and give you a Cursor back. The Cursor is what your query() method then returns.

For example, here is query() from Provider:

```
@Override
public Cursor query(Uri url, String[] projection, String selection,
                    String[] selectionArgs, String sort) {
    SQLiteQueryBuilder qb=new SQLiteQueryBuilder();

    qb.setTables(TABLE);

    String orderBy;

    if (TextUtils.isEmpty(sort)) {
        orderBy=Constants.DEFAULT_SORT_ORDER;
    }
    else {
        orderBy=sort;
    }

    Cursor c=
        qb.query(db.getReadableDatabase(), projection, selection,
                selectionArgs, null, null, orderBy);

    c.setNotificationUri(getContext().getContentResolver(), url);

    return(c);
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

We create a `SQLiteQueryBuilder` and pour the query details into the builder, notably the name of the table that we query against and the sort order (substituting in a default sort if the caller did not request one). When done, we use the `query()` method on the builder to get a `Cursor` for the results. We also tell the resulting `Cursor` what `Uri` was used to create it, for use with the content observer system.

### **insert()**

Since this is a SQLite-backed content provider, once again, the implementation is mostly boilerplate: validate that all required values were supplied by the activity, merge your own notion of default values with the supplied data, and call `insert()` on the database to actually create the instance.

For example, here is `insert()` from `Provider`:

```
@Override
public Uri insert(Uri url, ContentValues initialValues) {
    long rowID=
        db.getWritableDatabase().insert(TABLE, Constants.TITLE,
                                       initialValues);

    if (rowID > 0) {
        Uri uri=
            ContentUris.withAppendedId(Provider.Constants.CONTENT_URI,
                                       rowID);
        getContext().getContentResolver().notifyChange(uri, null);

        return(uri);
    }

    throw new SQLException("Failed to insert row into " + url);
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

The pattern is the same as before: use the provider particulars plus the data to be inserted to actually do the insertion.

### **update()**

Here is `update()` from `Provider`:

```
@Override
public int update(Uri url, ContentValues values, String where,
```

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

```
        String[] whereArgs) {  
    int count=  
        db.getWritableDatabase()  
            .update(TABLE, values, where, whereArgs);  
  
    getContext().getContentResolver().notifyChange(url, null);  
  
    return(count);  
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

In this case, updates are always applied across the entire collection, though we could have a smarter implementation that supported updating a single instance via an instance Uri.

### delete()

Similarly, here is delete() from Provider:

```
@Override  
public int delete(Uri url, String where, String[] whereArgs) {  
    int count=db.getWritableDatabase().delete(TABLE, where, whereArgs);  
  
    getContext().getContentResolver().notifyChange(url, null);  
  
    return(count);  
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

This is almost a clone of the update() implementation described above.

### getType()

The last method you need to implement is getType(). This takes a Uri and returns the MIME type associated with that Uri. The Uri could be a collection or an instance Uri; you need to determine which was provided and return the corresponding MIME type.

For example, here is getType() from Provider:

```
@Override  
public String getType(Uri url) {  
    if (isCollectionUri(url)) {
```

---

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

```
    return("vnd.android.cursor.dir/constant");
}

    return("vnd.android.cursor.item/constant");
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

### Step #2: Supply a Uri

You may wish to add a public static member... somewhere, containing the `Uri` for each collection your content provider supports, for use by your own application code. Typically, this is a public static final `Uri` put on the content provider class itself:

```
public static final Uri CONTENT_URI=
    Uri.parse("content://com.commonsware.android.constants.Provider/constants");
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

You may wish to use the same namespace for the content `Uri` that you use for your Java classes, to reduce the chance of collision with others.

Bear in mind that if you intend for third parties to access your content provider, they will not have access to this public static data member, as your class is not in their project. Hence, you will need to publish the string representation of this `Uri` that they can hard-wire into their application.

### Step #3: Declare the “Columns”

Remember those “columns” you referenced when you were using a content provider, [in the previous chapter](#)? Well, you may wish to publish public static values for those too for your own content provider.

Specifically, you may want a public static class implementing `BaseColumns` that contains your available column names, such as this example from `Provider`:

```
public static final class Constants implements BaseColumns {
    public static final Uri CONTENT_URI=
        Uri.parse("content://com.commonsware.android.constants.Provider/constants");
    public static final String DEFAULT_SORT_ORDER="title";
    public static final String TITLE="title";
    public static final String VALUE="value";
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](#))

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

Since we are using SQLite as a data store, the values for the column name constants should be the corresponding column names in the table, so you can just pass the projection (array of columns) to SQLite on a query(), or pass the ContentValues on an insert() or update().

Note that nothing in here stipulates the types of the properties. They could be strings, integers, or whatever. The biggest limitation is what a Cursor can provide access to via its property getters. The fact that there is nothing in code that enforces type safety means you should document the property types well, so people attempting to use your content provider know what they can expect.

### Step #4: Update the Manifest

Finally, we need to add the provider to the AndroidManifest.xml file, by adding a <provider> element as a child of the <application> element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.constants"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="18"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <provider
            android:name=".Provider"
            android:authorities="com.commonware.android.constants.Provider"
            android:exported="false"/>

        <activity
            android:name=".ConstantsBrowser"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

```
        <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
</activity>
</application>

</manifest>
```

(from [ContentProvider/ConstantsPlus/app/src/main/AndroidManifest.xml](#))

## The Local-File Content Provider

Implementing a content provider that supports serving up files based on `Uri` values is similar, and generally simpler, than creating a content provider for the database-style API. In this section, we will examine the [ContentProvider/Files](#) sample project. This project demonstrates a common use of the filesystem-style API: serving files from internal storage to third-party applications (who, by default, cannot read your internally-stored files).

Note that this sample project will only work on devices that have an application capable of viewing PDF files accessed via `content://Uri` values.

### The FileProvider Class

Our `ContentProvider` is named `FileProvider`. However, most of the logic is contained in an `AbstractFileProvider` that will be used for a handful of sample apps in this chapter. We will look at both of those classes, focusing first on the `FileProvider`.

#### `onCreate()`

We have an `onCreate()` method. In many cases, this would not be needed for this sort of provider. After all, there is no database to open. In this case, we use `onCreate()` to copy the file(s) out of assets into the app-local file store. In principle, this would allow our application code to modify these files as the user uses the app (versus the unmodifiable editions in assets/).

```
@Override
public boolean onCreate() {
    File f=new File(getContext().getFilesDir(), "test.pdf");

    if (!f.exists()) {
```

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

```
AssetManager assets=getContext().getAssets();

try {
    copy(assets.open("test.pdf"), f);
}
catch (IOException e) {
    Log.e("FileProvider", "Exception copying from assets", e);

    return(false);
}

return(true);
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/FileProvider.java](#))

This uses a static `copy()` method, inherited from `AbstractFileProvider`, that can copy an `InputStream` from an asset to a local `File`. We will take a peek at this later in this chapter.

### openFile()

We need to implement `openFile()`, to return a `ParcelFileDescriptor` corresponding to the supplied `Uri`:

```
@Override
public ParcelFileDescriptor openFile(Uri uri, String mode)
    throws FileNotFoundException {
    File root=getContext().getFilesDir();
    File f=new File(root, uri.getPath()).getAbsolutePath();

    if (!f.getPath().startsWith(root.getPath())) {
        throw new
            SecurityException("Resolved path jumped beyond root");
    }

    if (f.exists()) {
        return(ParcelFileDescriptor.open(f, parseMode(mode)));
    }

    throw new FileNotFoundException(uri.getPath());
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/FileProvider.java](#))

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

We are passed in a \*nix-style string mode, which will be a value like r for read access, wt for write access (and truncate the file), etc. In API Level 19+, ParcelFileDescriptor has a convenience method for converting such modes into the equivalent ParcelFileDescriptor flag values. For older devices, you can simply use the parseMode() code that Google added:

```
// following is from ParcelFileDescriptor source code
// Copyright (C) 2006 The Android Open Source Project
// (even though this method was added much after 2006...)

private static int parseMode(String mode) {
    final int modeBits;
    if ("r".equals(mode)) {
        modeBits=ParcelFileDescriptor.MODE_READ_ONLY;
    }
    else if ("w".equals(mode) || "wt".equals(mode)) {
        modeBits=
            ParcelFileDescriptor.MODE_WRITE_ONLY
            | ParcelFileDescriptor.MODE_CREATE
            | ParcelFileDescriptor.MODE_TRUNCATE;
    }
    else if ("wa".equals(mode)) {
        modeBits=
            ParcelFileDescriptor.MODE_WRITE_ONLY
            | ParcelFileDescriptor.MODE_CREATE
            | ParcelFileDescriptor.MODE_APPEND;
    }
    else if ("rw".equals(mode)) {
        modeBits=
            ParcelFileDescriptor.MODE_READ_WRITE
            | ParcelFileDescriptor.MODE_CREATE;
    }
    else if ("rwt".equals(mode)) {
        modeBits=
            ParcelFileDescriptor.MODE_READ_WRITE
            | ParcelFileDescriptor.MODE_CREATE
            | ParcelFileDescriptor.MODE_TRUNCATE;
    }
    else {
        throw new IllegalArgumentException("Bad mode '" + mode + "'");
    }
    return modeBits;
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/FileProvider.java](#))

Our openFile() method then uses parseMode() in the call to the static open()

---

method on `ParcelFileDescriptor`, which opens the file (with the desired access mode) and gives us our `ParcelFileDescriptor` back that we can return. If the file is not found, we can throw a `FileNotFoundException` to indicate that.

However, we also check to see that the `File` that we are trying to access is inside `getFilesDir()`, by comparing paths. A `Uri` can have `..` path segments to move up directory levels. Using that with the `File` constructor means that a rogue `Uri` could move outside of our designated root directory (`getFilesDir()`), to perhaps try to access other data on our internal storage (e.g., databases). `getAbsoluteFile()` will net out any path-traversal segments (e.g., `..`). If `getAbsoluteFile()` lies within `getFilesDir()`, we go ahead, otherwise we throw a `SecurityException`.

### **getDataLength()**

`AbstractFileProvider` gives us a callback — `getDataLength()` — where we can indicate how big a file is, given its `Uri`. That information will be made available to clients consuming this stream. The default will be to indicate that the file size is unknown... and that usually works. However, if it is easy for you to determine the file size, do so, and it will increase the compatibility of your app with possible consumers.

In this case, determining the size of a local file is easy:

```
@Override
protected long getDataLength(Uri uri) {
    File f=new File(getContext().getFilesDir(), uri.getPath());

    return(f.length());
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/FileProvider.java](#))

## **The AbstractFileProvider Class**

`AbstractFileProvider` is designed to handle a lot of common boilerplate for streaming providers like the one provided in this sample.

### **getType()**

Just as our database-style `ContentProvider` needed to implement `getType()` to provide a MIME type given a `Uri`, so too do our streaming providers. The difference is that a streaming provider usually wants to use “real” MIME types, values that

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

third-party apps are likely to recognize. For example, a PDF file should use a MIME type of `application/pdf`, as that is what PDF viewing apps will expect.

Android has some convenience code for determining a likely MIME type. You can use `MimeTypeMap` to convert a file extension to a MIME type, or you can use `guessContentTypeFromName()` on `URLConnection` to get a MIME type for a URL. Both use the same underlying database — the difference is mostly a matter of whether you have a bare file extension already or not. So, the default implementation of `getType()` in `AbstractFileProvider` uses `guessContentTypeFromName()`:

```
@Override
public String getType(Uri uri) {
    return(URLConnection.guessContentTypeFromName(uri.toString()));
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/AbstractFileProvider.java](#))

If you know that *your* MIME type is unlikely to be recognized by Android (e.g., you invented your own), a subclass of `AbstractFileProvider` could handle those cases, chaining to the superclass for other `Uri` values.

### insert(), update(), and delete()

`ContentProvider` itself is abstract, requiring us to implement a variety of methods to satisfy the compiler. Three of them — `insert()`, `update()`, and `delete()` — have no role in a pure-streaming `ContentProvider`, so `AbstractFileProvider` has stub implementations:

```
@Override
public Uri insert(Uri uri, ContentValues initialValues) {
    throw new RuntimeException("Operation not supported");
}

@Override
public int update(Uri uri, ContentValues values, String where,
    String[] whereArgs) {
    throw new RuntimeException("Operation not supported");
}

@Override
public int delete(Uri uri, String where, String[] whereArgs) {
    throw new RuntimeException("Operation not supported");
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/AbstractFileProvider.java](#))

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

A `ContentProvider` that supports *both* the database-style and streaming APIs will need real implementations of those methods for the database operations, perhaps throwing an `Exception` for requests to insert, update, or delete a `Uri` that represents a stream.

### `query()` and `getFileName()`

We also need to implement `query()`. You can get by with having this be a stub similar to `insert()` and `kin`. However, for better compatibility, you should have a more robust `query()` implementation, as it will be used by `ContentResolver` to retrieve two pieces of metadata about a `Uri`:

- What is a valid filename to use to represent this `Uri`, should we need a human-readable name? After all, a `ContentProvider Uri` does not have to represent a human-readable path, and so the last segment of that `Uri` could be a cryptic string of hex digits or something, not a filename.
- What is the length of the data that should be delivered by the stream?

`query()` will be called with a projection that contains either `OpenableColumns.DISPLAY_NAME`, `OpenableColumns.SIZE`, or both. A streaming `ContentProvider` ideally supports returning a `Cursor` with this data. The `AbstractFileProvider` implementation of `query()` handles this for us:

```
abstract class AbstractFileProvider extends ContentProvider {
    private final static String[] OPENABLE_PROJECTION= {
        OpenableColumns.DISPLAY_NAME, OpenableColumns.SIZE };

    @Override
    public Cursor query(Uri uri, String[] projection, String selection,
        String[] selectionArgs, String sortOrder) {
        if (projection == null) {
            projection=OPENABLE_PROJECTION;
        }

        final MatrixCursor cursor=new MatrixCursor(projection, 1);

        MatrixCursor.RowBuilder b=cursor.newRow();

        for (String col : projection) {
            if (OpenableColumns.DISPLAY_NAME.equals(col)) {
                b.add(getFileName(uri));
            }
            else if (OpenableColumns.SIZE.equals(col)) {
                b.add(getDataLength(uri));
            }
        }
    }
}
```

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

```
    }  
    else { // unknown, so just add null  
        b.add(null);  
    }  
}  
  
return(new LegacyCompatCursorWrapper(cursor));  
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/AbstractFileProvider.java](#))

If the supplied projection is null, we assume that the caller wants the standard `OpenableColumns`; otherwise, we will use the supplied projection.

Our results will be packaged in a `MatrixCursor`. This amounts to a `Cursor` interface on a two-dimensional array, where you build up the rows in that array via a `MatrixCursor.RowBuilder`. In our case, there will only be one such row, for the relevant values for the file to be streamed in support of the requested `Uri`.

We iterate over the columns in the projection, calling out to `getFileName()` and `getDataLength()` methods for `OpenableColumns.DISPLAY_NAME` and `OpenableColumns.SIZE` respectively (and using null as the result for anything else). The default implementations of those methods return the last path segment of the `Uri` and `AssetFileDescriptor.UNKNOWN_LENGTH`, respectively:

```
protected String getFileName(Uri uri) {  
    return(uri.getLastPathSegment());  
}  
  
protected long getDataLength(Uri uri) {  
    return(AssetFileDescriptor.UNKNOWN_LENGTH);  
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/AbstractFileProvider.java](#))

Subclasses can override those as needed, as we saw with `getDataLength()` in the concrete `FileProvider` class.

However, `query()` does not return the `MatrixCursor` directly. Instead, it wraps it in a `LegacyCompatCursorWrapper`. This class comes from [the CWAC-Provider project](#), from the author of this book. `LegacyCompatCursorWrapper` is designed to try to improve compatibility with clients that are expecting `query()` results to include a `_DATA` column, the way that `MediaStore` does. Poorly-written clients will crash if this column does not exist. `LegacyCompatCursorWrapper` wraps a `Cursor` and serves up

an empty `_DATA` column for those clients that need one.

### `copy()`

`AbstractFileProvider` also has a convenience `copy()` static method that copies an `InputStream` to a `File`, used from the `FileProvider` `onCreate()` method:

```
static void copy(InputStream in, File dst)
                                throws IOException {
    FileOutputStream out=new FileOutputStream(dst);
    byte[] buf=new byte[1024];
    int len;

    while ((len=in.read(buf)) >= 0) {
        out.write(buf, 0, len);
    }

    in.close();
    out.close();
}
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/AbstractFileProvider.java](#))

## The Manifest

Finally, we need to add the provider to the `AndroidManifest.xml` file, by adding a `<provider>` element as a child of the `<application>` element, as with any other content provider:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonsware.android.cp.files"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
```

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

```
    android:name="FilesCPDemo"
    android:label="@string/app_name"
    android:theme="@android:style/Theme.Translucent.NoTitleBar">
    <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
</activity>

<provider
    android:name=".FileProvider"
    android:authorities="com.commonware.android.cp.files"
    android:exported="true"/>
</application>
</manifest>
```

(from [ContentProvider/Files/app/src/main/AndroidManifest.xml](#))

Note, however, that we have `android:exported="true"` set in our `<provider>` element. This means that this content provider can be accessed from third-party apps or other external processes (e.g., the media framework for playing back videos).

### Using this Provider

The activity is fairly trivial, simply creating an `ACTION_VIEW` Intent on our PDF file and starting up an activity for it, then finishing itself:

```
package com.commonware.android.cp.files;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;

public class FilesCPDemo extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        startActivity(new Intent(Intent.ACTION_VIEW,
                                Uri.parse(FileProvider.CONTENT_URI
                                    + "test.pdf")));

        finish();
    }
}
```

---

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

```
}
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/FilesCPDemo.java](#))

Here, we use a `CONTENT_URI` published by `FileProvider` as the basis for identifying the file:

```
public static final Uri CONTENT_URI=  
    Uri.parse("content://com.commonsware.android.cp.files/");
```

(from [ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/FileProvider.java](#))

## The Protected Provider

The problem with the preceding example is that any app on the device, if it knows the right `Uri` to ask for, will be able to access the file. This may be desired, but often times it will not be. Instead, you may want to specifically indicate which apps, at specific points in time, can view the file.

Particularly if your objective is to start a third-party app to work with that file, setting up this sort of security is not that difficult. To see how that works, we will walk through the [ContentProvider/GrantUriPermissions](#) sample project. This is a clone of the `ContentProvider/Files` project with this extra security added on.

The way the defense works is by using [Android's permission system](#). We will mark the `ContentProvider` as being not exported, then selectively grant that access to a specific `Uri` to the app that we want to view our file.

### Step #1: Mark the Provider as Not Exported

Putting `android:exported="false"` on the `<provider>` element indicates that no app has the ability to make requests of your `ContentProvider`, except for specific cases where you authorize it:

```
<provider  
    android:name="FileProvider"  
    android:authorities="com.commonsware.android.cp.files"  
    android:exported="false"  
    android:grantUriPermissions="false">  
    <grant-uri-permission android:path="/test.pdf"/>  
</provider>
```

(from [ContentProvider/GrantUriPermissions/app/src/main/AndroidManifest.xml](#))

With no other changes, if we tried to use the app, the third-party PDF viewer would crash when trying to read our PDF file from the Uri.

### Step #2: Grant Access to the Uri

To allow third parties to get access only when we specify, we need to make a few more changes.

This `<provider>` element also has `android:grantUriPermissions="false"`. That is the default value for this attribute, shown here purely for illustration purposes. It also has a `<grant-uri-permissions>` child element, listing the local path (within the ContentProvider) to our PDF file.

