CWAC-CrossPort does not include everything from the Design Support library, but it does include most of it.

As with the rest of the CWAC libraries, using it requires that you add the CWAC artifact repository to your Gradle configuration:

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

Then, add a dependency on the artifact itself, for some version:

dependencies {
    implementation 'com.commonsware.cwac:crossport:0.3.0'
}
Snackbars: Sweeter than Toasts

The Toast has been in Android since the beginning. It allows you to pop up a message to show the user, one that does not interfere with the rest of your activity layout. And, it is fairly easy to use.

However, some people get burned by Toast:

- A Toast is modeless, so you cannot get user input via a Toast
- Because a Toast is modeless, it is time-limited, and therefore the user might never see your message, because the user is not glancing at the screen during the short window your Toast is visible
- A Toast is a separate window from the window that is displaying your activity, so your Toast will remain visible even if the user navigates to some other activity, which can be annoying at times

The Material Design guidelines instead call for the use of a “snackbar”, and the Design Support Library offers a Snackbar implementation of this UI pattern. In contrast to a Toast:

- A Snackbar is part of your activity’s UI, and so it can collect input from the user, while it is around, usually in the form of some sort of “action”
- A Snackbar can be time-limited (for information notices) or durable (for errors or getting user input)
- While a Snackbar is part of your activity (and will go away when the user leaves your activity), you do not have to declare it in your layout files

With that in mind, let’s take a look at some use cases for a Snackbar and how they can be implemented.

Alerts

The quintessential reason to use a Toast was to display a simple message to the user. You can use a Snackbar in the same role, with most of the same code.

Snackbar has a static make() method, mirroring the makeText() method on Toast. make() takes three parameters, only slightly different from those on makeText():

1. A View in the activity that wishes to show the Snackbar
2. The message, in the form of a CharSequence (e.g., a String) or a string
resource ID
3. The duration of the Snackbar, which is either Snackbar.LENGTH_SHORT, Snackbar.LENGTH_LONG, or possibly something else (the documentation is inconsistent on this point)

As with makeText() on Toast, simply calling make() on Snackbar creates a Snackbar object for you, but does not display anything. You need to call show() on the Snackbar instance to get it to appear.

The DesignSupport/Snackbar sample project is a clone of the Threads/AsyncDemo sample from earlier in the book. The app shows a list of 25 Latin words, progressively added to the list via an AsyncTask. When the list is fully populated, the original sample would display a Toast, from onPostExecute() of the AsyncTask.

The revised sample substitutes a Snackbar:

```java
@Override
protected void onPostExecute(Void unused) {
    Snackbar.make(getListView(), R.string.done, Snackbar.LENGTH_LONG).show();

    task=null;
}
```

(from DesignSupport/Snackbar/app/src/main/java/com/commonsware/android/snackbar/async/AsyncDemoFragment.java)
The Snackbar will be centered along the bottom:

![Figure 492: Official Snackbar](image)

Unfortunately, there does not seem to be much support for styling the look of the Snackbar. To do this manually, you can obtain the actual View for the Snackbar via `getView()`. While you should make few assumptions about what this View actually is, you should be able to call setters on that View to change things like background colors.

Also note that the user can get rid of a Snackbar via a swipe gesture, in addition to allowing the Snackbar to time out on its own. This is not possible with Toast, as a Toast is modeless.

**Action Bars. No, Not Those Action Bars.**

We can expand upon the user interaction with a Snackbar by adding an action to it. To do this, just call `setAction()` on the Snackbar after creating it, passing in the display string for the action (what the user will see on the Snackbar) and a `View.OnClickListener` that will get control when the user taps on that action. The look and feel of the action is up to the Snackbar implementation.
The Android Design Support Library

The DesignSupport/SnackbarAction sample project is a clone of the previous sample, adding one of these actions. Specifically, once the list is loaded, we want a “Restart” action to clear the list and load it again. Perhaps the user found loading the list to be exciting and wishes to see it happen all over again.

To that end, we should pull out the work of loading our list into a loadModel() method that can be used from multiple places:

```java
private void loadModel() {
    task = new AddStringTask();
    task.execute();
}
```

(from DesignSupport/SnackbarAction/app/src/main/java/com/commonsware/android/snackbar/action/AsyncDemoFragment.java)

The onCreate() method now delegates to loadModel():

```java
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    adapter =
        new ArrayAdapter<String>(getActivity(),
                                   android.R.layout.simple_list_item_1,
                                   model);

    loadModel();
}
```

(from DesignSupport/SnackbarAction/app/src/main/java/com/commonsware/android/snackbar/action/AsyncDemoFragment.java)

And, more importantly for this section, we also call loadModel() from the View.OnClickListener of the action that we add to our Snackbar:

```java
@Override
protected void onPostExecute(Void unused) {
    Snackbar munchie = Snackbar.make(getListView(), R.string.done,
                                       Snackbar.LENGTH_LONG);

    munchie.setAction(R.string.snackbar_action_restart,
                      new View.OnClickListener() {
                          @Override
                          public void onClick(View view) {
                              adapter.clear();
                          }
                      });
}
```

(from DesignSupport/SnackbarAction/app/src/main/java/com/commonsware/android/snackbar/action/AsyncDemoFragment.java)
The Android Design Support Library

```java
loadModel();
}
});
munchie.show();
task=null;
```

(from DesignSupport/SnackbarAction/app/src/main/java/com/commonsware/android/snackbar/action/AsyncDemoFragment.java)

The action will appear on the Snackbar itself:

![Figure 493: Official Snackbar, with an Action](image)

Tapping the action triggers the listener, which in our case clears the list and starts the load all over again.

**CWAC-CrossPort**

CWAC-CrossPort supports Snackbar, with all the same features as are in the original Design Support implementation. The DesignSupport/SnackbarActionCP sample project is a clone of the previous sample, where we have migrated to CWAC-CrossPort.
Our app/build.gradle file not only adds the CWAC-CrossPort dependency, but it sets the minSdkVersion to 21:

```gradle
apply plugin: 'com.android.application'

repositories {
  maven {
    url "https://s3.amazonaws.com/repo.commonsware.com"
  }
}

dependencies {
  implementation 'com.android.support:support-fragment:27.1.1'
  implementation 'com.commonsware.cwac:crossport:0.3.0'
}

android {
  compileSdkVersion 27
  buildToolsVersion '27.0.3'

  defaultConfig {
    minSdkVersion 21
    targetSdkVersion 27
    applicationId 'com.commonsware.android.snackbar.action.crossport'
  }
}
```

(from DesignSupport/SnackbarActionCP/app/build.gradle)

Removing appcompat-v7 has rippling effects across the rest of the code:

- We switch to inheriting from Theme.Material.Light.DarkActionBar in Theme.Apptheme, replacing the former Theme.AppCompat theme
- We change the theme colors to use the android: prefix (e.g., android:colorPrimary), instead of the bare names used by appcompat-v7
- Our activity now just inherits from Activity, instead of AppCompatActivity
- Our fragment now just inherits from android.app.Fragment, instead of android.support.v4.app.Fragment
- Our Snackbar import is now for com.commonsware.cwac.crossport.design.widget.Snackbar
Otherwise, the code is identical, and we get identical results, though with an inverse theme and adjusted title bar, to help distinguish the original from the CWAC-CrossPort edition:

![CWAC-CrossPort Snackbar](image)

*Figure 494: CWAC-CrossPort Snackbar*
Absolutely FABulous

Perhaps no single element of the Material Design aesthetic has gotten more attention than has the floating action button, or FAB. These are round buttons, usually floating towards the bottom of the screen over top of the main UI:

![Google Maps, with a Pair of FABs, on a Nexus 4](image)

**Figure 495: Google Maps, with a Pair of FABs, on a Nexus 4**

The job of the FAB is to provide rapid access to the primary action that users might take on that particular screen. Typically, in a master/detail sort of UI, the FAB will allow creating a new item for the collection:

- A voice recording app showing a list of previous recordings might have a FAB to make a new recording
- A blood pressure monitoring app showing a list of previous readings might have a FAB to take a new reading
- A to-do list app showing the current tasks might have a FAB to add a new task

However, the FAB does not have to be an “add” operation. The only real limitation is that it should be a screen-level operation, not affecting only some selected item on
that screen. So, for example, in the video recording app example, you would not use a FAB to play back one of the existing videos... at least on a screen listing those videos. If tapping a video in that list brings up some sort of detail screen, *that* screen could possibly have a FAB to play back the video.

The Design Support library has a rudimentary FAB implementation, and there are third-party alternatives that either add power or solve other FAB-related problems.

**FAB Mechanics**

In many respects, setting up a FAB is not that different from setting up any other widget: put it in your layout, positioned where you want it, then access it in Java code to set up listeners. In particular, Google's FAB implementation supports a `View.OnClickListener` much like a regular `Button`.

The [DesignSupport/FAB](https://github.com/material-components/material-components-android) sample project is a clone of the first Snackbar sample from earlier in this chapter. The second Snackbar sample added a “restart” action to the Snackbar. In this sample, we instead have a “restart” action on a FAB.

Before, we did not need a layout resource for the AsyncDemoFragment, as it was an ordinary ListFragment and therefore would supply a ListView automatically. However, this time, we want to have a FAB as well, so we need our own layout file:

```xml
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ListView
        android:id="@android:id/list"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:drawSelectorOnTop="false" />

    <android.support.design.widget.FloatingActionButton
        android:id="@+id/refresh"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_alignParentBottom="true"
        android:layout_alignParentEnd="true"
        android:layout_alignParentRight="true"
        android:layout_marginBottom="@dimen/fab_margin"
        android:layout_marginEnd="@dimen/fab_margin"
        android:layout_marginRight="@dimen/fab_margin" />
</RelativeLayout>
```
Here, the FAB (a.k.a., android.support.design.widget.FloatingActionButton) is later in a RelativeLayout than is the ListView, so the FAB will have higher elevation and will appear to float over the ListView. The android:src attribute points to a drawable resource, much like how that attribute works on an ImageButton.

However, the interesting bit is the pair of margin attributes (android:layout_marginRight and android:layout_marginBottom). They point to a fab_margin dimension resource, one with some specific values required due to bugs (or curious implementation choices) in Google's FAB implementation.

By default, the fab_margin in res/values/dimens.xml is used, which has a dimension of 0dp:

```xml
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="fab_margin">0dp</dimen>
</resources>
```

You might think that this would cause the FAB to be slammed up against the side and bottom of the RelativeLayout. However, the FAB has built-in margins... on older devices.

But, for whatever reason, on API Level 21+, that automatic margin vanishes. So, we have another definition of fab_margin, in res/values-v21/dimens.xml, setting it to 16dp:

```xml
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="fab_margin">16dp</dimen>
</resources>
```

Furthermore, Google's Material Design docs state that there should be 24dp margin on tablets, not 16dp. So, we have a third definition of fab_margin, in res/values-sw720dp-v21, to set the margin to 24dp:
It is possible that a full implementation of this would need a fourth `fab_margin` value, for Android 4.x tablets, where `fab_margin` would be set to something that gives a 24dp margin but takes into account the automatic margin that the FAB seems to have prior to API Level 21. This sample avoids this, going with the automatic margin on all tablets, regardless of API level.

The Java code is fairly straightforward, retrieving the FAB in `onViewCreated()` and hooking up a `View.OnClickListener` to the FAB, where that listener is the `AsyncDemoFragment` itself:

```java
@Override
public void onViewCreated(View v, Bundle savedInstanceState) {  
  super.onViewCreated(v, savedInstanceState);

  getListView().setScrollbarFadingEnabled(false);
  setListAdapter(adapter);

  FloatingActionButton fab=v.findViewById(R.id.refresh);

  fab.setOnClickListener(this);
}
```

In `onClick()`, if the `AsyncTask` is still running, we `cancel()` it. Then, we clear the list and kick off a fresh task via the same sort of `loadModel()` method as seen in the second SnackBar example:

```java
@Override
public void onClick(View view) {
  if (task!=null) {
    task.cancel(false);
  }

  adapter.clear();
  loadModel();
}
```

```java
void loadModel() {
```
This gives us our FAB:

**Coordinating with Snackbars**

However, what the above screenshots do *not* illustrate is what happens when our Snackbar appears:

![Official FAB, Conflicting with the Snackbar](image)

*Figure 496: Official FAB, Conflicting with the Snackbar*

The fact that the Snackbar overlaps the FAB should not be much of a surprise. After all, the Snackbar overlaps the ListView as well. A Toast would also overlap the list and FAB. Hence, to some extent, the fact that there is this lack of coordination between the Snackbar and the FAB seems to be fairly normal.

That being said, the Design Support library has a container designed for coordinating between different children as those children animate and scroll. This container — CoordinatorLayout — is a subclass of FrameLayout, meaning other
than Z-axis ordering (elevation) and gravity, it has no other notable layout rules. It merely exists to perform this sort of coordination.

As it turns out, CoordinatorLayout has special awareness of Snackbar and the FAB, so simply using CoordinatorLayout will cause the FAB to slide upwards to make room for the Snackbar.

The DesignSupport/CoordinatedFAB sample project is a clone of the previous FAB example, except that we switch from a RelativeLayout root container to a CoordinatorLayout:

```xml
<?xml version="1.0" encoding="utf-8"?>
<android.support.design.widget.CoordinatorLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
   <ListView
        android:id="@android:id/list"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:drawSelectorOnTop="false"/>
   <android.support.design.widget.FloatingActionButton
        android:id="@+id/refresh"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="bottom|end"
        android:layout_marginBottom="@dimen/fab_margin"
        android:layout_marginEnd="@dimen/fab_margin"
        android:src="@drawable/ic_refresh_black_24dp"/>
</android.support.design.widget.CoordinatorLayout>
```

Since CoordinatorLayout is based on FrameLayout, not RelativeLayout, we have to adjust the layout rules on the FAB to match, using android:layout_gravity to position the FAB towards the bottom right corner.
With no other changes, we now get coordinated movements of the FAB and the Snackbar as the Snackbar appears and disappears:

![Figure 497: Official FAB, Coordinated with the Snackbar](image)

**CWAC-CrossPort**

CWAC-CrossPort also has ports of FloatingActionButton and CoordinatorLayout, as can be seen in the [DesignSupport/CoordinatedFABCP](https://github.com/android/design-support-library/tree/master/examples/CoordinatedFABCP) sample project.

In addition to the sorts of changes needed before (e.g., replace appcompat-v7 with crossport, change imports, change the theme), our layout now uses crossport classes:

```xml
<?xml version="1.0" encoding="utf-8"?>
<android.support.design.widget.CoordinatorLayout
   xmlns:android="http://schemas.android.com/apk/res/android"
   android:layout_width="match_parent"
   android:layout_height="match_parent">

   <ListView
      android:id="@android:id/list"
      android:layout_width="match_parent"
      android:layout_height="match_parent">

</android.support.design.widget.CoordinatorLayout>
```

1483
And, as before, we get the same results as with the official implements, just without the appcompat-v7 overhead:

![Coordinated FAB CrossPort Demo](from DesignSupport/CoordinatedFABCP/app/src/main/res/layout/main.xml)

**Figure 498: Coordinated FAB CrossPort Demo**

### Third-Party FABs... and FAMs

The Design Support implementation of a FAB works, and it works nicely “out of the box” with CoordinatorLayout. However, it implements only a subset of the Material
Design FAB capabilities, let alone related structures like the floating action menu (FAM).

As a result, there are many FAB projects listed on the Android Arsenal, offering other implementations of a FAB.

In addition to complete FAB and FAM implementations, developers have been publishing libraries that add on other Material Design features to existing FAB implementations, such as:

- Wrapping a progress bar around a FAB, perhaps to show the progress of some work triggered by a previous click on the FAB
- Using a “material sheet” or a “floating action toolbar” as an alternative to the FAM pattern

**Material Tabs with TabLayout**

Android has had a myriad of tab implementations over the years:

- TabHost and TabWidget
- FragmentTabHost and TabWidget
- the now-deprecated action bar tabs
- PagerTabStrip, used in conjunction with a ViewPager

The Design Support library adds yet another tab implementation: TabLayout. Specifically, this implementation’s claim to fame is a faithful implementation of a subset of Google’s Material Design guidelines for how tabs should look and behave.

TabLayout can be used with or without a ViewPager. If you elect to skip the ViewPager, TabLayout works in a form reminiscent of action bar tabs, where it is responsible for the tab UI and you are responsible for updating the rest of your UI based upon the chosen tab (e.g., commit a FragmentTransaction). If you elect to use a ViewPager, TabLayout can lightly integrate with the ViewPager, so navigating by one means (e.g., swiping the pager) updates the other UI (e.g., changing the selected tab).

From a layout standpoint, you use TabLayout much like you would use TabWidget: put it where the tabs should go. Since Material Design wants the tabs on top, that means that typically you would put TabLayout inside a vertical LinearLayout, with the actual tabbed content beneath the TabLayout.
This is illustrated in the DesignSupport/TabLayout sample project. It is based on the original ViewPager samples, showing a set of editors in pages, this time using a TabLayout as the tab implementation (as opposed to PagerTabStrip or the TabPagerIndicator from the ViewPagerIndicator library).

The layout loaded by the activity has a setup much as described above: a vertical LinearLayout wrapped around a TabLayout and our ViewPager:

```xml
    <android.support.design.widget.TabLayout android:id="@+id/tabs" android:layout_width="match_parent" android:layout_height="wrap_content"/>
</LinearLayout>
```

(from DesignSupport/TabLayout/app/src/main/res/layout/main.xml)

TabLayout can have its tabs operate in one of two modes: fixed and scrollable. With fixed tabs, all tabs will be on the screen at all times, where they divide the available horizontal space between them. This works fine for just a few tabs. But for lots of tabs, each tab becomes very small, making it unlikely that the user can read the tab caption. Scrollable tabs each take up as much room as their caption requires, and if the roster of tabs becomes too wide for the screen, the user can swipe the tabs.

The sample app demonstrates both of these approaches, using a checkable action bar item to toggle between three editors with fixed tabs or ten editors with scrollable tabs. The default state is to be in fixed-tab mode:

```xml
    <item android:id="@+id/fixed"
        android:title="@string/menu_fixed"/>
</menu>
```

(from DesignSupport/TabLayout/app/src/main/res/menu/main.xml)
The entire app was switched over to use AppCompatActivity and the fragment backport, as that is what the Design Support library requires. Beyond that, the EditorFragment is pretty much unchanged from the original implementations, just showing a large EditText widget with a hint based on the page number.

Our PagerAdapter — SamplePagerAdapter — has one change beyond the switch to the fragment backport. To accommodate switching between fixed and scrollable tabs, rather than hard-coding the number of pages, the adapter offers a setPageCount() method to stipulate the number of pages. The page count defaults to 3.

```java
package com.commonsware.android.tablayout;
import android.content.Context;
import android.support.v4.app.Fragment;
import android.support.v4.app.FragmentManager;
import android.support.v4.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
  private final Context ctxt;
  private int pageCount=3;

  public SampleAdapter(Context ctxt, FragmentManager mgr) {
    super(mgr);

    this.ctxt=ctxt;
  }

  @Override
  public int getCount() {
    return(pageCount);
  }

  @Override
  public Fragment getItem(int position) {
    return(EditorFragment.newInstance(position));
  }

  @Override
}
```
public String getPageTitle(int position) {
    return(EditorFragment.getTitle(ctxt, position));
}

void setPageCount(int pageCount) {
    this.pageCount = pageCount;
}

In MainActivity, in onCreate(), we set up the ViewPager and the TabLayout:

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    pager = (ViewPager)findViewById(R.id.pager);
    adapter = new SampleAdapter(this, getSupportFragmentManager());
    pager.setAdapter(adapter);

    tabs = (TabLayout)findViewById(R.id.tabs);
    tabs.setupWithViewPager(pager);
    tabs.setTabMode(TabLayout.MODE_FIXED);
}

The bulk of the TabLayout setup work is handled with one call to setupWithViewPager(). This:

- Creates one tab for every page, based on whatever the PagerAdapter in the ViewPager is reporting at the time of this call
- Sets up the appropriate listeners, so that taps on a tab switches pages in the ViewPager, and swipes between pages update the selected tab

We also call setTabMode(TabLayout.MODE_FIXED), as we are going with fixed tabs at the outset.
This gives us our three tabs:

![TabLayout Sample, As Initially Launched, Showing Three Fixed Tabs](image)

*Figure 499: TabLayout Sample, As Initially Launched, Showing Three Fixed Tabs*

But we also have that menu resource, to allow the user to switch between fixed and scrollable tabs. We inflate() that resource in onCreateOptionsMenu() as usual, and we handle the checked state change in onOptionsItemSelected():

```java
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
    return (super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.fixed) {
        item.setChecked(!item.isChecked());
        if (item.isChecked()) {
            adapter.setPageCount(3);
            tabs.setTabMode(TabLayout.MODE_FIXED);
        }
    }
    return (super.onOptionsItemSelected(item));
}
```
If the user taps on our checkable overflow item, we invert the item’s checked state (which, unfortunately, does not happen automatically). Then, we call setPageCount() on the SampleAdapter and setTabMode() on the TabLayout based on the now-current checked state, to either have three fixed tabs or ten scrollable tabs.

Changing the page count of the SampleAdapter requires calling notifyDataSetChanged() to alert the ViewPager that the data set changed and it needs to repaint. However, while the associated TabLayout repaints, the selected page is left alone. That is fine when going from 3 pages to 10, but it could be a problem when going from 10 pages to 3, if the selected page is after those three. So, we use setCurrentItem() to manually move the selection to the last valid page, if that situation occurs.
Clicking on the “Fixed” checkable overflow item, and thereby unchecking it from its initial checked state, gives us ten scrollable tabs:

![TabLayout Demo](image)

**Figure 500: TabLayout Sample, Showing Scrollable Tabs**

Note that while this particular sample app shows TabLayout working with a ViewPager, a ViewPager is not required to be able to use TabLayout. You can simply have the TabLayout plus your own system for whatever the tabs switch in your UI. Then, you can use methods like addTab() and setOnTabSelectedListener() to set up tabs and find out when the user taps on them, so you can adjust your UI to match the selected tab. That being said, many users may come to expect that they can horizontally swipe to move between pages of content, and so definitely consider using a ViewPager if practical.

**CWAC-CrossPort**

CWAC-CrossPort has a port of TabLayout. The DesignSupport/TabLayoutCP sample project is identical to the DesignSupport/TabLayout sample app, except that it uses CWAC-CrossPort. The same sorts of modifications as seen earlier in this chapter are required, such as changing the layout to refer to the appropriate package for the ported TabLayout:
In this particular sample, since we are using menu resources, we have one additional change to make: switching from app:showAsAction to android:showAsAction, as we are using the native action bar:

```xml
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android"
     xmlns:app="http://schemas.android.com/apk/res-auto">
  <item
    android:id="@+id/fixed"
    android:title="@string/menu_fixed"
    android:checkable="true"
    android:checked="true"
    android:showAsAction="never"/>
</menu>
```

(From DesignSupport/TabLayoutCP/app/src/main/res/menu/actions.xml)

**Floating Labels**

The EditText widget supports the android:hint attribute. The hint is shown in the EditText when the EditText is otherwise empty. However, if the EditText has actual text in it (whether typed by the user, loaded from a database, or whatever), the hint is not shown. This saves screen space compared to having a TextView label always visible; the hint itself serves as the label.
However, the hint-as-label pattern has a major drawback: the hint is not visible if there is text in the EditText. In the long term, as the user learns your UI, this is not a big problem. However, particularly early on, the user might look at a filled-in field and wonder what that field is for. This is even more likely in cases where the user is not the one who typed the text into the field in the first place, such as editing a database entry pulled from a server, where somebody (or something) else had created the entry in the first place.

The “floating label” pattern starts with a hint in the field. However, when the field is used, the hint animates out of the field itself and “floats” above the field in a shrunken form. This way, the label is always visible. However, in its smaller floating state, it takes up less screen space, yet while the field is otherwise empty, we can take advantage of that space to offer a “full-size” label instead.

The Design Support library offers TextInputLayout as a way of implementing the floating label pattern. This is not a subclass of EditText, but rather a ViewGroup that is wrapped around the EditText. This is convenient, insofar as it allows developers to use other EditText subclasses and still get the floating-label behavior.

TextInputLayout also supports an error state, where we can optionally show an error message below the EditText, such as an indication of an invalid bit of data entry.

**Using TextInputLayout**

The DesignSupport/FloatingLabel sample project is a clone of an earlier sample where we allowed the user to enter in a URL and then, upon a button click, would parse the URL into a Uri, wrap that in an ACTION_VIEW Intent, then try to start an activity for that Intent.

The original sample’s layout looks like:

```xml
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <EditText
        android:id="@+id/url"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>

</LinearLayout>
```
In this revised sample, the original EditText is augmented with a TextInputLayout:

```xml
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:id="@+id/browse"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:onClick="showMe"
        android:text="@string/show_me"/>

    <android.support.design.widget.TextInputLayout
        android:id="@+id/til"
        android:layout_width="match_parent"
        android:layout_height="wrap_content">

        <EditText
            android:id="@+id/url"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:hint="@string/url"
            android:inputType="textUri"/>

    </android.support.design.widget.TextInputLayout>

</LinearLayout>
```

(from DesignSupport/FloatingLabel/app/src/main/res/layout/main.xml)
You will notice that there are a few changes here:

- The EditText is wrapped by an `android.support.design.widget.TextInputLayout` container that provides the actual floating label itself.
- The Button is moved ahead of the EditText, in terms of the top-down organization of our `vertical LinearLayout`.
- The Button has a `[requestFocus/]` child element, indicating to Android that this widget should get the focus first.

Those latter two changes are due to one major limitation with `TextInputLayout`: the hint moves out of the EditText into the floating position when either there is text in the EditText or the EditText gains the focus. Strangely, simply putting the Button before the EditText is insufficient, as is simply adding `[requestFocus/]` on the Button. Both have to be implemented to cause the `TextInputLayout` to show the hint in its default location at the outset.

The Java code is also augmented a bit from the original sample, to take advantage of the error-reporting feature of `TextInputLayout`:

```java
package com.commonsware.android.design.til;

import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.support.design.widget.TextInputLayout;
import android.support.v7.app.AppCompatActivity;
import android.util.Patterns;
import android.view.View;
import android.widget.EditText;

public class LaunchDemo extends AppCompatActivity {
  private TextInputLayout til;

  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);

    til=(TextInputLayout)findViewById(R.id.til);
    til.setErrorEnabled(true);
  }

  public void showMe(View v) {
    EditText urlField=(EditText)findViewById(R.id.url);
  }
}
```
The Patterns class in Android contains a series of stock regular expressions. One, 
WEB_URL, is designed to see if the URL that was entered looks like a Web URL. When 
the user taps the button, if the pattern matches what the user entered in the field, 
we go ahead and try to start the activity. If not, we show an error.

To show the error, we need to do two things:

1. Up front, we call setErrorEnabled(), to tell TextInputLayout to reserve 
some space for an error message
2. At the point where we want to show the error, we call setError() on the 
   TextInputLayout
When we run the app, the TextInputLayout leaves the hint in the EditText itself, as the EditText is empty and does not have the focus:

![TextInputLayout Demo](image)

*Figure 501: FloatingLabel Sample, As Initially Launched*
Once the user taps on the field, though, the hint “floats” above the EditText:

![FloatingLabel Sample, After Focus Change](image)

*Figure 502: FloatingLabel Sample, After Focus Change*
And, if the user tries entering an invalid URL, the error message appears when the user taps the button to try to visit the invalid URL:

![Figure 503: FloatingLabel Sample, After Erroneous Data Entry](image)

**CWAC-CrossPort**

CWAC-CrossPort has a port of `TextInputLayout` and `TextInputEditText`, the latter being the `EditText` subclass that actually winds up being used with a `TextInputLayout`.

The [DesignSupport/FloatingLabelCP](#) sample project is a port of the `FloatingLabel` sample, converted to using CWAC-CrossPort. The standard sorts of changes seen earlier in this chapter, such as artifact dependencies and themes, are needed. In addition, the layout needs to change to use the CWAC-CrossPort editions of the classes:

```xml
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">
```

1499
Third-Party Floating Labels

As with the rest of the Design Support library, TextInputLayout requires appcompat-v7. There are other implementations of the floating label pattern that do not require appcompat-v7, or perhaps offer additional features that you may want.

FloatLabeledEditText is one such implementation. It lacks the error message capability of TextInputLayout. However:

- It only floats the hint when there is text in the EditText widget, not when the EditText gets the focus, and
- It does not require appcompat-v7

The DesignSupport/FloatingLabelNative sample project is a clone of the previous sample, where the TextInputLayout is replaced by a FloatLabeledEditText:

```xml
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
              android:id="@+id/til"
              android:layout_width="match_parent"
              android:layout_height="wrap_content">
  <com.commonsware.cwac.crossport.design.widget.TextInputEditText
      android:id="@+id/url"
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
      android:hint="@string/url"
      android:inputType="textUri" />
</LinearLayout>
```
As with TextInputLayout, FloatLabeledEditText is a decorating container around a regular EditText. Here, since the hint is left alone when the EditText gets focus, we have it back in its original position at the top of the form.
Visually, it is fairly similar to `TextInputLayout`, albeit with the native action bar:

![FloatingLabelNative Sample, As Initially Launched](image)

*Figure 504: FloatingLabelNative Sample, As Initially Launched*
RecyclerView is the “Swiss army knife” of Android selection widgets. You can use it for a wide range of scenarios, well beyond what classic AdapterView widgets — like ListView or GridView — could handle.

In this chapter, we will “go outside the (AdapterView) box” and explore some advanced uses of RecyclerView.

**Prerequisites**

Understanding this chapter requires that you have read the core chapter on RecyclerView.

One section involves the use of custom XML drawables. Another section demonstrates using content pulled from the MediaStore ContentProvider.

This chapter also covers things like action modes and comparisons with other advanced ListView techniques.

**What About Cursors?**

So far, our model data has been a simple static array. Often times, though, we need to be working with model data culled from a database or ContentProvider. It may be that, for other reasons, we want to convert the Cursor we get back from queries into an array of ordinary Java objects. However, there is nothing stopping us from using a Cursor more directly as the model for a RecyclerView.

The RecyclerView.Adapter is responsible for teaching the
ADVANCED RecyclerView

RecyclerView.ViewHolder the model data to bind against. The RecyclerView.Adapter base class is oblivious to how that model data is organized: array, ArrayList, Cursor, JSONArray, etc. And the actual bind-the-data logic for the RecyclerView.ViewHolder is our responsibility — again, the base class is oblivious to where the data is coming from. Hence, we can create our own protocol for passing the model data for the needed position from the RecyclerView.Adapter to the RecyclerView.ViewHolder. If we want to use a Cursor as the vehicle for doing this, we are welcome to do so.

This is illustrated in the RecyclerView/VideoList sample project, which is a clone of the VideoList project introduced in the chapter on the MediaStore ContentProvider. In the original sample, the list was a ListView; in this sample, the list is a RecyclerView.

The core “plumbing” of the app is akin to the previous RecyclerView samples, such as using RecyclerViewActivity for handling getting the RecyclerView on the screen. However, our row layout is now based on the original VideoList row:

```xml
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    android:padding="8dp"
    android:background="?android:attr/selectableItemBackground">
    <ImageView
        android:id="@+id/thumbnail"
        android:layout_width="64dp"
        android:layout_height="64dp"
        android:contentDescription="@string/thumbnail"/>
    <TextView
        android:id="@android:id/text1"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginLeft="8dp"
        android:layout_gravity="center_vertical"
        android:textSize="24sp"/>
</LinearLayout>
```

(from RecyclerView/VideoList/app/src/main/res/layout/row.xml)

However, as we will now be accessing media, we need the READ_EXTERNAL_STORAGE permission, so we request that in the manifest:

```
<uses-permission android:name="android.permission.READ_EXTERNAL_STORAGE" />
```
And our app/build.gradle file gives us a targetSdkVersion of 23, requiring us to deal with runtime permissions on Android 6.0+:

```groovy
apply plugin: 'com.android.application'

dependencies {

    implementation 'com.android.support:recyclerview-v7:27.1.1'
    implementation 'com.android.support:support-fragment:27.1.1'
    implementation 'com.squareup.picasso:picasso:2.5.2'

}

android {

    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {

```
onCreate() sets up the empty RecyclerView with a LinearLayoutManager and a VideoAdapter (that we will examine shortly). However, we also confirm whether we have READ_EXTERNAL_STORAGE already — if yes, we call loadVideos() to get the videos. If we do not have permission, and we are not in the middle of requesting permission, we ask for permission using requestPermissions():

```java
private static final String STATE_IN_PERMISSION = "inPermission";
private static final int REQUEST_PERMS = 137;
private boolean isInPermission = false;

@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setLayoutManager(new LinearLayoutManager(this));
    setAdapter(new VideoAdapter());

    if (state != null) {
        isInPermission = state.getBoolean(STATE_IN_PERMISSION, false);
    }

    if (hasFilesPermission()) {
        loadVideos();
    } else if (!isInPermission) {
        isInPermission = true;

        ActivityCompat.requestPermissions(this,
            new String[] {Manifest.permission.READ_EXTERNAL_STORAGE,
                    REQUEST_PERMS};
    }
}
```

hasFilesPermission() just uses checkSelfPermission() to see whether we can read external storage:

```java
private boolean hasFilesPermission() {
```
We then call `loadVideos()` once we have permission, plus keep track of whether or not we are in the process of requesting permissions (so we do not raise the permission dialog again if we undergo a configuration change while the permission dialog is already on-screen):

```java
return(ContextCompat.checkSelfPermission(this,
    Manifest.permission.READ_EXTERNAL_STORAGE)==
    PackageManager.PERMISSION_GRANTED);
}
```

`loadVideos()` just calls `initLoader()` to request that we load the videos from the MediaStore:

```java
private void loadVideos() {
    getSupportLoaderManager().initLoader(0, null, this);
}
```

The CursorLoader logic, for getting details about videos from the MediaStore, is
pretty much the same as before, other than providing the Cursor to the VideoAdapter when it is ready:

```java
@Override
public Loader<Cursor> onCreateLoader(int arg0, Bundle arg1) {
    return (new CursorLoader(this,
        MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
        null, null, null,
        MediaStore.Video.Media.TITLE));
}

@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    ((VideoAdapter)getAdapter()).setVideos(c);
}

@Override
public void onLoaderReset(Loader<Cursor> loader) {
    ((VideoAdapter)getAdapter()).setVideos(null);
}
```

(from RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/video/MainActivity.java)

VideoAdapter is another subclass of RecyclerView.Adapter, this time with smarts for dealing with a Cursor as the source of model data:

```java
class VideoAdapter extends RecyclerView.Adapter<RowController> {
    Cursor videos = null;

    @Override
    public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
        return (new RowController(getLayoutInflater().
            inflate(R.layout.row, parent, false)));
    }

    void setVideos(Cursor videos) {
        this.videos = videos;
        notifyDataSetChanged();
    }

    @Override
    public void onBindViewHolder(RowController holder, int position) {
        videos.moveToPosition(position);
        holder.bindModel(videos);
    }

    @Override
    public int getItemCount() {
        return 0;
    }
    
    @Override
    public void onAttachedToRecyclerView(Toolbar toolbar) {
    }
    
    @Override
    public void onDetachedFromRecyclerView(RecyclerView recyclerView) {
    }
}
```

1510
### Advanced RecyclerView

```java
public int getItemCount() {
    if (videos == null) {
        return 0;
    }

    return videos.getCount();
}
```

(from RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java)

Specifically:

- `getItemCount()` returns the count of videos from the `Cursor`, or 0 if the `Cursor` is null (mimicking the behavior of `CursorAdapter`, which also treats a null `Cursor` as merely being one that has no rows)
- `onCreateViewHolder()` creates the `RowController`
- `onBindViewHolder()` moves the `Cursor` to the desired position, then passes the `Cursor` over to the `RowController`

Also note that we have a `setVideos()` method that is used to associate our `Cursor` of video information with the adapter. This also triggers a call to `notifyDataSetChanged()`, to ensure that the `RecyclerView` knows that our model has changed and it should re-render its contents.

The `RowController` constructor retrieves the necessary widgets from the row and setting up an `OnClickListener`:

```java
RowController(View row) {
    super(row);

    title = row.findViewById(android.R.id.text1);
    thumbnail = row.findViewById(R.id.thumbnail);

    row.setOnClickListener(this);
}
```

(from RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/RowController.java)

The `bindModel()` method invoked by `onBindViewHolder()` on `VideoAdapter` uses the same basic logic from the original `VideoList` sample to populate the row widgets, plus holds onto the `Uri` and MIME type of the video in data members for the current row:

```java
void bindModel(Cursor row) {
```

1511
Advanced RecyclerView

title.setText(row.getString(row.getColumnIndex(MediaStore.Video.Media.TITLE)));

videoUri = ContentUris.withAppendedId(MediaStore.Video.Media.EXTERNAL_CONTENT_URI, row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));

Picasso.with(thumbnail.getContext()).load(videoUri.toString()).fit().centerCrop().placeholder(R.drawable.ic_media_video_poster).into(thumbnail);

int mimeTypeColumn = row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);

videoMimeType = row.getString(mimeTypeColumn);
}

The `onClick()` method uses those saved Uri and MIME type values for starting up the activity to play the selected video:

```java
@override
public void onClick(View v) {
    Intent i = new Intent(Intent.ACTION_VIEW);

    i.setDataAndType(videoUri, videoMimeType);
    title.getContext().startActivity(i);
}
```

Other than the lack of dividers, the UI is very similar to the original VideoList.

This sample app is used as the basis for many other samples in this book, such as the drag-and-drop examples.

Grids

So far, we have focused on one visual representation of our collection of model data: a vertically-scrolling list. In the AdapterView family, a given AdapterView subclass has a specific visual representation (ListView for a vertically-scrolling list, GridView
for a two-dimensional grid, etc.). With RecyclerView, the choice of layout manager determines most of the visual representation, and so switching from a list to a grid can be as simple as a single-line change to our code.

The key, though, is the word *can* in the previous sentence. Depending upon what you want to do, a grid-styled RecyclerView can be more complicated, simply because you now have two dimensions’ worth of power and configuration to play with.

### A Simple Grid

Making a RecyclerView use a grid is a matter of swapping out LinearLayoutManager for GridLayoutManager. In the [RecyclerView/Grid](https://github.com/commonsware/android-recyclerview-grid) sample project, you will see a clone of the CardRippleList3 sample app, where we are now using GridLayoutManager in onCreate() of MainActivity:

```java
@Override
google
public void onCreate(Bundle state) {
google
    super.onCreate(state);
google
    setLayoutManager(new GridLayoutManager(this, 2));
google
    setAdapter(new IconicAdapter());
google
}
```

(GridLayoutManager takes a number of “spans”, as well as a Context, as constructor parameters. In the simple case, as is with this app, “spans” will equate to “columns”: each item returned by the RecyclerView.Adapter will go into a single-row, single-span cell.)
In our case, we requested two spans, and so our result resides in two columns:

![Figure 505: Grid RecyclerView Demo](image)

In this case, this is a “true” grid, with rows and columns of cells. Hence, the height of a row is determined by the tallest cell in that row. The “amet” cell in the left column of the third row is taller than required because of the word-wrap of the “consectetuer” cell in the right column of the same row, for example. Later in this chapter, we will examine yet another option, StaggeredGridLayoutManager, where cells do not necessarily line up neatly in rows.
Choosing the Number of Columns

If we rotate the screen for the above sample, you will see that the cells fit a bit better, since they are really repurposed list-style rows:

![Figure 506: Grid RecyclerView Demo, Landscape](image)

However, some apps may have smaller per-cell content. Plus, we have tablets to consider, and perhaps even televisions. It may be that you want to determine how many spans to use based on screen size and orientation.

One approach for doing that would be to use integer resources. You could have a res/values/intents.xml file with `<integer>` elements, giving the integer a name (name attribute) and value (text of the `<integer>` node). You could also have res/values-w600dp/intents.xml or other variations of the resource, where you provide different values to use for different screen sizes. Then, at runtime, call getResources().getInteger() to retrieve the correct value of the resource to use for the current device, and use that in your GridLayoutManager constructor. Now, you are in control over how many columns there are, by controlling how many spans are supplied to the constructor.

Another approach, suggested by Chiu-Ki Chan, is to create a subclass of RecyclerView, on which you provide a custom attribute for a desired approximate column width. Then, in your subclass’ onMeasure() method, you can calculate the number of spans to use to give you the desired column width.
Of course, another way to take advantage of screen space is to grow the cells. By default, they will grow evenly, as each cell takes up one span, and the spans are evenly sized. However, you can change that behavior, by attaching a GridLayoutManager.SpanSizeLookup to the GridLayoutManager. The GridLayoutManager.SpanSizeLookup is responsible for indicating, for a given item’s position, how many spans it should take up in the grid. We will examine how this works later in this chapter.

Varying the Items

So far, all of the items in the RecyclerView have had the same basic structure, just with varying content in the widgets in those items. But, it is entirely possible that we will want to have some items be more substantively different, based on different layouts. ListView and kin handle this via getViewTypeCount() and getItemViewType() in the ListAdapter. RecyclerView and RecyclerView.Adapter offer a similar mechanism, including their own variant of the getItemViewType() method. In this section, we will examine how this works, both with lists and grids.

A List with Headers

There are many cases where we want to have a list with some sort of section headers. The look of the headers usually is substantially different than the look of the rest of the rows, and therefore the best way to handle this is to teach the adapter about multiple row types.

This can be seen in the RecyclerView/HeaderList sample project. This is a clone of a similar project for ListView, where we want to put the 25 Latin words into 5 groups of 5 words each, with each group getting its own header.

Hence, our model data is now a two-dimensional String array:

```java
private static final String[][] items = {
    {"lorem", "ipsum", "dolor", "sit", "amet"},
    {"consectetuer", "adipiscing", "elit", "morbi", "vel"},
    {"ligula", "vitae", "arcu", "aliquet", "mollis"},
    {"etiam", "vel", "erat", "placerat", "ante"},
    {"porttitor", "sodales", "pellentesque", "augue", "purus"};
```

Our getItemCount() method now needs to take into account the headers, as well as the regular rows. There is one header row per batch of items, and so getItemCount()
serves up the sizes of the batches with the extra header rows:

```java
@Override
public int getItemCount() {
    int count = 0;

    for (String[] batch : items) {
        count += 1 + batch.length;
    }

    return count;
}
```

(from RecyclerView/HeaderList/app/src/main/java/com/commonsware/android/recyclerview/headerlist/MainActivity.java)

In order to teach RecyclerView about our different rows, we need to implement getItemCountType(). Unlike its counterpart on ListAdapter, getItemCountType() can return any int value, so long as it is unique for the row type. In fact, the recommendation is to use dedicated ID resources to ensure that uniqueness.

To that end, we define two ID resources, in a res/values/ids.xml file:

```xml
<resources>
    <item type="id" name="header"/>
    <item type="id" name="detail"/>
</resources>
```

(from RecyclerView/HeaderList/app/src/main/res/values/ids.xml)

Then, getItemCountType() can return R.id.header or R.id.detail to identify the two row types, and specifically which row type corresponds to the supplied position:

```java
@Override
public int getItemCountType(int position) {
    if (getItem(position) instanceof Integer) {
        return R.id.header;
    }

    return R.id.detail;
}

private Object getItem(int position) {
    int offset = position;
    int batchIndex = 0;
```
for (String[] batch : items)
    if (offset == 0)
        return Integer.valueOf(batchIndex);

    offset--;

    if (offset < batch.length)
        return batch[offset];

    offset -= batch.length;
    batchIndex++;

throw new IllegalArgumentException("Invalid position: 
    + String.valueOf(position));

This leverages a copy of the getItem() method from the original ListView version of this sample, which returns an Integer for a header item (identifying which header it is) and a String for detail item (identifying what Latin word to use). Note that getItem() is not part of the RecyclerView.Adapter protocol, but you are certainly welcome to have one if you want it.

In onCreateViewHolder(), we can now start paying attention to the second parameter, which we have been studiously ignoring until now. That value, viewType, will be a value that we returned from getItemViewType(), and it indicates what sort of RecyclerView.ViewHolder we should return. In our case, there are only two possibilities, and so we just inflate the appropriate layout and use a dedicated controller class (HeaderController for headers, RowController for detail):

@Override
public RecyclerView.ViewHolder onCreateViewHolder(ViewGroup parent, int viewType) {
    if (viewType == R.id.detail) {
        return new RowController(getLayoutInflater()
            .inflate(R.layout.row, parent, false));
    }

    return new HeaderController(getLayoutInflater()
        .inflate(R.layout.header, parent, false));
}
Similarly, our binding logic in `onBindViewHolder()` needs to route the right sort of model information to the proper controller:

```java
@Override
public void onBindViewHolder(RecyclerView.ViewHolder holder, int position) {
    if (holder instanceof RowController) {
        ((RowController)holder).bindModel((String)getItem(position));
    } else {
        ((HeaderController)holder).bindModel((Integer)getItem(position));
    }
}
```

RowController is the same sort of setup as we have had in past examples. HeaderController is too, though it is far simpler, as we have only one widget needing to be updated (a `TextView` named `label`) and we do not care about click events:

```java
package com.commonsware.android.recyclerview.headerlist;

import android.support.v7.widget.RecyclerView;
import android.view.View;
import android.widget.TextView;

class HeaderController extends RecyclerView.ViewHolder {
    TextView label = null;
    String template = null;

    HeaderController(View row) {
        super(row);

        label = (TextView)row.findViewById(R.id.label);

        template = label.getContext().getString(R.string.header_template);
    }

    void bindModel(Integer headerIndex) {
        label.setText(String.format(template, headerIndex.intValue()+1));
    }
}
```

(Advanced RecyclerView)
The results are header rows with one look-and-feel, and detail rows with a different look-and-feel:

![Figure 507: HeaderList RecyclerView Demo](image)

**A Grid-Style Table**

In the discussion of RecyclerView grids, we saw that one way to take advantage of larger screens is to have more cells, in part by having more spans across the screen.

Another way to take advantage of screen space is to grow the cells. By default, they will grow evenly, as each cell takes up one span, and the spans are evenly sized. However, you can change that behavior, by attaching a `GridLayoutManager.SpanSizeLookup` to the `GridLayoutManager`. The `GridLayoutManager.SpanSizeLookup` is responsible for indicating, for a given item’s position, how many spans it should take up in the grid.

One way of employing a `GridLayoutManager.SpanSizeLookup` is to make a table. If you want a table, but the user should only be able to select rows, that would be a matter of using a `LinearLayoutManager` and setting up the rows with “cells” that are of consistent size per row. For example, each row could be a horizontal `LinearLayout`, where the “column” widths are determined using
**ADVANCED RecyclerView**

android:layout_weight. But sometimes you want a table where individual cells can be clicked upon (or selected via a five-way navigation option, like a trackball). In this case, GridLayoutManager.SpanSizeLookup will let you indicate, for a “column” of your output, how many spans the cell should take up. By using a consistent number of spans for each column, you can get the same sort of weighted column width that you might get with LinearLayout-based rows in a LinearLayoutManager-powered RecyclerView.

And that will make a lot more sense (hopefully) when you see an example.

The RecyclerView/VideoTable sample project is a clone of the VideoList sample project from earlier in the chapter, with a few changes:

- We are going to use a GridLayoutManager, yet still organize our output into logical rows, by having three cells per row (title, thumbnail, and video duration)
- We are going to use GridLayoutManager.SpanSizeLookup to control the widths of each column in our grid
- Because our cells have varying content (ImageView in one, TextView in others), we will use different controllers for those cells, each optimized for handling that cell’s sort of content

The two columns that will hold text (title and video duration) will use the following layout:

```xml
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:background="?android:attr/selectableItemBackground"
    android:orientation="horizontal"
    android:padding="8dp">
    <TextView
        android:id="@android:id/text1"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:layout_marginLeft="8dp"
        android:layout_marginStart="8dp"
        android:textSize="20sp" />
</LinearLayout>
```

(from RecyclerView/VideoTable/app/src/main/res/layout/label.xml)
ADVANCED RECYCLER VIEW

The LinearLayout root element may seem superfluous, but we are using it for the selectableItemBackground, to provide a response when the cell is clicked upon.

Similarly, we have a layout dedicated to the thumbnail:

```xml
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    android:padding="8dp"
    android:background="?android:attr/selectableItemBackground">
    <ImageView
        android:id="@+id/thumbnail"
        android:layout_width="96dp"
        android:layout_height="72dp"
        android:contentDescription="@string/thumbnail"/>
</LinearLayout>
```

(on from RecyclerView/VideoTable/app/src/main/res/layout/thumbnail.xml)

onCreate() of MainActivity is largely the same as before. This time, though, we are creating an instance of a ColumnWeightSpanSizeLookup class and using it for two things:

1. Calling its getTotalSpans() to tell the GridLayoutManager how many spans to use
2. Using it as a GridLayoutManager.SpanSizeLookup, attaching it to the GridLayoutManager via setSpanSizeLookup():

```java
ColumnWeightSpanSizeLookup spanSizer = new ColumnWeightSpanSizeLookup(COLUMN_WEIGHTS);
GridLayoutManager mgr = new GridLayoutManager(this, spanSizer.getTotalSpans());

mgr.setSpanSizeLookup(spanSizer);
setLayoutManager(mgr);
setAdapter(new VideoAdapter());
```

(on from RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/MainActivity.java)

The latter point means that ColumnWeightSpanSizeLookup is a subclass of the abstract GridLayoutManager.SpanSizeLookup base class. The one method that you need to override in a GridLayoutManager.SpanSizeLookup subclass is getSpanSize(). Given an item's position, getSpanSize() returns the number of spans that the item's cell should... um... span.
ADVANCED RecyclerView

(we overload the word “span” a lot in Android...)