The `<grant-uri-permissions>` element (or elements, plural) allow us to override the permission requirement for certain pieces of content, granting access to that content on a per-request basis. There are three possibilities:

1. If `android:grantUriPermissions` is true, then we will be able to grant access to any content within our provider
2. If `android:grantUriPermissions` is false, but we have `<grant-uri-permissions>` sub-elements, we can only grant access to the content identified by the Uri paths specified in those sub-elements
3. If `android:grantUriPermissions` is false, and we have no `<grant-uri-permissions>` sub-elements (the default case), we cannot grant access to any content within our provider

In this case, we specify that we will only grant access to `/test.pdf`. Since that is the only content in this provider, we could have the same net effect by setting `android:grantUriPermissions` to true.

Then, when we create an Intent used to interact with another component, we can include a flag indicating what permission we wish to grant:

```
package com.commonware.android.cp.perms;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;

public class FilesCPDemo extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
    }
}
```

---

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

```
Intent i=new Intent(Intent.ACTION_VIEW, Uri.parse(FileProvider.CONTENT_URI + "test.pdf"));

i.addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);
startActivity(i);
finish();
}
}
```

(from [ContentProvider/GrantUriPermissions/app/src/main/java/com/commonsware/android/cp/perms/FilesCPDemo.java](#))

In this revised version of our activity, we add `FLAG_GRANT_READ_URI_PERMISSION` to the Intent used with `startActivity()`. This will grant the activity that responds to our Intent read access to the specific Uri in the Intent, overriding the exported status. That is why, when you run this app on a device, the PDF viewer will still be able to view the file.

There is also `FLAG_GRANT_WRITE_URI_PERMISSION` for granting write access, not needed here, as our provider only supports read access.

While this is most commonly used with `startActivity()` (e.g., allowing a mail program limited access to your attachments provider), this can also be used with `startService()`, `bindService()`, and the various flavors of sending broadcasts (e.g., `sendBroadcast()`).

## The Stream Provider

Sometimes, we want a provider that looks like the local-file provider from the preceding section... but we do not have a file. Instead, we have data in some other form, such as a byte array, or a String, or an InputStream. Writing that material to a file may be problematic, or even counterproductive.

For example, imagine an app that stores data on the user's behalf in an encrypted fashion. One such file is a PDF, that the user would like to view. There are PDF viewers that can view files served via `content://Uri` values, as the previous section demonstrated... but that assumes an unencrypted file. While we could decrypt the file, writing the decrypted results to another file, and serve the decrypted data to the PDF viewer, now we have a persistent decrypted version of the data. That opens a window of time when the data might be accessed by people with nefarious intent, which is something we are trying to avoid by using the encrypted store in the first place. Rather, it would be nice if we could decrypt the data *on the fly* and give that decrypted result to the PDF viewer. Of course, there are security risks intrinsic to that too — after all, we do not know what the PDF viewer might do with the unencrypted data — but it is at least an improvement.

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

The good news is that Android does support streaming options for `openFile()`-style `ContentProvider` implementations. However, as one might expect, they are not the simplest things to implement.

In this section, we will examine the [ContentProvider/Pipe](#) sample project. This is a near clone of the `ContentProvider/Files` sample from the preceding section. However, rather than simply handing the file to Android to serve as content, we will stream it in ourselves. In principle, as part of this streaming, we could be decrypting it from an encrypted state. Since this sample shares much code with the previous sample, we will focus solely on the changes here.

Note that this sample was inspired by the sample found at <https://github.com/nandeeshwar/Pfd-Create-Pipe>.

### The Pipes

Starting with API Level 9, it is possible to create a pipe between two processes, from the Android SDK, via `ParcelFileDescriptor`. In the previous section, we saw how `ParcelFileDescriptor` could be used to open a local file and make that available to other processes — the `createPipe()` method gives us a pipe.

The “pipe” returned by `createPipe()` is a two-element array of `ParcelFileDescriptor` objects. The first element in the array represents the “read” end of the pipe. In our case, that is the end that should be used by a PDF viewer to read in the file contents. The second element of the array represents the “write” end of the pipe, which we will use to supply the file’s contents to the “read” end (and to the PDF viewer by extension).

### The Revised `openFile()`

With that in mind, here is our revised `openFile()` method:

```
@Override
public ParcelFileDescriptor openFile(Uri uri, String mode)
    throws FileNotFoundException {
    ParcelFileDescriptor[] pipe=null;

    try {
        pipe=ParcelFileDescriptor.createPipe();
        AssetManager assets=getContext().getAssets();

        new TransferThread(assets.open(uri.getLastPathSegment()),
```

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

```
        new AutoCloseOutputStream(pipe[1])).start();
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception opening pipe", e);
        throw new FileNotFoundException("Could not open pipe for: "
            + uri.toString());
    }

    return(pipe[0]);
}
```

(from [ContentProvider/Pipe/app/src/main/java/com/commonsware/android/cp/pipe/PipeProvider.java](#))

We create our pipe via `createPipe()`, then get an `InputStream` on our PDF file stored as an asset — unlike the `ContentProvider/Files` sample, we do not need to copy the asset to a local file now. We then kick off a background thread, implemented in an inner class named `TransferThread`, to actually copy the data from the asset to the write end of the pipe.

Rather than supply `TransferThread` with a `ParcelFileDescriptor` for the write end of the pipe, we supply an `OutputStream`. Specifically, we pass in a `ParcelFileDescriptor.AutoCloseOutputStream`. This is an `OutputStream` that knows to close the `ParcelFileDescriptor` when we close the stream. Otherwise, it behaves like a fairly typical `OutputStream`.

### The Transfer

`TransferThread` is a fairly conventional copy-data-from-stream-to-stream implementation:

```
static class TransferThread extends Thread {
    InputStream in;
    OutputStream out;

    TransferThread(InputStream in, OutputStream out) {
        this.in=in;
        this.out=out;
    }

    @Override
    public void run() {
        byte[] buf=new byte[1024];
        int len;

        try {
```

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

```
while ((len=in.read(buf)) >= 0) {
    out.write(buf, 0, len);
}

in.close();
out.flush();
out.close();
}
catch (IOException e) {
    Log.e(getClass().getSimpleName(),
        "Exception transferring file", e);
}
}
}
```

(from [ContentProvider/Pipe/app/src/main/java/com/commonsware/android/cp/pipe/PipeProvider.java](#))

Here, we read in data in 1KB blocks from the `InputStream` (our asset) and write the data to our `OutputStream` (obtained from the `ParcelFileDescriptor`).

### The Results

Our activity logic has not substantially changed. We still create an `ACTION_VIEW` Intent on the `content://Uri` from our provider, pointing to our `test.pdf` asset. Any PDF viewer capable of handling `content://Uri` values will use a `ContentResolver` to open an `InputStream` for our `Uri`. In the `ContentProvider/Files` sample, that `InputStream` would receive the contents of the file directly from Android. In this new sample, that `InputStream` is reading in bytes off of our pipe, until such time as it has read in all the streamed data and we have closed the `OutputStream`.

Not every possible consumer of a `Uri` will be able to work with our stream, though. For example, `MediaPlayer` expects to be able to move forwards and backwards within the stream, and while that works for file-backed `ParcelFileDescriptors`, it does not work for those representing a pipe. Hence, `MediaPlayer` will crash when trying to use a `Uri` to a pipe-based stream, which is certainly unfortunate.

The author would like to thank Reuben Scratton for his assistance in [tracking down this MediaPlayer limitation](#).

### FileProvider

The Android Support package now contains its own implementation of a

FileProvider that greatly simplifies serving files from internal or external storage to another app.

Here, we will see Google's FileProvider in action via the [ContentProvider/V4FileProvider](#) sample project. This is a near clone of the ContentProvider/Pipe sample from the preceding section, just leveraging FileProvider to help us serve a file from internal storage.

### The Rationale

The [documentation for FileProvider](#) states:

Apps should generally avoid sending raw filesystem paths across process boundaries, since the receiving app may not have the same access as the sender. Instead, apps should send Uri backed by a provider like FileProvider.

This is not just an issue for passing files from internal storage to other apps. On Android 4.2+ tablets, it could even be an issue for external storage, as each user account gets its own portion of external storage. There may be scenarios in which your app (associated with one user) winds up needing to pass the contents of a file on external storage to another app (associated with another user). Regular filesystem paths will not work in this case, as one user account cannot directly access another user account's files, even on external storage.

### The Sources of Files

Google's FileProvider offers automatic serving of files from a few root points:

- `getFilesDir()` (i.e., the standard portion of internal storage for your app)
- `getCacheDir()` (i.e., internal storage, but files that the OS can purge if needed to free up disk space)
- `Environment.getExternalStorageDirectory()` (i.e., the root of external storage)
- `getExternalFilesDir(null)` and `getExternalCacheDir()` (i.e., unique directories on external storage for your app)

For each of these, you will be able to specify a specific subdirectory's worth of files that should be served, if you do not want the entire directory's contents published via FileProvider. You will also be able to specify an alias, which serves as the first path segment (after the authority in the content:// Uri) — FileProvider maps that path segment to a specific location of files to serve.

## The Manifest Entry

The information about what files to serve comes in the form of an XML resource file. You can name the file whatever you like, but its content needs to be a root `<paths>` element, with a series of children for the different directories you wish to serve. Those directories will be denoted via child elements with specific names:

- `<files-path>` for `getFilesDir()`
- `<cache-path>` for `getCacheDir()`
- `<external-path>` for `Environment.getExternalStorageDirectory()`
- `<external-files-path>` for `getExternalFilesDir(null)`
- `<external-cache-path>` for `getExternalCachePath()`

Note that the latter two require version 24.2.0 or higher of the support library, as they are fairly new.

For example, our sample project has a `res/xml/provider_paths.xml` file with the following contents:

```
<?xml version="1.0" encoding="utf-8"?>
<paths>
  <files-path name="stuff" />
</paths>
```

(from [ContentProvider/V4FileProvider/app/src/main/res/xml/provider\\_paths.xml](#))

Here, we are saying that we want to serve the contents of `getFilesDir()`, using a virtual root path of `stuff`. With an authority of `com.commonware.android.cp.v4file`, this means that a `Uri` of `content://com.commonware.android.cp.v4file/stuff/test.pdf` would serve up a `test.pdf` file in the `getFilesDir()` directory.

The optional `path` attribute of the `<files-path>`, etc. elements indicates a particular subdirectory, relative to the element-specific root, that should be used as the source of files. So, for example, had the `provider_paths.xml` file looked like:

```
<?xml version="1.0" encoding="utf-8"?>
<paths xmlns:android="http://schemas.android.com/apk/res/android">
  <files-path name="stuff" path="help/" />
</paths>
```

...then `content://com.commonware.android.cp.v4file/stuff/test.pdf` would map to `help/test.pdf` inside of `getFilesDir()`.

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

You then point to this XML resource from a `<meta-data>` element in the `<provider>` element in the manifest, teaching `FileProvider` what to serve. For example, our `<provider>` element in this sample app is:

```
<provider
  android:name="LegacyCompatFileProvider"
  android:authorities="com.commonware.android.cp.v4file"
  android:exported="false"
  android:grantUriPermissions="true">
  <meta-data
    android:name="android.support.FILE_PROVIDER_PATHS"
    android:resource="@xml/provider_paths"/>
</provider>
```

(from [ContentProvider/V4FileProvider/app/src/main/AndroidManifest.xml](#))

Here, our `android:name` points to a `LegacyCompatFileProvider` class that we will examine shortly. We still provide the `android:authorities` value, along with any permission rules that we want. Beyond that, we have a `<meta-data>` element, with an `android:name` of `android.support.FILE_PROVIDER_PATHS`, that points to our XML resource with the path information.

You will also notice that our `android:exported` attribute is set to `false`. As it turns out, `FLAG_GRANT_READ_URI_PERMISSION` trumps the exported status of a provider. If you pass a `Uri` to an activity using `FLAG_GRANT_READ_URI_PERMISSION`, the activity will be able to read the contents of that `Uri`, even if the provider itself is not exported.

## The Legacy Compatibility

`LegacyCompatFileProvider` is a simple subclass of `FileProvider`, one that overrides `query()` and wraps its `Cursor` in a `LegacyCompatCursorWrapper` to try to improve compatibility with ill-behaved clients:

```
package com.commonware.android.cp.v4file;

import android.database.Cursor;
import android.net.Uri;
import android.support.v4.content.FileProvider;
import com.commonware.cwac.provider.LegacyCompatCursorWrapper;

public class LegacyCompatFileProvider extends FileProvider {
    @Override
    public Cursor query(Uri uri, String[] projection, String selection, String[] selectionArgs, String
sortOrder) {
        return(new LegacyCompatCursorWrapper(super.query(uri, projection, selection, selectionArgs,
sortOrder)));
    }
}
```

```
}  
}
```

(from [ContentProvider/V4FileProvider/app/src/main/java/com/commonsware/android/cp/v4file/LegacyCompatFileProvider.java](#))

### The Usage

At this point, the provider is ready for use, insofar as we can specify Uri values like `content://com.commonsware.android.cp.v4file/stuff/test.pdf` and get results. Of course, we actually need to have files in our internal storage, and we need to use such a Uri.

Hence, our activity combines the unpack-the-file-from-assets logic from our own providers in earlier samples, plus starts up a PDF viewer on our designated `test.pdf` file:

```
package com.commonsware.android.cp.v4file;  
  
import android.app.Activity;  
import android.content.Intent;  
import android.content.res.AssetManager;  
import android.os.Bundle;  
import android.support.v4.content.FileProvider;  
import android.util.Log;  
import java.io.File;  
import java.io.FileOutputStream;  
import java.io.IOException;  
import java.io.InputStream;  
  
public class FilesCPDemo extends Activity {  
    private static final String AUTHORITY="com.commonsware.android.cp.v4file";  
  
    @Override  
    public void onCreate(Bundle state) {  
        super.onCreate(state);  
  
        File f=new File(getFilesDir(), "test.pdf");  
  
        if (!f.exists()) {  
            AssetManager assets=getAssets();  
  
            try {  
                copy(assets.open("test.pdf"), f);  
            }  
            catch (IOException e) {  
                Log.e("FileProvider", "Exception copying from assets", e);  
            }  
        }  
    }  
}
```

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

```
}

Intent i=
    new Intent(Intent.ACTION_VIEW,
        FileProvider.getUriForFile(this, AUTHORITY, f));

i.addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);

startActivity(i);
finish();
}

static private void copy(InputStream in, File dst) throws IOException {
    FileOutputStream out=new FileOutputStream(dst);
    byte[] buf=new byte[1024];
    int len;

    while ((len=in.read(buf)) > 0) {
        out.write(buf, 0, len);
    }

    in.close();
    out.close();
}
}
```

(from [ContentProvider/V4FileProvider/app/src/main/java/com/commonsware/android/cp/v4file/FilesCPDemo.java](#))

FileProvider offers a handy `getUriForFile()` static helper method that will return a `Uri` for a given file, incorporating our specified content provider authority.

The result of running this activity is the same as the other file-serving provider samples from this chapter: a PDF viewer (if one is available) will display the `test.pdf` file.

## StreamProvider

FileProvider is rather nice: you can serve up typical file-based content without having to roll your own implementation of `ContentProvider` and `openFile()`. However, it only supports a few sources of data.

The author of this book has written `StreamProvider`, a fork of `FileProvider` that adds support for serving content from assets and raw resources. Plus, through subclassing, you can readily serve up content from other sources as well.

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

StreamProvider can be found in [the CWAC-Provider project](#).

You can add this library to your Android Studio project much in the same way as you can other CWAC libraries: add the CWAC repository and request the dependency:

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    implementation 'com.commonsware.cwac.provider:0.5.0'
}
```

Once you have added the CWAC-Provider dependency to your project, you use it much the same as you would use FileProvider:

- Define an XML metadata file with a <paths> root element, containing one or more elements describing what you want the provider to serve
- Add com.commonsware.cwac.provider.StreamProvider as a <provider> to your manifest, under your own android:authority, with a <meta-data> element (with a name of com.commonsware.cwac.provider.STREAM\_PROVIDER\_PATHS), pointing to that XML metadata

```
<provider
    android:name="com.commonsware.cwac.provider.StreamProvider"
    android:authorities="..."
    android:exported="false"
    android:grantUriPermissions="true">
    <meta-data
        android:name="com.commonsware.cwac.provider.STREAM_PROVIDER_PATHS"
        android:resource="@xml/..." />
    <meta-data
        android:name="com.commonsware.cwac.provider.USE_LEGACY_CURSOR_WRAPPER"
        android:value="true" />
</provider>
```

- Consider adding the USE\_LEGACY\_CURSOR\_WRAPPER <meta-data> element, shown in the above example, to automatically add in LegacyCompatCursorWrapper support, described elsewhere in this chapter
- Use FLAG\_GRANT\_READ\_URI\_PERMISSION and

FLAG\_GRANT\_WRITE\_URI\_PERMISSION in Intent objects you use to have third parties use the files the StreamProvider serves, to allow those apps selective, temporary access to the file

### Exporting and Usage Patterns

If your StreamProvider is exported, all of your streams will be considered read-only, regardless of any other configuration. Mostly, this mode is here for cases where you need a streaming provider and cannot grant Uri permissions (e.g., [implementing a ChooserTargetService](#)).

If your StreamProvider is not exported, and it has android:grantUriPermissions set, then you can control, on a per-Uri basis, which clients get access to your streams. This works identically to how FileProvider works. Whether a particular source of streams is read-only or read-write will depend on whether the stream is a file and your metadata configuration.

Wherever possible, elect to not export the provider and use FLAG\_GRANT\_READ\_URI\_PERMISSIONS or similar techniques to selectively grant access to your content.

Note that the exported-and-read-only rule is on a per-provider basis. If you have some content that needs to be published globally and others that are not:

- Use StreamProvider and one <provider> element for one set of content, with one authority and android:exported setting
- Subclass StreamProvider and have a separate <provider> element for the other set of content, with a separate authority and android:exported setting

### Metadata Elements

Google's FileProvider supports:

- <files-path> for serving files from your app's getFilesDir()
- <external-path> for serving files from Environment.getExternalStorageDirectory()
- <cache-path> for serving files from your app's getCacheDir()
- <external-files-path> for serving files from getExternalFilesDir()
- <external-cache-path> for serving files from getExternalCacheDir()

Each of those take a name attribute, indicating the first path segment of the Uri that

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

should identify this particular source of files. For example, a name of foo would mean that content://your.authority.here/foo/... would look for a ... file in that particular element's source of files.

Each of those optionally take a path attribute, indicating a subdirectory under the element-defined root to use as the source of files, rather than the root itself. So, a <files-path> with a path="stuff" attribute would serve files from the stuff/ subdirectory within getFilesDir(). Note that path can point to a file as well, to limit access to a single file rather than a directory. Note that path is required for <files-path>, so you do not accidentally serve everything under getFilesDir().

Also, each can optionally take a readOnly attribute. If this is set to true, then the files will be readable, but not writeable.

<external-files-path> also can take an optional dir attribute. If missing, the files are served from getExternalFilesDir(). If a valid value of dir is supplied, that value is passed into getExternalFilesDir(). As such, dir is limited to be one of the Environment.DIRECTORY\_\* constants:

- Alarms
- DCIM
- Documents
- Download
- Movies
- Music
- Notifications
- Pictures
- Podcasts
- Ringtones

However, you cannot have *both* <external-files-path> with no dir (indicating that you are serving from getExternalFilesDir(null)) *and* one or more <external-files-path> elements with dir values, as they will conflict.

StreamProvider adds support for:

- <raw-resource> for serving a particular raw resource, where the path is the name of the raw resource (without file extension)
- <asset> for serving files from assets/
- <dir-path>, for serving files from locations identified by getDir()
- <external-public-path>, for serving files from locations identified by

---

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