ColumnWeightSpanSizeLookup handles this via a set of column weights, which it gets as an int array in the constructor. onCreate() referenced a COLUMN_WEIGHTS static data member for the weights:

```java
private static final int[] COLUMN_WEIGHTS={1, 4, 1};
```

This int array tells us both how many columns there are and how wide each column should be, in terms of spans.

Converting the position to a column index is a matter of applying the modulo (%) operator, so the implementation of getSpanSize() on ColumnWeightSpanSizeLookup just returns the columnWeights value for the desired column:

```java
package com.commonsware.android.recyclerview.videotable;

import android.support.v7.widget.GridLayoutManager;

class ColumnWeightSpanSizeLookup extends GridLayoutManager.SpanSizeLookup {
    private final int[] columnWeights;

    ColumnWeightSpanSizeLookup(int[] columnWeights) {
        this.columnWeights=columnWeights;
    }

    @Override
    public int getSpanSize(int position) {
        return(columnWeights[position % columnWeights.length]);
    }

    int getTotalSpans() {
        int sum=0;

        for (int weight : columnWeights) {
            sum+=weight;
        }

        return(sum);
    }
}
```

(from RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/MainActivity.java)
getTotalSpans() is a convenience method, to sum all of the column weights. That is how many spans the GridLayoutManager will use overall, with each column getting its specific number of spans based upon the int array. Note that while we hard-coded the int array values in this case, there is nothing stopping us from using <integer-array> resources to pull these values out of the Java code, and perhaps even vary them by screen size or other configuration variations.

All of that will set up our grid with the correct number of spans and the right number of spans to use per column of the output. The combination will give us the row structure, as each row’s worth of columns uses all of the spans for that row, forcing GridLayoutManager to put subsequent items on the next row.

The rest of the project is focused on having different widgets for those different cells, using getItemViewType() and so on.

The VideoAdapter implementation of getItemViewType() simply returns the position modulo 3, to return a unique value (in this case, 0, 1, or 2):

```java
@override
public int getItemViewType(int position) {
    return(position % 3);
}
```

getItemCount() takes into account that there are three cells per video, and so the number of items being managed by this adapter is triple the number of videos:

```java
@override
public int getItemCount() {
    if(videos == null) {
        return(0);
    }

    return(videos.getCount()*3);
}
```

The onCreateViewHolder() and onBindViewHolder() methods take into account those three item types, using a VideoThumbnailController or a VideoTextController depending on the item type. Both of those classes will inherit from a BaseVideoController, which defines a bindModel() method that onBindViewHolder() can use:
BaseVideoController handles click events on the cell, along with collecting the Uri and MIME type of the video to use on click events:

```java
package com.commonsware.android.recyclerview.videotable;

import android.content.ContentUris;
import android.content.Intent;
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;
import android.support.v7.widget.RecyclerView;
import android.view.View;
```

(from RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/MainActivity.java)
abstract class BaseVideoController extends RecyclerView.ViewHolder
    implements View.OnClickListener {
    protected Uri videoUri = null;
    private String videoMimeType = null;

    BaseVideoController(View cell) {
        super(cell);
        cell.setOnClickListener(this);
    }

    @Override
    public void onClick(View v) {
        Intent i = new Intent(Intent.ACTION_VIEW);
        i.setDataAndType(videoUri, videoMimeType);
        itemView.getContext().startActivity(i);
    }

    void bindModel(Cursor row) {
        int mimeTypeColumn = row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);

        videoUri = ContentUris.withAppendedId(
            MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
            row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));
        videoMimeType = row.getString(mimeTypeColumn);
    }
}

VideoTextController extends BaseVideoController and handles binding some column from the MediaStore Cursor to a TextView with some ID:

package com.commonsware.android.recyclerview.videotable;

import android.database.Cursor;
import android.view.View;
import android.widget.TextView;

class VideoTextController extends BaseVideoController {
    private TextView label = null;
    private int cursorColumn;

    VideoTextController(View cell, int labelId, int cursorColumn) {
        super(cell);
        this.cursorColumn = cursorColumn;
    }
VideoThumbnailController handles using Picasso to get the video thumbnail asynchronously and binding it to an ImageView in the inflated cell View:

```java
package com.commonsware.android.recyclerview.videotable;

import android.content.ContentUris;
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;
import android.view.View;
import android.widget.ImageView;
import com.squareup.picasso.Picasso;

class VideoThumbnailController extends BaseVideoController {
    private ImageView thumbnail=null;

    VideoThumbnailController(View cell) {
        super(cell);

        thumbnail=(ImageView)cell.findViewById(R.id.thumbnail);
    }

    @Override
    void bindModel(Cursor row) {
        super.bindModel(row);

        Picasso.with(thumbnail.getContext())
            .load(videoUri.toString())
            .fit().centerCrop()
            .placeholder(R.drawable.ic_media_video_poster)
            .into(thumbnail);
    }
}

(from RecyclerView/VideoTable/app/src/main/java/com/commonsware/android/recyclerview/videotable/VideoTextController.java)
```
The result is the same information as was in the original VideoList demo, but organized into a table, where each cell is clickable:

![VideoTable RecyclerView Demo](image)

The duration is returned by MediaStore in milliseconds, which is not a great choice to present directly to the user. An improved version of this app might use a dedicated RecyclerView.ViewHolder that would convert the millisecond count into a duration measured in hours, minutes, and seconds (e.g., shown as HH:MM:SS to the user).
ADVANCED RECYCLERVIEW

Also note that the cell sizes are purely driven by their weights, which will not necessarily handle all content in all configurations very well. The chosen weights barely work on a 10” tablet in portrait, for example:

![VideoTable RecyclerView Demo, Portrait](image)

**Mutable Row Contents**

So far, all of the items we have used have been display-only. At most, they might respond to click events, along the lines of clicking a ListView row or GridView cell.

But, what about choice modes?

Listview and GridView — by way of their common AbsListView ancestor — have the concept of choice modes, where the user can “check” and “uncheck” items, and the list or grid will keep track of those states.

Well, as with lots of other things involving RecyclerView, RecyclerView does not offer choice modes... though you can implement that yourself. The RecyclerView/ChoiceList sample project turns our list-style RecyclerView into a checklist, with CheckBox widgets in each row, where the RecyclerView.Adapter will keep track of
the CheckBox checked states for us.

First, we need to add a CheckBox to the row:

```xml
<android.support.v7.widget.CardView

<LinearLayout

<ImageView

<LinearLayout

<TextView

<TextView

<LinearLayout

<ImageView

<LinearLayout

<TextView

<LinearLayout

<LinearLayout

<LinearLayout

<LinearLayout

<LinearLayout

<LinearLayout

<LinearLayout

<LinearLayout

<LinearLayout

<LinearLayout

<LinearLayout

<LinearLayout
```
Our IconicAdapter is only slightly different than before:

- it inherits from a ChoiceCapableAdapter that we will examine shortly, and
- it supplies a MultiChoiceMode instance to ChoiceCapableAdapter as part of chaining to the ChoiceCapableAdapter constructor

```java
class IconicAdapter extends ChoiceCapableAdapter<RowController> {
    IconicAdapter() {
        super(new MultiChoiceMode());
    }

    @Override
    public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
        return new RowController(this, getLayoutInflater()
                                   .inflate(R.layout.row, parent, false));
    }

    @Override
    public void onBindViewHolder(RowController holder, int position) {
        holder.bindModel(items[position]);
    }

    @Override
    public int getItemCount() {
        return items.length;
    }
}
```

ChoiceCapableAdapter is simply a RecyclerView.Adapter that knows how to handle choice modes, as implemented via the ChoiceMode interface:
A ChoiceMode is effectively a strategy class, responsible for tracking the checked states, not only for the current ChoiceCapableAdapter instance, but for future ones created as part of a configuration change. It requires four methods:

- `setChecked()` and `isChecked()` are getters and setters for whether or not a given position is checked
- `onSaveInstanceState()` and `onRestoreInstanceState()` manage storing and restoring those check states from the saved instance state Bundle of an activity or fragment

This project uses a MultiChoiceMode implementation of ChoiceMode:

```java
package com.commonsware.android.recyclerview.chooseList;

import android.os.Bundle;

public class MultiChoiceMode implements ChoiceMode {
    private static final String STATE_CHECK_STATES = "checkStates";
    private ParcelableSparseBooleanArray checkStates = new ParcelableSparseBooleanArray();

    @Override
    public void setChecked(int position, boolean isChecked) {
        checkStates.put(position, isChecked);
    }

    @Override
    public boolean isChecked(int position) {
        return checkStates.get(position, false);
    }

    @Override
    public void onSaveInstanceState(Bundle state) {
        state.putParcelable(STATE_CHECK_STATES, checkStates);
    }

    @Override
    public void onRestoreInstanceState(Bundle state) {
        checkStates = state.getParcelableView(STATE_CHECK_STATES);
    }
}
```

(from RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choicelist/ChoiceMode.java)
MultiChoiceMode, in turn, is mostly handled by a ParcelableSparseBooleanArray. SparseBooleanArray is a class, supplied in the Android SDK, that is a space-efficient mapping of int values to boolean values, as opposed to using a HashMap and having to convert those primitives to Integer and Boolean objects. However, for inexplicable reasons, SparseBooleanArray was not implemented to be Parcelable, and therefore it cannot be stored in a Bundle. ParcelableSparseBooleanArray is a subclass of SparseBooleanArray that handles the Parcelable aspects:

```java
package com.commonsware.android.recyclerview.choiceist;

import android.os.Parcel;
import android.os.Parcelable;
import android.util.SparseBooleanArray;

public class ParcelableSparseBooleanArray extends SparseBooleanArray implements Parcelable {
    public static Parcelable.Creator<ParcelableSparseBooleanArray> CREATOR = new Parcelable.Creator<ParcelableSparseBooleanArray>() {
        @Override
        public ParcelableSparseBooleanArray createFromParcel(Parcel source) {
            return new ParcelableSparseBooleanArray(source);
        }

        @Override
        public ParcelableSparseBooleanArray[] newArray(int size) {
            return new ParcelableSparseBooleanArray[size];
        }
    };

    public ParcelableSparseBooleanArray() {
        super();
    }

    private ParcelableSparseBooleanArray(Parcel source) {
        int size = source.readInt();

        for (int i=0; i < size; i++) {
            put(source.readInt(), (Boolean)source.readValue(null));
        }
    }

    @Override
    public int describeContents() {
        return 0;
    }
}
```
The net effect is that MultiChoiceMode, by means of ParcelableSparseBooleanArray, can track the checked/unchecked states of particular item position values.

ChoiceCapableAdapter, then, is a RecyclerView.ViewHolder that surfaces a ChoiceMode implementation:

```java
package com.commonsware.android.recyclerview.choiceList;

import android.os.Bundle;
import android.support.v7.widget.RecyclerView;

abstract public class ChoiceCapableAdapter<T extends RecyclerView.ViewHolder>
    extends RecyclerView.Adapter<T> {

    private final ChoiceMode choiceMode;

    public ChoiceCapableAdapter(ChoiceMode choiceMode) {
        super();
        this.choiceMode=choiceMode;
    }

    void onChecked(int position, boolean isChecked) {
        choiceMode.setChecked(position, isChecked);
    }

    boolean isChecked(int position) {
        return(choiceMode.isChecked(position));
    }

    void onSaveInstanceState(Bundle state) {
        choiceMode.onSaveInstanceState(state);
    }

    // ...}
```

(from RecyclerView/ChoiceList/app/src/main/java/com/commonsware/android/recyclerview/choiceList/ParcelableSparseBooleanArray.java)
The methods exposed by ChoiceCapableAdapter can then be used by outside parties. Specifically, MainActivity delegates onSaveInstanceState() and onRestoreInstanceState() to ChoiceCapableAdapter, so checked states can span configuration changes and the like. Plus, RowController can hook up on OnCheckedChangeListener and to update ChoiceCapableAdapter based on the state of checkbox changes:

```java
package com.commonsware.android.recyclerview.choiceList;

import android.annotation.TargetApi;
import android.os.Build;
import android.support.v7.widget.RecyclerView;
import android.view.MotionEvent;
import android.view.View;
import android.widget.CheckBox;
import android.widget.CompoundButton;
import android.widget.ImageView;
import android.widget.TextView;
import android.widget.Toast;

class RowController extends RecyclerView.ViewHolder {
    private ChoiceCapableAdapter adapter;
    private TextView label = null;
    private TextView size = null;
    private ImageView icon = null;
    private String template = null;
    private CheckBox cb = null;

    RowController(ChoiceCapableAdapter adapter, View row) {
        super(row);

        this.adapter = adapter;
        label = (TextView)row.findViewById(R.id.label);
        size = (TextView)row.findViewById(R.id.size);
        icon = (ImageView)row.findViewById(R.id.icon);
        cb = (CheckBox)row.findViewById(R.id.cb);
    }
}
```
Advanced RecyclerView

template = size.getContext().getString(R.string.size_template);

row.setOnClickListener(this);

if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
    row.setOnTouchListener(new View.OnTouchListener() {
        @TargetApi(Build.VERSION_CODES.LOLLIPOP)
        @Override
        public boolean onTouch(View v, MotionEvent event) {
            v.findViewById(R.id.row_content).getBackground().setHotspot(event.getX(), event.getY());

            return(false);
        }
    });
}

cb.setOnCheckedChangeListener(this);

@Override
public void onClick(View v) {
    Toast.makeText(v.getContext(), String.format("Clicked on position %d", getAdapterPosition()), Toast.LENGTH_SHORT).show();
}

@Override
public void onCheckedChanged(CompoundButton buttonView, boolean isChecked) {
    adapter.onChecked(getAdapterPosition(), isChecked);
}

void bindModel(String item) {
    label.setText(item);
    size.setText(String.format(template, item.length()));

    if (item.length() > 4) {
        icon.setImageResource(R.drawable.delete);
    } else {
        icon.setImageResource(R.drawable.ok);
    }

    cb.setChecked(adapter.isChecked(getAdapterPosition()));
}
Here, bindModel() updates the CheckBox based upon the ChoiceCapableAdapter isChecked() value for the RecyclerView.ViewHolder position (obtained via getPosition()). And, onCheckedChanged() updates the ChoiceCapableAdapter to keep track of whether this position is checked or unchecked, to handle row recycling, configuration changes, etc.

The result is much as you would expect: a version of our same sort of UI as before, except that if the user clicks the CheckBox, instead of the rest of the row, the CheckBox toggles its checked state, and that state survives row recycling, configuration changes, and so on:

![Figure 510: ChoiceList RecyclerView Demo](image)

Note that since this sample is using Theme.Material on Android 5.0+ devices, and since the screenshot is from an Android 5.0 emulator, the CheckBox styling is based on the accent color, here shown as bright yellow.

**Switching to the Activated Style**

Also note that ChoiceCapableAdapter, MultiChoiceMode, and kin are oblivious to
how the user is informed about what is checked and unchecked. RowController in
the previous sample happens to use a CheckBox. RowController could use some
other widget, like a Switch.

Another approach is to use the activated state. Once again, this is the sort of thing
that is automatically handled for us by ListView and its choice modes, but with
some minor tweaks, we can get our RowController to use this approach. This is
shown in the RecyclerView/ActivatedList sample project.

First, we need to give our row a background that has a StateListDrawable that
supports the activated state. The simplest approach — and the one traditionally
used with ListView — is to set up an activated style with the stock theme-supplied
background drawable, then apply that style to the row.

So, this sample app defines activated in res/values/styles.xml:

```xml
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="@android:style/Theme.Holo.Light.DarkActionBar">
  </style>
  <style name="activated" parent="Theme.Apptheme">
    <item name="android:background">?android:attr/activatedBackgroundIndicator</item>
  </style>
</resources>
```

Note that activated inherits from Theme.Apptheme. This means that we will get the
Theme.Holo-flavored background normally, but on API Level 21+, we will get the
Theme.Material-flavored background, courtesy of a res/values-v21/styles.xml
override of Theme.Apptheme:

```xml
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="@android:Theme.Material.Light.DarkActionBar">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
</resources>
```

Our row layout now dumps the CardView (whose own background may conflict with
the activated one) and applies the activated style to the root LinearLayout:
The row also no longer has the CheckBox, as it is no longer needed.

RowController now uses the OnClickListener interface to respond to clicks and use that to toggle the activated state for that row:

```java
@Override
```
Advanced RecyclerView

```java
public void onClick(View v) {
    boolean isCheckedNow = adapter.isChecked(getAdapterPosition());
    adapter.onChecked(getAdapterPosition(), !isCheckedNow);
    row.setActivated(!isCheckedNow);
}
```

(from RecyclerView/ActivatedList/app/src/main/java/com/commonsware/android/recyclerview/activatedlist/RowController.java)

setActivated(), applied to a View, indicates that it is (or is not) activated, affecting anything in that View that depends upon that state, such as the background.

Similarly, bindModel() uses setActivated() to update the activated state when binding our data:

```java
void bindModel(String item) {
    label.setText(item);
    size.setText(String.format(template, item.length()));

    if (item.length() > 4) {
        icon.setImageResource(R.drawable.delete);
    } else {
        icon.setImageResource(R.drawable.ok);
    }
    row.setActivated(adapter.isChecked(getAdapterPosition()));
}
```

(from RecyclerView/ActivatedList/app/src/main/java/com/commonsware/android/recyclerview/activatedlist/RowController.java)
Everything else is the same as the original CheckBox version of the sample. But now, the “checked” state is indicated by the activated highlight:

![ActivatedList RecyclerView Demo](image)

And, since this demo is running on Android 5.0, the activated highlight color is the accent color, which in this case is set to be yellow.

**But, What About Single-Choice?**

Both of the preceding examples illustrate multiple-choice behavior. Sometimes, though, single-choice behavior is the better option. For example, in a master-detail structure, in dual-pane mode (e.g., tablets, where the master and the detail are both visible), you probably normally want single-choice mode.

That is certainly possible, though, once again, RecyclerView does not offer it. It also adds a wrinkle: how do we arrange to uncheck a previously-checked item, when the user checks another item? Like RadioButton widgets in a RadioGroup, we need to ensure that only one item at a time is checked, and that will require us to update the UI of the formerly-checked-but-now-unchecked item.

With some tweaks, the last sample project, where we used the activated state for a
multiple-choice list, can be revised to limit the user to a single choice. Those tweaks are illustrated in the RecyclerView/SingleActivatedList sample project.

The ChoiceMode interface now has two new methods:

1. `isSingleChoice()` will return `true` for a single-choice `ChoiceMode` strategy, `false` otherwise
2. `getCheckedPosition()` will return the position of whatever the currently-checked item is

```java
package com.commonsware.android.recyclerview.singleactivatedlist;

import android.os.Bundle;

public interface ChoiceMode {
    boolean isSingleChoice();
    int getCheckedPosition();
    void setChecked(int position, boolean isChecked);
    boolean isChecked(int position);
    void onSaveInstanceState(Bundle state);
    void onRestoreInstanceState(Bundle state);
}
```

(from RecyclerView/SingleActivatedList/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/ChoiceMode.java)

SingleChoiceMode is now our implementation of `ChoiceMode`:

```java
package com.commonsware.android.recyclerview.singleactivatedlist;

import android.os.Bundle;

public class SingleChoiceMode implements ChoiceMode {
    private static final String STATE_CHECKED = "checkedPosition";
    private int checkedPosition = -1;

    @Override
    public boolean isSingleChoice() {
        return true;
    }

    @Override
    public int getCheckedPosition() {
        return checkedPosition;
    }
}
```

SingleChoiceMode tracks the currently-checked position, using -1 to indicate no position is checked. Of note, if a position was checked, then setChecked() unchecks it, SingleChoiceMode goes back to -1 and indicates that there is no currently-checked position.

ChoiceCapableAdapter also has a couple of modifications. First, it now accepts the RecyclerView itself as a constructor parameter, holding onto it in an rv data member. And, onChecked() needs to be modified to take care of removing the activated state from whatever item had been previously checked when some new item is checked:
ChoiceCapableAdapter<
T extends RecyclerView.ViewHolder
extends RecyclerView.Adapter<T> {

private final ChoiceMode choiceMode;
private final RecyclerView rv;

public ChoiceCapableAdapter(RecyclerView rv, ChoiceMode choiceMode) {
    super();
    this.rv=rv;
    this.choiceMode=choiceMode;
}

void onChecked(int position, boolean isChecked) {
    if (choiceMode.isSingleChoice()) {
        int checked=choiceMode.getCheckedPosition();

        if (checked>=0) {
            RowController row=(RowController)rv.findViewHolderForAdapterPosition(checked);

            if (row!=null) {
                row.setChecked(false);
            }
        }
    }

    choiceMode.setChecked(position, isChecked);
}

boolean isChecked(int position) {
    return(choiceMode.isChecked(position));
}

void onSaveInstanceState(Bundle state) {
    choiceMode.onSaveInstanceState(state);
}

void onRestoreInstanceState(Bundle state) {
    choiceMode.onRestoreInstanceState(state);
}

@Override
public void onViewAttachedToWindow(T holder) {
    super.onViewAttachedToWindow(holder);

    if (holder.getAdapterPosition()!=choiceMode.getCheckedPosition()) {
        ((RowController)holder).setChecked(false);
    }
}
To do that, onChecked() asks the ChoiceMode if it is single choice. If yes, it gets the last checked position. If that position is plausible (0 or higher), it gets the RecyclerView.ViewHolder for that position via findViewHolderForAdapterPosition(), called on the RecyclerView. If this returns something other than null, then it must be a RowController, and so onChecked() calls setChecked(false) on that row to remove the activated state.

findViewHolderForAdapterPosition() and findViewHolderForLayoutPosition() replace the now-deprecated findViewHolderForPosition() method. All three methods do the same basic thing: given a position, return the ViewHolder for that position, if any. findViewHolderForPosition() and findViewHolderForLayoutPosition() have the same implementation, at least at the present time. The primary thing that findViewHolderForAdapterPosition() does differently is it always returns null if the data has been changed (e.g., notifyDataSetChanged() was called on the adapter) but those changes have not yet been laid out. In this sample app, that difference is academic, but findViewHolderForAdapterPosition() probably is a safer choice for most use cases.

However, these find...() methods have a wrinkle: they only return a ViewHolder if the row is visible. If the ViewHolder is cached, but not visible, find...() will still not return it. This causes a problem where we need to de-select a row that is not visible (and so find...() does not work) but will not be re-bound using onBindView() (as the ViewHolder is already set up). This requires us to implement onViewAttachedToWindow() — called whenever a ViewHolder contents are actually attached as children to the RecyclerView — and update the checked state there, as a fallback.

(and many thanks to Mahmoud Abou-Eita for reporting that problem)

setChecked() did not exist in the previous sample, as the activated state was handled purely internally to RowController. So, now RowController has a setChecked() method to toggle the activated state:

```java
void setChecked(boolean isChecked) {
    row.setActivated(isChecked);
}
```
MainActivity now must supply the RecyclerView to the IconicAdapter in
onCreate():

```java
@override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setLayoutManager(new LinearLayoutManager(this));
    adapter = new IconicAdapter(getRecyclerView());
    setAdapter(adapter);
}
```

...so that IconicAdapter() can supply it to the ChoiceCapableAdapter superclass
constructor:

```java
IconicAdapter(RecyclerView rv) {
    super(rv, new SingleChoiceMode());
}
```

Visually, the results are identical to the previous example, except that at most only
one item can be checked at a time. The key is the phrase “at most” — this
implementation allows the user to tap on a checked item to uncheck it. This may be
fine, as your app may simply hide the detail in this scenario, still allowing the user to
interact with action bar items (e.g., a “create new model” item). If you wanted to
prevent that, have SingleChoiceMode not set checkedPosition to -1 when the user
taps on a previously-checked item, to leave the currently-checked position intact.

**Keyboard Navigation**

If you try using the RecyclerView/SingleActivatedList app — or any of the
sample apps presented so far — on a device that has a physical keyboard or five-way
navigation option (e.g., D-pad), you will find that RecyclerView has no built-in
keyboard navigation. This is in contrast with standard AdapterView classes like
ListAdapter, where key events are handled automatically. Once again, if you want the
behavior, you have to add it yourself.
**Advanced RecyclerView**

The exact details of what you want to do when the user tries navigating with a keyboard will vary, based on lots of things:

- What sort of layout manager are you using? If it is a list, you only need to worry about moving up and down, while if it is a grid, you will need to handle movement along both axes.
- Do you have focusable widgets in your RecyclerView items? If so, how will navigation between those widgets blend with navigation through the RecyclerView overall?
- Are you using any sort of “selection” or “choice” model? If so, do you want keyboard navigation to change the choice? Or, do you want keyboard navigation to only make a choice when the user does something special (e.g., presses an Enter key or a center D-pad button), with the two-way or four-way navigation showing up as something separate from the user’s choice?

The RecyclerView/SingleActivatedListKB sample project is a clone of the SingleActivatedList sample, except that we now support keyboard events. Specifically, the user can use the up and down arrow keys to change the selected row in the list. This is perhaps the simplest scenario:

- We have no focusable widgets, so key events can just change the selected row
- It is just a list, so we only need to worry about two directions, not four
- We want either zero or one selected row, and so we do not need to have a distinction between navigation and selection, as we might with a multiple-choice list

And, the best part is that we only need to change ChoiceCapableAdapter — the rest of the app can remain unchanged.

First, we override another method on RecyclerView.Adapter: onAttachedToRecyclerView(). As the name suggests, this method is called when our adapter is assigned to a RecyclerView instance. Here, if we are in single-choice mode, we register an OnKeyListener on the RecyclerView itself, to find out when it receives key events:

```java
// inspired by http://stackoverflow.com/a/28838834/115145

@Override
public void onAttachedToRecyclerView(RecyclerView rv) {
    super.onAttachedToRecyclerView(rv);
}
```
When the user presses down either the up or down arrow key (or equivalents on a D-pad), we call out to private choosePrevious() and chooseNext() methods, which will return true if we moved the selection in that direction, false otherwise. If the key event is not one of those, we return false to indicate that we are not consuming the key event.

The choosePrevious() and chooseNext() methods are responsible for determining what our next selection should be, assuming that the selection can change in the designated direction:

```java
private boolean chooseNext() {
    long now = System.currentTimeMillis();
    boolean result = false;

    if (lastDownKeyTime == -1 || now - lastDownKeyTime > KEY_TIME_DELTA) {
        lastDownKeyTime = now;
        lastUpKeyTime = -1L;
    }

    int checked = choiceMode.getCheckedPosition();

    if (checked < 0) {
        onChecked(0, true, true);
        result = true;
    } else if (checked < getItemCount() - 1) {
```

(from RecyclerView/SingleActivatedListKB/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/ChoiceCapableAdapter.java)
In both cases, we find out what the current selection is. If it is a negative number, we do not have a selection yet, so we select the first row. Otherwise, if we can still move in the desired direction, add or subtract one from the current selection.

However, in this crude implementation, we need to slow down how frequently we change the selection. Simply changing which row is highlighted is fast, but if the list has to scroll to uncover that row, doing too many of those too quickly results in a “smearing” effect. The simplest way to avoid that smearing is to limit how many consecutive identical key events we process (e.g., user holds down an arrow key).

The approach taken in this code is to track the last time we were called to process an arrow key event for each direction, in lastUpKeyTime and lastDownKeyTime fields.
We use -1 to indicate that we have not just processed another one of that type. If, when we get a key event, either the related time value is -1 or is within KEY_TIME_DELTA of now, we go ahead and update the checked position (if needed), plus update the times. KEY_TIME_DELTA is defined as 250, limiting us to four updates per second.

We change the current selection, where needed, via a call to a new three-parameter onChecked() method:

```java
void onChecked(int position, boolean isChecked) {
    onChecked(position, isChecked, false);
}

void onChecked(int position, boolean isChecked, boolean updateUI) {
    if (choiceMode.isSingleChoice()) {
        int checked = choiceMode.getCheckedPosition();

        if (checked >= 0) {
            RowController row =
                (RowController)rv.findViewHolderForAdapterPosition(checked);

            if (row != null) {
                row.setChecked(false);
            }
        }
    }

    choiceMode.setChecked(position, isChecked);

    if (updateUI) {
        notifyItemChanged(position);
        rv.scrollToPosition(position);
    }
}
```

(from RecyclerView/SingleActivatedListKB/app/src/main/java/com/commonsware/android/recyclerview/singleactivatedlist/ChoiceCapableAdapter.java)

The third parameter indicates if we need to update the UI or not. For touchscreen events, activating rows and such is enough to ensure that the UI is properly updated. With key events, we need to:

- Make sure that Android is going to repaint the affected row and pick up the change in the activated state (notifyItemChanged()), and
- Make sure that the user can see the affected row, since they key event might
now select a row that is not visible on the screen (scrollToPosition())

**Action Modes**

Another thing that ListView gave us was support for action modes. In particular, the “multiple-choice modal” setting would automatically start and finish an action mode for us.

And, once again, RecyclerView has no hooks for action modes, though you can do it yourself if desired. We have to manually start and destroy the action mode, in addition to responding to the user’s interaction with the action mode (tapping on items, or dismissing the action mode manually).

Where things get interesting is in the connection between checked items and the action mode. There are two UX rules:

1. When there are no checked items, there should be no action mode
2. When there is no action mode, there should be no checked items

You might think that those two rules are the same, and to some extent they are. They are phrased this way to emphasize the state changes that are involved:

- When the user checks an item, an action mode should appear
- When the user unchecks the last checked item, and therefore there are no more checked items, the action mode should disappear
- When the user dismisses the action mode (e.g., presses BACK), all checked items should become unchecked

Handling these transitions takes a bit of work, demonstrated in the RecyclerView/ActionModeList sample project. This is a clone of the ChoiceList sample from earlier, augmented with an action mode when 1+ items are checked. The action mode logic is largely cloned from one of the book’s action mode samples, where we want to allow the user to capitalize or remove the checked items.

Once again, we have some tweaks to ChoiceMode, adding two methods:

1. `getCheckedCount()`, to return the number of checked items, which we will use for the subtitle of the action mode
2. `clearChecks()`, to uncheck all checked items

```
package com.commonsware.android.recyclerview.actionmodelist;
```
import android.os.Bundle;

public interface ChoiceMode {
    void setChecked(int position, boolean is_checked);
    boolean is_checked(int position);
    void onSaveInstanceState(Bundle state);
    void onRestoreInstanceState(Bundle state);
    int getCheckedCount();
    void clearChecks();
}

(from RecyclerView/ActionModeList/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist/ChoiceMode.java)

MultiChoiceMode implements those, plus adds a subtle change to setChecked().
Previous editions of MultiChoiceMode would simply put the checked state boolean
into the ParcelableSparseBooleanArray, with false as a default value for any
position not in the array. Now, we specifically remove items that are unchecked, so
the only items in the ParcelableSparseBooleanArray are those that are checked.
This makes getCheckedCount() and clearChecks() very simple to implement:

package com.commonsware.android.recyclerview.actionmodelist;
import android.os.Bundle;

public class MultiChoiceMode implements ChoiceMode {
    private static final String STATE_CHECK_STATES = "checkStates";
    private ParcelableSparseBooleanArray checkStates = new ParcelableSparseBooleanArray();

    @Override
    public void setChecked(int position, boolean is_checked) {
        if (is_checked) {
            checkStates.put(position, is_checked);
        } else {
            checkStates.delete(position);
        }
    }

    @Override
    public boolean is_checked(int position) {
        return checkStates.get(position, false);
    }

    @Override
    public void onSaveInstanceState(Bundle state) {
        state.putParcelable(STATE_CHECK_STATES, checkStates);
    }

    @Override
    public void onRestoreInstanceState(Bundle state) {
        checkStates = state.getParcelable(STATE_CHECK_STATES);
    }
}
ChoiceCapableAdapter exposes the two new ChoiceMode capabilities to its subclasses:

```java
package com.commonsware.android.recyclerview.actionmodelist;

import android.os.Bundle;
import android.support.v7.widget.RecyclerView;

abstract public class ChoiceCapableAdapter<T extends RecyclerView.ViewHolder> extends RecyclerView.Adapter<T> {
    private final ChoiceMode choiceMode;

    public ChoiceCapableAdapter(ChoiceMode choiceMode) {
        super();
        this.choiceMode=choiceMode;
    }

    void onChecked(int position, boolean isChecked) {
        choiceMode.setChecked(position, isChecked);
    }

    boolean isChecked(int position) {
        return(choiceMode.isChecked(position));
    }

    void onSaveInstanceState(Bundle state) {
        choiceMode.onSaveInstanceState(state);
    }

    void onRestoreInstanceState(Bundle state) {
        choiceMode.onRestoreInstanceState(state);
    }

    int getCheckedCount() {
```
IconicAdapter now not only extends ChoiceCapableAdapter, but it implements the ActionMode.Callback interface, and therefore will be responsible for managing the action mode:

```java
public class IconicAdapter extends ChoiceCapableAdapter<RowController>
    implements ActionMode.Callback {

    @Override
    void onChecked(int position, boolean isChecked) {
        super.onChecked(position, isChecked);

        if (getCheckedCount() == 0 && activeMode != null) {
            activeMode.finish();
        } else {
            updateSubtitle(activeMode);

            if (isChecked) {
                if (activeMode == null) {
                    activeMode = startActionMode(this);
                }
            }
        }
    }
}
```

IconicAdapter now overrides onChecked(), normally just handled by ChoiceCapableAdapter. In addition to chaining to the superclass for standard behavior, IconicAdapter manages the action mode:

- If we do not have any checked items, and we have an active action mode, finish() that action mode, as the user has unchecked the last checked item and the action mode is no longer needed
- Otherwise, update the subtitle, and if we are checking an item (isChecked is true), and if we do not already have an action mode going (tracked by an activeMode data member), start the action mode using startActionMode()
Because IconicAdapter implements ActionMode.Callback, it needs to implement the methods required by that interface. This includes:

- `onCreateActionMode()`, to set up the action mode
- `onPrepareActionMode()`, just because it is required by the interface
- `onActionItemClicked()`, where we should do some real work, but for the moment just have a TODO comment
- `onDestroyActionMode()`, where we make sure that all checked items are unchecked (`clearChecks()`) and tell the RecyclerView.Adapter that the data set changed, to force a repaint of all the visible rows, so they will now reflect the fact that they are no longer checked

```java
@Override
public boolean onCreateActionMode(ActionMode mode, Menu menu) {
    MenuInflater inflater = getMenuInflater();
    inflater.inflate(R.menu.context, menu);
    mode.setTitle(R.string.context_title);
    activeMode = mode;
    updateSubtitle(activeMode);
    return true;
}

@Override
public boolean onPrepareActionMode(ActionMode mode, Menu menu) {
    return false;
}

@Override
public boolean onActionItemClicked(ActionMode mode, MenuItem item) {
    // TODO: do something based on the action
    updateSubtitle(activeMode);
    return true;
}

@Override
public void onDestroyActionMode(ActionMode mode) {
    if (activeMode != null) {
```
The updateSubtitle() method, referred to by some of the previous methods, just updates the subtitle of the action mode to reflect the current count of checked items:

```java
private void updateSubtitle(ActionMode mode) {
    if (mode != null) {
        mode.setSubtitle("("+getCheckedCount()+")");
    }
}
```

The resulting app looks a lot like the original ChoiceList sample, until we check one or more items, at which point the action mode appears:

*Figure 512: ActionModeList RecyclerView Demo*
Changing the Contents

The obvious problem with the preceding sample is that we are not actually doing anything in response to user clicks on action mode items. We really should be capitalizing and/or removing words. However, this involves modifying the model data and how that model data is being visually displayed by the RecyclerView.

The less-obvious problem is that we are calling notifyDataSetChanged() when the action mode is dismissed, to force a full repaint of the RecyclerView contents. While this works, it is overkill, as probably only a subset of the visible items are checked. Ideally, we would only update the specific positions that were checked and now, with the action mode finished, are unchecked. We could find the affected RowController instances, using findViewHolderByPosition() on RecyclerView, as we did in the single-choice list sample. But, really, updating the checked state is just another manifestation of the same problem that capitalizing or removing words causes: we need to ensure that the RecyclerView depicts the current model state, ideally with minimum work.

So, let's see how this is accomplished, by looking at the RecyclerView/ActionModeList2 sample project. As the name suggests, this is a clone of the ActionModeList shown in the preceding section. This time, we will fully implement onActionItemClicked() and allow our model data to be mutable.

Updating Existing Contents

With AdapterView and Adapter classes based on BaseAdapter, the only way we had to tell the AdapterView about model data changes was notifyDataSetChanged(). This would trigger a rebuild of the entire AdapterView, which is slow and expensive.

While RecyclerView.Adapter has its own notifyDataSetChanged(), that is really for total reloads of the model data, such as having gotten a fresh Cursor from a database and not knowing exactly what the changes are. If you are driving the changes yourself from the UI — and particularly if your model data is something like an ArrayList of model objects – you can use methods on RecyclerView.Adapter that are more fine-grained than is notifyDataSetChanged().

If an item was updated in place — such as a word now being capitalized – you can use notifyItemChanged() on RecyclerView.Adapter to point out the specific position that changed. Alternatives include:
notifyItemMoved(), to indicate that an item is still in the model data but now is in a new position

notifyItemRangeChanged(), to indicate a range of positions that were modified, instead of having to repeatedly call notifyItemChanged()

ActionModeList2 uses notifyItemChanged() when the user capitalizes words, to get those items repainted, if needed. It may not be needed immediately, if one or more of those items are not presently visible within the RecyclerView.

However, so far, our model data has been a static String array, and now we need a mutable model. So, we take the same approach as the ListView action mode samples use, converting our model to be an ArrayList that happens to be populated by a static String array.

The items data member of MainActivity is now an ArrayList of String, with the static String array being converted into ORIGINAL_ITEMS:

```java
private static final String[] ORIGINAL_ITEMS=
```

Places that used to refer to items now use a private getItems() method, which lazy-instantiates the list if needed:

```java
private ArrayList<String> getItems() {
    if (items==null) {
        items=new ArrayList<String>();
        for (String s : ORIGINAL_ITEMS) {
            items.add(s);
        }
    }
    return(items);
}
```

We also need to ensure that we hold onto the items across configuration changes,
since those items could be changed by the user. So, our onSaveInstanceState() and onRestoreInstanceState() methods on MainActivity now handle that chore, in addition to their original behavior of having the ChoiceCapableAdapter persist checked states:

```java
@Override
public void onSaveInstanceState(Bundle state) {
    adapter.onSaveInstanceState(state);
    state.putStringArrayList(STATE_ITEMS, items);
}

@Override
public void onRestoreInstanceState(Bundle state) {
    adapter.onRestoreInstanceState(state);
    items = state.getStringArrayList(STATE_ITEMS);
}
```

(here, STATE_ITEMS is a static data member, serving as the constant key for the Bundle entry)

In order to be able to capitalize or remove the checked words from the list, we need to know which ones are checked. Rather than expose that data directly, ChoiceMode now has a visitChecks() method, where we can supply a Visitor to be invoked for every checked position:

```java
package com.commonsware.android.recyclerview.actionmodelist2;

import android.os.Bundle;

public interface ChoiceMode {
    void setChecked(int position, boolean isChecked);
    boolean isChecked(int position);
    void onSaveInstanceState(Bundle state);
    void onRestoreInstanceState(Bundle state);
    int getCheckedCount();
    void clearChecks();
    void visitChecks(Visitor v);
}

public interface Visitor {
    void onCheckedPosition(int position);
}
```

(ADVANCED RecyclerView)

(from RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/MainActivity.java)

(from RecyclerView/ActionModeList2/app/src/main/java/com/commonsware/android/recyclerview/actionmodelist2/ChoiceMode.java)
MultiChoiceMode implements visitChecks() by iterating over a copy of the checkStates ParcelableSparseBooleanArray. That way, if the visitor modifies checkStates (e.g., unchecks a position), our loop is unaffected.

```java
@Override
public void visitChecks(Visitor v) {
    SparseBooleanArray copy = checkStates.clone();
    for (int i=0; i<copy.size(); i++) {
        v.onCheckedPosition(copy.keyAt(i));
    }
}
```

visitChecks() is also exposed by ChoiceCapableAdapter, as are all the other methods on ChoiceMode.

Now, IconicAdapter can capitalize the words, by using visitChecks():

```java
case R.id.cap:
    visitChecks(new ChoiceMode.Visitor() {
        @Override
        public void onCheckedPosition(int position) {
            String word = getItems().get(position);
            word = word.toUpperCase(Locale.ENGLISH);
            getItems().set(position, word);
            notifyItemChanged(position);
        }
    });
    break;
```

Here, for each checked item, we capitalize the word, replace the original word with its capitalized equivalent, and call notifyItemChanged() to let the RecyclerView know that this position had its model data changed and therefore should be repainted, if needed.

We also use visitChecks() now in onDestroyActionMode(), to avoid the notifyDataSetChanged() call:

```java
@Override
public void onDestroyActionMode(ActionMode mode) {
```

1560
Each item that was checked is unchecked, and we use notifyItemChanged() to ensure that the item is repainted if needed.

Now, checking some items and choosing “CAPITALIZE” from the action mode will capitalize those words:

![Figure 513: ActionModeList2 RecyclerView Demo, with Capitalized Words](image)
Adding and Removing Items

There are also methods on RecyclerView.Adapter to specifically call out when you are adding or removing items from the adapter. Not only does this cause the RecyclerView to update itself, but it will animate the changes, if the relevant position(s) are visible.

Specifically, you can call:

- `notifyItemInserted()`, to indicate that a new item was inserted at a specified position, with everything else moving one position later in the roster
- `notifyItemRangeInserted()`, to insert several items in a block
- `notifyItemRemoved()`, to indicate a position that had an item removed from the roster, with later items moving up to take over earlier positions
- `notifyItemRangeRemoved()`, to remove several items in a block

The ActionModeList2 sample uses `notifyItemRemoved()` as part of its handling of the remove action mode item:

```java
case R.id.remove:
    final ArrayList<Integer> positions = new ArrayList<Integer>();

    visitChecks(new ChoiceMode.Visitor()
        @Override
        public void onCheckedPosition(int position) {
            positions.add(position);
        }
    );

    Collections.sort(positions, Collections.reverseOrder());

    for (int position : positions) {
        getItems().remove(position);
        notifyItemRemoved(position);
    }

    clearChecks();
    activeMode.finish();
    break;
```

Because items slide up to take over vacated positions, when removing items, it is
important to remove the lowest items first and work your way up the roster. That is why this code:

- Aggregates the list of positions that are checked
- Sorts the checked items in reverse order
- Iterates over the checked items, removing each from the ArrayList and calling notifyItemRemoved() to inform the adapter that the old item at this position is now gone
- Clears all of the checks from the ChoiceMode (as all checked items are now removed) and finishes the action mode (as there are no more checked items)

The result is that when the user removes items, they rapidly fade out, then later items in the list slide up to occupy the now-vacated space. If you would prefer to use other animations, you can do so, by creating your own subclass of RecyclerView.ItemAnimator and attaching it to the RecyclerView with setItemAnimator().

The Order of Things

Version 22+ of recyclerview-v7 offers SortedList. On the surface, the class appears to be a regular List that offers sorting. However, it also has a callback interface designed to be tied into RecyclerView, so that changes made to the SortedList can be reflected in the RecyclerView itself, complete with animations, optional batched processing, and so on.

This is illustrated in the RecyclerView/SortedList sample project. Along the way, we will also see how to use RecyclerView in a fragment and how to populate RecyclerView from the background thread.

The Gradle Change

This project requires version 22 or higher of recyclerview-v7, as the original v21 release of recyclerview-v7 did not have SortedList. So, the Gradle build file requests something appropriate:

```groovy
implementation 'com.android.support:recyclerview-v7:27.0.2'
implementation 'com.android.support:cardview-v7:27.0.2'
```

(from RecyclerView/SortedList/app/build.gradle)
The RecyclerViewFragment

Prior samples in this chapter used a RecyclerViewActivity for basic RecyclerView setup. However, in this sample, we want to use a retained fragment for managing the AsyncTask, which suggests putting the RecyclerView in a fragment, rather than having it be managed directly by the activity.

So, this project has a reworking of RecyclerViewActivity into RecyclerViewFragment:

```java
package com.commonsware.android.recyclerview.sorted;

import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.support.v7.widget.RecyclerView;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class RecyclerViewFragment extends Fragment {
    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup container, Bundle savedInstanceState) {
        RecyclerView rv = new RecyclerView(getActivity());
        rv.setHasFixedSize(true);
        return rv;
    }

    public void setAdapter(RecyclerView.Adapter adapter) {
        getRecyclerView().setAdapter(adapter);
    }

    public RecyclerView.Adapter getAdapter() {
        return getRecyclerView().getAdapter();
    }

    public void setLayoutManager(RecyclerViewLayoutManager mgr) {
        getRecyclerView().setLayoutManager(mgr);
    }

    public RecyclerView getRecyclerView() {
        return ((RecyclerView)getView());
    }
}
```
Basically, what had been in `onCreate()` mostly moves into `onCreateView()`, where we set up the RecyclerView. The rest of the core API is unchanged.

The project has `SortedFragment`, which extends `RecyclerViewFragment` and handles loading of the data — we will examine more of it later in this chapter.

The revised `MainActivity` then just loads up `SortedFragment` via a `FragmentTransaction`:

```java
package com.commonsware.android.recyclerview.sorted;

import android.support.v4.app.FragmentActivity;
import android.os.Bundle;

public class MainActivity extends FragmentActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setRetainInstance(true);
        getSupportFragmentManager().beginTransaction()
            .add(android.R.id.content, new SortedFragment()).commit();
    }
}
```

The `SortedFragment`

Most of `SortedFragment` is reminiscent of the original `AsyncTask` demo from the chapter on threads, mashed up with one of the CardView/RecyclerView samples from earlier in this chapter. However, the `SortedList` gets weaved throughout.

The `SortedList`

The model in the original `AsyncTask` demo was a simple `ArrayList`. Now it is a `SortedList`, initialized in `onCreate()` of the `SortedFragment`:

```java
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setRetainInstance(true);
}
```
The SortedList constructor takes two parameters:

- the Java class object for the models inside the list (in this case, `String.class`)
- a `SortedList.Callback` object that will be invoked when the model changes based on List APIs (e.g., `add()`, `insert()`, `remove()`)

There is an optional third parameter for the capacity, unused in this sample.

We will take a peek at the `SortedList.Callback` implementation, named `sortCallback`, shortly.

The IconicAdapter

The IconicAdapter from earlier RecyclerView samples worked directly off of the static array of `String` values. Now, we want it to work off of the model `SortedList`. Hence, `onBindViewHolder()` and `getItemCount()` need to be modified to refer to appropriate methods on the model:

```java
class IconicAdapter extends RecyclerView.Adapter<RowController> {
    @Override
    public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
        return (new RowController(getActivity().getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    @Override
    public void onBindViewHolder(RowController holder, int position) {
        holder.bindModel(model.get(position));
    }

    @Override
    public int getItemCount() {
        return (model.size());
    }
}
```
Also note that when we create the adapter in `onViewCreated()`, that we hold onto it in an adapter data member of the fragment:

```java
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);
    setLayoutManager(new LinearLayoutManager(getActivity()));
    adapter = new IconicAdapter();
    setAdapter(adapter);
}
```

### The SortedList.Callback

The job of the `SortedList.Callback` is to serve as the bridge between the `SortedList` and the `RecyclerView.Adapter`.

`SortedList`, as the name suggests, sorts its contents. That means that any change to the `SortedList` contents can have different impacts on the `RecyclerView`. For example, while an `add()` to an `ArrayList` would just add a new row to the end of the `RecyclerView`, an `add()` on `SortedList` might need to insert a row in the middle of the `RecyclerView`, to maintain the sorted order.

Hence, your `SortedList.Callback` is responsible for two things:

- Helping with the sorting itself, by comparing elements
- Passing information about how the sorting is done out to the `RecyclerView.Adapter`, so the appropriate moves can be made there, complete with animations

With that in mind, here is the `sortedCB` implementation of `SortedList.Callback`:

```java
private SortedList.Callback<String> sortCallback = new SortedList.Callback<String>() {
    @Override
    public int compare(String o1, String o2) {
        return o1.compareTo(o2);
    }

    @Override
    public boolean areContentsTheSame(String oldItem, String newItem) {
        return areItemsTheSame(oldItem, newItem);
    }
};
```
The first method is your standard sort of `compare()` comparison method, as you might implement on a `Comparator`. It should return zero if the two model objects are the same from a sorting standpoint, a negative number if the first parameter sorts before the second parameter, or a positive number if the first parameter sorts after the second parameter.

Then there are two similarly-named methods that serve as more-or-less replacements for the `equals()` that you might have on a `Comparator`: `areContentsTheSame()` and `areItemsTheSame()`.

`areItemsTheSame()` should return `true` if the two passed-in values represent the same actual logical item. In the case of `SortedFragment`, that is simply whether or not the strings are equal. But, with a more complex data model, you might be comparing primary keys or some other form of immutable identifier.

`areContentsTheSame()` should return `true` if the visual representation of the items look the same, as this will be used to optimize the changes made to the RecyclerView.