```
Environment.getExternalStoragePublicDirectory()
```

Hence, `StreamProvider` is especially useful when you want to package some content — such as a PDF file for online help — that you want to serve from your app. Just drop the file in `assets/` in your project, set up `StreamProvider` to serve up assets, and use an appropriate `Intent` with `startActivity()` to view that file.

In the case of `<dir-path>`, two attributes are required:

- `dir`, which indicates what directory to serve (this is passed into `getDir()`)
- `path`, which serves its normal role, to determine what to serve from the directory identified by `dir`

In the case of `<external-public-path>`, `dir` is required. It needs to be the string value of one of the `Environment.DIRECTORY_*` constants, listed above.

### Assets and Gradle

For files you are looking to share from your app's `assets/`, you will need to teach the build system to avoid compressing those files. While annoying, it helps `StreamProvider` be more compatible with various client apps.

To do this, add an `aaptOptions` closure to your `android` closure in your module's `build.gradle` file. For example, you might have:

```
android {
    compileSdkVersion 25
    buildToolsVersion "25.0.0"

    aaptOptions {
        noCompress 'pdf', 'mp4', 'ogg'
    }
}
```

This would tell Gradle and the build system to not compress files ending in `pdf`, `mp4`, and `ogg`. For your own project, you would choose the file extensions of relevance for the content that you are looking to serve out of `assets/`.

### I Can Haz Uri?

`FileProvider` has the static `getUriForFile()` convenience method, to build a `Uri` pointing to the `FileProvider`, given the `File` that you wish to serve.

`StreamProvider` has a similar `getUriForFile()` method, with three key differences:

1. It only takes the authority string and the `File`; no `Context` is necessary
2. It only works for files, not assets or raw resources
3. Rather than throwing an exception for an unrecognized `File` (the way `FileProvider` does), `StreamProvider` just returns null, indicating that the `File` you requested is not one that the `StreamProvider` is configured to serve

So, you can call `StreamProvider.getUriForFile(AUTHORITY, f)`, for some `String` for your `AUTHORITY` and some `File` (here named `f`) to get a `Uri` pointing to that file, for the purposes of using that `Uri` in an `Intent`, etc.

### Uri Prefixes

Activities that support `ACTION_SEND` through an appropriate `<intent-filter>` are likely to have a flaw: they probably do not validate the `Uri` being supplied via `EXTRA_STREAM`. The [“surreptitious sharing” attack](#) takes advantage of this, tricking the app into sharing *its own content*. While the researchers who reported this flaw focused on `file:Uri` schemes, `content:is` also vulnerable, if your provider’s `Uri` values are predictable.

To help defeat this attack, `StreamProvider` automatically adds a per-install UUID to each `Uri`. So, instead of:

```
content://your.authority.here/something/and/a/relative/path.xml
```

the `Uri` will be something like:

```
content://your.authority.here/9b80af30-4507-4f34-956a-3b47e4a7f27f/  
something/and/a/relative/path.xml
```

By using a UUID unique for this installation of your app, it makes your `Uri` values dependent upon the device. This makes it more difficult for attackers to hand you a valid `Uri` to your own content to send somewhere that you might not want.

On the flip side, this makes constructing your own `Uri` values a bit more difficult. For files, you can use the `getUriForFile()` method. For assets and raw resources, you can call the static `getUriPrefix()` method to get the prefix that is being used, and add that to your `Uri`, such as by using a `Uri.Builder`:

```
PROVIDER
    .buildUpon()
    .appendPath(StreamProvider.getUriPrefix(AUTHORITY))
    .appendPath(path)
    .build()
```

`getUriPrefix()` takes the authority string of your `StreamProvider` and returns the prefix... or null, if by subclassing `StreamProvider`, you disabled this prefix.

### Extending StreamProvider

You are welcome to create subclasses of `StreamProvider`, to extend its capabilities for things that you may want to do in your app. For example, the instrumentation tests for `StreamProvider` demonstrate creating a subclass that supports serving database files, via a custom `<database-path>` element in the metadata.

By and large, you just create a subclass of `StreamProvider` and use it in your `<provider>` element. Of importance are the hooks in `StreamProvider` to allow subclasses to change critical behavior.

### Customizing the Uri Prefix

In your subclass, you have three options for changing the `Uri` prefix used by `StreamProvider`:

- If you want a per-install value, but just not a UUID, override `buildUriPrefix()` and return your own generated `String`
- If you want a fixed prefix, to be used for all installs of this provider, override `getUriPrefix()` and return your constant
- If you do not want a prefix, override `getUriPrefix()` and return `null`

### Supporting Other Stream Locations

You may have content located in directories other than what `StreamProvider` supports out of the box, such as the path for SQLite databases. To handle that, you can add support for new XML elements in the `<paths>` element (e.g., `<database-path>` for serving up databases).

To do this, in your `StreamProvider` subclass, override `buildStrategy()` and return a `StreamStrategy` implementation that is configured for your scenario. For files located in unusual spots, `LocalPathStrategy` should work.

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

In the library's `androidTest/` source set, you will find a `DatabaseProvider` that, at the time of this writing, looks like this:

```
public class DatabaseProvider extends StreamProvider {
    private static final String TAG="database-path";

    @Override
    protected StreamStrategy buildStrategy(Context context,
                                           String tag, String name,
                                           String path, boolean readOnly,
                                           HashMap<String, String> attrs)
        throws IOException {
        if (TAG.equals(tag)) {
            return(new LocalPathStrategy(name,
                context.getDatabasePath(path)));
        }

        return(super.buildStrategy(context, tag, name, path, attrs));
    }
}
```

The parameters to `buildStrategy()` are:

- a `Context`, should you need one (though do not assume it is any particular sort of `Context`)
- the tag we encountered (e.g., `database-path`)
- the value of the name attribute, which all of these need to have, as that is how we determine which `StreamStrategy` handles this request
- the value of the path attribute, which can be `null`
- a `HashMap` of all attributes, in case you wish to have some custom ones

Either return your own `StreamStrategy` instance based off of this information or chain to the superclass' implementation, so `StreamProvider` can handle the stock tags.

If your provider is intrinsically read-only (i.e., it is impossible to modify the content), you can ignore the `readOnly` flag. If, however, your content could be modified, and you support modification, please honor the `readOnly` flag and block modifications/deletions when that is set to true.

### Supporting Other Stream Strategies

You may have content located in things that are not files, such as BLOB columns in a

database. In theory, you can create a custom `StreamStrategy` implementation that handles this. However, this has not been tried much, and so there are likely to be some gaps in the implementation.

That being said, you can examine the built-in strategies (e.g., `AssetStrategy`, `LocalPathStrategy`) and their superclasses (e.g., `AbstractPipeStrategy`) to see how to implement strategies.

### **Adding Columns to `query()`**

You may wish to add other columns in response to a `query()` call, beyond the `OpenableColumns` that `StreamProvider` handles itself and the `_DATA` and `MIME_TYPE` columns added by `LegacyCompatCursorWrapper`.

To do that, override `getValueForQueryColumn()` in your `StreamProvider` subclass. This is supplied the `Uri` of the content and the name of the column requested by the client. You can return an `Object` suitable for stuffing into a `MatrixCursor` to send back – typically, this will be a `String`, `int`, or `long`.

### **Totally Overhauling Uri Handling**

`StreamProvider` itself holds onto a `CompositeStreamStrategy`, delegating all operations to it. If you wish to extend `CompositeStreamStrategy` and do things differently, also override `buildCompositeStrategy()` on your `StreamProvider` subclass, to return the instance of the `CompositeStreamStrategy` that you want the `StreamProvider` to use.

### **Overriding Standard Methods**

You can override standard `ContentProvider` methods (e.g., `getType()`) if needed.

Alternatively, you can override the methods on a `StreamStrategy`, then use that alternative `StreamStrategy` implementation in your `buildStrategy()` method.

### **Adding Support for `insert()` and `update()`**

By default, none of the `StreamStrategy` implementations support `insert()` or `update()`. However, your custom `StreamStrategy` can, whether you are extending one of the stock strategy classes or are implementing your own from scratch.

## CONTENT PROVIDER IMPLEMENTATION PATTERNS

---

First, override `canInsert()` and/or `canUpdate()`, returning `true` for those operations you do support. Then, you can override `insert()` and `update()`, which have the same method signatures on `StreamStrategy` as they do on `ContentProvider`. There, you can do what you wish.

# The Loader Framework

---

A perpetual problem in Android app development is getting long-running work off of the main application thread. In modern times, we have lots of flexible solutions for this.

Another problem in Android app development is holding onto data across configuration changes. In modern times, we have lots of flexible solutions for this as well.

However, back in 2011, we did not have nearly as many options. To try to fill the gap, Android 3.0 introduced the Loader framework. A Loader is an abstraction around loading data and retaining it across configuration changes.

In truth, the Loader framework never became particularly popular. The one scenario where it is worth exploring is when you are trying to query a `ContentProvider` from an activity or fragment. That scenario is what we will focus on in this chapter.

## Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [database access](#)
- [content provider theory](#)
- [content provider implementations](#)

## Introducing the Loader Framework

There are three major pieces to the Loader framework: `LoaderManager`,

LoaderCallbacks, and the Loader itself.

And, for historical reasons, there are two implementations of all three of these:

- one in the framework classes (e.g., `android.app.LoaderManager`)
- one in the Support Library (e.g., `android.support.v4.app.LoaderManager`)

As with the framework implementation of `Fragment`, the framework implementation of `Loader` and `kin` is deprecated as of Android 9.0. The expectation is that you are using `FragmentActivity` (or things that extend from it, like `AppCompatActivity`) and therefore can use the library implementation of `Loader`.

### LoaderManager

`LoaderManager` is your gateway to the `Loader` framework. You obtain one by calling `getSupportLoaderManager()` on your `FragmentActivity` or `Fragment`. Via the `LoaderManager` you can initialize a `Loader`, restart that `Loader` (e.g., if you have a different query to use for loading the data), etc.

### LoaderCallbacks

Much of your interaction with the `Loader`, though, comes from your `LoaderCallbacks` object, such as your activity if that is where you elect to implement the `LoaderCallbacks` interface. Here, you will implement three “lifecycle” methods for consuming a `Loader`:

1. `onCreateLoader()` is called when your activity requests that a `LoaderManager` initialize a `Loader`. Here, you will create the instance of the `Loader` itself, teaching it whatever it needs to know to go load your data
2. `onLoadFinished()` is called when the `Loader` has actually loaded the data — you can take those results and pour them into your UI, such as calling `swapCursor()` on a `CursorAdapter` to supply the fresh `Cursor`’s worth of data
3. `onLoaderReset()` is called when you should stop using the data supplied to you in the last `onLoadFinished()` call (e.g., the `Cursor` is going to be closed), so you can arrange to make that happen (e.g., call `swapCursor(null)` on a `CursorAdapter`)

When you implement the `LoaderCallbacks` interface, you will need to provide the data type of whatever it is that your `Loader` is loading (e.g., `LoaderCallbacks<Cursor>`). If you have several loaders returning different data types, you may wish to consider implementing `LoaderCallbacks` on multiple objects

(e.g., instances of anonymous inner classes), so you can take advantage of the type safety offered by Java generics, rather than implementing `LoaderCallbacks<Object>` or something to that effect.

### Loader

Then, of course, there is `Loader` itself.

Consumers of the `Loader` framework will use some concrete implementation of the abstract `Loader` class in their `LoaderCallbacks.onCreateLoader()` method.

However, there is only one concrete implementation: `CursorLoader`, designed to perform queries on a `ContentProvider`, and described in [a later section](#).

In theory, the `Loader` framework was designed to “load” arbitrary stuff, and while some projects have done that, it is not a particularly popular technique.

## Using CursorLoader

Let’s start off by examining the simplest case: using a `CursorLoader` to asynchronously populate and update a `Cursor` retrieved from a `ContentProvider`. This is illustrated in the [Loaders/LoaderRV](#) sample project, which is the same basic show-the-list-of-gravity-constants sample application that [we examined previously](#), updated to use the `Loader` framework.

In `onViewCreated()` of our `ConstantsFragment`, we ask our `LoaderManager` to initialize a loader:

```
@Override
public void onViewCreated(View v, Bundle savedInstanceState) {
    super.onViewCreated(v, savedInstanceState);

    RecyclerView rv=v.findViewById(android.R.id.list);

    rv.setLayoutManager(new LinearLayoutManager(getActivity()));
    rv.addItemDecoration(new DividerItemDecoration(getActivity(),
        DividerItemDecoration.VERTICAL));
    rv.setAdapter(adapter);

    getActivity().getSupportLoaderManager().initLoader(0, null, this);
}
```

(from [Loaders/LoaderRV/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

## THE LOADER FRAMEWORK

---

The `initLoader()` call on `LoaderManager` (retrieved via `getLoaderManager()`) takes three parameters:

- A locally-unique identifier for this loader
- An optional `Bundle` of data to supply to the loader
- A `LoaderCallbacks` implementation to use for the results from this loader (here set to be the `ConstantsFragment` itself, as it implements the `LoaderManager.LoaderCallbacks<Cursor>` interface)

Shortly thereafter, your `onCreateLoader()` method of the `LoaderCallbacks` will be called. Here, you need to initialize the `Loader` to use for this identifier. You are passed the identifier plus the `Bundle` (if any was supplied). In our case, we want to use a `CursorLoader`:

```
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return(new CursorLoader(getActivity(), Provider.Constants.CONTENT_URI,
        PROJECTION, null, null, null));
}
```

(from [Loaders/LoaderRV/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

`CursorLoader` takes a `Context` plus all of the parameters you would ordinarily use with `query()` on a `ContentResolver`, such as the provider `Uri`.

At this point, the `CursorLoader` will query the provider, but do so on a background thread, so the main application thread is not tied up. When the `Cursor` has been retrieved, it is supplied to your `onLoadFinished()` method of your `LoaderCallbacks`:

```
public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {
    adapter.changeCursor(cursor);
}
```

(from [Loaders/LoaderRV/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

We are using a `RecyclerView.Adapter` named `RVCursorAdapter` as before, and we call its `changeCursor()` method to supply it the `Cursor` to use to populate the `RecyclerView` that is the UI of the fragment.

Your `onLoadFinished()` method will also be called whenever the data represented by your `Uri` changes. That is because the `CursorLoader` is registering a `ContentObserver`, so it will find out about data changes and will automatically requery the `Cursor` and supply you with the updated data.

---

## THE LOADER FRAMEWORK

---

Eventually, `onLoaderReset()` will be called. You are passed a `Cursor` object that you were supplied previously in `onLoadFinished()`. You need to make sure that you are no longer using that `Cursor` at this point — in our case, we swap `null` back into our `RVCursorAdapter`:

```
public void onLoaderReset(Loader<Cursor> loader) {  
    adapter.changeCursor(null);  
}
```

(from [Loaders/LoaderRV/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

And that's pretty much it, at least for using `CursorLoader`. Of course, you need a content provider to make this work, and creating a content provider involves a bit of work.

## What Else Is Missing?

The Loader framework does an excellent job of handling queries in the background. What it does not do is help us with anything else that is supposed to be in the background, such as inserts, updates, deletes, or creating/upgrading the database. It is all too easy to put those on the main application thread and therefore possibly encounter issues. Moreover, since the thread(s) used by the Loader framework are an implementation detail, we cannot use those threads ourselves necessarily for the other CRUD operations.

## What Happens When...?

Here are some common development scenarios and how the Loader framework addresses them.

### ... the Data Behind the Loader Changes?

According to [the Loader documentation](#), “They monitor the source of their data and deliver new results when the content changes”.

The documentation is incorrect.

A Loader *can* “monitor the source of their data and deliver new results when the content changes”. There is nothing in the framework that requires this behavior. Moreover, there are some cases where it is clearly a bad idea to do this — imagine a Loader loading data off of the Internet, needing to constantly poll some server to

look for changes.

The documentation for a Loader implementation should tell you the rules. Android's built-in `CursorLoader` does deliver new results, by means of a behind-the-scenes `ContentObserver`. However, it is not automatic that a Loader deliver new results, and it may be impractical for a Loader to deliver new results.

### ... the Configuration Changes?

Your Loader objects are retained across the configuration change automatically. Barring bugs in a specific Loader implementation, your Loader should then hand the new activity instance the data that was retrieved on behalf of the old activity instance (e.g., the `Cursor`).

Hence, you do not have to do anything special for configuration changes.

### ... the Activity is Destroyed?

The Loader framework triggers a reset of the Loader when the activity is destroyed, which obligates the Loader to release any loaded data.

## Writing a Custom Loader

Perhaps, despite the above issues, and despite the author's assertion that [the Loader framework is a failed abstraction](#), you want to implement a custom Loader.

You have two main choices for doing that:

- If the API that you are using is intrinsically asynchronous, you can extend `Loader`
- If the API that you are using is synchronous, most likely you should extend `AsyncTaskLoader`, which manages an `AsyncTask` for you, giving you a background thread for loading the content

If your API can work either way — synchronously or asynchronously — either option works. In terms of getting the Loader implementation right, you may want to use `AsyncTaskLoader`, as it will ensure that everything is delivered on the right thread. On the other hand, you may have greater control over the nature of the asynchronous work using the API's native asynchronous capability, such as configuring a thread pool.

---

## THE LOADER FRAMEWORK

---

The [HTTP/RetroLoader](#) sample project is a clone of the HTTP/Retrofit sample app from [the chapter on Internet access](#). However, this time, the Retrofit work to load the most recent android Stack Overflow questions will be mediated by a QuestionsLoader.

### Changing the Retrofit Interface

Retrofit offers both synchronous and asynchronous APIs. For the purposes of this sample, we will use the synchronous API, to see how one might implement an AsyncTaskLoader. That, in turn, requires us to modify StackOverflowInterface, having questions() return the SOQuestions directly, rather than by using a callback:

```
package com.commonware.android.retrofit;

import retrofit2.Call;
import retrofit2.http.GET;
import retrofit2.http.Query;

public interface StackOverflowInterface {
    @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
    Call<SOQuestions> questions(@Query("tagged") String tags);
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonware/android/retrofit/StackOverflowInterface.java](#))

Otherwise, this is unchanged from the original edition of this sample.

### Implementing QuestionsLoader

QuestionsLoader is an implementation of AsyncTaskLoader. The documentation for Loader and AsyncTaskLoader leave a lot to be desired. QuestionsLoader is based on “triangulation” between the installed-applications loader included in [the AsyncTaskLoader documentation](#) and [the source code to CursorLoader](#).

Loader uses Java generics. Its declaration requires the type of content being loaded by the Loader. So, QuestionsFragment is a Loader of SOQuestions:

```
public class QuestionsLoader extends AsyncTaskLoader<SOQuestions> {
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonware/android/retrofit/QuestionsLoader.java](#))

### The Constructor

A Loader needs to have a constructor that takes a Context as a parameter. So, QuestionsLoader has one, that chains to the superclass constructor, plus sets up the StackOverflowInterface using Retrofit:

```
public QuestionsLoader(Context context) {
    super(context);

    Retrofit retrofit=
        new Retrofit.Builder()
            .baseUrl("https://api.stackexchange.com")
            .addConverterFactory(GsonConverterFactory.create())
            .build();
    so=retrofit.create(StackOverflowInterface.class);
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java))

### Loading the Questions

The real work for loading the questions comes in loadInBackground(). Subclasses of AsyncTaskLoader need to implement this to return the content being loaded. As the name suggests, loadInBackground() is called on a background thread, so you can take time here.