For example, suppose a shopping cart fragment wanted to use `SortedList`. Further suppose that if you added three boxes of laundry detergent to the cart, rather than...
having one row in the list with “Quantity: 3”, you were representing them as three rows in the RecyclerView. In this case:

- `compare()` returns a value to indicate the sorting rules of those shopping cart items, perhaps based on the title of the item
- `areItemsTheSame()` might return `false` for any combination of these three items, as they are logically distinct rows within the RecyclerView
- `areContentsTheSame()` might return `true` for any combination of these three items, as while they are three separate line items, each is visually identical in terms of what the RecyclerView rows look like

In many cases, `areContentsTheSame()` can simply invoke `areItemsTheSame()`, under the premise that different items *probably* have different visual representations. That is what is done in this sample, where `areItemsTheSame()` in turn uses `compare()` to see whether or not the items are the same.

Finally, there are four `on...()` methods that are simply forwarded along to their RecyclerView.Adapter counterparts, so changes to the SortedList make the corresponding changes to the RecyclerView contents.

Note that there is a SortedListAdapterCallback that takes a RecyclerView.Adapter as a constructor parameter and handles the `on...()` methods for you. However, since we want to retain the SortedList across configuration changes, and since SortedList does not allow us to change the SortedList.Callback object, we cannot readily switch the SortedList to the new fragment and new adapter after a configuration change.

**The AsyncTask**

The AddStringTask is the same as with the original AsyncTask sample, except that now it adds the words to the SortedList, which (via its Callback) will update the RecyclerView:

```java
private class AddStringTask extends AsyncTask<Void, String, Void> {
  @Override
  protected Void doInBackground(Void... unused) {
    for (String item : items) {
      if (isCancelled())
        break;

      publishProgress(item);
      SystemClock.sleep(400);
    }
  }
```
ADVANCED RECYCLERVIEW

```java
return(null);

@Override
protected void onProgressUpdate(String... item) {
    if (!isCancelled()) {
        model.add(item[0]);
    }
}

@Override
protected void onPostExecute(Void unused) {
    Toast.makeText(getActivity(), R.string.done, Toast.LENGTH_SHORT)
        .show();

    task=null;
}
```

(from RecyclerView/SortedList/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java)
The Results

If you run this sample, you will see the words be added to the list, every 400ms. However, in the original ListView-based sample, new rows were appended to the end, and so you would not see new rows appear after the ListView space was filled. In this sample, the Latin words are sorted by SortedList, and you will see them animate into position at the appropriate spots as they are added. In the end, you get the same look as in earlier CardView-based RecyclerView implementations, except that the words are sorted:

![Figure 514: SortedList RecyclerView Demo]

Other Bits of Goodness

To quote the infamous American infomercial line: “But wait! There’s more!”

In addition to LinearLayoutManager and GridLayoutManager, there is StaggeredGridLayoutManager. With a vertically-scrolling GridLayoutManager, rows are all a consistent height, but the cell widths might vary. With a vertically-scrolling StaggeredGridLayoutManager, the columns are all the same width, but the cell heights might vary.

1571
All three of the standard layout managers support horizontal operation as well, through a boolean on a constructor. In these cases, the content will scroll horizontally, rather than vertically. This eliminates the need for third-party horizontal ListView implementations and the like.

And, of course, you can implement your own RecyclerView.LayoutManagers, avoiding any of the built-in ones.

**Animating the Deltas**

SortedList is interesting, but it is inflexible. For example, you cannot readily change the sort order, without completely replacing the SortedList.

Moreover, it assumes that the changes that you want to make are simply to keep a list in sorted order. There are plenty of other possible changes to your data set that might occur, such as from the results of some Web service call to synchronize your local data with that on a server. You would have to somehow perform your own “diff” on the data shown in your RecyclerView and the new roster of data, to determine what changed, what did not change, and how those changes affect things like item positions within the list or grid.

We have two options for handling this:

- The low-level approach offered by DiffUtil
- The simplified approach offered by ListAdapter

First, let’s look at DiffUtil. This handles all of the difference calculations to identify the specific changes needed to switch the RecyclerView from one list to another. You hand it two collections (old and new), plus an object that can help determine what the changes are (one reminiscent of a SortedList.Callback). It gives you a results object that, in turn, can update the RecyclerView to affect those changes.

The Java8/VideoLambda sample project is yet another rendition of the “list of videos” sample app from earlier in this chapter. However, it shows the list in sorted order, but using DiffUtil rather than SortedList. This allows us to offer the user the ability to change the sort order (ascending or descending).

**Model**

The original version of this sample used a Cursor directly, wrapping it in a
RecyclerView.Adapter. That is fine, but we cannot readily sort a Cursor. It is simpler to convert the Cursor into a list of model objects, so we can sort the list.

To that end, the VideoLambda sample app has a Video class, with a constructor that can populate itself from a Cursor positioned on a valid row:

```java
package com.commonsware.android.recyclerview.videolist;

import android.content.ContentUris;
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;

class Video implements Comparable<Video> {
    final String title;
    final Uri videoUri;
    final String mimeType;

    Video(Cursor row) {
        this.title = row.getString(row.getColumnIndex(MediaStore.Video.Media.TITLE));
        this.videoUri = ContentUris.withAppendedId(
            MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
            row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));
        this.mimeType = row.getString(row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE));
    }

    @Override
    public boolean equals(Object obj) {
        if (!(obj instanceof Video)) {
            return false;
        }

        return videoUri.equals(((Video)obj).videoUri);
    }

    @Override
    public int hashCode() {
        return videoUri.hashCode();
    }

    @Override
    public int compareTo(Video video) {
        return title.compareTo(video.title);
    }
}
```
Note that Video has an implementation of equals() considering two Video objects to be equal if they point to the same Uri. That will be important when we use DiffUtil, as DiffUtil (and our helper code) need to know when two Video objects logically represent the same video.

Video also implements Comparable and therefore has a compareTo() method, implemented by comparing the titles of the videos. This will be used as part of our sorting logic.

The VideoAdapter has a setVideos() method, taking a Cursor that we loaded from the MediaStore, as before. However, now VideoAdapter does not hold that Cursor in a field. Rather, it holds an ArrayList of Video objects as the videos field, with setVideos() handling the conversion of data from the Cursor into the Video objects:

```java
void setVideos(Cursor c) {
    if (c==null) {
        videos=null;
        notifyDataSetChanged();
    } else {
        ArrayList<Video> temp=new ArrayList<>();

        while (c.moveToNext()) {
            temp.add(new Video(c));
        }

        if (videos==null) {
            videos=new ArrayList<>();
        }

        sortAndApply(temp);
    }
}
```

We will see the sortAndApply() method, and understand what the temp local variable is all about, a bit later in this section. For now, take it on faith that:

- If the Cursor is null (e.g., onLoaderReset() was called), we null out the
videos field and call notifyDataSetChanged(), to let the RecyclerView know that our entire roster of videos changed

- If the Cursor is not null, we convert it into an ArrayList of Video objects, then use sortAndApply() to update the RecyclerView

The Menu

The other time we need to sort the videos is if the user chooses to switch from ascending to descending sort (or back again).

The app has a menu resource with a checkable menu <item>, named sort, that the user will be able to use to toggle the sort order:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/sort"
    android:checkable="true"
    android:checked="true"
    android:enabled="false"
    android:showAsAction="never"
    android:title="@string/sort_ascending" />
</menu>
```

(from Java8/VideoLambda/app/src/main/res/menu/actions.xml)

Note that it is disabled initially. When the app starts up, we do not yet have our videos, since they need to be loaded from the MediaStore. Hence, we keep the item disabled until the videos are ready.

In the activity’s onCreateOptionsMenu() method, we inflate the resource, get the sort MenuItem, hold onto it in a field (also named sort), and enable it if the VideoAdapter happens to already have some videos:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
  getMenuInflater().inflate(R.menu.actions, menu);
  sort=menu.findItem(R.id.sort);
  sort.setEnabled(adapter.getItemCount()>0);

  return(super.onCreateOptionsMenu(menu));
}
```

(from Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java)
Then, in onOptionsItemSelected(), if the user taps on this action bar item, we toggle its checked state, then tell the VideoAdapter to sort() based upon that state:

```java
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.sort) {
        item.setChecked(!item.isChecked());
        adapter.sort(item.isChecked());
        return(true);
    }
    return(super.onOptionsItemSelected(item));
}
```

sort(), in turn, keeps track of the current sort order, then calls the same sortAndApply() that we did in setVideos():

```java
sortAscending=checked;
sortAndApply(new ArrayList< POV videos>);
}
```

The Diff-ing

The job of sortAndApply() is to do what the name suggests: sort the videos and apply the sorted list to the RecyclerView. In principle, there are two possible scenarios:

1. We are showing the videos for the very first time
2. We are showing the videos again, after a re-sort, or perhaps after a new video was scanned by the MediaStore, triggering the Loader framework to hand us a fresh Cursor

Fortunately, we can handle both the same way:

```java
Collections.sort(newVideos,
    (one, two) -> one.compareTo(two));
```
else {
    Collections.sort(newVideos,
            (one, two) -> two.compareTo(one));
}

DiffUtil.Callback cb = new SimpleCallback<>(videos, newVideos);
DiffUtil.DiffResult result = DiffUtil.calculateDiff(cb, true);

videos=newVideos;
result.dispatchUpdatesTo(this);
}

private void sort(boolean checked) {

(The from Java8/VideoLambda/app/src/main/java/com/commonsware/android/recyclerview/videolist/MainActivity.java)

The new list of videos is the newVideos parameter to sortAndApply(). Based on the
sortAscending value, we use Collections.sort() to sort the newVideos list... using
a Java 8 lambda expression. Lambda expressions are covered elsewhere in the book.
However, we could just sort using an anonymous inner class implementation of
Comparator, such as this for sorting in ascending order:

Collections.sort(temp, new Comparator<Video>() {
    @Override
    public int compare(Video one, Video two) {
        return one.compareTo(two);
    }
});

Given the newly-sorted list, we create an instance of a DiffUtil.Callback object,
called SimpleCallback. We will see its implementation shortly. Its role is to help
DiffUtil calculate the nature of the changes to list of videos, comparing what is in
the RecyclerView now (videos) with what we want the RecyclerView to show
(newVideos).

That DiffUtil.Callback object is passed to the calculateDiff() method on
DiffUtil. The second parameter — true — indicates whether or not objects in the
list may have moved. Sometimes, we know that the updates do not move objects
around in the list, but merely insert new ones or remove existing ones. In such cases,
calculateDiff() can optimize its tracking algorithm to run more efficiently. In our
case, we most definitely are changing the positions of existing objects, and therefore
we need to pass true.

In principle, calculateDiff() should be called on a background thread. For long
lists and complicated comparisons, calculateDiff() could take long enough that you might exhibit some jank by taking up too much time on the main application thread. In this case, the comparisons are cheap, and hopefully you do not have too many videos on your test device.

The result of calculateDiff() is a DiffUtil.DiffResult object. After updating our video field to be the sorted newVideos collection, we call dispatchUpdatesTo() on the DiffResult, to have it apply the changes to the VideoAdapter. We need to update videos first because dispatchUpdatesTo() may trigger fresh onBindViewHolder() calls, and we need to make sure that we are using the newly-sorted list for those.

**The SimpleCallback**

SimpleCallback, as the name suggests, is a naive implementation of DiffUtil.Callback:

```java
package com.commonsware.android.recyclerview.videolist;

import android.support.v7.util.DiffUtil;
import java.util.ArrayList;

class SimpleCallback<T extends Comparable> extends DiffUtil.Callback {
    private final ArrayList<T> oldItems;
    private final ArrayList<T> newItems;

    public SimpleCallback(ArrayList<T> oldItems, ArrayList<T> newItems) {
        this.oldItems=oldItems;
        this.newItems=newItems;
    }

    @Override
    public int getOldListSize() {
        return(oldItems.size());
    }

    @Override
    public int getNewListSize() {
        return(newItems.size());
    }

    @Override
    public boolean areItemsTheSame(int oldItemPosition, int newItemPosition) {
```

---

ADVANCED RECYCLERVIEW

---

1578
Any DiffUtil.Callback needs to implement four key abstract methods:

- `getOldListSize()` and `getNewListSize()`, which return pretty much what their names would indicate
- `areItemsTheSame()`, where you need to indicate if a particular item from the old list (identified by position) represents the same logical entity as does a particular item from the new list (also identified by position)
- `areContentsTheSame()`, where you need to indicate if objects from the old and new list (identified by positions) are similar enough that the user would not notice a visual difference

Those latter two methods basically fill the same roles as do methods of the same names on a SortedList.Callback.

In the case of SimpleCallback, `areItemsTheSame()` uses `equals()`. Since Video implements `equals()` to compare the video Uri values, `areItemsTheSame()` will return true if the two Video objects point to the same video.

`areContentsTheSame()` leverages `compareTo()`, which compares the titles of the videos. If `compareTo()` return 0, the titles are the same, and so `areContentsTheSame()` returns true to indicate that the visual representation of the videos is the same. This might not actually be the case, as we are showing the video thumbnails in the rows, and so it is possible that we have two videos that have the same title but different thumbnails. In that case, DiffUtil might not cause RecyclerView to redraw one or the other row. An alternative approach would be to have `areContentsTheSame()` simply return the value of `areItemsTheSame()`. This covers the thumbnails issue, at the expense of possibly doing some unnecessary shuffling of RecyclerView items, for cases where we have two videos with identical titles and thumbnails. It will be up to you, in your own app, to determine the best
implementation of areContentsTheSame() based on your UI.

**ListAdapter. No, Not That ListAdapter.**

android.widget.ListAdapter is what we use with ListView.

android.support.v7.recyclerview.extensions.ListAdapter is a ListAdapter designed to work with RecyclerView. In particular, it integrates the DiffCallback behavior, so that as you provide updated lists of content, it calculates the differences and animates the necessary changes.

The RecyclerView/ListAdapter sample project illustrates the use of ListAdapter. It has the same functionality as the SortedList sample shown earlier in this chapter: animate the changes as we load 25 Latin words slowly into a RecyclerView, keeping the list sorted. The differences are:

- We use ListAdapter rather than SortedList
- We use RxJava instead of an AsyncTask
- We have to sort the contents ourselves, since SortedList is not doing that for us

**The Callback**

ListAdapter uses DiffUtil.ItemCallback. This is very similar to DiffUtil.Callback. In particular, it too uses areItemsTheSame() and areContentsTheSame() for the same roles:

- areItemsTheSame() should return true if the two items represent the same thing (e.g., have the same primary key)
- areContentsTheSame() should return true if the visual representation of the two items would be identical

However, ListAdapter and ItemCallback do not expect you to hold onto the lists in the callback — instead, you are passed actual objects for comparison:

```java
class StringDiffCallback extends DiffUtil.ItemCallback<String> {
    @Override
    public boolean areItemsTheSame(String oldItem, String newItem) {
        return oldItem.equals(newItem);
    }
}
```
In this case, our “models” are simple strings, so StringDiffCallback is handed strings for comparison purposes. Strings are very simple, so areItemsTheSame() and areContentsTheSame() have an identical implementation: use equals(). Having both callback methods use the same logic is a reasonable starting point even for more complex models.

The Adapter

The revised IconicAdapter now extends from ListAdapter:

```java
class IconicAdapter extends ListAdapter<String, RowController> {
    IconicAdapter() {
        super(new StringDiffCallback());
    }

    @NonNull
    @Override
    public RowController onCreateViewHolder(@NonNull ViewGroup parent, int viewType) {
        return new RowController(getActivity().getLayoutInflater()
            .inflate(R.layout.row, parent, false));
    }

    @Override
    public void onBindViewHolder(@NonNull RowController holder, int position) {
        holder.bindModel(getItem(position));
    }
}
```

This works similar to a regular RecyclerView.Adapter, with a few differences:

- We need to provide an instance of a suitable DiffUtil.ItemCallback in the constructor, so we pass a StringDiffCallback
- We do not need to keep track of the actual list of model objects ourselves, as ListAdapter does that for us
- In onBindViewHolder(), we can call getItem() to return the model object for a given position, for use in binding our RecyclerView.ViewHolder

To give a ListAdapter the models to show, call submitList(). If this is the first list
that the ListAdapter has seen, the items just get displayed in the associated RecyclerView. If, however, the ListAdapter already has a list, the ListAdapter uses the DiffUtil.ItemCallback to determine what changes are needed in the RecyclerView to switch from the old list to the new one. Then, it makes the appropriate calls to make those incremental changes, triggering animated effects along the way.

**The Rx Stuff**

This particular sample happens to use RxJava and Java 8 lambda expressions for feeding our list of words, 400 milliseconds at a time, to the RecyclerView. That is handled in the onViewCreated() method of our SortedFragment:

```java
@Override
public void onViewCreated(@NonNull View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    IconicAdapter adapter = new IconicAdapter();
    setAdapter(adapter);
    setLayoutManager(new LinearLayoutManager(getActivity()));

    ArrayList<String> wordsSoFar = new ArrayList<>();

    sub = Observable.fromArray(ITEMS)
            .zipWith(Observable.interval(400, TimeUnit.MILLISECONDS), (item, interval) -> item)
            .subscribeOn(Schedulers.newThread())
            .observeOn(AndroidSchedulers.mainThread())
            .map(word -> {
                wordsSoFar.add(word);
                Collections.sort(wordsSoFar);
                return new ArrayList<>(wordsSoFar);
            })
            .doOnComplete(() ->
                Toast.makeText(getActivity(), R.string.done, Toast.LENGTH_SHORT)
                        .show())
            .subscribe(adapter::submitList);
}
```

(From RecyclerView/ListAdapter/app/src/main/java/com/commonsware/android/recyclerview/sorted/SortedFragment.java)

We start an Observable chain with fromArray(), which points to our static array of 25 Latin words.

Next, we attach a zipWith() operator. For every item emitted from our array, zipWith() will wait for an item to be emitted from some other Observable, then let us combine those two objects as we see fit. The other Observable that we use is created from interval(), which simply emits an object every so often, based on a
supplied period. The net effect of this line is that we introduce a 400 millisecond
delay for each of the items in the array.

Right now, our Observable chain is emitting individual words. What we want to give
the ListAdapter is the list of words that we have so far, in the order that we want
them to appear in the RecyclerView. So, we attach a map() operator to the chain. For
each word that comes in, we:

- Add it to a master copy of the words that we have received so far
- Sort that master copy
- Emit a copy of the master copy, as ListAdapter needs a fresh ArrayList in
submitList(), not a modified edition of the list that it already has
(otherwise, it loses track of what the old list was, since you changed it)

Then, after setting up the threads, we use doOnComplete() to find out when our
array is finished so we can show a Toast to let the user know that all the words were
added.

Finally, we subscribe() and pass each edition of the sorted list over to the
ListAdapter by means of submitList().

The net effect is the same as the earlier SortedList example: each item appears in
the list, with animated effects to handle the inserted values.

Expandable Rows

A common pattern in vertically-scrolling lists is to have the rows expand and
contract when clicked. This allows you to have more information inline in the list,
without always taking up all of the vertical space that the information might require.

This might not sound very hard: just toggle the visibility of some widgets, perhaps
using an animation.

However, what we really want is that when a row is expanded, that the entirety of
the expanded row is visible, assuming that there is sufficient screen space for it.
Otherwise, if the user happens to expand some row at the bottom of the list, the
user might not realize that more information is available off the bottom of the
screen.

Making this work requires knowing where the row is in the list, how much space will
Advanced RecyclerView

be required when it is expanded, whether the expanded row will fit given the RecyclerView size, and how to scroll the RecyclerView to make the row fit if needed.

That sounds complicated.

And so, we turn to a library: the ExpandableLayout provided by com.github.SilenceDut:ExpandableLayout. This library is demonstrated in the RecyclerView/ExpandableRow sample project. However, this sample project makes extensive use of the data binding framework, so you may wish to read that chapter before continuing with this section.

This app is another “list the recent questions on Stack Overflow” apps that have been profiled elsewhere in the book, starting with the chapter on Internet access. In this case, we are using a RecyclerView for the list, with the data binding framework populating the rows.

A Stack Overflow question has lots of possible pieces of data, far more than we would want to display in a RecyclerView row. Even showing a subset of this information would make for a really long list, as each row would be fairly large. So, instead, we will use ExpandableLayout to show the title, owner’s avatar, and question score all the time and show the tags, view count, and answer count after the user taps on a row. Since we are “stealing” the click event to expand and collapse the row, we cannot use it for anything else, so we also want a “View” button in the expanded area, to allow the user to view the Stack Overflow question on the Stack Overflow Web site.

Our build.gradle file pulls in libraries for accessing the Stack Exchange API (Retrofit and Picasso), libraries for displaying the results (recyclerview-v7 and cardview-v7), plus ExpandableLayout:

```groovy
apply plugin: 'com.android.application'

repositories {
    maven { url "https://jitpack.io" }
}

dependencies {
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit:retrofit:1.9.0'
    implementation 'com.android.support:recyclerview-v7:27.1.0'
    implementation 'com.android.support:cardview-v7:27.1.0'
    implementation('com.android.support:support-v4:27.1.0') {
pdexEntry
```
An ExpandableLayout contains two children. The first child will be shown all the time, while the second child represents the additional content to be shown when the ExpandableLayout is expanded. So, our res/layout/row.xml resource contains an ExpandableLayout, wrapping around the desired UI. The ExpandableLayout itself is wrapped in a CardView for formatting, and the whole thing is inside a <layout> for the data binding framework:
<android.support.v7.widget.CardView
xmlns:cardview="http://schemas.android.com/apk/res-auto"
android:layout_width="match_parent"

Advanced RecyclerView

We do not need to do anything to teach ExpandableLayout to expand and collapse based upon click events, as that is built into the class. However, we do opt into one optional feature, via app:expWithParentScroll="true". This indicates that we want to scroll the parent (here, referring to the RecyclerView) to allow the expanded ExpandableLayout to be fully visible where possible.
When the activity is launched, the rows are collapsed:

![Expandable RecyclerView Rows, Collapsed](image)

*Figure 515: Expandable RecyclerView Rows, Collapsed*
Tapping on one expands it to show the rest of the content, including scrolling the RecyclerView so it is visible:

![Expandable RecyclerView Rows, One Row Expanded](image)

**Recyclerview as Pager**

ViewPager has been used for horizontally-swiped page-at-a-time user interfaces since its debut in 2011.

However, ViewPager is not that flexible:

- You can only swipe horizontally. It has no `setSwipeDirection()` or similar method to switch to vertical swiping.
- It was designed to work with fragments as pages. While PagerAdapter itself can work with views as pages, even the minimum required API is difficult to understand. And using fragments as pages means that you may wind up in cases with nested fragments, which adds to the complexity.
- While PagerAdapter has enough hooks to allow you to add and remove pages on the fly, neither FragmentPagerAdapter nor FragmentStatePagerAdapter support this use case, requiring you to roll your own PagerAdapter implementation.
And so on.

However, as it turns out, RecyclerView can be readily adapted to serve as a ViewPager replacement. Instead of a PagerAdapter, you use an ordinary RecyclerView.Adapter, where your pages are simple views. RecyclerView itself is far more flexible than is ViewPager, giving you a stronger foundation for more advanced paging scenarios.

**Using RecyclerViewPager**

The original solution for using RecyclerView as a ViewPager replacement came in the form of a third-party library, com.github.lsjwzh.RecyclerViewPager. This library offers a RecyclerViewPager subclass of RecyclerView that offers the page-at-a-time swiping metaphor.

The RecyclerViewPager/PlainRVP sample project illustrates its use. This is another rendition of the 10-EditText-widgets pager that was used in the chapter on ViewPager, swapping in RecyclerViewPager for the ViewPager.

**Adding the Dependency**

The com.github.lsjwzh.RecyclerViewPager library is not on JCenter or Maven Central. Instead, it is on jitpack.io, an artifact repository that builds artifacts directly from GitHub source repositories. So, to use this library, we need to add jitpack.io as a repository, in addition to adding the RecyclerViewPager library itself:

```groovy
apply plugin: 'com.android.application'

repositories {
    maven { url "https://jitpack.io" }
}

dependencies {
    implementation 'com.android.support:recyclerview-v7:25.1.0'
    implementation 'com.github.lsjwzh.RecyclerViewPager:lib:v1.1.2'
}

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'
    defaultConfig {
```
ADVANCED RECYCLERVIEW

Using the Widget

In the equivalent ViewPager sample app, the main.xml layout resource held the ViewPager. In this sample, it holds the RecyclerViewPager (or, more accurately, the com.lsjwzh.widget.recyclerviewpager.RecyclerViewPager, since the class name needs to be fully-qualified since it is coming from a library):

```xml
<?xml version="1.0" encoding="utf-8"?>
<com.lsjwzh.widget.recyclerviewpager.RecyclerViewPager android:id="@+id/pager"
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:clipToPadding="false"
    android:layout_margin="@dimen/pager_padding"
    app:rvp_singlePageFling="true"
    app:rvp_triggerOffset="0.1" />
```

The app:rvp_singlePageFling indicates that we want to limit the user to switch one page at a time, rather than a long fling gesture resulting in moving through many pages at once. The app:rvp_triggerOffset attribute is undocumented but appears to control how much of a swipe gesture is necessary to trigger a page change.

Populating the Pages

With ViewPager, you supply the pages via a PagerAdapter, typically a FragmentPagerAdapter or a FragmentStatePagerAdapter. With RecyclerViewPager, you supply the pages via a RecyclerView.Adapter, just as you would with any other RecyclerView.

So, in onCreate() of the MainActivity, we get the RecyclerViewPager, hand it a horizontal LinearLayoutManager, create a PageAdapter, and attach that PageAdapter to the RecyclerViewPager:
By using a horizontal LinearLayoutManager, the RecyclerViewPager will behave akin to a regular ViewPager, with navigation occurring via horizontal swipes. Want a vertical ViewPager? Replace the horizontal LinearLayoutManager with a vertical one, and you are set.

Our PageAdapter is a RecyclerView.Adapter, for a RecyclerView.ViewHolder named PageController. The basic setup for PageAdapter is not that different than any other RecyclerView.Adapter:

- We create a PageController in onCreateViewHolder()
- We populate that PageController with model data in onBindViewHolder()
- We indicate how many items there are in getItemCount()
In this case, our model data is an ArrayList of String objects, representing the text that the user enters into each page's EditText. PAGE_COUNT caps the number of editors (and pages) at 10, and so we initialize 10 buffers in the PageAdapter constructor.

The layout used for the pages — inflated by onCreateViewHolder() — is just a full-page multi-line EditText widget:

PageController is a fairly basic RecyclerView.ViewHolder, wrapping our EditText and offering a getter and setter for manipulating the text in the editor:
In case the buffer is empty (as it is at the outset), we also set the hint of the EditText to be the current page's index, adding one to adjust the range to start at 1 rather than 0. The hint text itself is in a string resource, with a %d placeholder for the page number:

```
<?xml version='1.0' encoding='utf-8'?>
<resources>
    <string name="app_name">RVP Demo</string>
    <string name="hint">Editor #%d</string>
</resources>
```

We use the N-parameter getString() method to not only retrieve the hint string resource but run it through String.format() to populate the placeholders, in this case using getAdapterPosition() to determine our page number.

### Dealing with Recycling

RecyclerView wants to recycle its items. That is in contrast to how the stock PagerAdapter implementation works:

- FragmentPagerAdapter holds onto every fragment created due to the user's navigation
- FragmentStatePagerAdapter holds onto some fragments, but lets others get garbage-collected, to minimize memory consumption

If our pages were read-only, we would not have to worry about recycling. This is how many RecyclerView implementations work — they just focus on binding the right data into the right RecyclerView.ViewHolder at the right time, based on calls to onBindViewHolder in the RecyclerView.Adapter.
However, when the RecyclerView items are interactive, we need to make sure that we hold onto the changed data, rather than having it be overwritten when we bind fresh data into the recycled item’s views.

In PageAdapter, we handle this by overriding `onViewDetachedFromWindow()`, which is called when the views of a PageController are no longer part of our activity’s window. Typically, this will occur as part of scrolling. In our case, we use this opportunity to grab the current contents of that EditText widget and update our buffers data model to match:

```java
@Override
public void onViewDetachedFromWindow(PageController holder) {
    super.onViewDetachedFromWindow(holder);

    buffers.set(holder.getAdapterPosition(), holder.getText());
}
```

(From RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java)

Alternatively, you could aim to deal with this more in “real time”, such as by using a TextWatcher to update the model as the user types. That adds a fair bit of overhead, though.

**Dealing with Configuration Changes**

We need to make sure that we do not lose what the user types into the pages when we undergo a configuration change. Since our model is a simple ArrayList of String objects, we can use the saved instance state Bundle to hold onto the in-flight information.

A RecyclerView.Adapter does not have its own onSaveInstanceState() method, but we can add one, then call it from MainActivity:

```java
@Override
protected void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);

    Bundle adapterState=new Bundle();

    adapter.onSaveInstanceState(adapterState);
    state.putBundle(STATE_ADAPTER, adapterState);
}
```

(From RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/MainActivity.java)
Here, MainActivity provides a fresh Bundle to the adapter. This way, values that the adapter wishes to save in the instance state will not collide with anything else the activity would want to save in the instance state, due to accidental key collisions. In this case, this may well be superfluous, but it is a worthwhile practice.

The challenge in our PageAdapter is that buffers only has text from those PageController objects that have been recycled. That will not include the currently-visible page or possibly some adjacent pages.

So, we iterate over all pages and call findViewHolderForAdapterPosition() on the RecyclerView itself. This will return null for any positions for which no PageController is presently allocated, or the PageController for the position for those positions that are actively being used. For those latter ones, we update the buffers to reflect whatever is in the EditText widgets, saving that into the instance state Bundle:

```java
void onSaveInstanceState(Bundle state) {
    for (int i=0; i<PAGE_COUNT; i++) {
        PageController holder =
            (PageController)pager.findViewHolderForAdapterPosition(i);

        if (holder != null) {
            buffers.set(i, holder.getText());
        }
    }

    state.putStringArrayList(STATE_BUFFERS, buffers);
}
```

(from RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/PageAdapter.java)

MainActivity has a corresponding onRestoreInstanceState() method:

```java
@override
protected void onRestoreInstanceState(Bundle state) {
    super.onRestoreInstanceState(state);

    adapter.onRestoreInstanceState(state.getBundle(STATE_ADAPTER));
}
```

(from RecyclerViewPager/PlainRVP/app/src/main/java/com/commonsware/android/rvp/MainActivity.java)

That delegates the work to the onRestoreInstanceState() method on the PageAdapter:
This sets up our buffers for use in populating pages again.

**Using SnapHelper**

RecyclerViewPager was first released in 2014. Since then, RecyclerView and its supporting classes have evolved. Now, you can get much of the functionality of RecyclerViewPager with an ordinary RecyclerView, with the assistance of SnapHelper. As Lisa Wray profiled in a droidcon NYC 2016 presentation, SnapHelper is a utility class that forces swipe gestures to “snap” to certain locations or boundaries. And, there is a PagerSnapHelper that, in conjunction with properly-configured RecyclerView and items, gives you ViewPager-like behavior.

The RecyclerViewPager/PlainSnap sample project is a clone of the PlainRVP sample, except that the RecyclerViewPager is replaced by a RecyclerView and a PagerSnapHelper.

There are three requirements of PagerSnapHelper. Two are tied to the layouts: both the RecyclerView and its items need to have match_parent for android:layout_width and android:layout_height. That was how PlainRVP was set up already, though PlainSnap swaps in a RecyclerView for the RecyclerViewPager in main.xml:

```xml
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.RecyclerView android:id="@+id/pager"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:layout_margin="@dimen/pager_padding"
    android:clipToPadding="false" />
```

The other requirement is that we create an instance of PagerSnapHelper and call attachToRecyclerView() on it, supplying our RecyclerView. This is handled in an updated MainActivity:
We hold onto the `PagerSnapHelper` in a field, to ensure that it will not be garbage-

1598
collected unexpectedly. Probably the PagerSnapHelper has sufficient connections to the RecyclerView to ensure that it will stay around as long as its associated RecyclerView does, but that is not apparent from the API or the documentation.

Beyond that, we configure the RecyclerView much as we had configured the RecyclerViewPager, and our PageAdapter and PageController are largely unaffected by the UI switch. In the end, we wind up once again with page-at-a-time horizontal swiping, though this time we can skip the third-party library.

**Adding Tabs**

Many times, with a pager-style interface, we want an indicator to help the user understand where they are within the range of pages offered by the pager. One of the more popular indicator styles is tabs, as those also provide an alternative navigation option, with the user tapping on tabs to switch to particular pages.

For adding tabs to a RecyclerView-powered pager, you need a tab implementation that is not tied inextricably to ViewPager, the way PagerTabStrip is. At the same time, you need one that is not tied inextricably to some other particular UI setup, the way that FragmentTabHost is. Instead, you need tabs that “stick to their knitting” and focus solely on handling the tab UI, giving you the hooks necessary to update your UI based on tab changes, and to update the tabs based on other UI changes.

TabLayout, from the Design Support library, is one such tab implementation. While it offers hooks into ViewPager, those are optional. You have two main options for using TabLayout:

1. Literally use the version from the Design Support library, which will require you to use appcompat-v7. This works back to API Level 7, as does RecyclerView itself.
2. Use the TabLayout from the CWAC-CrossPort library, which is the official TabLayout code, with all references to appcompat-v7 replaced by references to Theme.Material and related native items. However, this limits this cross-ported TabLayout to API Level 21 and higher (Android 5.0).

The RecyclerViewPager/TabSnap sample project is a clone of the PlainSnap sample, with tabs added, via the TabLayout from CWAC-CrossPort. As a result, we need the CWAC-CrossPort dependency and need to raise our minSdkVersion to 21:

```groovy
apply plugin: 'com.android.application'
```
The tabs themselves can then go above the RecyclerView, in a vertical LinearLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <com.commonsware.cwac.crossport.design.widget.TabLayout
        android:id="@+id/tabs"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        app:tabMode="scrollable"/>

    <android.support.v7.widget.RecyclerView
        android:id="@+id/pager"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_margin="@dimen/pager_padding"
        android:clipToPadding="false" />
</LinearLayout>
```
Next, we need to set up the tab contents in `onCreate()` of `MainActivity`. To do that, we get our hands on the `TabLayout` using `findViewById()`, then iterate through the items in the `PageAdapter` to set up tabs for each:

```java
final TabLayout tabs = (TabLayout) findViewById(R.id.tabs);

for (int i = 0; i < adapter.getItemCount(); i++) {
    tabs.addTab(tabs.newTab().setText(adapter.getTabText(this, i)));
}
```

We ask the `PageAdapter` for the text to show in the tab, via a `getTabText()` method:

```java
String getTabText(Context ctxt, int position) {
    return PageController.getTitle(ctxt, position);
}
```

That, in turn, delegates to a static version of the `getTitle()` method on `PageController`, to fill in the string resource template with the proper page number:

```java
static String getTitle(Context ctxt, int position) {
    return ctxt.getString(R.string.hint, position + 1);
}
```

We now need to add code in `onCreate()` of `MainActivity` to tie the navigation together:

- When the user taps a tab, we need to update the pager
- When the user swipes the pager, we need to update the tabs to show the new selection

This is handled by event listeners:

```java
tabs.addOnTabSelectedListener(new TabLayout.OnTabSelectedListener() {
    @Override
    public void onTabSelected(TabLayout.Tab tab) {
        pager.smoothScrollToPosition(tab.getPosition());
    }
});
```
When a tab is selected, our anonymous `TabLayout.OnTabSelectedListener` implementation will get control in `onTabSelected()`. There, we tell the `RecyclerView` to scroll to show a particular position, tied to the position of the selected tab.

Similarly, when the user scrolls the pager, we need to update the tabs to show the new selection. To do that, we take advantage of the `findFirstCompletelyVisibleItemPosition()` method on `LinearLayoutManager`. As the (lengthy) method name suggests, this returns the position of the first item that is completely visible within the pager. This might return –1, if we are in the middle of a swipe, as no item may be completely visible at that point. But, once we get a plausible value, we tell the `TabLayout` to select that tab.

`RecyclerViewPager` has a more sophisticated algorithm for integrating with the official Design Support library implementation of `TabLayout`. `RecyclerViewPager` calculates the position of the tab highlight, based upon the current swipe position, and updates that. This provides visual feedback within the tabs while the swipe is going on. The approach shown in the sample app has the effect of only updating the tabs once the swipe is completed.
Declaring a LayoutManager in the Layout

The typical way of setting up a LayoutManager is to call setLayoutManager() on the RecyclerView. There may be no choice in some cases, if the LayoutManager that you wish to use has a custom constructor that you need.

However, in some cases, where the LayoutManager has adequate setters to configure it beyond the constructor, you can set up the LayoutManager in your layout resource file. Just add the app:layoutManager attribute to the RecyclerView element, with the value being:

- the bare class name of a standard LayoutManager, such as LinearLayoutManager, or
- the fully-qualified class name of some custom LayoutManager, one that you wrote or are using from a library

The app XML namespace (xmlns:app="http://schemas.android.com/apk/res-auto") can be added to the layout resource file by an Android Studio quick-fix.

Transcript Mode

“Transcript mode” with ListView means that the ListView automatically scrolls to keep the bottom entries in view. This is useful for things like chat transcripts, where you want to append new messages and show those new messages to the user, and the new messages (traditionally) go below older messages. This approach — using setTranscriptMode() — has been used a couple of times in this book, such as in the chapter profiling various event bus implementations.

RecyclerView also supports this approach, though it is set up somewhat differently.

The RecyclerView/Transcript sample project is a clone of the EventBus/GreenRobot3 sample project, where the ListView is replaced by a RecyclerView.

In a layout resource, we declare our RecyclerView, with a few interesting attributes:

```xml
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.RecyclerView android:id="@+id/transcript"
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>
```
Specifically, we have:

- `app:layoutManager` defines the layout manager that we want to use, in this case a LinearLayoutManager
- `app:reverseLayout="true"` and `app:stackFromEnd="true"`, which combine to give us a transcript-style effect

Note that those latter two attributes are actually documented on LinearLayoutManager, not on RecyclerView (and, even then, they are largely undocumented). Those attributes may not work with other layout managers (e.g., GridLayoutManager).

Beyond that, the rest of the code works pretty much as the original sample app did, except that we need to substitute in RecyclerView equivalents for the ListView functionality. So, for example, rather than inheriting from ListViewFragment, the EventLogFragment is now a regular Fragment, where we inflate our layout in `onCreateView()` and attach its EventLogAdapter in `onViewCreated()`:

```java
@Nullable
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup container, Bundle savedInstanceState) {
    return inflater.inflate(R.layout.main, container, false);
}

@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    if (adapter==null) {
        adapter=new EventLogAdapter();
    }

    RecyclerView transcript=(RecyclerView)view.findViewById(R.id.transcript);
    transcript.setAdapter(adapter);
}
```

(from RecyclerView/Transcript/app/src/main/java/com/commonsware/android/rv/transcript/EventLogFragment.java)
ADVANCED RECYCLERVIEW

The old ArrayAdapter is gone, so EventLogAdapter is now a RecyclerView.Adapter, managing a series of RowHolder objects for our rows:

class EventLogAdapter extends RecyclerView.Adapter<RowHolder> {
    private final ArrayList<RandomEvent> events = new ArrayList<>();

    @Override
    public RowHolder onCreateViewHolder(ViewGroup parent, int viewType) {
        View row = get.Activity().getLayoutInflater().inflate(android.R.layout.simple_list_item_1, parent, false);
        return new RowHolder(row);
    }

    @Override
    public void onBindViewHolder(RowHolder holder, int position) {
        holder.bind(events.get(position));
    }

    @Override
    public int getItemCount() {
        return events.size();
    }

    void add(RandomEvent event) {
        events.add(event);
        notifyItemInserted(getItemCount());
    }
}

static class RowHolder extends RecyclerView.ViewHolder {
    private static final DateFormat fmt = new SimpleDateFormat("HH:mm:ss", Locale.US);
    private final TextView tv;

    RowHolder(View itemView) {
        super(itemView);

        tv = (TextView) itemView.findViewById(android.R.id.text1);
    }

    void bind(RandomEvent event) {
        tv.setText(String.format("%s = %x", fmt.format(event.when),
        });
    }
}
And, when we get a RandomEvent, we add() that to our EventLogAdapter, which adds it to its array of events and updates the RecyclerView to match:

```java
@Subscribe(threadMode = ThreadMode.MAIN)
public void onRandomEvent(final RandomEvent event) {
    adapter.add(event);
}
```
Advanced Uses of WebView

Android uses the WebKit browser engine as the foundation for both its Browser application and the WebView embeddable browsing widget. The Browser application, of course, is something Android users can interact with directly; the WebView widget is something you can integrate into your own applications for places where an HTML interface might be useful.

Earlier in this book, we saw a simple integration of a WebView into an Android activity, with the activity dictating what the browsing widget displayed and how it responded to links.

Here, we will expand on this theme, and show how to more tightly integrate the Java environment of an Android application with the JavaScript environment of WebKit.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one covering WebView. Some of the samples use LocationManager for obtaining a GPS fix.

Friends with Benefits

When you integrate a WebView into your activity, you can control what Web pages are displayed, whether they are from a local provider or come from over the Internet, what should happen when a link is clicked, and so forth. And between WebView, WebViewClient, and WebSettings, you can control a fair bit about how the embedded browser behaves. Yet, by default, the browser itself is just a browser, capable of showing Web pages and interacting with Web sites, but otherwise gaining
nothing from being hosted by an Android application.

However, WebView offers a few options for more tightly integrating the Java and JavaScript realms, so Web content can call into your app to get data to display, and your app can push data into the Web page for JavaScript to render.

Unfortunately, the techniques for doing this have changed over the years. Partially that is due to changes in WebView, particularly starting with Android 4.4. But, some of the changes are due to security issues, particularly when you are loading arbitrary content, such as Web-based ads from an ad network, into your WebView.

The following sections will go over four separate sample apps. All do the same thing: provide data about the ambient light level, using the sensor on the phone or tablet, to the Web page for rendering. The differences are whether we are pushing data from Java into JavaScript (e.g., as the light level changes), or whether we are pulling data from Java using JavaScript (e.g., in response to a user tapping on something in the Web page). Also, we will see two approaches to push and two approaches to pull.

**JavaScript Calling Java: addJavascriptInterface()**

The addJavascriptInterface() method on WebView allows you to inject a Java object into the WebView, exposing its methods, so they can be called by JavaScript loaded by the Web content in the WebView itself.

Now you have the power to provide access to a wide range of Android features and capabilities to your WebView-hosted content. If you can access it from your activity, and if you can wrap it in something convenient for use by JavaScript, your Web pages can access it as well.

The WebKit/SensorPull sample project demonstrates using addJavascriptInterface() to pull light sensor data into a Web page to display to the user.

For all four of these sample apps, the UI is just a WebView:

```xml
<?xml version="1.0" encoding="utf-8"?>
<WebView android:id="@+id/webkit"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
</WebView>
ADVANCED USES OF WebView

In `onCreate()`, we set things up:

```java
@SuppressLint({"AddJavascriptInterface", "SetJavaScriptEnabled"})
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    mgr=(SensorManager) getSystemService(Context.SENSOR_SERVICE);
    light=mgr.getDefaultSensor(Sensor.TYPE_LIGHT);

    wv=(WebView) findViewById(R.id.webkit);
    wv.getSettings().setJavaScriptEnabled(true);
    wv.addJavascriptInterface(jsInterface, "LIGHT_SENSOR");
    wv.loadUrl("file:///android_asset/index.html");
}
```

Specifically, we:

- Get a `SensorManager` and the appropriate `Sensor` for measuring ambient light levels, saving those in fields
- Get our `WebView` via `findViewById()`
- Enable JavaScript (which comes disabled by default), using `getSettings()` and `setJavaScriptEnabled(true)`
- Call `addJavascriptInterface()`, and
- Load a Web page from assets (which we will examine shortly)

Because we are enabling JavaScript, Lint will complain that this poses security risks, so `onCreate()` has a `@SuppressLint` annotation for `SetJavaScriptEnabled` to indicate that we are aware of the risks. Similarly, because we are calling `addJavascriptInterface()`, Lint will complain that this poses even more security risks. So, `@SuppressLint` suppresses both the `SetJavaScriptEnabled` warning and the `AddJavascriptInterface` warning.

Also, you may notice that there is a significant debate within the Android SDK as to whether the "s" in “JavaScript” gets capitalized or not. In general, it does, but `addJavascriptInterface()` shipped in API Level 1 with a lowercase “s” in its name, and so that method, and variations of it (e.g., the `AddJavascriptInterface` annotation) will use a lowercase “s”. Eventually, you just get used to this.
addJavascriptInterface() takes two parameters: a Java object to inject into the JavaScript of the Web page, and a String that is the name by which JavaScript can reference that object. So, we have a jsInterface object that JavaScript can reference via LIGHT_SENSOR.

jsInterface is an instance of JSInterface, a static nested class inside MainActivity:

```java
private static class JSInterface {
    float lux=0.0f;

    private void updateLux(float lux) {
        this.lux=lux;
    }

    @JavascriptInterface
    public String getLux() {
        return(String.format(Locale.US, "\"lux\": %f", lux));
    }
}
```

(from WebKit/SensorPull/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java)

It just has a getter and setter around the current light level, which is a float named lux (referring to the unit of brightness used for the values coming from the ambient light sensor). The getter, however, has two interesting traits:

- It returns a String, representing a JSON object wrapped around the lux value
- It is annotated with @JavascriptInterface

This annotation is required of apps with android:targetSdkVersion set to 17 or higher, though it is a good idea to start using it anyway. With such an android:targetSdkVersion, in an app running on an Android 4.2 or higher device, only public methods with the @JavascriptInterface annotation will be accessible by JavaScript code. On earlier devices, or with an earlier android:targetSdkVersion, all public methods on the JsInterface object would be accessible by JavaScript, including those inherited from superclasses like Object. Note that your build target (i.e., compileSdkVersion in Android Studio) will need to be Android 4.2 or higher in order to reference the @JavascriptInterface annotation.

The reason for returning a JSON object (in string form), rather than just the float, is for two reasons:
1. For more complex APIs, you cannot pass into JavaScript an arbitrary Java object. All return types from @JavascriptInterface objects need to be something that JavaScript can use, and a simple way to do that is to create data structures in JSON.

2. float did not seem to work well as a return type, as it always seemed to turn into 0.0 on the JavaScript side, for unknown reasons

We register with the SensorManager to find out when the light level changes, via registerListener() (in onStart()) and unregisterListener() (in onStop()):

```java
@Override
protected void onStart() {
    super.onStart();

    mgr.registerListener(this, light, SensorManager.SENSOR_DELAY_UI);
}
```

That, in turn, will trigger a call to onSensorChanged() when the light level changes. There, we pass the light level (the first float out of the values array from the SensorEvent) to the JsInterface instance, ready to be retrieved by the JavaScript code in our Web page:

```java
@Override
public void onSensorChanged(SensorEvent sensorEvent) {
    jsInterface.updateLux(sensorEvent.values[0]);
}
```

In the Web page, we set it up to show the current light level, starting with a value of 0.0. When the user taps on the Light Level caption, we call a pull() JavaScript
function, which:

- Calls our getLux() method on the LIGHT_SENSOR global object
- Parses our JSON into a JavaScript object
- Calls an update_lux() function to update the lux span with the new light level

```html
<html>
<head>
<title>Android Light Sensor Demo</title>
<script language="javascript">
  function update_lux(lux) {
    document.getElementById("lux").innerHTML = lux;
  }

  function pull() {
    var result = JSON.parse(LIGHT_SENSOR.getLux());
    update_lux(result.lux);
  }
</script>
</head>
<body>
<p><b><a onClick="pull()">Light Level</a></b>: 0.0 lux</p>
</body>
</html>
```

(from WebKit/SensorPull/app/src/main/assets/index.html)
ADVANCED USES OF WebView

If you run the app, you get our trivial Web page in the WebView:

![WebView Bridge Pull Demo](image)

*Light Level*: 0.0 lux

*Figure 517: SensorPull Demo, As Initially Launched*
ADVANCED USES OF WebView

Tapping on the words “Light Level” will cause JavaScript to request the light level, updating the page to match:

![Web View Bridge Pull Demo](image)

**Light Level**: 30.532272 lux

*Figure 518: SensorPull Demo, Showing Light Level*

Note that this sample app will only work on devices with an ambient light sensor. It is rather likely that the app will crash spectacularly on devices lacking such a sensor.

Unfortunately, `addJavascriptInterface()` opens up a number of security issues, outlined *later in this chapter*. Where possible, avoid the use of this API.

**Java Calling JavaScript: loadUrl() and evaluateJavascript()**

Now that we have seen how JavaScript can call into Java, it would be nice if Java could somehow call out to JavaScript. Well, as luck would have it, we can do that too. This is a good thing, otherwise, this would be a really weak section of the book.

What is unusual is how you call out to JavaScript. One might imagine there would be an `evaluateJavaScript()` counterpart to `addJavascriptInterface()`, where you could supply some JavaScript source and have it executed within the context of the currently-loaded Web page.

Actually, there is such a method on Android 4.4. However, earlier versions of
Android lacked that method. Instead, on older versions of Android, given your snippet of JavaScript source to execute, you call `loadUrl()` on your `WebView`, as if you were going to load a Web page, but you put `javascript:` in front of your code and use that as the “address” to load.

If you have ever created a “bookmarklet” for a desktop Web browser, you will recognize this technique as being the Android analogue—the `javascript:` prefix tells the browser to treat the rest of the address as JavaScript source, injected into the currently-viewed Web page.

The [WebKit/SensorPush](https://example.com) sample project expands upon the SensorPull app. This time, though, in addition to pulling via `addJavascriptInterface()`, we support pushing light levels as sensor readings come in.