The key piece of the loadInBackground() of QuestionsFragment is the call to questions() on the StackOverflowInterface, to retrieve the desired questions:

```
@Override
synchronized public SOQuestions loadInBackground() {
    if (isLoadInBackgroundCanceled()) {
        throw new OperationCanceledException();
    }

    try {
        return(so.questions("android").execute().body());
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception loading questions", e);
        throw new OperationCanceledException();
    }
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java))

## THE LOADER FRAMEWORK

---

However, it is possible that before `loadInBackground()` is called, that something cancels the `AsyncTask` in the `AsyncTaskLoader`. A subclass of `AsyncTaskLoader` needs to check `isLoadInBackgroundCanceled()` in `loadInBackground()`, and throw an `OperationCanceledException` if `isLoadInBackgroundCanceled()` returns true.

### Delivering Results

Not only do subclasses of `AsyncTaskLoader` have to load the content, they also have to cache the results of the previous load. So, `QuestionsLoader` has a `lastResult` field, holding onto an `SOQuestions` object.

In `deliverResult()`, we need to do three things:

1. If `isReset()` returns true, indicating that the Loader was reset, we need to clean up anything associated with the previous load results
2. We need to cache the new load results, which are passed into `deliverResult()` as a parameter
3. If the loader is started (`isStarted()` returns true), we need to chain to the superclass implementation of `deliverResult()` to actually deliver the data to the `LoaderCallbacks` implementation:

```
@Override
public void deliverResult(SOQuestions data) {
    if (isReset()) {
        // actual cleanup, if any
    }

    lastResult=data;

    if (isStarted()) {
        super.deliverResult(data);
    }
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java](http://retroloader.app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java))

Here, `lastResult` is just a POJO holding onto other POJOs, so there is nothing specific for us to do in case the loader was reset. If our results were a `Cursor`, a `Bitmap`, or other objects with clear “close” or “release” semantics, you might do that work if `onReset()` returned true.

### Starting, Stopping, and Resetting

You also need to implement three additional methods.

First is `onStartLoading()`. Here is where we use the cached result, delivering it via `deliverResults()`. If we do not have a cached result, we need to call `forceLoad()` to trigger the `AsyncTask` which, in turn, triggers `loadInBackground()` and the rest of the work to actually retrieve the results:

```
@Override
protected void onStartLoading() {
    super.onStartLoading();

    if (lastResult!=null) {
        deliverResult(lastResult);
    }
    else {
        forceLoad();
    }
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java))

There is a corresponding `onStopLoading()`, where we need to call `cancelLoad()`, to cancel the `AsyncTask`:

```
@Override
protected void onStopLoading() {
    super.onStopLoading();

    cancelLoad();
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java))

Finally, there is `onReset()`, where we need to call `onStopLoading()` (as loading should stop if the Loader is reset), plus do any cleanup of our cached results as needed:

```
@Override
protected void onReset() {
    super.onReset();

    onStopLoading();
    // plus any actual cleanup
}
```

---

## THE LOADER FRAMEWORK

---

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java))

### Using QuestionsLoader

You might think that with 70-odd lines of QuestionsLoader code that we would have a corresponding savings in QuestionsFragment.

Alas, no, though it is a bit shorter.

QuestionsFragment now implements LoaderCallbacks instead of Retrofit's Callback interface:

```
public class QuestionsFragment extends ListFragment implements
    LoaderManager.LoaderCallbacks<SQQuestions> {
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java))

In the original QuestionsFragment, we fired off the asynchronous Retrofit work in onCreateView(), and we processed the results in the success() and failure() methods.

Now, we just need to call initLoader(), in this case from onViewCreated():

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    getLoaderManager().initLoader(0, null, this);
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java))

Then, our LoaderCallbacks methods create the QuestionsLoader and apply the results:

```
@Override
public Loader<SQQuestions> onCreateLoader(int id, Bundle args) {
    return(new QuestionsLoader(getActivity()));
}

@Override
public void onLoadFinished(Loader<SQQuestions> loader,
    SQQuestions data) {
    setListAdapter(new ItemsAdapter(data.items));
}
```

```
@Override
public void onLoaderReset(Loader<SOQuestions> loader) {
    setListAdapter(null);
}
```

(from [HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java](http://RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java))

### Considering the Loader Contract

As noted earlier in this chapter, there are three key pieces of the Loader contract: asynchronicity, data retention, and automatic delivery of updates on content changes.

So, how does `QuestionsLoader` stack up?

- `AsyncTaskLoader` provides the asynchronous operation for us, so we inherit that
- All loaders are automatically retained by the `LoaderManager`, so there is nothing specific that we need to do for that
- However, we are unaware of any changes in our content, such as new questions being asked, so we are not delivering updated content to clients of the `QuestionsLoader`

This is a common gap with loader implementations. Occasionally, we may be in position to find out when the content changes. More often, we are not, or the work to find out about content changes has to be handled by a much larger subsystem, beyond a simple Loader subclass.

For example, if we *really* wanted to have `QuestionsLoader` automatically deliver a fresh `SOQuestions` object when new Stack Overflow android questions were asked, we could: use some sort of timing mechanism (e.g., `ScheduledExecutorService`) to poll the Stack Exchange API every so often. However, then we would need to implement some sort of “diff” algorithm to determine if relevant data changed in the JSON response, so we knew to deliver a fresh `SOQuestions` to clients. However, our polling period would be somewhat arbitrary. Frequent polling would consume a fair amount of battery and bandwidth as well.

# The ContactsContract and CallLog Providers

---

One of the more popular stores of data on your average Android device is the contact list. Ever since Android 2.0, Android tracks contacts across multiple different “accounts”, or sources of contacts. Some may come from your Google account, while others might come from Exchange or other services.

This chapter will walk you through some of the basics for accessing the contacts on the device. Along the way, we will revisit and expand upon our knowledge of using a ContentProvider.

First, we will review the [contacts APIs](#), past and present. We will then demonstrate how you can connect to the contacts engine to let users [pick and view contacts](#)... all without your application needing to know much of how contacts work. We will then show how you can [query](#) the contacts provider to obtain contacts and some of their details, like email addresses and phone numbers. We wrap by showing how you can invoke a built-in activity to let the user [add a new contact](#), possibly including some data supplied by your application.

In addition, we will take a peek at the CallLog provider, which, as the name suggests, gives you access to a log of calls made on the device.

## Prerequisites

Understanding this chapter requires that you have read these chapters in addition to the core chapters:

- [content provider theory](#)

- [content provider implementations](#)
- [the Loader framework](#)

## Introducing You to Your Contacts

Android makes contacts available to you via a complex `ContentProvider` framework, so you can access many facets of a contact's data — not just their name, but addresses, phone numbers, groups, etc. Working with the contacts `ContentProvider` set is simple... only if you have an established pattern to work with. Otherwise, it may prove somewhat daunting.

### Organizational Structure

The contacts `ContentProvider` framework can be found as the set of `ContactsContract` classes and interfaces in the `android.provider` package. Unfortunately, there is a dizzying array of inner classes to `ContactsContract`.

Contacts can be broken down into two types: raw and aggregate. Raw contacts come from a sync provider or are hand-entered by a user. Aggregate contacts represent the sum of information about an individual culled from various raw contacts. For example, if your Exchange sync provider has a contact with an email address of `jdoe@foo.com`, and your Facebook sync provider has a contact with an email address of `jdoe@foo.com`, Android may recognize that those two raw contacts represent the same person and therefore combine those in the aggregate contact for the user. The classes relating to raw contacts usually have `Raw` somewhere in their name, and these normally would be used only by custom sync providers.

The `ContactsContract.Contacts` and `ContactsContract.Data` classes represent the “entry points” for the `ContentProvider`, allowing you to query and obtain information on a wide range of different pieces of information. What is retrievable from these can be found in the various `ContactsContract.CommonDataKinds` series of classes. We will see examples of these operations later in this chapter.

### A Look Back at Android 1.6

Prior to Android 2.0, Android had no contact synchronization built in. As a result, all contacts were in one large pool, whether they were hand-entered by users or were added via third-party applications. The API used for this is the `ContactsContentProvider`.

The Contacts ContentProvider still works, as it is merely deprecated in Android 2.0.1, not removed. In practice, it has one big limitation: it will only report contacts added directly to the device (as opposed to ones synchronized from Microsoft Exchange, Facebook, or other sources). As a result, modern Android apps should **not** be using Contacts in general — use ContactsContract.

## Pick a Peck of Pickled People

Back in [the chapter on resource sets and configurations](#), we saw a series of examples of handling [configuration changes](#). Those samples allowed the user to pick a contact and view a contact. There, we focused on the configuration change aspect. Here, let's examine the actual pick and view logic a bit more closely.

### Picking a Contact

When the user picks a contact, we call `startActivityForResult()` with an `ACTION_PICK` Intent:

```
public void pickContact(View v) {
    Intent i=
        new Intent(Intent.ACTION_PICK,
            ContactsContract.Contacts.CONTENT_URI);

    startActivityForResult(i, PICK_REQUEST);
}
```

(from [ConfigChange/Fragments/app/src/main/java/com/commonsware/android/rotation/frag/RotationFragment.java](#))

The Intent has `ContactsContract.Contacts.CONTENT_URI` as its `Uri`. Here, `ContactsContract.Contacts.CONTENT_URI` is defined by the Android SDK and points to the contacts “table” inside the ContactsContract “database”, as it were. Whether there is really a database or a table involved is up to the implementation of ContactsContract, of course.

When we call `startActivityForResult()`, Android needs to find an activity to fulfill this request. However, at the outset, all it has is an action string and a `Uri`. There could be all sorts of activities on the device that advertise that they can pick from a collection identified by a `Uri` starting with the content scheme.

To help refine the request, Android asks the ContactsContract ContentProvider what the MIME type is for this `Uri`. Then, Android knows an action string, a MIME type, and a `Uri`. It so happens that the contacts apps that ship on Android have an

activity that has an `<intent-filter>` that indicates that it can handle `ACTION_PICK` of the relevant MIME type from a content `Uri`. And so that is the activity that the user sees.

The `Uri` that we get back in `onActivityResult()` not only points to the contact that the user picked, but also gives us *temporary read access* to that contact's personally identifying information. In effect, it is as if the normal `READ_CONTACTS` permission requirement was suspended, for this one `Uri`, for our app alone. Once our process terminates, we may no longer have the ability to get at details about that contact via its `Uri`, as this read access is temporary.

### Viewing a Contact

As it turns out, the sample app does not take advantage of the temporary read access. Instead, when the user clicks the “View” button, the app just brings up an activity to go view that contact:

```
public void viewContact(View v) {
    startActivity(new Intent(Intent.ACTION_VIEW, contact));
}
```

(from [ConfigChange/Fragments/app/src/main/java/com/commonsware/android/rotation/frag/RotationFragment.java](#))

Once again, Android has an action string (`ACTION_VIEW`) and a `Uri` (the one that we got in response to the `ACTION_PICK` request). And, once again, Android asks `ContactsContract` for the MIME type of the data associated with this `Uri`, so that the MIME type can help identify the right activity to handle this request. The contacts app that comes on the device should have an activity that complies, and so we can view the contact.

In truth, the only reason why we as developers can count on these activities existing is because of Google Play Services and the Play Store. The Compatibility Definition Document (CDD) that manufacturers must comply with to get Google's proprietary Android apps requires that the device ship with apps that fulfill all of the `<intent-filter>` elements supported by the apps in the Android Open Source Project (AOSP). Hence, for devices that legitimately have the Play Store on them, there should always be an app that offers activities to allow users to pick and view contacts. However, on devices that do *not* legitimately have the Play Store, those activities might not exist. Manufacturers who avoid Google's proprietary apps *should* still aim to comply with the CDD as much as possible, if they want third-party apps like yours to work successfully on those devices. However, there is no contractual requirement that they do, and so, as the saying goes, your mileage may vary

(YMMV).

## Spin Through Your Contacts

The preceding example allows you to work with contacts, yet not actually have any contact data other than a transient `Uri`. All else being equal, it is best to use the contacts system this way, as it means you do not need any extra permissions that might raise privacy issues.

Of course, all else is rarely equal.

Your alternative, therefore, is to execute queries against the contacts `ContentProvider` to get actual contact detail data back, such as names, phone numbers, and email addresses. The [Contacts/Spinners](#) sample application will demonstrate this technique.

## Contact Permissions

Since contacts are privileged data, you need certain permissions to work with them. Specifically, you need the `READ_CONTACTS` permission to query and examine the `ContactsContract` content and `WRITE_CONTACTS` to add, modify, or remove contacts from the system. This only holds true if your code will have access to personally-identifying information, which is why the `Pick` sample above — which just has an opaque `Uri` — does not need any permission.

For example, here is the manifest for the `Contacts/Spinners` sample application:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonware.android.contacts.spinners"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission android:name="android.permission.READ_CONTACTS" />

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.Apptheme">
    <activity
      android:name=".ContactSpinners"
      android:label="@string/app_name">
```

## THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

---

```
<intent-filter>
  <action android:name="android.intent.action.MAIN" />
  <category android:name="android.intent.category.LAUNCHER" />
</intent-filter>
</activity>
</application>
</manifest>
```

(from [Contacts/Spinners/app/src/main/AndroidManifest.xml](#))

And, since this app has a `targetSdkVersion` of 26, we also need to deal with runtime permissions, as `READ_CONTACTS` has a `protectionLevel` of `dangerous`, so we need to ask the user for permission at runtime. To that end, we use the same `AbstractPermissionActivity` seen elsewhere in the book as the base class for our `ContactSpinners` activity, so we can delegate all of the runtime permission logic to `AbstractPermissionActivity`.

### Pre-Joined Data

While the database underlying the `ContactsContract` content provider is private, one can imagine that it has several tables: one for people, one for their phone numbers, one for their email addresses, etc. These are tied together by typical database relations, most likely 1:N, so the phone number and email address tables would have a foreign key pointing back to the table containing information about people.

To simplify accessing all of this through the content provider interface, Android pre-joins queries against some of the tables. For example, you can query for phone numbers and get the contact name and other data along with the number — you do not have to do this join operation yourself.

### The UI

The `ContactSpinners` activity has a `RecyclerView` along with a `Spinner`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <Spinner
    android:id="@+id/spinner"
```

## THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

---

```
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:drawSelectorOnTop="true" />

<android.support.v7.widget.RecyclerView
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="match_parent" />
</LinearLayout>
```

(from [Contacts/Spinners/app/src/main/res/layout/main.xml](#))

In `onReady()` of the activity, we load up the Spinner, plus configure the RecyclerView:

```
@Override
public void onReady() {
    setContentView(R.layout.main);

    Spinner spin=findViewById(R.id.spinner);
    spin.setOnItemSelectedListener(this);

    ArrayAdapter<String> aa=new ArrayAdapter<String>(this,
        android.R.layout.simple_spinner_item,
        getResources().getStringArray(R.array.options));

    aa.setDropDownViewResource(
        android.R.layout.simple_spinner_dropdown_item);
    spin.setAdapter(aa);

    RecyclerView rv=findViewById(android.R.id.list);

    rv.setLayoutManager(new LinearLayoutManager(this));
    rv.addItemDecoration(new DividerItemDecoration(this,
        DividerItemDecoration.VERTICAL));
    adapter=new RVCursorAdapter(getLayoutInflater());
    rv.setAdapter(adapter);
}
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

In particular, we populate the Spinner based on a `<string-array>` resource from the `res/values/arrays.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <string-array name="options">
```

## THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

---

```
<item>Contact Names</item>
<item>Contact Names & Numbers</item>
<item>Contact Names & Email Addresses</item>
</string-array>
</resources>
```

(from [Contacts/Spinners/app/src/main/res/values/arrays.xml](#))

### Reacting to the Spinner

We set up the activity to be the `OnItemSelectedListener` for the Spinner, which means that we have to implement `onItemSelected()` and `onNothingSelected()`:

```
@Override
public void onItemSelected(AdapterView<?> parent,
                           View v, int position, long id) {
    getSupportLoaderManager().initLoader(position, null, this);
}

@Override
public void onNothingSelected(AdapterView<?> parent) {
    // ignore
}
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

When the user selects something in the Spinner — and for the default selection — we will use the Loader framework and use a `CursorLoader` to query the `ContactsContract` `ContentProvider`. In this case, though, we want three different `Cursor` values, one for each option in the Spinner. That will mean that we need three different `CursorLoader` objects. To identify which loader we are going to initialize, we pass in the position of the Spinner to `initLoader()`, so the `0/1/2` value that we get as the position forms our loader ID.

### Loading the Data

In `onCreateLoader()` of our `LoaderCallbacks`, we need to return a `CursorLoader` for whichever `loaderId` was passed in. What varies is the `Uri` that we want to query and the “projection” of “columns” that we want to get back. So, `onCreateLoader()` uses a switch statement to decide what `Uri` and projection to use, then creates a `CursorLoader` based upon that:

```
@Override
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
```

## THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

---

```
String[] projection;
Uri uri;

switch (loaderId) {
    case LOADER_NAMES:
        projection=PROJECTION_NAMES;
        uri=ContactsContract.Contacts.CONTENT_URI;
        break;

    case LOADER_NAMES_NUMBERS:
        projection=PROJECTION_NUMBERS;
        uri=ContactsContract.CommonDataKinds.Phone.CONTENT_URI;
        break;

    default:
        projection=PROJECTION_EMAILS;
        uri=ContactsContract.CommonDataKinds.Email.CONTENT_URI;
        break;
}

return new CursorLoader(this, uri, projection, null, null,
    ContactsContract.Contacts.DISPLAY_NAME);
}
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

The two case values are just constants tied to the positions from the Spinner, defined as static data members:

```
private static final int LOADER_NAMES=0;
private static final int LOADER_NAMES_NUMBERS=1;
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

Similarly, the three projections are defined as static data members:

```
private static final String[] PROJECTION_NAMES=new String[]{
    ContactsContract.Contacts._ID,
    ContactsContract.Contacts.DISPLAY_NAME,
};
private static final String[] PROJECTION_NUMBERS=new String[]{
    ContactsContract.Contacts._ID,
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Phone.NUMBER
};
private static final String[] PROJECTION_EMAILS=new String[]{
    ContactsContract.Contacts._ID,
```

## THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

---

```
ContactsContract.Contacts.DISPLAY_NAME,  
ContactsContract.CommonDataKinds.Email.DATA  
};
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

For the “names” Spinner entry, we are going to retrieve the ID and display name of the contact, using the standard `ContactsContract.Contacts.CONTENT_URI` Uri value.

For the “names and phone numbers” Spinner entry, we still want the display name of the contact, but we also want phone numbers. Fortunately, as mentioned earlier, `ContactsContract` denormalizes its data in response to queries, so we can get the display name of the contact even when we are querying the “table” of phone numbers, via `ContactsContract.CommonDataKinds.Phone.CONTENT_URI`. The same basic process holds true for the “names and emails” entry, where we query `ContactsContract.CommonDataKinds.Email.CONTENT_URI`. Note that we will get somewhat redundant information back — if a contact has two phone numbers, we get two rows in our `Cursor`, both for the same contact, and one per phone number.

We can sort by `DISPLAY_NAME` for all three cases, courtesy of the aforementioned denormalization of the data.

### Showing the Results

We also have to implement `onLoadFinished()`, to take in the `Cursor` that is the result of the query against `ContactsContract` and put the results in the `RecyclerView`. Once again, the rendering will differ a bit based upon whether we are showing just names or names along with other data (e.g., phone numbers). So, we have another `switch` statement, where we determine what columns we want, what layout ID to use, and what roster of widgets in that layout map to those columns:

```
@Override  
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {  
    String[] columns;  
  
    switch (loader.getId()) {  
        case LOADER_NAMES:  
            columns=COLUMNS_NAMES;  
            break;  
  
        case LOADER_NAMES_NUMBERS:  
            columns=COLUMNS_NUMBERS;  
    }  
}
```

## THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

---

```
        break;

        default:
            columns=COLUMNS_EMAILS;
            break;
    }

    adapter.changeCursor(c, columns);
}
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

The lists of columns and views are defined as static data members and map positionally (i.e., the first view is for the first column):

```
private static final String[] COLUMNS_NAMES=new String[]{
    ContactsContract.Contacts.DISPLAY_NAME
};
private static final String[] COLUMNS_NUMBERS=new String[]{
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Phone.NUMBER
};
private static final String[] COLUMNS_EMAILS=new String[]{
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Email.DATA
};
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

Then, we update a RecyclerView.Adapter, named RVCursorAdapter, with the fresh Cursor and column list. That adapter, along with a RecyclerView.ViewHolder implementation named RowHolder, populate a framework-supplied `simple_list_item_2` widget with the 1 or 2 columns that we want from the Cursor:

```
private static class RVCursorAdapter extends RecyclerView.Adapter<RowHolder> {
    private Cursor cursor;
    private final LayoutInflater inflater;
    private String[] columns;

    private RVCursorAdapter(LayoutInflater inflater) {
        this.inflater=inflater;
    }

    @NonNull
    @Override
    public RowHolder onCreateViewHolder(@NonNull ViewGroup parent,
                                       int viewType) {
        View row=
            inflater.inflate(android.R.layout.simple_list_item_2, parent, false);
```

## THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

---

```
        return new RowHolder(row);
    }

    @Override
    public void onBindViewHolder(@NonNull RowHolder holder,
                                int position) {
        cursor.moveToPosition(position);
        holder.bind(cursor, columns);
    }

    @Override
    public int getItemCount() {
        return cursor==null ? 0 : cursor.getCount();
    }

    private void changeCursor(Cursor cursor, String[] columns) {
        if (this.cursor!=null) {
            this.cursor.close();
        }

        this.cursor=cursor;
        this.columns=columns;
        notifyDataSetChanged();
    }

    private void clearCursor() {
        cursor=null;
        notifyDataSetChanged();
    }
}

private static class RowHolder extends RecyclerView.ViewHolder {
    private final TextView text1;
    private final TextView text2;

    RowHolder(View itemView) {
        super(itemView);
        text1=itemView.findViewById(android.R.id.text1);
        text2=itemView.findViewById(android.R.id.text2);
    }

    public void bind(Cursor cursor, String[] columns) {
        int index=cursor.getColumnIndex(columns[0]);

        text1.setText(cursor.getString(index));

        if (columns.length==2) {
            index=cursor.getColumnIndex(columns[1]);
            text2.setText(cursor.getString(index));
        }
    }
}
```

(from [Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java](#))

## Makin' Contacts

Let's now take a peek at the reverse direction: adding contacts to the system. This was never particularly easy and now is... well, different.

First, we need to distinguish between sync providers and other apps. Sync providers are the guts underpinning the accounts system in Android, bridging some existing source of contact data to the Android device. Hence, you can have sync providers for Exchange, Facebook, and so forth. These will need to create raw contacts for newly-added contacts to their backing stores that are being sync'd to the device for the first time. Creating sync providers is outside of the scope of this book for now.

It is possible for other applications to create contacts. These, by definition, will be phone-only contacts, lacking any associated account, no different than if the user added the contact directly. The recommended approach to doing this is to collect the data you want, then spawn an activity to let the user add the contact — this avoids your application needing the `WRITE_CONTACTS` permission and all the privacy/data integrity issues that creates.

To that end, take a look at the [Contacts/Inserter](#) sample project. It defines a simple activity with a two-field UI, with one field apiece for the person's first name and phone number:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1"
    >
    <TableRow>
        <TextView
            android:text="First name:"
        />
        <EditText android:id="@+id/name"
        />
    </TableRow>
    <TableRow>
        <TextView
            android:text="Phone:"
        />
        <EditText android:id="@+id/phone"
            android:inputType="phone"
        />
    </TableRow>
</TableLayout>
```

## THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

---

```
    />
  </TableRow>
  <Button android:id="@+id/insert" android:text="Insert!" />
</TableLayout>
```

(from [Contacts/Inserter/app/src/main/res/layout/main.xml](#))

The trivial UI also sports a button to add the contact:

*Figure 748: The ContactInserter sample application*

When the user clicks the button, the activity gets the data and creates an Intent to be used to launch the add-a-contact activity. This uses the ACTION\_INSERT\_OR\_EDIT action and a couple of extras from the ContactsContract.Intents.Insert class:

```
package com.commonware.android.inserter;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.provider.ContactsContract.Contacts;
import android.provider.ContactsContract.Intents.Insert;
import android.view.View;
import android.widget.Button;
import android.widget.EditText;
```

## THE CONTACTS CONTRACT AND CALLLOG PROVIDERS

---

```
public class ContactsInserter extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        Button btn=(Button)findViewById(R.id.insert);

        btn.setOnClickListener(onInsert);
    }

    View.OnClickListener onInsert=new View.OnClickListener() {
        public void onClick(View v) {
            EditText fld=(EditText)findViewById(R.id.name);
            String name=fld.getText().toString();

            fld=(EditText)findViewById(R.id.phone);

            String phone=fld.getText().toString();
            Intent i=new Intent(Intent.ACTION_INSERT_OR_EDIT);

            i.setType(Contacts.CONTENT_ITEM_TYPE);
            i.putExtra(Insert.NAME, name);
            i.putExtra(Insert.PHONE, phone);
            startActivity(i);
        }
    };
}
```

(from [Contacts/Inserter/app/src/main/java/com/commonsware/android/inserter/ContactsInserter.java](#))

## THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

---

We also need to set the MIME type on the Intent via `setType()`, to be `CONTENT_ITEM_TYPE`, so Android knows what sort of data we want to actually insert. Then, we call `startActivity()` on the resulting Intent. That brings up an add-or-edit activity:

*Figure 749: The add-or-edit-a-contact activity*

## THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

---

... where if the user chooses “Create new contact”, they are taken to the ordinary add-a-contact activity, with our data pre-filled in:

*Figure 750: The edit-contact form, showing the data from the ContactInserter activity*

Note that the user could choose an existing contact, rather than creating a new contact. If they choose an existing contact, the first name of that contact will be overwritten with the data supplied by the ContactsInserter activity, and a new phone number will be added from those Intent extras.

## Looking at the CallLog

A closely-related ContentProvider to ContactsContract is CallLog. As the name suggests, it contains a log of calls for this device, including things like the date/time of the call, the call duration, and the other party on the call (e.g., a phone number).

If you wish to give the user another look at their calls, independent from the UI available on the device (e.g., Dialer app), you might wish to query the CallLog, as we do in the [Contacts/CallLog](#) sample application

### Pondering Permissions

In the beginning, there was no `READ_CALL_LOG` permission. To read the `CallLog` provider, you needed to hold `READ_CONTACTS`. The reason for the `READ_CONTACTS` permission is that the `CallLog` denormalizes the data, copying into its own table contact data about the other party, so that the `CallLog` can remain independent of `ContactsContract`.

In API Level 16, though, they added the `READ_CALL_LOG` permission. If your `minSdkVersion` is 16 or higher, you can just request `READ_CALL_LOG`. If your `minSdkVersion` is lower than that, though, you will want to request both permissions, to make sure that you are covered. You might consider using the `android:maxSdkVersion` attribute on the `READ_CONTACTS` `<uses-permission>` element, as you will not need it on newer devices, unless you are also working with `ContactContract`.

Both `READ_CALL_LOG` and `READ_CONTACTS` are dangerous permissions, and therefore if your `targetSdkVersion` is 23 or higher, you need to request those permissions at runtime. Of course, you only need to request the permissions that you need, and so if your `minSdkVersion` is 16 or higher and you are only using `READ_CALL_LOG`, you only need to request `READ_CALL_LOG` at runtime.

Our sample app uses the same `AbstractPermissionActivity` as did the first sample app in this chapter, though this time our `CallLogConsumerActivity` will request `READ_CALL_LOG` instead of `READ_CONTACTS`.

### Contents of `CallLog.Calls`

The sample app requests the `READ_CALL_LOG` permission, so it can query the `CallLog`:

```
<uses-permission android:name="android.permission.READ_CALL_LOG" />
```

(from [Contacts/CallLog/app/src/main/AndroidManifest.xml](#))

To request this permission when our app launches, this project uses the same `AbstractPermissionActivity` seen elsewhere in the book and profiled in [the chapter on permissions](#). That logic gives us control in an `onReady()` method in our `CallLogConsumerActivity` when we can start setting up the UI and requesting the call log data.

## THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

---

In `onReady()` — among other bits of work that we will explore shortly — we call `initLoader()`, to query the `CallLog` via a `CursorLoader`. The activity itself implements the `LoaderManager.LoaderCallbacks` interface needed by `initLoader()`, and so the activity has the three required `LoaderCallbacks` methods:

```
@Override
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return(new CursorLoader(this, CallLog.Calls.CONTENT_URI,
        PROJECTION, null, null, CallLog.Calls.DATE
            + " DESC"));
}

@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {
    adapter.changeCursor(cursor);
}

@Override
public void onLoaderReset(Loader<Cursor> loader) {
    adapter.changeCursor(null);
}
```

(from [Contacts/CallLog/app/src/main/java/com/commonsware/android/callog/consumer/CallLogConsumerActivity.java](#))

Here, we retrieve the data from the `CallLog.Calls` “table” via its `CONTENT_URI`, asking for the “columns” indicated by the `PROJECTION`:

```
private static final String[] PROJECTION=new String[] {
    CallLog.Calls.NUMBER, CallLog.Calls.DATE };
```

(from [Contacts/CallLog/app/src/main/java/com/commonsware/android/callog/consumer/CallLogConsumerActivity.java](#))

We sort the data descending by date. It would be nice if the documentation for `CallLog` included some indication that this approach was endorsed and supported. Based on the `CallLog` implementation, it should be stable.

### Showing the CallLog

`onLoadFinished()` and `onLoaderReset()` each call a `changeCursor()` method on our adapter. That is an instance of `RVCursorAdapter`, set up in `onReady()`:

```
@Override
public void onReady() {
    adapter=new RVCursorAdapter(getLayoutInflater());
}
```

## THE CONTACTS CONTRACT AND CALLLOG PROVIDERS

---

```
RecyclerView rv=getRecyclerView();

setLayoutManager(new LinearLayoutManager(this));
rv.addItemDecoration(new DividerItemDecoration(this,
    DividerItemDecoration.VERTICAL));
rv.setAdapter(adapter);

getSupportLoaderManager().initLoader(0, null, this);
}
```

(from [Contacts/CallLog/app/src/main/java/com/commonsware/android/calllog/consumer/CallLogConsumerActivity.java](#))

RVCursorAdapter wraps around the Cursor of calendar data:

```
private static class RVCursorAdapter extends RecyclerView.Adapter<RowHolder> {
    private Cursor cursor;
    private final LayoutInflater inflater;

    private RVCursorAdapter(LayoutInflater inflater) {
        this.inflater=inflater;
    }

    @NonNull
    @Override
    public RowHolder onCreateViewHolder(@NonNull ViewGroup parent,
        int viewType) {
        View row=inflater.inflate(R.layout.row, parent, false);

        return new RowHolder(row);
    }

    @Override
    public void onBindViewHolder(@NonNull RowHolder holder,
        int position) {
        cursor.moveToPosition(position);
        holder.bind(cursor);
    }

    @Override
    public int getItemCount() {
        return cursor==null ? 0 : cursor.getCount();
    }

    private void changeCursor(Cursor cursor) {
        if (this.cursor!=null) this.cursor.close();
        this.cursor=cursor;
        notifyDataSetChanged();
    }
}
```

(from [Contacts/CallLog/app/src/main/java/com/commonsware/android/calllog/consumer/CallLogConsumerActivity.java](#))

changeCursor() closes the old Cursor (if there was one), holds onto the new one, and tells the RecyclerView to reload its contents, as our data has changed.

## THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

---

Our row layout (res/layout/row.xml) has two TextView widgets for the two pieces of data that we want to display:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content">

    <TextView
        android:id="@+id/date"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_alignParentEnd="true"
        android:layout_alignParentRight="true"
        android:textSize="28sp" />

    <TextView
        android:id="@+id/number"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_alignParentLeft="true"
        android:layout_alignParentStart="true"
        android:textSize="28sp" />
</RelativeLayout>
```

(from [Contacts/CallLog/app/src/main/res/layout/row.xml](#))

Each row in the list is managed by a RowHolder:

```
private static class RowHolder extends RecyclerView.ViewHolder {
    private final TextView date;
    private final TextView number;

    RowHolder(View itemView) {
        super(itemView);
        date=itemView.findViewById(R.id.date);
        number=itemView.findViewById(R.id.number);
    }

    public void bind(Cursor cursor) {
        number.setText(cursor.getString(0));

        long time=cursor.getLong(1);
        String formattedTime=DateUtils.formatDateTime(date.getContext(), time,
            DateUtils.FORMAT_ABBREV_RELATIVE);

        date.setText(formattedTime);
    }
}
```

## THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

---

```
}  
}
```

(from [Contacts/CallLog/app/src/main/java/com/commonsware/android/callog/consumer/CallLogConsumerActivity.java](#))

The DATE column is returned to use as milliseconds since the Unix epoch, so we use `DateUtils.formatDateTime()` to convert that into something that is human-readable and matches the user's chosen locale settings.

The result is a list of calls by date and phone number.

# The CalendarContract Provider

---

The Android Open Source Project (AOSP) has had a Calendar application from its earliest days. This application originally was designed to sync with Google Calendar, later extended to other sync sources, such as Microsoft's Exchange. However, this application was not part of the Android SDK, so there was no way to access it from your Android application.

At least, no officially documented and supported way.

Many developers poked through the AOSP source code and found that the Calendar application had a `ContentProvider`. Moreover, this `ContentProvider` was exported (by default). So many developers used undocumented and unsupported means for accessing calendar information. This occasionally broke, as Google modified the Calendar app and changed these pseudo-external interfaces.

Android 4.0 added official SDK support for interacting with the Calendar application via its `ContentProvider`. As part of the SDK, these new interfaces should be fairly stable — if nothing else, they should be supported indefinitely, even if new and improved interfaces are added sometime in the future. So, if you want to tie into the user's calendars, you can. Bear in mind, though, that the new `CalendarContract` `ContentProvider` is not identical to the older undocumented providers, so if you are aiming to support pre-4.0 devices, you have some more work to do.

Of course, similar to the `ContactsContract` `ContentProvider`, the `CalendarContract` `ContentProvider` is severely lacking in documentation, and anything not documented is subject to change.

## Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [content provider theory](#)
- [content provider implementations](#)

## You Can't Be a Faker

While the Android emulator has the `CalendarContract` `ContentProvider`, it will do you little good. While you can define a Google account on the emulator, the emulator lacks any ability to sync content with that account. Hence, you cannot see any events for your calendars in the Calendar app, and you cannot access any calendar data via `CalendarContract`.

You may be able to use an `outlook.com` account, [to sync with an Outlook calendar](#).

Otherwise, in order to test your use of `CalendarContract`, you will need to have hardware that runs Android 4.0 (or higher), with one or more accounts set up that have calendar data.

## Do You Have Room on Your Calendar?

As a `ContentProvider`, `CalendarContract` is not significantly different from any other such provider that Android supplies or that you write yourself, in that there are `Uri` values representing collections of data, upon which you can query, insert, update, and delete as needed.

The two main collections of data that you are likely to be interested in are `CalendarContract.Calendars` (the collection of all defined calendars) and `CalendarContract.Events` (the collection of all defined events across all calendars). Each of those has a `CONTENT_URI` static data member that you would use with `ContentResolver` or a `CursorLoader` to perform operations on those collections. An entry in `CalendarContract.Events` points back to its corresponding calendar via a `CALENDAR_ID` column that you can query upon; the remaining columns on `CalendarContract.Events` have names apparently designed to match with the [iCalendar specification](#) (e.g., `DTSTART` and `DTEND` for the start and end times of the event).

Three other collections may be of interest:

1. `CalendarContract.Instances` has one entry per occurrence of an event, so recurring events get multiple rows
2. `CalendarContract.Attendees` has information about each attendee of an event
3. `CalendarContract.Reminders` has information about each reminder scheduled for an event (e.g., when to remind the user), for those events with associated reminders

Each of those ties back to its associated `CalendarContract.Events` row via an `EVENT_ID` column.

## Calendar Permissions

There are two permissions for working with `CalendarContract`: `READ_CALENDAR` and `WRITE_CALENDAR`. As you might expect, querying `CalendarContract` requires the `READ_CALENDAR` permission; modifying `CalendarContract` data requires the `WRITE_CALENDAR` permission.

These permissions have existed since Android's earliest days, even in the SDK, as a side effect of the "meat cleaver" approach the core Android team employed to create the initial SDK. Hence, you can request these permissions in the manifest with any Android build target, without compiler errors. Of course, actually referring to `CalendarContract` will require a build target (i.e., `compileSdkVersion` in Android Studio) of API Level 14 or higher.

## Querying for Events

For example, let's populate a `RecyclerView` with the roster of all events the user has across all calendars, using a `CursorLoader`, showing the name of each event, the event's start date, and the event's end date. You can find this in the [Calendar/Query](#) sample project in the book's source code.

## The Permission

Our manifest has the `READ_CALENDAR` permission, as you would expect:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
```

## THE CALENDARCONTRACT PROVIDER

---

```
package="com.commonware.android.cal.query"
android:versionCode="1"
android:versionName="1.0">

<uses-permission android:name="android.permission.READ_CALENDAR"/>

<application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
        android:name=".CalendarQueryActivity"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>

</manifest>
```

(from [Calendar/Query/app/src/main/AndroidManifest.xml](#))

To request this permission when our app launches, this project uses the same `AbstractPermissionActivity` seen elsewhere in the book and profiled in [the chapter on permissions](#). That logic gives us control in an `onReady()` method in our `CalendarQueryActivity` when we can start setting up the UI and requesting the calendar data.

### The CursorLoader

As part of our `onReady()` work, we call `initLoader()` on a `LoaderManager`:

```
getSupportLoaderManager().initLoader(0, null, this);
```

(from [Calendar/Query/app/src/main/java/com/commonware/android/cal/query/CalendarQueryActivity.java](#))

That triggers a call to our `LoaderCallbacks` methods:

```
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return(new CursorLoader(this, CalendarContract.Events.CONTENT_URI,
        PROJECTION, null, null,
        CalendarContract.Events.DTSTART));
}
```

## THE CALENDARCONTRACT PROVIDER

---

```
public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {
    adapter.changeCursor(cursor);
}

public void onLoaderReset(Loader<Cursor> loader) {
    adapter.changeCursor(null);
}
```

(from [Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java](#))

`onCreateLoader()` requests data from `CalendarContract.Events.CONTENT_URI`, the `Uri` that represents the virtual table of calendar event data. We request three columns, identified by the `PROJECTION`:

```
private static final String[] PROJECTION=
    new String[] { CalendarContract.Events.TITLE,
        CalendarContract.Events.DTSTART,
        CalendarContract.Events.DTEND };
```

(from [Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java](#))

`onCreateLoader()` also requests that the calendar data be sorted by starting date.