That comes courtesy of a revised `onSensorChanged()` method:

```java
@Override
public void onSensorChanged(SensorEvent sensorEvent) {
    float lux = sensorEvent.values[0];
    jsInterface.updateLux(lux);

    String js = String.format(Locale.US, "update_lux(%f)", lux);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.KITKAT) {
        wv.evaluateJavascript(js, null);
    } else {
        wv.loadUrl("javascript:"+js);
    }
}
```

Before, we just updated the `JsInterface` object with the new light level. Now, we also format a JavaScript call to `update_lux()`, supplying our light level. Then, based on Android OS version (`Build.VERSION.SDK_INT`), we either call `evaluateJavascript()` or `loadUrl()`, the latter also employing the `javascript:` scheme.

Because we had pulled out `update_lux()` as a separate function before, our HTML and JavaScript does not need to change at all:

```html

```

1615
If you run this sample app, you will find that the Web page updates in real time as you wave your hand in front of the light sensor, shine a light on that sensor, etc.

**Java Calling JavaScript: WebMessage**

Both of those techniques have worked since API Level 1. But, as mentioned, `addJavascriptInterface()` has security issues. Also, `evaluateJavascript()` (or its `loadUrl()` equivalent) requires the Java code to know what functions are available in the Web page. That may tie the Java and JavaScript more tightly than you might like.

Android 6.0 introduced another pair of options for communicating between Java and JavaScript — `WebMessage` and `WebMessagePort` — that try to eliminate these issues.

The simpler of the two approaches is `WebMessage`. Instead of calling `evaluateJavascript()` or `loadUrl()`, you create a `WebMessage` object and call `postWebMessage()` to deliver it to the JavaScript in your Web page. So, in the `WebKit/SensorMessage` sample project, we have an updated `onSensorChanged()` method that does this:

```java
@Override
public void onSensorChanged(SensorEvent sensorEvent) {
    float lux = sensorEvent.values[0];

    jsInterface.updateLux(lux);

    String js = String.format(Locale.US, "update_lux(%f)", lux);

```
The WebMessage constructor that we are using here takes a simple string that is the content of the message. In this case, it is the JSON object wrapping our light level in lux, using the same getLux() method that JavaScript can call on our JsInterface instance that we registered via addJavascriptInterface().

postWebMessage() takes two parameters. The first is the WebMessage to deliver to the page. The other is supposed to be the Uri of the Web page. This is supposed to be used to confirm that you are sending the message to the page that you think you are sending it to.

Unfortunately, this is not behaving especially well.

It only works as advertised for http/https URLs, or for data that you load using loadDataWithBaseURL() and supply some http or https URL. If you load from a file URL, as we are doing here, you cannot use the actual URL. Instead, you have to use Uri.EMPTY, which is a “wildcard” that skips over this test, which is what we use here. Apparently, this is all working as intended.

To receive these messages, our JavaScript needs to define an onmessage() global function:

```html
<html>
<head>
<title>Android Light Sensor Demo</title>
<script language="javascript">

function update_lux(lux) {
    document.getElementById("lux").innerHTML=lux;
}

function parse(json) {
    var result=JSON.parse(json);

```
This receives the HTML Web message equivalent of the WebMessage that we posted. The data field on the supplied event object (e in the sample) contains our string. So, we turn around and parse() it, just as we would parse() the JSON we got from calling getLux() on our LIGHT_SENSOR.

If you run this sample app on an Android 6.0+ device, you should get the same results as with SensorPush, where the light level changes automatically. However, in this case, we will be using code that relies upon WebMessage and postWebMessage(), instead of evaluateJavascript() or loadUrl(). In particular, our Java code does not need to know anything about the internal workings of the JavaScript (e.g., function names) — it just passes over the message and relies on the JavaScript to have registered itself appropriately to receive the message.

JavaScript Calling Java: WebMessagePort

What would be nice is to use this WebMessage system to be able to replace addJavascriptInterface() and allow JavaScript to call back into Java. This is possible, but it is fairly complex.

For our Java code to receive messages sent to it from JavaScript, we need to do three things:

1. Call createWebMessageChannel() on the WebView. This creates a private communications channel between us and our target Web page. It returns a two-element WebMessagePort array. Index 0 of that array is our end of the channel; index 1 is the JavaScript end of the channel.
2. Call setWebMessageCallback() on our WebMessagePort, supplying a
WebMessageCallback that will be called with onMessage() when a message arrives on the port from JavaScript.

3. Send the other WebMessagePort to JavaScript using a WebMessage.

In the WebKit/SensorPort sample project, this is handled by an initPort() method:

```java
@TargetApi(Build.VERSION_CODES.M)
private void initPort() {
    final WebMessagePort[] channel = wv.createWebMessageChannel();

    port = channel[0];
    port.setWebMessageCallback(new WebMessagePort.WebMessageCallback() {
        @Override
        public void onMessage(WebMessagePort port, WebMessage message) {
            postLux();
        }
    });

    wv.postMessage(new WebMessage("", new WebMessagePort[]{channel[1]}), Uri.EMPTY);
}
```

(from WebKit/SensorPort/app/src/main/java/com/commonsware/android/webkit/bridge/MainActivity.java)

The WebMessage constructor that we use this time takes two parameters: an arbitrary string (here, just set to "", as we are not using it) and a one-element WebMessagePort array containing the JavaScript end of the communications channel.

However, we cannot do any of this work until the Web page is ready to be used. Otherwise, the JavaScript code will not receive our WebMessage, since it is not yet ready.

So, we have to postpone calling initPort() until a WebViewClient is called with onPageFinished(), as we do in onCreate():

```java
@SuppressLint({"AddJavascriptInterface", "SetJavaScriptEnabled"})
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    mgr=(SensorManager) getSystemService(Context.SENSOR_SERVICE);
    light =mgr.getDefaultSensor(Sensor.TYPE_LIGHT);

    wv=(WebView) findViewById(R.id.webkit);
```
Our WebMessageCallback, upon receipt of a WebMessage from the JavaScript, calls a postLux() method. We are just using the existence of the message as a “ping” from the JavaScript to Java, asking for us to send it the ambient light level. So, in postLux(), we create a WebMessage and send it to JavaScript... but not via the postWebMessage() method on WebView. Instead, we use our end of the WebMessagePort communications channel, calling postMessage() on it, in a postLux() method:

```
@TargetApi(Build.VERSION_CODES.M)
private void postLux() {
    port.postMessage(new WebMessage(jsInterface.getLux()));
}
```

So, when the JavaScript sends a WebMessage to Java, Java sends a WebMessage right back, supplying the light level JSON.

To prove that this is working, this sample comments out the automated push of the light level in onSensorChanged() — ordinarily, we would call postLux() to push over the light level when we get it:

```
@Override
public void onSensorChanged(SensorEvent sensorEvent) {
    float lux = sensorEvent.values[0];

    jsInterface.updateLux(lux);

    String js = String.format(Locale.US, "update_lux(%f)", lux);
```
In JavaScript, our onmessage global function is now a bit more complex as well. We get our end of the communications channel by retrieving our `port` from `ports` on the event delivered to `onmessage()`. Then, we register an `onmessage` function on **that port**, which is how we receive the light levels that Java delivers via `postMessage()` on its `WebMessagePort`. When the user taps the label, we call a `pull()` function in JavaScript, that calls `postMessage()` on the port, supplying some string as a message (here, hardcoded as "ping" and ignored by our Java code):

```html
<html>
<head>
<title>Android Light Sensor Demo</title>
<script language="javascript">
    function update_lux(lux) {
        document.getElementById("lux").innerHTML=lux;
    }

    function parse(json) {
        var result=JSON.parse(json);
        update_lux(result.lux);
    }

    var port;

    function pull() {
        port.postMessage("ping");
    }

    onmessage = function (e) {
        port = e.ports[0];
        port.onmessage = function (f) {
            parse(f.data);
        }
    }
</script>
</head>
<body>
<p><a onClick="pull()">Light Level</a>: 0.0 lux</p>
</body>
</html>
```
If you run this sample on Android 6.0+, and you tap the “Light Level” label, you will get the light level, delivered by means of our WebMessagePort-based communications channel.

(NOTE: the author would like to thank Diego Torres Milano for his assistance in finding out how this stuff works).

Navigating the Waters

There is no navigation toolbar with the WebView widget. This allows you to use it in places where such a toolbar would be pointless and a waste of screen real estate. That being said, if you want to offer navigational capabilities, you can, but you have to supply the UI. WebView offers ways to perform garden-variety browser navigation, including:

- `reload()` to refresh the currently-viewed Web page
- `goBack()` to go back one step in the browser history, and `canGoBack()` to determine if there is any history to go back to
- `goForward()` to go forward one step in the browser history, and `canForward()` to determine if there is any history to go forward to
- `goBackOrForward()` to go backwards or forwards in the browser history, where negative numbers represent a count of steps to go backwards, and positive numbers represent how many steps to go forwards
- `canGoBackOrForward()` to see if the browser can go backwards or forwards the stated number of steps (following the same positive/negative convention as `goBackOrForward()`)
- `clearCache()` to clear the browser resource cache and `clearHistory()` to clear the browsing history

Settings, Preferences, and Options (Oh, My!)

With your favorite desktop Web browser, you have some sort of “settings” or “preferences” or “options” window. Between that and the toolbar controls, you can tweak and twiddle the behavior of your browser, from preferred fonts to the behavior of JavaScript.
Similarly, you can adjust the settings of your WebView widget as you see fit, via the WebSettings instance returned from calling the widget's getSettings() method.

There are lots of options on WebSettings to play with. Most appear fairly esoteric (e.g., setFantasyFontFamily()). However, here are some that you may find more useful:

- Control the font sizing via setDefaultFontSize() (to use a point size) or setTextSize() (to use constants indicating relative sizes like LARGER and SMALLEST)
- Control Web site rendering via setUserAgent(), so you can supply your own user agent string to make the Web server think you are a desktop browser, another mobile device (e.g., iPhone), or whatever. The settings you change are not persistent, so you should store them somewhere (such as via the Android preferences engine) if you are allowing your users to determine the settings, versus hard-wiring the settings in your application.

Security and Your WebView

More so than normal widgets, WebView opens up potential security issues, just as a Web browser could. If all you are doing is displaying your own content, the risks are minimal. If, on the other hand, you are displaying content from third parties, it is possible that their content is malicious in a way that can compromise your app's security, to your users' detriment.

Rogue JavaScript Risks

If you call setJavaScriptEnabled(true) on your WebSettings, you are allowing JavaScript code to be loaded and executed by WebView. In many cases, this is essential to get your content to render properly (e.g., the JavaScript is issuing AJAX calls). However, if you did not write the scripts, you do not know what they might be doing. If there are flaws in WebView — such as those discussed in the next sections — then your users may be at risk.

Even in the absence of such bugs, JavaScript can always:

- Consume so much CPU that it represents an attempt at a denial-of-service attack on the user's device
- Access anything the user enters into the Web page
- Access anything you enter into the Web page, using approaches as
The addJavascriptInterface() Bugs

Another way that rogue JavaScript can attack users is if you use addJavascriptInterface() to allow JavaScript code to call out to a Java object that you supply.

As was noted earlier in this chapter, when addJavascriptInterface() was introduced, there is this @JavascriptInterface annotation that we should apply to the methods we want JavaScript to be able to call on the object we supply via addJavascriptInterface(). This is because of a bug in the addJavascriptInterface() implementation, whereby on 4.1 and below any method on the Java object could be called by JavaScript. This includes methods like getClass()... which in turn would allow JavaScript to use Class.forName() to get at arbitrary stuff. This was used by various bits of malware.

Hence, using addJavascriptInterface() on Android 4.1 and below is rather risky, if you are loading arbitrary third-party JavaScript. If you have the means of examining that JavaScript (e.g., you are loading the scripts yourself), you might perform some simple scans of it to see if they appear to be doing anything unfortunate with your Java object that you injected into JavaScript via addJavascriptInterface().

Worse, Android sometimes also injects its own objects, without our requesting them.

In particular, this security bug points out that, through Android 4.3, if users have enabled an accessibility service, Android automatically injects objects into WebView, using addJavascriptInterface(), named accessibility and accessibilityTraversal. So, even if you do not inject any objects yourself via addJavascriptInterface(), your WebView may be at risk. The security researchers who uncovered this attack vector suggest using removeJavascriptInterface() to specifically get rid of those objects.

The Same-Origin Policy Bug

Due to a bizarre bug in the parsing of URLs, it is possible for JavaScript code to violate the “same-origin policy” of a WebView on Android 4.3 and earlier. 

Quoting Wikipedia from September 2014:
the same-origin policy is an important concept in the web application security model. The policy permits scripts running on pages originating from the same site — a combination of scheme, hostname, and port number — to access each other’s DOM with no specific restrictions, but prevents access to DOM on different sites. This mechanism bears a particular significance for modern web applications that extensively depend on HTTP cookies to maintain authenticated user sessions, as servers act based on the HTTP cookie information to reveal sensitive information or take state-changing actions. A strict separation between content provided by unrelated sites must be maintained on the client side to prevent the loss of data confidentiality or integrity.

All modern Web browsers implement the same-origin policy (SOP)... but there can be bugs. A security researcher disclosed that the original AOSP Browser application failed to implement the SOP properly, when a javascript: URL has a null byte before the j in javascript. And while the report was focused on the AOSP Browser app, the problem really lies with WebView.

To see this in action, load https://commonsware.com/misc/sop-demo.html in the AOSP Browser app on Android 4.3 or lower. This Web page consists of:

```html
<html>
<head>
<title>WebView SOP Test</title>
</head>
<body>
<h1>WebView SOP Test</h1>
<iframe name="test" src="http://developer.android.com"></iframe>
<input type="button" value="test" onclick="window.open('\u0000javascript:alert(document.domain)','test')">
</body>
</html>
```

It is derived from a similar example found in the blog post outlining the security flaw.

In an SOP-compliant browser, clicking the button will have no effect. In the AOSP Browser app, clicking the button shows the domain name of the document in the iframe. And, loading this HTML into a WebView has the same effect.

Part of the WebView overhaul in Android 4.4 — replacing the original implementation with a new one backed by Chromium — had the effect of fixing this bug, whether intentionally or inadvertently.
There is no obvious mitigation approach for this bug, insofar as for the attack shown above, none of the callbacks on WebViewClient or WebChromeClient seem to allow us to intercept this URL before its JavaScript is executed. If you are loading HTML yourself from a third party, you might consider scanning that HTML for obvious signs of the attack (e.g., regular expression check for \u0000javascript), but that will be limited at best. Beyond that, try to limit the content in a WebView to be from only one origin, so that there is nothing for attackers to obtain via this bug.

Also note that the security researcher who found this bug has also found another SOP violation, suggesting that mitigation strategies may be impractical.

**Android 8.0 WebView Changes**

WebView, as Android developers use it, is really a facade API, as of Android 5.0. Previously, the WebView implementation was part of the Android framework. Nowadays, the implementation is delegated to the Android System WebView, which allows Google to update the WebView implementation without relying upon manufacturers to distribute firmware updates.

Hence, to some extent, WebView continuously changes, as the Android System WebView app gets updated a few times per year.

However, it is only in a new version of Android that Google changes the API or the general approach taken by a WebView implementation. In Android 8.0, two significant changes arrived: multi-process mode and support for banning of cleartext traffic.

**Multi-Process Mode**

Historically, WebView code ran in your app’s regular process. Because we often load JavaScript into a WebView, having the WebView in our process would raise the risks of WebView bugs. If JavaScript could cause arbitrary code to execute in our own process, it would have whatever rights our own application code does, including everything for which we have runtime permissions.

Android 7.0 added a developer option for moving the WebView execution to a separate process, and that is now standard on Android 8.0. As the documentation describes it, “Web content is handled in a separate, isolated process from the containing app’s process for enhanced security.”
In principle, this should not require code changes. However, this is a significant architectural change, and so it is worthwhile to fully test your WebView usage on Android 8.0+, to make sure nothing breaks compared with that same code running on Android 7.1 or older devices.

**Honors Cleartext Traffic Setting**

If your app has a `targetSdkVersion` over 25, and in your network security configuration you banned cleartext traffic, WebView will honor that setting on Android 8.0+. On older devices, WebView ignores the network security configuration, and it appears that it still ignores the rest of the configuration (e.g., certificate pinning).

However, this allows you to block the accidental transmission of data over unencrypted channels. Most apps doing network I/O should ban cleartext traffic, at least for debug builds, to identify where they are accidentally using a plain http URL. Apps for which security is a priority might also ban cleartext traffic for release builds.

The WebKit/BrowserSecure sample project demonstrates this. It has a network security configuration XML file that bands cleartext traffic:

```xml
<?xml version="1.0" encoding="utf-8"?>
<network-security-config>
  <base-config cleartextTrafficPermitted="false">
    <trust-anchors>
      <certificates src="system" />
    </trust-anchors>
  </base-config>
</network-security-config>
```

(from WebKit/BrowserSecure/app/src/main/res/xml/net_security_config.xml)

It applies that configuration in the manifest via the `android:networkSecurityConfig` attribute on the `<application>` element:

```xml
<application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:networkSecurityConfig="@xml/net_security_config">
    <activity android:name=".BrowserDemo1">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />
      </intent-filter>
    </activity>
</application>
```

1627
The activity just loads up a plain HTTP-served Web page:

```java
package com.commonsware.android.browser1;

import android.app.Activity;
import android.os.Bundle;
import android.webkit.WebView;

public class BrowserDemo1 extends Activity {
    WebView browser;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);
        browser=(WebView) findViewById(R.id.webkit);
        browser.loadUrl("http://www.andglobe.com");
    }
}
```

The project is set up to target 26:

```groovy
apply plugin: 'com.android.application'

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'

    defaultConfig {
        minSdkVersion 25
        targetSdkVersion 26
        applicationId 'com.commonsware.android.browser.secure'
    }
}
```

(From WebKit/BrowserSecure/app/build.gradle)
ADVANCED USES OF WebView

If you change that to have it target 25, the app will run “normally” on Android 8.0, showing the designated Web page. But, with a targetSdkVersion set at 26, the WebView will not show that page, as it would be loaded over a cleartext (HTTP) connection:

![Figure 519: BrowserSecure Sample, Showing Banned Cleartext Traffic](image)

Chrome Custom Tabs

Chrome custom tabs serve as middle ground between using a WebView in your own app and launching a URL into a separate Web browser.

With a WebView, you have complete control over the overall user experience within your app. However, your WebView is decoupled from any other browser the user may be using on the device. Conversely, launching URLs into the user’s chosen browser gives the user their normal browsing experience, but you have no control over the user experience, as the user is now in the browser app, not your app.

With Chrome custom tabs, while Chrome is handling the URL, it will allow you limited control over the action bar (color and custom actions). It also simplifies some things that you might otherwise have had to handle yourself, such as pre-
ADVANCED USES OF WebView

fetching a Web page to be able to quickly switch to it. Basic integration is also fairly easy, coming in the form of extras on the same sort of ACTION_VIEW Intent that you might have used for launching the URL in a standalone browser.

At the same time, there are some concerns:

- The documentation states that there is a “Shared Cookie Jar and permissions model so users don’t have to log in to sites they are already connected to, or re-grant permissions they have already granted”, which would require significant testing to ensure that you are not leaking information into Chrome that might be somehow delivered to other sites (including Google).
- While it uses an ACTION_VIEW Intent, and so the user can choose to view the URL in a different browser, you will not get the custom integration in that case. This may be fine, but you will need to make sure that from a marketing and documentation standpoint you handle both the case where the user chooses Chrome (and you get the “custom tab”) and the case where the user chooses something else.
- Since any app could handle the ACTION_VIEW Intent, you need to take into account that any information in the custom extras, like the PendingIntent to use for a custom action bar item, is stuff that you are willing for arbitrary apps to get their hands on. Do not assume that your communications will solely be with Chrome.
The Input Method Framework

We think of Android devices as having “soft keyboards”. The official term for this is that Android devices offer one or more “input method editors” (or “input methods” for short). These input methods allow for text entry on a touchscreen, avoiding the need for a physical keyboard. This chapter is focused on how ordinary app developers are affected by input methods, and how an app can help steer the behavior of the input method to benefit the user.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the section covering the EditText widget.

Keyboards, Hard and Soft

Some Android devices have a hardware keyboard that is visible some of the time (when it is slid out). A few Android devices have a hardware keyboard that is always visible (so-called “bar” or “slab” phones). Most Android devices, though, have no hardware keyboard at all.

The IMF handles all of these scenarios. In short, if there is no hardware keyboard, an input method editor (IME) will be available to the user when they tap on an enabled EditText.

This requires no code changes to your application... if the default functionality of the IME is what you want. Fortunately, Android is fairly smart about guessing what you want, so it may be you can just test with the IME but otherwise make no specific code changes.
Of course, the keyboard may not quite behave how you would like. For example, in the Basic/Field sample project, the FieldDemo activity has the IME overlaying the multiple-line EditText:

![Screenshot of FieldDemo activity with IME overlaying the EditText](image)

*Figure 520: The input method editor, as seen in the FieldDemo sample application*

It would be nice to have more control over how this appears, and for other behavior of the IME. Fortunately, the framework as a whole gives you many options for this, as is described over the bulk of this chapter.

**Tailored To Your Needs**

Android 1.1 and earlier offered many attributes on EditText widgets to control their style of input, such as `android:password` to indicate a field should be for password entry (shrouding the password keystrokes from prying eyes). Starting in Android 1.5, with the IMF, many of these have been combined into a single `android:inputType` attribute.

The `android:inputType` attribute takes a class plus modifiers, in a pipe-delimited list (where `|` is the pipe character). The class generally describes what the user is allowed to input, and this determines the basic set of keys available on the soft
keyboard. The available classes are:

1. text (the default)
2. number
3. phone
4. datetime
5. date
6. time

Many of these classes offer one or more modifiers, to further refine what the user will be entering. To help explain those, take a look at the res/layout/main.xml file from the InputMethod/IMEDemo1 project:

```xml
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
android:layout_width="match_parent"
android:layout_height="match_parent"
android:stretchColumns="1"  />
<TableRow>
    <TextView  
        android:text="No special rules:"  />
<EditText  
    android:inputType="text|textEmailAddress" />
</TableRow>
<TableRow>
    <TextView  
        android:text="Email address:"  />
<EditText  
    android:inputType="text|textEmailAddress" />
</TableRow>
<TableRow>
    <TextView  
        android:text="Signed decimal number:"  />
<EditText  
    android:inputType="number|numberSigned|numberDecimal" />
</TableRow>
<TableRow>
    <TextView  
        android:text="Date:"  />
```
Here, you will see a TableLayout containing five rows, each demonstrating a slightly different flavor of EditText:

- One has no attributes at all on the EditText, meaning you get a plain text entry field
- One has android:inputType = "text|textEmailAddress", meaning it is text entry, but specifically seeks an email address
- One allows for signed decimal numeric input, via android:inputType = "number|numberSigned|numberDecimal"
- One is set up to allow for data entry of a date (android:inputType = "date")
- The last allows for multi-line input with auto-correction of probable spelling errors (android:inputType = "text|textMultiLine|textAutoCorrect")
The class and modifiers tailor the keyboard. So, a plain text entry field results in a plain soft keyboard:

![A standard input method editor (a.k.a., soft keyboard)](image)

*Figure 521: A standard input method editor (a.k.a., soft keyboard)*
An email address field might put the @ symbol on the soft keyboard, perhaps at the cost of a smaller spacebar, depending on the keyboard implementation:

![Image](image.png)

*Figure 522: The input method editor for email addresses*

Note, though, that this behavior is specific to the input method editor. Some editors might put an @ sign on the primary keyboard for an email field. Some might put a “.com” button on the primary keyboard. Some might not react at all. It is up to the implementation of the input method editor — all you can do is supply the hint.
Numbers and dates restrict the keys to numeric keys, plus a set of symbols that may or may not be valid on a given field:

![Image of input method editor for signed decimal numbers]

*Figure 523: The input method editor for signed decimal numbers*

And so on.

By choosing the appropriate `android:inputType`, you can give the user a soft keyboard that best suits what it is they should be entering.

**Tell Android Where It Can Go**

You may have noticed a subtle difference between the first and second input method editors, beyond the addition of the @ key. If you look in the lower-right corner of the soft keyboard, the second field’s editor has a “Next” button, while the first field’s editor has a newline button.

This points out two things:

- EditText widgets are multi-line by default if you do not specify `android:inputType`
THE INPUT METHOD FRAMEWORK

• You can control what goes on with that lower-right-hand button, called the action key

By default, on an EditText where you have specified android:inputType, the action key will be “Next”, moving you to the next EditText in sequence, or “Done”, if you are on the last EditText on the screen. You can manually stipulate what the action key will be labeled via the android:imeOptions attribute. For example, in the res/layout/main.xml from the InputMethod/IMEDemo2 sample project, you will see an augmented version of the previous example, where two input fields specify what their action key should look like:

```xml
<ScrollView
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
>

    <TableLayout
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:stretchColumns="1"
        android:imeOptions="actionSend"
    >
        <TableRow>
            <TextView
                android:text="No special rules:"
            />
            <EditText
                android:inputType="text|textEmailAddress"
            />
        </TableRow>
        <TableRow>
            <TextView
                android:text="Email address:"
            />
            <EditText
                android:inputType="text|textEmailAddress"
                android:imeOptions="actionSend"
            />
        </TableRow>
        <TableRow>
            <TextView
                android:text="Signed decimal number:"
            />
            <EditText
                android:inputType="number|numberSigned|numberDecimal"
                android:imeOptions="actionDone"
            />
        </TableRow>
    </TableLayout>
</ScrollView>
```
Here, we attach a “Send” action to the action key for the email address (android:imeOptions = "actionSend"), and the “Done” action on the middle field (android:imeOptions = "actionDone").