## The RecyclerView

`onLoadFinished()` and `onLoaderReset()` each call a `changeCursor()` method on our adapter. That is an instance of `RVCursorAdapter`, set up in `onReady()`:

```
@Override
public void onReady() {
    adapter=new RVCursorAdapter(getLayoutInflater());

    RecyclerView rv=getRecyclerView();

    setLayoutManager(new LinearLayoutManager(this));
    rv.addItemDecoration(new DividerItemDecoration(this,
        DividerItemDecoration.VERTICAL));
    rv.setAdapter(adapter);

    getSupportLoaderManager().initLoader(0, null, this);
}
```

(from [Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java](#))

`RVCursorAdapter` wraps around the `Cursor` of calendar data:

## THE CALENDARCONTRACT PROVIDER

---

```
private static class RVCursorAdapter extends RecyclerView.Adapter<RowHolder> {
    private Cursor cursor;
    private final LayoutInflater inflater;

    private RVCursorAdapter(LayoutInflater inflater) {
        this.inflater=inflater;
    }

    @NonNull
    @Override
    public RowHolder onCreateViewHolder(@NonNull ViewGroup parent,
                                       int viewType) {
        View row=inflater.inflate(R.layout.row, parent, false);

        return new RowHolder(row);
    }

    @Override
    public void onBindViewHolder(@NonNull RowHolder holder,
                                int position) {
        cursor.moveToPosition(position);
        holder.bind(cursor);
    }

    @Override
    public int getItemCount() {
        return cursor==null ? 0 : cursor.getCount();
    }

    private void changeCursor(Cursor cursor) {
        if (this.cursor!=null) this.cursor.close();
        this.cursor=cursor;
        notifyDataSetChanged();
    }
}
```

(from [Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java](#))

`changeCursor()` closes the old `Cursor` (if there was one), holds onto the new one, and tells the `RecyclerView` to reload its contents, as our data has changed.

Our row layout (`res/layout/row.xml`) has three `TextView` widgets for the three pieces of data that we want to display:

```
<LinearLayout android:id="@+id/linearLayout1"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <TextView
        android:id="@+id/title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical">
```

## THE CALENDARCONTRACT PROVIDER

---

```
    android:layout_marginLeft="4dip"
    android:layout_marginRight="4dip"
    android:layout_weight="1"
    android:ellipsize="end"
    android:textSize="20sp" />

<LinearLayout
    android:id="@+id/linearLayout2"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_marginEnd="4dip"
    android:layout_marginRight="4dip"
    android:orientation="vertical">

    <TextView
        android:id="@+id/dtstart"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="top"
        android:textSize="12sp" />

    <TextView
        android:id="@+id/dtend"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="bottom"
        android:textSize="12sp" />
</LinearLayout>
</LinearLayout>
```

(from [Calendar/Query/app/src/main/res/layout/row.xml](#))

Each row in the list is managed by a RowHolder:

```
private static class RowHolder extends RecyclerView.ViewHolder {
    private final TextView title, dtstart, dtend;

    RowHolder(View itemView) {
        super(itemView);
        title=itemView.findViewById(R.id.title);
        dtstart=itemView.findViewById(R.id.dtstart);
        dtend=itemView.findViewById(R.id.dtend);
    }

    public void bind(Cursor cursor) {
        title.setText(cursor.getString(0));
        dtstart.setText(getFormattedDate(cursor, 1));
    }
}
```

## THE CALENDARCONTRACT PROVIDER

```
dtend.setText(getFormattedDate(cursor, 2));
}

private String getFormattedDate(Cursor cursor, int column) {
    long time=cursor.getLong(column);

    return
        DateUtils.formatDateTime(dtstart.getContext(), time,
            DateUtils.FORMAT_ABBREV_RELATIVE);
}
}
```

(from [Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java](#))

The DTSTART and DTEND values are returned to use as milliseconds since the Unix epoch, so we use `DateUtils.formatDateTime()` to convert that into something that is human-readable and matches the user's chosen locale settings.

## The Results

If you run this on a device with available calendar data, you will get a list of those events:

Figure 751: The Calendar Query sample application, with some events redacted

## Pencil In an Event

What is rarely documented in the Android SDK is what activities might exist that support the MIME types of a given ContentProvider. In part, that is because device manufacturers have the right to remove or replace many of the built-in applications.

The Calendar application is considered by Google to be a “core” application. Quoting the Android 2.3 version of the [Compatibility Definition Document](#) (CDD):

The Android upstream project defines a number of core applications, such as a phone dialer, calendar, contacts book, music player, and so on. Device implementers MAY replace these applications with alternative versions. However, any such alternative versions MUST honor the same Intent patterns provided by the upstream project. For example, if a device contains an alternative music player, it must still honor the Intent pattern issued by third-party applications to pick a song.

Hence, in theory, so long as the CDD does not change and device manufacturers correctly honor it, those Intent patterns described by the Calendar application’s manifest should be available across Android 4.0 devices. The Calendar application appears to support ACTION\_INSERT and ACTION\_EDIT for both the collection MIME type (vnd.android.cursor.dir/event) and the instance MIME type (vnd.android.cursor.item/event). Notably, there is no support for ACTION\_PICK to pick a calendar or event, the way you can use ACTION\_PICK to pick a contact.

# The MediaStore Provider

---

Playing back media is a popular pastime on Android devices, one in which your app may want to participate. The easiest way for you to find out what media is available for you to display, edit, or otherwise work with is via the MediaStore content provider. MediaStore is part of the Android framework and allows you to query for images, audio files, and video files that are indexed on the device.

This chapter will review the general workings of MediaStore, plus work through an example of getting video files — and their thumbnails — from MediaStore.

## Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [RecyclerView](#)
- [content provider theory](#)
- [content provider implementations](#)

It is also a pretty good idea to have read the chapters on media recording and playback that might be of relevance, depending on what you intend to do with the MediaStore:

- [Audio Playback](#)
- [Audio Recording](#)
- [Video Playback](#)
- [Using the Camera via 3rd-Party Apps](#)
- [Working Directly with the Camera](#)

You might also wish to consider skimming through [the chapter on files](#) again, as it

will be cross-referenced in several places in this chapter.

## What Is the MediaStore?

[The documentation for MediaStore](#) describes it this way:

The Media provider contains meta data for all available media on both internal and external storage devices.

This definition... leaves a bit to be desired.

From our standpoint as Android developers, the MediaStore is a ContentProvider, supplied by Android. We can use it much like we use other system-supplied providers, like ContactsContract and CalendarContract. In this case, the primary role of MediaStore is for us to find media, just as the primary role of ContactsContract is for us to find contacts.

The “meta data” reference in the documentation refers to the fact that MediaStore itself does not store the media, even though that’s what the name MediaStore would suggest. MediaMetadataStore would be a more accurate description. We can learn *about* available media — names, durations, etc. — and we can get a Uri from MediaStore pointing to the media, but the media itself lives as a file somewhere else.

## Indexed Media

MediaStore has media as a primary focus. Here, “media” refers to:

- Images (typically photos)
- Audio (music, podcasts, etc.)
- Video (whether recorded by the device, downloaded from somewhere, etc.)

MediaStore has intrinsic knowledge of these, particularly for the file formats and codecs that Android supports. As a result, the index maintained by MediaStore will contain some metadata in common for all file types, such as:

- title
- MIME type
- dates (when the file was added, when the file was modified)

...and other metadata that will be unique to one or two of the major types, such as:

- duration for audio and video (but not images)
- height and width for images and video (but not audio)
- geotagging for images and video (but not audio)

### Indexed Non-Media

As was mentioned in passing in [the chapter on files](#), Android uses MTP for Android 4.0+ as the USB protocol for sharing files with a desktop or notebook computer.

To power this, Android does not go straight to the filesystem, but rather works with MediaStore. MediaStore maintains an index of *all* files, not just “media”. Whatever shows up in MediaStore is what shows up to the user in their Windows drive letter, macOS mounted volume, etc.

You too can query MediaStore for non-media files. Android will try to maintain a MIME type — probably based on file extensions — and so you can find all indexed PDF files, for example, by querying MediaStore.

### MediaStore and “Other” External Storage

In [the chapter on files](#), we covered the difference between internal storage and external storage. Primarily, MediaStore maintains an index of external storage.

However, many Android devices today have multiple locations that could be considered “external storage”. While the vast majority of Android devices have “external storage” as a portion of on-board flash memory, Android device manufacturers are welcome to add other options, such as:

- card slots (typically microSD)
- USB host ports (capable of mounting thumb drives and the like)

From the standpoint of the Android SDK, such secondary storage locations are off-limits, in that there is nothing in the Android SDK to tell us if there are any such locations, where they are located (in terms of `File` objects to their roots), whether they can be read from, or whether they can be written to. You will find various blog posts and Stack Overflow answers where developers have attempted to catalog all of the possibilities, using a mix of low-level Linux information and manufacturer-based heuristics, but these techniques will be generally unreliable across thousands of device models.

However, many manufacturers who have added such secondary storage options will arrange to have that storage be indexed and be part of MediaStore. So, if the user slides in a microSD card containing audio files, on many devices, when you query MediaStore for available audio files, you will find those on the microSD card in addition to those on “traditional” external storage. From the user’s standpoint, in terms of consuming media, this is sufficient.

## How Does My Content Get Indexed?

As was noted back in [the chapter on files](#), if you write files to external storage, you will want to use `MediaScannerConnection` to ensure that those files get indexed. In that chapter, the focus was on ensuring that your files would be visible to attached desktops/notebooks via MTP. However, what *really* happens is that `MediaScannerConnection` updates MediaStore, which in turn drives the MTP-served content.

Even if you fail to index content manually, at some point, Android is likely to pick up the files. For example, Android will scan external storage after a reboot. However, using `MediaScannerConnection` to “tap Android on the shoulder” and have it index your file means that it will show up in MediaStore more quickly. This is very important for multimedia assets — if you downloaded some media, you want that to be indexed as soon as possible, so the user can turn around and consume that media, whether through your app or another one on the user’s device.

## How Do I Retrieve Video from the MediaStore?

Video players will need to find out what videos are available on the device, eligible for playback. They may wish to retrieve other details, such as the video title, duration, and so forth. And, of course, they will need something that they can use to actually play back the video itself.

In this section, we will examine elements of the [RecyclerView/VideoList](#) sample project. This project will show the roster of available videos; tapping on a video in the list will launch the user’s video player to watch that video. See also [the chapter on advanced RecyclerView techniques](#) for more about the RecyclerView aspects of this app.

### Requesting Permission

Starting on API Level 19 devices, you need to hold the `READ_EXTERNAL_STORAGE` or `WRITE_EXTERNAL_STORAGE` permissions to be able to work with the MediaStore. Hence, the VideoList sample app has the `READ_EXTERNAL_STORAGE` permission in its manifest, as it has no need to write to external storage:

```
<?xml version="1.0"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.recyclerview.videolist"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-permission android:name="android.permission.READ_EXTERNAL_STORAGE" />

    <application
        android:icon="@drawable/ic_launcher"
        android:theme="@style/Theme.Apptheme">
        <activity
            android:name=".MainActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

(from [RecyclerView/VideoList/app/src/main/AndroidManifest.xml](#))

Since `READ_EXTERNAL_STORAGE` is a dangerous permission, we need to request this permission at runtime, in addition to requesting it in the manifest. `MainActivity` implements this logic, using the same basic approaches as is seen in [the chapter on permissions](#).

### Querying for Video

MainActivity uses [the Loader framework](#), since MediaStore is a ContentProvider and Loader is a convenient way to asynchronously load content from a ContentProvider. MainActivity implements the LoaderManager.LoaderCallbacks interface.

Calling `initLoader()` is done in a `loadVideos()` method:

```
private void loadVideos() {
    getSupportLoaderManager().initLoader(0, null, this);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

That method, in turn, is called in two places:

- `onCreate()`, if we already have the `READ_EXTERNAL_STORAGE` permission

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setLayoutManager(new LinearLayoutManager(this));
    setAdapter(new VideoAdapter());

    if (state!=null) {
        isInPermission=
            state.getBoolean(STATE_IN_PERMISSION, false);
    }

    if (hasFilesPermission()) {
        loadVideos();
    }
    else if (!isInPermission) {
        isInPermission=true;

        ActivityCompat.requestPermissions(this,
            new String[] {Manifest.permission.READ_EXTERNAL_STORAGE},
            REQUEST_PERMS);
    }
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java](#))

- `onRequestPermissionsResult()`, if we were just granted the

## THE MEDIASTORE PROVIDER

---

### READ\_EXTERNAL\_STORAGE permission

```
@Override
public void onRequestPermissionsResult(int requestCode,
                                     String[] permissions,
                                     int[] grantResults) {

    isInPermission=false;

    if (requestCode==REQUEST_PERMS) {
        if (hasFilesPermission()) {
            loadVideos();
        }
        else {
            finish(); // denied permission, so we're done
        }
    }
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videlist/MainActivity.java](#))

The `initLoader()` call triggers a call to `onCreateLoader()`, where `MainActivity` creates a `CursorLoader` to query the `MediaStore` for videos:

```
@Override
public Loader<Cursor> onCreateLoader(int arg0, Bundle arg1) {
    return(new CursorLoader(this,
                           MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
                           null, null, null,
                           MediaStore.Video.Media.TITLE));
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videlist/MainActivity.java](#))

The `Uri` for video content from `MediaStore` is `MediaStore.Video.Media.EXTERNAL_CONTENT_URI`. Passing in `null` for the list of columns to return will return all available columns — not the most efficient approach, but it is convenient. The sort order of `MediaStore.Video.Media.TITLE` has the results sorted by the `TITLE` column, so the videos are returned alphabetically.

Our other `LoaderManager.LoaderCallbacks` methods are fairly conventional, updating a `VideosAdapter` that our `RecyclerView` uses for displaying the videos:

```
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    ((VideoAdapter)getAdapter()).setVideos(c);
}
```

## THE MEDIASTORE PROVIDER

---

```
@Override
public void onLoaderReset(Loader<Cursor> loader) {
    ((VideoAdapter)getAdapter()).setVideos(null);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videlist/MainActivity.java](#))

### Showing the Thumbnails

If you have used a video player on Android, most have an activity (or fragment) akin to the one we are implementing in this section. And, most of those will show thumbnail images of the videos in question.

However, retrieving and showing those thumbnails is a bit complicated, because Android may need to *generate* the thumbnail, if there is not already a thumbnail for the video, or if its cache of thumbnails was cleared. Generating a thumbnail takes time, time that we do not want to spend on the main application thread. For that, we will use Picasso, as profiled in [the chapter on Internet access](#).

The thumbnail will need to be displayed using some sort of ImageView. That is handled by RowController, which is the ViewHolder that we are using with VideosAdapter. It, in turn, uses Picasso to load the thumbnail:

```
void bindModel(Cursor row) {
    title.setText(row.getString(
        row.getColumnIndex(MediaStore.Video.Media.TITLE)));

    videoUri=
        ContentUris.withAppendedId(
            MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
            row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));

    Picasso.with(thumbnail.getContext())
        .load(videoUri.toString())
        .fit().centerCrop()
        .placeholder(R.drawable.ic_media_video_poster)
        .into(thumbnail);

    int mimeTypeColumn=
        row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);

    videoMimeType=row.getString(mimeTypeColumn);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videlist/RowController.java](#))

## THE MEDIASTORE PROVIDER

---

We construct the `Uri` to the video using `ContentUris.withAppendedId()`. Picasso knows how to handle such `Uri` values, identifying them as coming from the `MediaStore` and using appropriate methods to retrieve a suitable thumbnail. That will be done in the background, with a placeholder image shown while the thumbnail is loading. The net result is that when we populate our `RecyclerView` with our videos, the rows will initially have the placeholder image, replaced by the actual video thumbnails as they get loaded.

### Playing the Selection

`RowController` also sets itself up to find out about clicks on the list rows. The objective is to play back the video when the user clicks on a row. It simply constructs an `Intent` to view the video and starts an activity with it:

```
@Override
public void onClick(View v) {
    Intent i=new Intent(Intent.ACTION_VIEW);

    i.setDataAndType(videoUri, videoMimeType);
    title.getContext().startActivity(i);
}
```

(from [RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videlist/RowController.java](#))

`videoUri` and `videoMimeType` were populated in the `bindModel()` method shown above, so they will have the proper values for whatever row the user clicked upon.

### The Results

Running this on a device with videos available should show the list of those videos, complete with title and thumbnail:

*Figure 752: The Video List Demo App*

Tapping on any entry in the list should bring up a video player on your device, assuming that one or more such players (that are capable of supporting content://Uri values) are installed.

# Consuming Documents

---

Android has long offered the ability for an app to pick some file or stream from another app and consume it. However, the original options were designed around an app loading content from another app. Even though our *code* would be requesting content based on abstractions like MIME types, the *implementation* and user experience would be based on the traditional “pick an app to fulfill this request” chooser.

Google, given its clear interest in cross-cutting storage engines like Google Drive, wanted something better. In Android 4.4, they added the Storage Access Framework (SAF) to provide a better user experience, with only modest changes to client code. With Android’s increasing reliance upon content and document providers for cross-app content sharing, understanding the Storage Access Framework is fairly important for modern app development.

In this chapter, we will examine what it takes to consume documents published via the SAF.

## Prerequisites

This chapter assumes that you have read [the chapter on ContentProvider patterns](#) or have equivalent experience with consuming streams published by a ContentProvider.

## The Storage Access... What?

Let’s think about photos for a minute.

## CONSUMING DOCUMENTS

---

A person might have photos managed as:

- on-device photos, mediated by an app like a gallery
- photos stored online in a photo-specific service, like Instagram
- photos stored online in a generic file-storage service, like Google Drive or Dropbox

Now, let's suppose that person is in an app that allows the user to pick a photo, such as to attach to an email.

The classic Android solution would be for the user to have to first choose the app to use to find the photo (e.g., Gallery, Instagram, Google Drive, Dropbox), then find the photo using that app. Then, if all goes well, the original app would receive a `Uri` to that photo and be able to make use of it.

However, this flow has three main problems:

1. From the user's standpoint, they need to know where they have the photo before they can go looking for it. Given the prominence of generic file-storage services, the user might not remember where the photo is stored, but might remember enough details about the photo (e.g., timeframe when taken, tags that might have been attached to the photo) to find it... but the user has to sequentially search each possible photo-storing app until the right one is found.
2. From the client app developer's standpoint, too many apps screw up handling the classic `ACTION_PICK` and `ACTION_GET_CONTENT` activities, failing to return a result in all cases. Users then are as likely to blame the client app for the mistake as they are to blame the photo-storing app or Android itself.
3. None of this was designed with online file-sharing services in mind. What happens if an app knows about a possible file, but the file is not available on the device right now, because it has not been downloaded from the online service?

The Storage Access Framework is designed to address these issues. It provides its own "picker" UI to allow users to find a file of interest that matches the MIME type that the client app wants. File providers simply publish details about their available files — including those that may not be on the device but could be retrieved if needed. The picker UI allows for easy browsing and searching across all possible file providers, to streamline the process for the user. And, since Android is the one providing the picker, the picker should more reliably give a result to the client app based upon the user's selection (if any).

## The Storage Access Framework Participants

**Providers** are specialized `ContentProvider` implementations, usually extending `DocumentsProvider`, that can tell Android about the documents that are published by an app. This includes providing any sort of organizational structure (directory tree, tag cloud, etc.)

The **clients** are apps that wish to consume (or create) documents managed by providers. Clients will indicate what sort of document they want, in the form of a MIME type, where applicable.

The **picker** is the system UI that allows the user to pick a document (or documents) from among the documents published by all providers that meet the criteria established by a client requesting access to the document(s).

## Picking How to Pick (a Peck of Pickled Pepper Photos)

`ACTION_PICK` would seem to be the Intent action to use to pick something. It works, but it is designed for the case where you know the specific collection of “somethings” you want to pick from. Use this, for example, to pick a contact specifically out of `ContactsContract`.

In cases where you know the MIME type you want, but you do not particularly know or care about the exact source of the file, use `ACTION_GET_CONTENT` on API Level 18 and below for everything.

For MIME types that clearly represent a document, file, or other sort of stream, use `ACTION_OPEN_DOCUMENT` (and the SAF) on API Level 19+. The SAF picker will incorporate both full-fledged SAF-compliant providers’ documents along with apps that only support `ACTION_GET_CONTENT`. However, since `ACTION_OPEN_DOCUMENT` is only available on API Level 19+ devices, if you are supporting older devices, you will need to check `Build.VERSION.SDK_INT` and choose an Intent action accordingly.

For MIME types that represent entries in a database (e.g., a calendar entry), use `ACTION_GET_CONTENT`, even on API Level 19+. Google also recommends using `ACTION_GET_CONTENT` on API Level 19+ “if you want your app to simply read/import data”, though it is unclear why they make this recommendation or why the user experience should differ based upon how the bytes would be used.

## Opening a Document

Technically, we do not “open” a document using `ACTION_OPEN_DOCUMENT`. Instead, we are requesting a `Uri` pointing to some document that the user chooses.

To do that, create an `Intent` with:

- `ACTION_OPEN_DOCUMENT` as the action
- `CATEGORY_OPENABLE` as the category
- your desired MIME type

Then, use that `Intent` with `startActivityForResult()`.

For example, the [Documents/Consumer](#) sample application contains a `ConsumerFragment` that adds an “Open” item to the action bar overflow. Clicking on “Open” triggers a call to the `open()` method on the fragment. And, for API Level 19+ devices, that will in turn request to “open” a document:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private void open() {
    Intent i=new Intent().setType("image/*");

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
        startActivityForResult(i.setAction(Intent.ACTION_OPEN_DOCUMENT)
            .addCategory(Intent.CATEGORY_OPENABLE),
            REQUEST_OPEN);
    }
    else {
        startActivityForResult(i.setAction(Intent.ACTION_GET_CONTENT)
            .addCategory(Intent.CATEGORY_OPENABLE),
            REQUEST_GET);
    }
}
```

(from [Documents/Consumer/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

This `open()` method also gracefully degrades for older devices, falling back to `ACTION_GET_CONTENT`. In both cases, we are trying to allow the user to pick some image (MIME type of `image/*`). The two `startActivityForResult()` calls use different request IDs (`REQUEST_OPEN` versus `REQUEST_GET`), so that we can distinguish the sort of result that we get in `onActivityResult()`:

```
@Override
public void onActivityResult(int requestCode, int resultCode,
```

## CONSUMING DOCUMENTS

---

```
        Intent resultData) {
    if (resultCode==Activity.RESULT_OK) {
        if (resultData!=null) {
            uri=resultData.getData();

            if (requestCode==REQUEST_OPEN) {
                getLoaderManager().initLoader(0, null, this);
            }
            else {
                logToTranscript(uri.toString());
            }
        }
    }
}
}
```

(from [Documents/Consumer/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

Both ACTION\_GET\_CONTENT and ACTION\_OPEN\_DOCUMENT should supply a Uri in the result Intent that points to the document the user chose, if the user actually chose one and we got RESULT\_OK as the result code. This sample logs that Uri value to a “transcript” (TextView inside of a ScrollView) to show what we get back.

If the result is from an ACTION\_OPEN\_DOCUMENT request (REQUEST\_OPEN request code), we can try to get some metadata about the document. The provider should support a query on the returned Uri that will give us the display name (OpenableColumns.DISPLAY\_NAME) and possibly the size of the file (OpenableColumns.SIZE). So, we use the Loader framework to run this query, with our fragment implementing the LoaderCallbacks:

```
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return(new CursorLoader(getActivity(), uri, PROJECTION, null, null, null));
}

public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    transcript.setText(null);
    logToTranscript(uri.toString());

    if (c!=null && c.moveToFirst()) {
        int displayNameColumn=
            c.getColumnIndex(OpenableColumns.DISPLAY_NAME);

        if (displayNameColumn>=0) {
            logToTranscript("Display name: "
                +c.getString(displayNameColumn));
        }
    }
}
```

## CONSUMING DOCUMENTS

---

```
int sizeColumn=c.getColumnIndex(OpenableColumns.SIZE);

if (sizeColumn<0 || c.isNull(sizeColumn)) {
    logToTranscript("Size not available");
}
else {
    logToTranscript(String.format("Size: %d",
        c.getInt(sizeColumn)));
}
}
else {
    logToTranscript("...no metadata available?");
}
}

public void onLoaderReset(Loader<Cursor> loader) {
    // unused
}
```

(from [Documents/Consumer/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

If we get results back, we try to read out these two values and record them to the transcript as well. Note, though, that:

- There is no guarantee that either column will be in the result set, or that the result set will have any rows
- The size might not be known, particularly if the file is not presently resident on the device (e.g., it is being downloaded now, given that the user chose the file), and so we need to call `isNull()` on the Cursor to see if we actually have a SIZE value before trying to get it as an integer

## CONSUMING DOCUMENTS

---

The user is presented with the system's picker, to choose an image, complete with a navigation drawer to get to various spots within the picker:

*Figure 753: Storage Access Framework Picker, Showing Images*

When the user taps on an image, the results wind up in our transcript UI:

*Figure 754: Uri, Display Name, and Size of Chosen File*

Note that the default behavior of `ACTION_OPEN_DOCUMENT` is to let the user choose a single file. If your Intent includes `EXTRA_ALLOW_MULTIPLE`, set to true, then the user can choose multiple documents. Rather than getting their `Uri` values via `getData()` on the result Intent, you will need to call `getClipData()` on the Intent and iterate over the “clipboard entries”.

The `Uri` itself can then be used to get an `InputStream` or `OutputStream` for the contents, using `openInputStream()` and `openOutputStream()` on `ContentResolver`, respectively. Note, though, that you cannot pass the `Uri` to other applications, as they may not have rights to work with that document the way that you do.

## Why We Want Things To Be Openable

You will notice that both the `ACTION_OPEN_DOCUMENT` and the `ACTION_GET_CONTENT` Intent objects created in the preceding example have `CATEGORY_OPENABLE` applied to them. This is supposed to guarantee that we can actually consume the content represented by the `Uri` that we get. In particular, we should be able to use a

ContentResolver and open streams on that content.

If we leave off `CATEGORY_OPENABLE`, it is possible that we will get a `Uri` that we cannot open ourselves.

The difference boils down to what use we intend to put the `Uri` toward:

- If all we plan to do is use that `Uri` for is to wrap it in an `ACTION_VIEW` Intent and start an activity on it, you could skip `CATEGORY_OPENABLE` and perhaps offer more choices to your user
- Otherwise, use `CATEGORY_OPENABLE`

## The Rest of the CRUD

`ACTION_OPEN_DOCUMENT` will give you a `Uri` for a document that you can open for reading — the “R” in “CRUD”.

However, the other CRUD operations are also entirely possible.

### Create

`ACTION_CREATE_DOCUMENT` will give you a `Uri` for a document that you can open for writing, as it is your document.

To do this, construct an Intent with:

- an action of `ACTION_CREATE_DOCUMENT`
- a category of `CATEGORY_OPENABLE`
- the MIME type of the content you wish to write
- an extra, named `EXTRA_TITLE`, containing your desired filename

Then, invoke `startActivityForResult()` on that Intent, and use the `Uri` supplied in the result Intent delivered to `onActivityResult()`.

### Update

The `Uri` returned from an `ACTION_OPEN_DOCUMENT` request may be writable. If it is, you can use `openOutputStream()` on a `ContentResolver` to write to that document. You can determine if a document is writable by examining the `COLUMN_FLAGS` value returned from a `query()` on the `Uri` — if it includes `FLAG_SUPPORTS_WRITE`, you can

write to the document.

### Delete

Similarly, if the `COLUMN_FLAGS` value includes `FLAG_SUPPORTS_DELETE`, you can delete the document by calling the static `deleteDocument()` method on the `DocumentsContract` class, supplying a `ContentResolver` plus the `Uri` of the document to be deleted.

## The DocumentFile Helper

The `support-core-utils` library from the Android Support libraries contains a `DocumentFile` class. This provides a light `File`-like layer atop the low-level API offered through a `ContentResolver` or `DocumentsContract`. Of note, `DocumentFile` offers convenience methods for:

- determining read/write access (`canRead()` and `canWrite()`)
- getting the display name (`getName()`) and length (`length()`) of the document
- getting the MIME type (`getType()`)
- deleting the document (`delete()`)
- and so on

`DocumentFile` can actually work with raw files — just create a `DocumentFile` using the static `fromFile()` method. More often, though, you will create a `DocumentFile` wrapped around the `Uri` that you get from `ACTION_OPEN_DOCUMENT` or `ACTION_CREATE_DOCUMENT`. For that, there is the static `fromSingleUri()` method.

## CWAC-Document and DocumentFileCompat

There is one significant problem with `DocumentFile`, though: it only works on document `Uri` values on API Level 19 and higher. However, we can get such `Uri` values on older devices, and we can get `Uri` values from other places than a `DocumentProvider` (e.g., `FileProvider`).

[The CWAC-Document library](#) offers a `DocumentFileCompat` class. This is forked from the official `DocumentFile` but adds support for older devices and non-document `Uri` values. Specifically, for a non-document content `Uri`, you can get:

## CONSUMING DOCUMENTS

---

- the display name, queried via the `OpenableColumns`
- the length, also from the `OpenableColumns`
- the MIME type, from `ContentResolver` and `getType()`

Also, some `DocumentFile` methods whose values can be safely hard-coded for legacy documents, like `isVirtual()` (`false`), `isDirectory()` (`false`), and `isFile()` (`true`) are supported.

`DocumentFileCompat` also offers convenience methods for:

- Accessing streams (`openInputStream()`, `openOutputStream()`)
- Copying the content to something else (`copyTo()`)
- Copying something else into this content (`copyFrom()`, `copyFromAsset()`)

We will see the use of `DocumentFileCompat` in the next couple of sample apps.

## Getting Durable Access

By default, you will have the rights to read (and optionally write) to the document represented by the `Uri` until the activity that requested the document via `ACTION_OPEN_DOCUMENT` or `ACTION_CREATE_DOCUMENT` is destroyed.

If you pass the `Uri` to another component — such as a service — you will need to add `FLAG_GRANT_READ_URI_PERMISSION` and/or `FLAG_GRANT_WRITE_URI_PERMISSION` to the `Intent` used to start that component. That extends your access until *that* component is destroyed.

If, however, you need the rights to survive your app restarting, you can call `takePersistableUriPermission()` on a `ContentResolver`, indicating the `Uri` of the document and the permissions (`FLAG_GRANT_READ_URI_PERMISSION` and/or `FLAG_GRANT_WRITE_URI_PERMISSION`) that you want persisted. Those rights will then survive a reboot. However:

- They will not survive the document being deleted, so just because you have a saved `Uri`, do not assume that the `Uri` will still be valid
- Not every storage provider will grant such persistable permissions
- This will only work for `Uri` values that you get from `ACTION_OPEN_DOCUMENT` or `ACTION_CREATE_DOCUMENT`, not ones that you get by other means (e.g., `ACTION_GET_CONTENT`)
- You can revoke those rights by calling `releasePersistableUriPermission()`

## CONSUMING DOCUMENTS

---

later on, and there is nothing stopping the storage provider from revoking those permissions itself at some time in the future

In addition, you can call `getPersistedUriPermissions()` to find out what persisted permissions your app has. This returns a List of `UriPermission` objects, where each one of those represents a `Uri`, what persisted permissions (read or write) you have, and when the permissions will expire.

If you do not have persistable permissions when you get the `Uri`, your primary recourse is to make a local copy of the content, while you still have temporary access to it. The [Documents/Durable](#) sample application illustrates this. It is based on the `Documents/Consumer` sample app from earlier in this chapter, with a few key changes:

- It provides menu options for opening a document via `ACTION_OPEN_DOCUMENT` or getting content via `ACTION_GET_CONTENT`
- It uses an `IntentService` (`DurablizerService`) to either obtain persistable permissions to the content or to make a local copy, delivering the results asynchronously via an event bus
- It uses `DocumentFileCompat` instead of direct `ContentResolver` queries to get the content metadata

For an event bus, we use greenrobot's `EventBus`, added as a dependency via `build.gradle`, along with the `CWAC-Document` library:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
        applicationId "com.commonware.android.documents.durable"
    }
}

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonware.com"
    }
}
```

## CONSUMING DOCUMENTS

---

```
dependencies {
    implementation 'com.android.support:support-fragment:27.1.0'
    implementation 'org.greenrobot:eventbus:3.0.0'
    implementation 'com.commonware.cwac:document:0.2.0'
}
```

(from [Documents/Durable/app/build.gradle](#))

MainActivity is the same as in the Documents/Consumer sample app, as is the core UI of ConsumerFragment (ScrollView with a TextView inside). However, ConsumerFragment registers for events in onStart() and unregisters in onStop():

```
@Override
public void onStart() {
    super.onStart();

    EventBus.getDefault().register(this);
}

@Override
public void onStop() {
    EventBus.getDefault().unregister(this);

    super.onStop();
}
```

(from [Documents/Durable/app/src/main/java/com/commonware/android/documents/consumer/ConsumerFragment.java](#))

The menu resource now has two items, open (for ACTION\_OPEN\_DOCUMENT) and get (for ACTION\_GET\_CONTENT):

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/get"
        android:showAsAction="never"
        android:title="@string/get" />
    <item
        android:id="@+id/open"
        android:enabled="false"
        android:showAsAction="never"
        android:title="@string/open" />

</menu>
```

(from [Documents/Durable/app/src/main/res/menu/actions.xml](#))

## CONSUMING DOCUMENTS

---

The open one is disabled (`android:enabled="false"`) at the outset, as `ACTION_OPEN_DOCUMENT` only works on API Level 19+ devices, and the `minSdkVersion` of this sample is 15.

In `onCreateOptionsMenu()`, we conditionally enable the open item, and in `onOptionsItemSelected()`, we route the menu items to `open()` and `get()` methods:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.actions, menu);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
        menu.findItem(R.id.open).setEnabled(true);
    }

    super.onCreateOptionsMenu(menu, inflater);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.open) {
        open();
    }
    else if (item.getItemId() == R.id.get) {
        get();
    }

    return super.onOptionsItemSelected(item);
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

Those methods invoke their associated Intent actions, using `/*/*` this time for the MIME type:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private void open() {
    Intent i =
        new Intent()
            .setType("/*/*")
            .setAction(Intent.ACTION_OPEN_DOCUMENT)
            .addCategory(Intent.CATEGORY_OPENABLE);

    startActivityForResult(i, REQUEST_OPEN);
}
```

## CONSUMING DOCUMENTS

---

```
private void get() {
    Intent i=
        new Intent()
            .setType("image/png")
            .setAction(Intent.ACTION_GET_CONTENT)
            .addCategory(Intent.CATEGORY_OPENABLE);

    startActivityForResult(i, REQUEST_GET);
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

However, whereas the Documents/Consumer sample app processed the resulting Uri directly in `onActivityResult()`, now we delegate that work to a `DurablizerService` that is responsible for ensuring that we have durable access to the content:

```
@Override
public void onActivityResult(int requestCode, int resultCode,
                             Intent resultData) {
    if (resultCode==Activity.RESULT_OK) {
        getActivity()
            .startService(new Intent(getActivity(), DurablizerService.class)
                .setData(resultData.getData())
                .addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION));
    }
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

We pass the Uri via the data facet of the Intent (`setData()`), plus add the `FLAG_GRANT_READ_URI_PERMISSION` flag. This ensures that `DurablizerService` will have access to the content even if `MainActivity` is destroyed before our work is complete.

`onHandleIntent()` in `DurablizerService` has a basic flow:

- Try to obtain persistable permissions
- If that does not work, try to make a local copy
- If either of those work, deliver a `DocumentFile` to the UI layer via a `ContentReadyEvent`

```
@Override
protected void onHandleIntent(Intent intent) {
    Uri document=intent.getData();
    boolean weHaveDurablePermission=obtainDurablePermission(document);
}
```

## CONSUMING DOCUMENTS

---

```
if (!weHaveDurablePermission) {
    document=makeLocalCopy(document);
}

if (weHaveDurablePermission || document!=null) {
    Log.d(getClass().getSimpleName(), document.toString());

    DocumentFileCompat docFile=buildDocFileForUri(document);

    Log.d(getClass().getSimpleName(),
        "Display name: "+docFile.getName());
    Log.d(getClass().getSimpleName(),
        "Size: "+Long.toString(docFile.length()));

    EventBus.getDefault().post(new ContentReadyEvent(docFile));
}
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/DurablizerService.java](#))

The job of `obtainDurablePermission()` is to use `takePersistableUriPermission()` on a `ContentResolver` to request read and write access, at least on Android 4.4 or higher. So, we create a perms value that requests both `FLAG_GRANT_READ_URI_PERMISSION` and `FLAG_GRANT_WRITE_URI_PERMISSION`, and pass that to `takePersistableUriPermission()`, along with the document Uri:

```
private boolean obtainDurablePermission(Uri document) {
    boolean weHaveDurablePermission=false;

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.KITKAT) {
        int perms=Intent.FLAG_GRANT_READ_URI_PERMISSION
            | Intent.FLAG_GRANT_WRITE_URI_PERMISSION;

        try {
            getContentResolver()
                .takePersistableUriPermission(document, perms);

            for (UriPermission perm :
                getContentResolver().getPersistedUriPermissions()) {
                if (perm.getUri().equals(document)) {
                    weHaveDurablePermission=true;
                }
            }
        }
        catch (SecurityException e) {
            // OK, we were not offered any persistable permissions
        }
    }
}
```

## CONSUMING DOCUMENTS

---

```
}  
  
return(weHaveDurablePermission);  
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/DurablizerService.java](#))

Unfortunately, while `takePersistableUriPermission()` is synchronous, it does not actually tell us if we *have* those permissions. The only way to find out if we have access is to call `getPersistedUriPermissions()`, which returns a roster of `UriPermission` objects listing *every* persisted `Uri` permission held by our app. Then, we have to sift through those, looking for one matching our desired document `Uri`.

`obtainDurablePermission()` then returns a boolean indicating whether or not our request for persistable permissions succeeded.

`makeLocalCopy()` will be called if `obtainDurablePermission()` returns false (e.g., we are on an older Android device or otherwise used `ACTION_GET_CONTENT`). Its job is to make a local copy of the content, so we have indefinite access:

```
private Uri makeLocalCopy(Uri document) {  
    DocumentFileCompat docFile=buildDocFileForUri(document);  
    Uri result=null;  
  
    if (docFile.getName()!=null) {  
        try {  
            String ext=  
                MimeTypeMap.getSingleton().getExtensionFromMimeType(docFile.getType());  
  
            if (ext!=null) {  
                ext="."+ext;  
            }  
  
            File f=File.createTempFile("cw_", ext, getFilesDir());  
  
            docFile.copyTo(f);  
            result=Uri.fromFile(f);  
        }  
        catch (Exception e) {  
            Log.e(getClass().getSimpleName(),  
                "Exception copying content to file", e);  
        }  
    }  
  
    return(result);  
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/DurablizerService.java](#))

We start off by getting a `DocumentFileCompat` for the document `Uri`, using a `buildDocFileForUri()` helper method:

## CONSUMING DOCUMENTS

---

```
private DocumentFileCompat buildDocFileForUri(Uri document) {
    DocumentFileCompat docFile;

    if (document.getScheme().equals(ContentResolver.SCHEME_CONTENT)) {
        docFile=DocumentFileCompat.fromSingleUri(this, document);
    }
    else {
        docFile=DocumentFileCompat.fromFile(new File(document.getPath()));
    }

    return(docFile);
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/DurablizerService.java](#))

This handles both likely scenarios:

- We get a content: Uri, and so our DocumentFileCompat needs to be created using the fromSingleUri() factory method
- We get a file: Uri, and so our DocumentFileCompat needs to be created using the fromFile() factory method

Back in makeLocalCopy(), we get the file extension associated with the content's MIME type, by way of MimeTypeMap and getExtensionFromMimeType(). Calling getType() on the DocumentFileCompat will fail if, for some reason, we have a content: Uri but do not have any permission to work with it. For example, had we failed to include FLAG\_GRANT\_READ\_URI\_PERMISSION on the Intent that started DurablizerService *and* if the MainActivity were destroyed by this point, we would not have any rights to use the content, and getType() will fail to get the MIME type for the content.

But, if getType() succeeds, we try to get that file extension. That too might fail, returning null, if the MIME type is not recognized by MimeTypeMap. We can live with a null file extension. However, if the file extension is *not* null, it will lack the leading ., so we add that. Then, we create a unique file in getFilesDir(), using that file extension and createTempFile() on File. From there, we use the convenient copyTo() method on DocumentFileCompat to copy that content into our temporary file.

The ContentReadyEvent simply wraps a DocumentFileCompat pointing to our final content: either the original Uri (if we obtained durable access to it) or on our local copy:

## CONSUMING DOCUMENTS

---

```
static class ContentReadyEvent {
    final DocumentFileCompat docFile;

    ContentReadyEvent(DocumentFileCompat docFile) {
        this.docFile=docFile;
    }
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/DurablizerService.java](#))

Back in ConsumerFragment, when the ContentReadyEvent is received, we log the details to the transcript:

```
@Subscribe(threadMode=ThreadMode.MAIN)
public void onContentReady(DurablizerService.ContentReadyEvent event) {
    logToTranscript(event.docFile.getUri().toString());
    logToTranscript("Display name: "+event.docFile.getName());
    logToTranscript("Size: "+Long.toString(event.docFile.length()));
}
```

(from [Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java](#))

For cases where we are granted persistable permissions, the output will show a content: Uri, as we can continue to use the original content:

*Figure 755: Durable Document Demo, Showing Document Result*

For cases where we were not granted persistable permissions — such as `ACTION_GET_CONTENT` — the output will show a `file: Uri`, representing the local copy of the content:

*Figure 756: Durable Document Demo, Showing Content Result*

## Another Durable Example: Diceware

Dealing with durable documents does not require a service. Services are a good idea when you might need to make a copy of the document (e.g., the `ACTION_GET_CONTENT` scenario) and you do not know how big that document might be. In cases where the document is known to be small, just using background threads is fine, such as via [RxJava](#).

With that in mind, here is another sample app that demonstrates using `ACTION_OPEN_DOCUMENT` and `ACTION_GET_CONTENT` to work with user-provided documents. Unlike most examples in this book, though, this app has some direct usefulness, as it is a passphrase generator, using the diceware approach.

### Dice? Where?!?

Simply put, [diceware](#) is a technique for generating a lengthy passphrase that still has

a chance of being memorable, by choosing words from a list of common words.

The name “diceware” comes from the canonical way of generating the passphrase: rolling five six-sided dice (the sorts of dice that you see in casinos and board games) and looking up words in a word list. The more randomly-chosen words in the passphrase, the stronger the passphrase and the more time it would take for it to be cracked by somebody.

Perhaps the most famous such passphrase is [correct horse battery staple](#), though a four-word passphrase is probably a bit short today.

### We Want Words!

To use the diceware approach to generate a passphrase, you need a list of words.

A traditional diceware word list contains two columns. The right-hand column is the word, and the left-hand column is the dice roll that corresponds to that word:

4244	liverwurst
4245	lizard
4246	llama
4251	luau
4252	lubricant
4253	lucidity
4254	ludicrous
4255	luggage

[The canonical diceware site](#) has a number of word lists for a variety of languages. Each of those lists has 7,776 words, which equates to  $6^5$ , or the number of combinations of five rolls of a six-sided die.

However, other word lists also exist. The EFF has [published](#) a few lists, aiming for more commonly-used words and eliminating ones that might cause confusion (e.g., [homophones](#)). They also have some short lists, with only 1,296 ( $6^4$ ) words, with an emphasis on shorter words. Shorter word lists require more words in the passphrase to get the same level of security (e.g., 8 words from the short lists result in similar security as 6 words from the longer lists).

The [Documents/Diceware](#) sample application packages one of the EFF word lists in the app itself, as an asset, so the app is usable “out of the box” to generate a passphrase. However, it also has action bar items to allow you to use

ACTION\_OPEN\_DOCUMENT or ACTION\_GET\_CONTENT to use a different word list, if you wanted.

### The Results

First, let's take a look at what the app does, before we see how it is built.

When you run the app, you immediately get a CardView showing a randomly-generated passphrase, using the word list that is baked into the app:

*Figure 757: Diceware App, As Initially Launched*

Clicking the refresh action bar item will generate a fresh passphrase, while tapping the “Words” action bar item lets you choose the length of the passphrase (from 4-10 words):

*Figure 758: Diceware App, Showing Word Count Submenu*

There are three options in the action bar overflow:

- “Get Word File”, which uses `ACTION_GET_CONTENT` to allow you to pick an alternative word list file
- “Open Word File”, which uses `ACTION_OPEN_DOCUMENT` to allow you to do the same
- “Reset”, which switches you back to the built-in word list

### How We Got There

The Diceware app consists of a single `PassphraseFragment`, loaded using a `FragmentManager` by the `MainActivity`.

### Loading Our Words

`PassphraseFragment` uses two RxJava `Observable` objects:

## CONSUMING DOCUMENTS

---

- One manages loading the list of words and randomly choosing a word from that list (`wordsObservable`)
- The other manages getting durable access to the external word file that you choose to load in (`docObservable`)

When the app first runs, neither of these are set up yet. In `onViewCreated()`, we confirm that we do not have a `docObservable` at the moment — if we did, that would indicate that we are still in the middle of getting durable access to some words. Normally, `docObservable` will be `null` here, and so we call a `loadWords()` method:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    passphrase=view.findViewById(R.id.passphrase);

    if (savedInstanceState!=null) {
        wordCount=savedInstanceState.getInt(STATE_WORD_COUNT);
    }

    if (docObservable!=null) {
        docSub();
    }
    else {
        loadWords(false, wordsObservable==null);
    }
}
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](https://github.com/commonsware/android-diceware/blob/master/PassphraseFragment.java))

(we will cover `docObservable`, `docSub()`, and `wordCount` later)

`loadWords()` takes two boolean parameters:

- The first is “should we forcibly reload our words, even if we already loaded them before?”
- The second is “do we want to generate a new passphrase?”

`PassphraseFragment` is a retained fragment. It is entirely possible that we already have our words loaded from disk, in which case we do not need to load them again (e.g., after the user rotated the screen). So, here we pass `false` for the first parameter.

---

## CONSUMING DOCUMENTS

---

However, just because the user rotated the screen does not mean that we want to generate a fresh passphrase. We only want to do that if we do not already have a passphrase, or have one being generated right now. If `wordsObservable` exists (is not null), then we know that a passphrase has either been displayed or is soon to be displayed, and so we can skip creating a new one. When the app is first launched, though, `wordsObservable` is null, and so we tell `loadWords()` to generate a passphrase.

`loadWords()` then sets up `wordsObservable`:

```
private void loadWords(boolean forceReload, boolean regenPassphrase) {
    if (wordsObservable==null || forceReload) {
        final Application app=getActivity().getApplication();

        wordsObservable=Observable
            .defer(() -> (Observable.just(PreferenceManager
                .getDefaultSharedPreferences(app))))
            .subscribeOn(Schedulers.io())
            .map(sharedPreferences -> {
                PassphraseFragment.this.prefs=sharedPreferences;

                return(sharedPreferences.getString(PREF_URI, ""));
            })
            .map(s -> {
                InputStream in;

                if (s.length()==0) {
                    in=app.getAssets().open(ASSET_FILENAME);
                }
                else {
                    in=app.getContentResolver().openInputStream(Uri.parse(s));
                }

                return(readWords(in));
            })
            .cache()
            .observeOn(AndroidSchedulers.mainThread());
    }

    unsubWords();

    if (regenPassphrase) {
        wordsSub=wordsObservable.subscribe(this::rollDemBones, error -> {
            Toast
                .makeText(getActivity(), error.getMessage(), Toast.LENGTH_LONG)
                .show();
        });
    }
}
```

## CONSUMING DOCUMENTS

---

```
        Log.e(getClass().getSimpleName(), "Exception processing request",
            error);
    });
}
}
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

We only need to set up `wordsObservable` if it does not already exist or `forceReload` is true. In either of those cases, we:

- Use `defer()` to set up an `Observable` that starts by loading the default `SharedPreferences` for our app, as that is where we will record the `Uri` of any external word list that we are supposed to be using
- Use `subscribeOn()` to move all this I/O to a background thread
- Use `map()` to extract the `String` preference value, keyed by `PREF_URI`, that is the `Uri` for our external word list, returning the empty string if there is no such `Uri` (note: we cannot return `null` because `RxJava` does not like that)
- Use another `map()` to create an `InputStream` either on that external word list or the one in `assets/`, then read in the words from that stream via `readWords()`
- Use `cache()` to get `RxJava` to hold onto the results of all that work, so long as we have the same `wordsObservable` object
- Use `observeOn()` to arrange to observe the results on the main application thread

`readWords()` simply reads in the lines from the asset or external word list, divides each line on the whitespace between the two columns, and extracts the word from the second column:

```
private static List<String> readWords(InputStream in) throws IOException {
    InputStreamReader isr=new InputStreamReader(in);
    BufferedReader reader=new BufferedReader(isr);
    String line;
    List<String> result=new ArrayList<>();

    while ((line = reader.readLine())!=null) {
        String[] pieces=line.split("\s");

        if (pieces.length==2) {
            result.add(pieces[1]);
        }
    }
}
```

## CONSUMING DOCUMENTS

---

```
return(result);  
}
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

loadWords() then calls unsubWords(). This will dispose() any existing subscription to wordsObservable:

```
private void unsubWords() {  
    if (wordsSub!=null && !wordsSub.isDisposed()) {  
        wordsSub.dispose();  
    }  
}
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

Then, if we need a passphrase (regenPassphrase is true), we subscribe() to the wordsObservable, routing the word list to a rollDemBones() method, and displaying a Toast and logging to Logcat in case there is some sort of error (e.g., IOException reading in the words).

rollDemBones() uses SecureRandom to pick wordCount words from the list and updates the passphrase TextView with those words:

```
private void rollDemBones(List<String> words) {  
    StringBuilder buf=new StringBuilder();  
    int size=words.size();  
  
    for (int i=0;i<wordCount;i++) {  
        if (buf.length(>0) {  
            buf.append(' ');  
        }  
  
        buf.append(words.get(random.nextInt(size)));  
    }  
  
    passphrase.setText(buf.toString());  
}
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

The net result, after all of that, is that when we first run the app, we create and subscribe to the wordsObservable, and after a brief bit of I/O, we show the initial passphrase to the user.

### Getting More Words

Handling the ACTION\_GET\_CONTENT and ACTION\_OPEN\_DOCUMENT scenarios is reminiscent of the Documents/Durable sample from before.

The two action bar items (“Get Word File”, “Open Word File”) route to get() and open() methods, each of which call startActivityForResult() with the appropriate action string:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private void open() {
    Intent i=
        new Intent()
            .setType("text/plain")
            .setAction(Intent.ACTION_OPEN_DOCUMENT)
            .addCategory(Intent.CATEGORY_OPENABLE);

    startActivityForResult(i, REQUEST_OPEN);
}

private void get() {
    Intent i=
        new Intent()
            .setType("text/plain")
            .setAction(Intent.ACTION_GET_CONTENT)
            .addCategory(Intent.CATEGORY_OPENABLE);

    startActivityForResult(i, REQUEST_GET);
}
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

In onActivityResult(), if we received a RESULT\_OK response, we set up docObservable, where we:

- Use defer() and just() to “observe” the results of calling createDurableContent(), supplying it the Intent that is the result of the startActivityForResult() call
- Use subscribeOn() to move that work to a background thread
- Use cache() to cache the results for as long as we have docObservable
- Use observeOn() to observe the results on the main application thread.

createDurableContent(), along with obtainDurablePermissions(), makeLocalCopy(), and buildDocFileForUri(), does the same work that the

## CONSUMING DOCUMENTS

---

DurablizerService did in the Documents/Durable sample app:

- Get the persistable Uri permissions, if we can have them
- Make a local copy of the content, if we cannot

The biggest differences are that `createDurableContent()` saves the Uri of either the opened document (if we got permission) or the local copy in `SharedPreferences`, and it returns a `DocumentFileCompat` representing the external word list:

```
private DocumentFileCompat createDurableContent(Intent result) throws IOException {
    Uri document=result.getData();
    ContentResolver resolver=getActivity().getContentResolver();
    boolean weHaveDurablePermission=obtainDurablePermission(resolver, document);

    if (!weHaveDurablePermission) {
        document=makeLocalCopy(getActivity(), resolver, document);
    }

    if (weHaveDurablePermission || document!=null) {
        prefs
            .edit()
            .putString(PREF_URI, document.toString())
            .commit();

        return(buildDocFileForUri(getActivity(), document));
    }

    throw new IllegalStateException("Could not get durable permission or make copy");
}

private static boolean obtainDurablePermission(ContentResolver resolver,
                                              Uri document) {
    boolean weHaveDurablePermission=false;

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.KITKAT) {
        int perms=Intent.FLAG_GRANT_READ_URI_PERMISSION
            | Intent.FLAG_GRANT_WRITE_URI_PERMISSION;

        try {
            resolver.takePersistableUriPermission(document, perms);

            for (UriPermission perm : resolver.getPersistedUriPermissions()) {
                if (perm.getUri().equals(document)) {
                    weHaveDurablePermission=true;
                }
            }
        }
        catch (SecurityException e) {
            // OK, we were not offered any persistable permissions
        }
    }

    return(weHaveDurablePermission);
}

private static Uri makeLocalCopy(Context ctxt, ContentResolver resolver,
```

## CONSUMING DOCUMENTS

---

```
        Uri document)
    throws IOException {
    DocumentFileCompat docFile=buildDocFileForUri(ctxt, document);
    Uri result=null;

    if (docFile.getName()!=null) {
        String ext=
            MimeTypeMap.getSingleton().getExtensionFromMimeType(docFile.getType());

        if (ext!=null) {
            ext="."+ext;
        }

        File f=File.createTempFile("cw_", ext, ctxt.getFilesDir());

        docFile.copyTo(f);
        result=Uri.fromFile(f);
    }

    return(result);
}

private static DocumentFileCompat buildDocFileForUri(Context ctxt, Uri document) {
    DocumentFileCompat docFile;

    if (document.getScheme().equals(ContentResolver.SCHEME_CONTENT)) {
        docFile=DocumentFileCompat.fromSingleUri(ctxt, document);
    }
    else {
        docFile=DocumentFileCompat.fromFile(new File(document.getPath()));
    }

    return(docFile);
}
```

(from [Documents/Diceware/app/src/main/java/com/commonware/android/diceware/PassphraseFragment.java](#))

onActivityResult() then calls docSub():

```
private void docSub() {
    docSub=docObservable.subscribe(documentFile -> {
        docObservable=null;
        loadWords(true, true);
    });
}
```

(from [Documents/Diceware/app/src/main/java/com/commonware/android/diceware/PassphraseFragment.java](#))

Here, we subscribe to docObservable, and when the work is complete, we set docObservable to null (indicating that we are done with it), then call loadWords(true, true) to reload the words from our new source and generate a new passphrase based on those words.

The net result is that tapping either of those action bar items brings up the

---

## CONSUMING DOCUMENTS

---

appropriate system UI to pick a piece of content, after which we start using that content. And, since we are persisting the `Uri` to that external word list in `SharedPreferences`, we will continue using that word source for the foreseeable future.

### Other Fiddly Bits

That “foreseeable future” may not be all that long. If the user taps the “Reset” action bar overflow item, we `clear()` our `SharedPreferences`, then call `loadWords(true, true)` to read in the asset’s words plus generate a passphrase based that word list:

```
case R.id.reset:
    prefs.edit().clear().apply();
    loadWords(true, true);
    return(true);
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

The action bar itself is populated from a menu resource, one that defines a submenu for the possible `wordCount` values:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/word_count"
    android:showAsAction="ifRoom"
    android:title="@string/menu_words">
    <menu>
      <group android:checkableBehavior="single">
        <item
          android:id="@+id/word_count_4"
          android:title="4" />
        <item
          android:id="@+id/word_count_5"
          android:title="5" />
        <item
          android:id="@+id/word_count_6"
          android:checked="true"
          android:title="6" />
        <item
          android:id="@+id/word_count_7"
          android:title="7" />
        <item
          android:id="@+id/word_count_8"
          android:title="8" />
      </group>
    </menu>
  </item>
</menu>
```

## CONSUMING DOCUMENTS

---

```
<item
  android:id="@+id/word_count_9"
  android:title="9" />
<item
  android:id="@+id/word_count_10"
  android:title="10" />
</group>
</menu>
</item>
<item
  android:id="@+id/refresh"
  android:icon="@drawable/ic_cached_white_24dp"
  android:showAsAction="ifRoom"
  android:title="@string/menu_refresh" />
<item
  android:id="@+id/get"
  android:showAsAction="never"
  android:title="@string/get" />
<item
  android:id="@+id/open"
  android:enabled="false"
  android:showAsAction="never"
  android:title="@string/open" />
<item
  android:id="@+id/reset"
  android:showAsAction="never"
  android:title="@string/menu_reset" />
</menu>
```

(from [Documents/Diceware/app/src/main/res/menu/actions.xml](#))

We start with the `word_count_6` item checked, and the `wordCount` field is also initialized to 6. If the user taps on any of those submenu items, we update the submenu to check the proper item, figure out the new `wordCount` (by cheating and parsing the menu title as an `Integer`), and if the user changed word count values we generate a fresh passphrase (without re-loading the word list):

```
case R.id.word_count_4:
case R.id.word_count_5:
case R.id.word_count_6:
case R.id.word_count_7:
case R.id.word_count_8:
case R.id.word_count_9:
case R.id.word_count_10:
    item.setChecked(!item.isChecked());
```

## CONSUMING DOCUMENTS

---

```
int temp=Integer.parseInt(item.getTitle().toString());

if (temp!=wordCount) {
    wordCount=temp;
    loadWords(false, true);
}

return(true);
```

(from [Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java](#))

Since that wordCount value can change, we save it as part of the saved instance state Bundle in onSaveInstanceState(), and we pull that value back out of that Bundle in onCreateView().

However, we are *not* putting the generated passphrase in the saved instance state Bundle ourselves, even though clearly that is being generated at runtime. Here, Diceware takes advantage of a bit of a trick. On the layout resource, the TextView that shows the passphrase has android:freezesText="true":

```
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:padding="8dp">

    <android.support.v7.widget.CardView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center"
        android:padding="8dp">

        <TextView
            android:id="@+id/passphrase"
            android:layout_width="wrap_content"