By default, “Next” will move the focus to the next EditText and “Done” will close up the input method editor. However, for those, or for any other ones like “Send”, you can use setOnEditorActionListener() on EditText (technically, on the TextView superclass) to get control when the action key is clicked or the user presses the <Enter> key. You are provided with a flag indicating the desired action (e.g., IME_ACTION_SEND), and you can then do something to handle that request (e.g., send an email to the supplied email address).

If you need more control over the action button, you can set:

- android:imeActionId, which provides a custom value for the actionId that is passed to onEditorAction() of your OnEditorActionListener
- android:imeActionLabel, where you provide your own caption for the button (bearing in mind that your desired caption may or may not fit)
Fitting In

You will notice that the IMEDemo2 layout shown above has another difference from its IMEDemo1 predecessor: the use of a ScrollView container wrapping the TableLayout. This ties into another level of control you have over the input method editors: what happens to your activity's own layout when the input method editor appears?

There are three possibilities, depending on circumstances:

1. Android can “pan” your activity, effectively sliding the whole layout up to accommodate the input method editor, or overlaying your layout, depending on whether the EditText being edited is at the top or bottom. This has the effect of hiding some portion of your UI.

2. Android can resize your activity, effectively causing it to shrink to a smaller screen dimension, allowing the input method editor to sit below the activity itself. This is great when the layout can readily be shrunk (e.g., it is dominated by a list or multi-line input field that does not need the whole screen to be functional).

3. In landscape mode, Android may display the input method editor full-screen, obscuring your entire activity. This allows for a bigger keyboard and generally easier data entry.

Android controls the full-screen option purely on its own. And, by default, Android will choose between pan and resize modes depending on what your layout looks like. If you want to specifically choose between pan and resize, you can do so via an android:windowSoftInputMode attribute on the <activity> element in your AndroidManifest.xml file. For example, here is the manifest from IMEDemo2:

```xml
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonsware.android.imf.two"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="7"/>

</manifest>
```
THE INPUT METHOD FRAMEWORK

```xml
<manifest>
  <application>
    android:targetSdkVersion="11"/>
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
      <activity>
        android:name="IMEDemo2"
        android:label="@string/app_name"
        android:windowSoftInputMode="adjustResize">
          <intent-filter>
            <action android:name="android.intent.action.MAIN">
            <category android:name="android.intent.category.LAUNCHER"></category>
          </intent-filter>
        </activity>
      </application>
    </manifest>
```

(from InputMethod/IMEDemo2/app/src/main/AndroidManifest.xml)
Because we specified resize, Android will shrink our layout to accommodate the input method editor. With the ScrollView in place, this means the scrollbar will appear as needed when the user is scrolling:

![Shrunken, Scrollable Layout](image)

*Figure 524: The shrunken, scrollable layout*

**Jane, Stop This Crazy Thing!**

Sometimes, you need the input method editor to just go away. For example, if you make the action button be “Search”, the user tapping that button will not automatically hide the editor.

To hide the editor, you will need to make a call to the `InputMethodManager`, a system service that controls these input method editors:

```java
InputMethodManager mgr = (InputMethodManager) getSystemService(INPUT_METHOD_SERVICE);
mgr.hideSoftInputFromWindow(fld.getWindowToken(), 0);
```

(where `fld` is the `EditText` whose input method editor you want to hide)
Inevitably, you'll get the question “hey, can we change this font?” when doing application development. The answer depends on what fonts come with the platform, whether you can add other fonts, and how to apply them to the widget or whatever needs the font change.

Android is no different. It comes with some fonts plus a means for adding new fonts. Though, as with any new environment, there are a few idiosyncrasies to deal with.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on files.

Love The One You’re With

Android natively knows three fonts, by the shorthand names of “sans”, “serif”, and “monospace”. For Android 1.x, 2.x, and 3.x, these fonts are actually the Droid series of fonts, created for the Open Handset Alliance by Ascender. A new font set, Roboto, is used in Android 4.x and beyond, though the look of the font changed somewhat in Android 5.0.

For those fonts, you can just reference them in your layout XML, if you choose, such as the following layout from the Fonts/FontSampler sample project:

```
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
```

1643
<table>
<thead>
<tr>
<th>Font</th>
<th>TextView Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sans</td>
<td>android:layout_marginRight=&quot;4dip&quot;</td>
</tr>
<tr>
<td></td>
<td>android:text=&quot;@string/label_sans&quot;</td>
</tr>
<tr>
<td></td>
<td>android:textSize=&quot;20sp&quot;</td>
</tr>
<tr>
<td></td>
<td>android:id=&quot;@+id/sans&quot;</td>
</tr>
<tr>
<td></td>
<td>android:text=&quot;@string/hello_world&quot;</td>
</tr>
<tr>
<td></td>
<td>android:textSize=&quot;20sp&quot;</td>
</tr>
<tr>
<td></td>
<td>android:typeface=&quot;sans&quot;</td>
</tr>
<tr>
<td>Serif</td>
<td>android:layout_marginRight=&quot;4dip&quot;</td>
</tr>
<tr>
<td></td>
<td>android:text=&quot;@string/label_serif&quot;</td>
</tr>
<tr>
<td></td>
<td>android:textSize=&quot;20sp&quot;</td>
</tr>
<tr>
<td></td>
<td>android:id=&quot;@+id/serif&quot;</td>
</tr>
<tr>
<td></td>
<td>android:text=&quot;@string/hello_world&quot;</td>
</tr>
<tr>
<td></td>
<td>android:textSize=&quot;20sp&quot;</td>
</tr>
<tr>
<td></td>
<td>android:typeface=&quot;serif&quot;</td>
</tr>
<tr>
<td>Monospace</td>
<td>android:layout_marginRight=&quot;4dip&quot;</td>
</tr>
<tr>
<td></td>
<td>android:text=&quot;@string/label_monospace&quot;</td>
</tr>
<tr>
<td></td>
<td>android:textSize=&quot;20sp&quot;</td>
</tr>
<tr>
<td></td>
<td>android:id=&quot;@+id/monospace&quot;</td>
</tr>
<tr>
<td></td>
<td>android:text=&quot;@string/hello_world&quot;</td>
</tr>
<tr>
<td></td>
<td>android:textSize=&quot;20sp&quot;</td>
</tr>
<tr>
<td></td>
<td>android:typeface=&quot;monospace&quot;</td>
</tr>
</tbody>
</table>

1644
This layout builds a table showing short samples of five fonts. Notice how the first three have the `android:typeface` attribute, whose value is one of the three built-in font faces (e.g., “sans”).

The three built-in fonts are very nice. However, it may be that a designer, or a manager, or a customer wants a different font than one of those three. Or perhaps you want to use a font for specialized purposes, such as an image font instead of a series of PNG graphics.

The easiest way to accomplish this is to package the desired font(s) with your application. To do this, simply create an `assets/` folder in the project root, and put your TrueType (TTF) fonts in the assets. You might, for example, create `assets/fonts/` and put your TTF files in there. Note that Android has some support for OpenType (OTF) fonts, as well.

Then, you need to tell your widgets to use that font. Unfortunately, you can no longer use layout XML for this, since the XML does not know about any fonts you may have tucked away as an application asset. Instead, you need to make the change in Java code:
package com.commonsware.android.fonts;

import android.app.Activity;
import android.graphics.Typeface;
import android.os.Bundle;
import android.os.Environment;
import android.view.View;
import android.widget.TextView;
import java.io.File;

public class FontSampler extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        TextView tv=(TextView) findViewById(R.id.custom);
        Typeface face=
            Typeface.createFromAsset(getAssets(), "fonts/HandmadeTypewriter.ttf");

        tv.setTypeface(face);

        File font=
            new File(Environment.getExternalStorageDirectory(), "MgOpenCosmeticaBold.ttf");

        if (font.exists()) {
            tv=(TextView) findViewById(R.id.file);
            face=Typeface.createFromFile(font);

            tv.setTypeface(face);
        } else {
            findViewById(R.id.filerow).setVisibility(View.GONE);
        }
    }
}

(from Fonts/FontSampler/app/src/main/java/com/commonsware/android/fonts/FontSampler.java)

Here we grab the TextView for our “custom” sample, then create a Typeface object via the static createFromAsset() builder method. This takes the application’s AssetManager (from getAssets()) and a path within your assets/ directory to the font you want.

Then, it is just a matter of telling the TextView to setTypeface(), providing the Typeface you just created. In this case, we are using the Handmade Typewriter font.

You can also load a font out of a local file and use it. The benefit is that you can customize your fonts after your application has been distributed. On the other hand, you have to somehow arrange to get the font onto the device. But just as you can get a Typeface via createFromAsset(), you can get a Typeface via createFromFile(). In our FontSampler, we look in the root of “external storage” (typically the SD card) for the MgOpenCosmeticaBold TrueType font file, and if it is found, we use it for the
fifth row of the table. Otherwise, we hide that row.

The results?

![Figure 525: The FontSampler application](image)

Note that Android does not seem to like all TrueType fonts. When Android dislikes a custom font, rather than raise an `Exception`, it seems to substitute Droid Sans ("sans") quietly. So, if you try to use a different font and it does not seem to be working, it may be that the font in question is incompatible with Android, for whatever reason.

**Yeah, But Do We Really Have To Do This in Java?**

One common complaint with font handling in Android is that you have to apply a custom font on a per-widget basis in Java code.

This gets old quickly.

It is not too bad with just a single `TextView`. But for a whole activity, or a whole application, changing all of the relevant `TextView` widgets (and descendents, like
Button) gets to be a bit tedious.

While there are “traverse the widget hierarchy and fix up the fonts” code snippets available, you are probably better served using a third-party library, like Christoper Jenkins’ Calligraphy, which lets you define custom fonts in layout XML files or style resources.

Here a Glyph, There a Glyph

TrueType fonts can be rather pudgy, particularly if they support an extensive subset of the available Unicode characters. The Handmade Typewriter font used above runs over 70KB; the DejaVu free fonts can run upwards of 500KB apiece. Even compressed, these add bulk to your application, so be careful not to go overboard with custom fonts, lest your application take up too much room on your users’ phones.

Conversely, bear in mind that fonts may not have all of the glyphs that you need. As an example, let us talk about the ellipsis.

Android’s TextView class has the built-in ability to “ellipsize” text, truncating it and adding an ellipsis if the text is longer than the available space. You can use this via the android:ellipsize attribute, for example. This works fairly well, at least for single-line text.

The ellipsis that Android uses is not three periods. Rather it uses an actual ellipsis character, where the three dots are contained in a single glyph. Hence, any font that you use in a TextView where you also use the “ellipsizing” feature will need the ellipsis glyph.

Beyond that, though, Android pads out the string that gets rendered on-screen, such that the length (in characters) is the same before and after “ellipsizing”. To make this work, Android replaces one character with the ellipsis, and replaces all other removed characters with the Unicode character ‘ZERO WIDTH NO-BREAK SPACE’ (U+FEFF). This means the “extra” characters after the ellipsis do not take up any visible space on screen, yet they can be part of the string.

However, this means any custom fonts you use for TextView widgets that you use with android:ellipsize must also support this special Unicode character. Not all fonts do, and you will get artifacts in the on-screen representation of your shortened strings if your font lacks this character (e.g., rogue X’s appear at the end of the line).
And, of course, Android’s international deployment means your font must handle any language your users might be looking to enter, perhaps through a language-specific input method editor.

Hence, while using custom fonts in Android is very possible, there are many potential problems, and so you must weigh carefully the benefits of the custom fonts versus their potential costs.

**Auto-Sizing TextView**

Text comes in all lengths.

Sometimes, when showing text in a TextView, we can allow that text to word-wrap and extend vertically. Other times, though, that proves to be impractical, such as when using a TextView as a label for another widget. However, even in those times, the text to be shown may vary in length by a significant amount. Translations of the label’s text might range from a couple of kanji in Japanese to a 20-letter word in German or Icelandic.

One long-standing solution to that problem has been to use an auto-sizing TextView. Here, what is being “auto-sized” is the size of the font used for the text, to keep the TextView at a fixed dimension regardless of translation. It is up to the developer to ensure that for a given screen size and translation that the font does not wind up being too small to be read.

However, Android itself never had a widget for this, so developers would rely instead upon third-party or home-grown implementations.

Android 8.0 adds this sort of auto-sizing capability to TextView itself (and, by extension, subclasses like Button). You have two main approaches for implementing this:

- Set android:autoSizeTextType="uniform" on the TextView to engage auto-size capability. Then, use android:autoSizeMinTextSize and android:autoSizeMaxTextSize to set the lower and upper bounds for the text size, where Android can choose any size in between those. If you also add android:autoSizeStepGranularity, you can choose the increments in which Android will move between the ends of the text size range (the default is 1px).
- Set android:autoSizeTextType="uniform" on the TextView, as in the above
option. Then, instead of providing the starting and ending values of a range, use an <array> resource to define specific sizes that you want to support, then use android:autoSizePresetSizes to point to that resource. This is a bit more difficult to set up, as you need to define the array resource, but it may simplify testing, as you are in complete control over the possible sizes.

To make this work, you need to constrain the size of the TextView, so that it does not expand to fill all available space. That might be through having both axes set to wrap_content, but have the container holding the TextView limit how big the TextView can get. It might be through TextView-specific configuration, such as android:maxLines. Or, it might be through setting the size of the axes to be some specific dimension or match_parent.

The Basic/AutoSize sample project illustrates the use of both forms of android:autoSizeTextType.

The activity’s layout consists of an EditText, a pair of TextView widgets, and a pair of divider lines (horizontal View widgets with background and margin), all inside of a vertical LinearLayout:

```xml
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    tools:context="com.commonsware.android.autosize.MainActivity">
    <EditText
        android:id="@+id/input"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_margin="4dp"
        android:hint="@string/hint_input" />
    <View
        android:layout_width="match_parent"
        android:layout_height="2dp"
        android:layout_margin="4dp"
        android:background="@android:color/black" />
    <TextView
        android:id="@+id/granular"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>
</LinearLayout>
```
Both TextView widgets have android:autoSizeTextType set to uniform. The top one uses android:autoSizeMinTextSize, android:autoSizeMaxTextSize, and android:autoSizeStepGranularity to allow the text size to float between 5sp and 40sp in 5sp increments. The bottom one uses android:autoSizePresetSizes to tie in an array resource for the valid sizes to use:

```xml
<resources>
  <array name="autosize_sizes">
    <item>10sp</item>
    <item>12sp</item>
    <item>14sp</item>
    <item>16sp</item>
    <item>18sp</item>
    <item>20sp</item>
  </array>
</resources>
```

Here, the size can float between 10sp and 20sp in 2sp increments. However, there is
no requirement that the sizes increment in a uniform fashion when using the array approach.

The MainActivity that uses the layout sets up a TextWatcher on the EditText and copies what you enter into the two TextView widgets, to allow you to experiment in real time with changes in the text size:

```java
EditText input=(EditText)findViewById(R.id.input);
final TextView granular=(TextView)findViewById(R.id.granular);
final TextView steps=(TextView)findViewById(R.id.steps);

input.addTextChangedListener(new TextWatcher() {
    @Override
    public void beforeTextChanged(CharSequence charSequence, int i, int i1, int i2) {
        // unused
    }

    @Override
    public void onTextChanged(CharSequence charSequence, int i, int i1, int i2) {
        // unused
    }

    @Override
    public void afterTextChanged(Editable editable) {
        granular.setText(editable.toString());
        steps.setText(editable.toString());
    }
});
```

(from Basic/AutoSize/app/src/main/java/com/commonsware/android/autosize/MainActivity.java)
When you run the app, initially the EditText and corresponding TextView widgets have no text. If you start typing, you will see your text appear in the TextView widgets:

*Figure 526: Auto-Sizing TextViews, with Some Text*
As you continue typing, the text size decreases:

![AutoSize Demo](image)

*Figure 527: Auto-Sizing TextViews, with Some More Text*

If you are using appcompat-v7, there are equivalent capabilities added to its wrapper backport of TextView.

### Justified Text

If you are reading the PDF edition of this book, its paragraphs do not use justified text. If you are reading the Kindle edition of this book — at least when using the Amazon Kindle app for Android — its paragraphs do use justified text.

Justified text is when text (e.g., in the middle of a paragraph) fills the entire line, usually with bits of extra space added between the words to get them to neatly fill the available horizontal space.

For years, TextView never supported justified text, though you could get it through [third-party libraries](https://developer.android.com/). In Android 8.0+, you can now enable justified text on a TextView via
setJustificationMode(). Android 9.0 adds android:justificationMode to be able to configure this from a layout resource or theme.
Plain text is so, well, plain.

Fortunately, Android has fairly extensive support for formatted text, before you need to break out something as heavy-weight as WebView. However, some of this rich text support has been shrouded in mystery, particularly how you would allow users to edit formatted text.

This chapter will explain how the rich text support in Android works and how you can take advantage of it, with particular emphasis on some open source projects to help you do just that.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on basic widgets and the input method framework.

The Span Concept

You may have noticed that many methods in Android accept or return a CharSequence. The CharSequence interface is little used in traditional Java, if for no other reason than there are relatively few implementations of it outside of String. However, in Android, CharSequence becomes much more important, because of a sub-interface named Spanned.

Spanned defines sequences of characters (CharSequence) that contain inline markup rules. These rules — mostly instances of CharacterStyle and ParagraphStyle subclasses – indicate whether the “spanned” portion of the characters should be
rendered in an alternate font, or be turned into a hyperlink, or have other effects applied to them.

Methods that take a CharSequence as a parameter, therefore, can work equally well with String objects as well as objects that implement Spanned.

**Implementations**

The base interface for rich-text CharSequence objects is Spanned. This is used for any CharSequence that has inline markup rules, and it defines methods for retrieving markup rules applied to portions of the underlying text.

The primary concrete implementation of Spanned is SpannedString. SpannedString, like String, is immutable — you cannot change either the text or the formatting of a SpannedString.

There is also the Spannable sub-interface of Spanned. Spannable is used for any CharSequence with inline markup rules that can be modified, and it defines the methods for modifying the formatting. There is a corresponding SpannableString implementation.

Finally, there is a related Editable interface, which is for a CharSequence that can have its text modified in-place. SpannableStringBuilder implements both Editable and Spannable, for modifying text and formatting at the same time.

**TextView and Spanned**

One of the most important uses of Spanned objects is with TextView. TextView is capable of rendering a Spanned, complete with all of the specified formatting. So, if you have a Spanned that indicates that the third word should be rendered in italics, TextView will faithfully italicize that word.

TextView, of course, is an ancestor of many other widgets, from EditText to Button to CheckBox. Each of those, therefore, can use and render Spannable objects. The fact that EditText has the ability to render Spanned objects — and even allow them to be edited — is key for allowing users to enter rich text themselves as part of your UI.

**Available Spans**

As noted above, the markup rules come in the form of instances of base classes
known as CharacterStyle and ParagraphStyle. Despite those names, most of the SDK-supplied subclasses of CharacterStyle and ParagraphStyle end in Span (not Style), and so you will likely see references to these as “spans” as often as “styles”. That also helps minimize confusion between character styles and style resources.

There are well over a dozen supplied CharacterStyle subclasses, including:

1. ForegroundColorSpan and BackgroundColorSpan for coloring text
2. StyleSpan, TextAppearanceSpan, TypefaceSpan, UnderlineSpan, and StrikethroughSpan for affecting the true “style” of text
3. AbsoluteSizeSpan, RelativeSizeSpan, SuperscriptSpan, and SubscriptSpan for affecting the size (and, in some cases, vertical position) of the text

And so on. Similarly, ParagraphStyle has subclasses like BulletSpan for bulleted lists.

You can implement your own custom subclasses of CharacterStyle and ParagraphStyle, though the book does not cover this subject at this time.

### Loading Rich Text

Spanned objects do not appear by magic. Plenty of things in Java will give you ordinary strings, from XML and JSON parsers to loading data out of a database to simply hard-coding string constants. However, there are only a few ways that you as a developer will get a Spanned complete with formatting, and that includes you creating such a Spanned yourself by hand.

### String Resource

The primary way most developers get a Spanned object into their application is via a string resource. String resources support inline markup in the form of HTML tags. Bold (<b>), italics (<i>), and underline (<u>) are officially supported, such as:

```xml
<string name="welcome">Welcome to <b>Android</b>!</string>
```

When you retrieve the string resource via `getText()`, you get back a `CharSequence` that represents a Spanned object with the markup rules in place.
The next-most common way to get a Spanned object is to use Html.fromHtml(). This parses an HTML string and returns a Spanned object, with all recognized tags converted into corresponding spans. You might use this for text loaded from a database, retrieved from a Web service call, extracted from an RSS feed, etc.

Unfortunately, the list of tags that fromHtml() understands is undocumented. Based upon the source code to fromHtml(), the following seem safe:

- [a href="..."]
- <b>
- <big>
- <blockquote>
- <br>
- <cite>
- <dfn>
- [div align="..."]
- <em>
- [font size="..." color="..." face="..."]
- <h1>
- <h2>
- <h3>
- <h4>
- <h5>
- <h6>
- <i>
- [img src="..."]
- <p>
- <small>
- <strong>
- <sub>
- <sup>
- <tt>
- <u>

However, do bear in mind that these are undocumented and therefore are subject to change. Also note that fromHtml() is perhaps slower than you might think, particularly for longer strings.

You might also wind up using some other support code to get your HTML. For
example, some data sources might publish text formatted as Markdown — Stack Overflow, GitHub, etc. use this extensively. Markdown can be converted to HTML, through any number of available Java libraries or via CWAC-AndDown, which wraps the native hoedown Markdown-to-HTML converter for maximum speed. CWAC-AndDown will be explored in a bit more detail in the chapter on the NDK.

From EditText

The reason why so much sample code calls getText() followed by toString() on an EditText widget is because EditText is going to return an Editable object from getText(), not a simple string. That’s because, in theory, EditText could be returning something with formatting applied. The call to toString() simply strips out any potential formatting as part of giving you back a String.

However, you could elect to use the Editable object (presumably a SpannableStringBuilder) if you wanted, such as for pouring the entered text into a TextView, complete with any formatting that might have wound up on the entered text.

Manually

You are welcome to create a SpannableString via its constructor, supplying the text that you wish to display, then calling various methods on SpannableString to format it.

Or, you are welcome to create a SpannableStringBuilder via its constructor. In some respects, SpannableStringBuilder works like the classic StringBuilder — you call append() to add more text. However, SpannableStringBuilder also offers delete(), insert(), and replace() methods to modify portions of the existing content. It also supports the same methods that SpannableString does, via the Spannable interface, for applying formatting rules to portions of text.

Editing Rich Text

If the Spannable you wound up with is a SpannedString, it is what it is — you cannot change it. If, however, you have a SpannableString, that can be modified by you, or by the user. Of course, allowing the user to modify a Spannable gets a wee bit tricky, and is why the RichEditText project was born.

Spannable offers two methods for modifying its formatting: setSpan() to apply
formatting, and removeSpan() to get rid of an existing span. And, since Spannable extends Spanned, a Spannable also has getSpans(), to return existing spans of a current type within a certain range of characters in the text. These methods, along with others on Spanned, allow you to get and set whatever formatting you wish to apply on a Spannable object, such as a SpannableString.

For example, let’s take a look at the RichText/Search sample project. Here, we are going to load some text into a TextView, then allow the user to enter a search string in an EditText, and we will use the Spannable methods to highlight the search string occurrences inside the text in the TextView.

Our layout is simply an EditText atop a TextView (wrapped in a ScrollView):

```xml
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <EditText
        android:id="@+id/search"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:singleLine="true">
        <requestFocus/>
    </EditText>

    <ScrollView
        android:id="@+id.scroll"
        android:layout_width="match_parent"
        android:layout_height="match_parent">

        <TextView
            android:id="@+id/prose"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:text="@string/address"
            android:textAppearance="?android:attr/textAppearanceMedium"/>
    </ScrollView>

</LinearLayout>
```

We pre-fill the TextView with a string resource (@string/address), which in this
project is the text of Lincoln's Gettysburg Address, with a bit of inline markup (e.g., “Four score and seven years ago” italicized). So, when we fire up the project at the outset, we see the formatted prose from the string resource:

![Image of Gettysburg Address](image.png)

*Figure 528: The RichTextSearch sample, as initially launched*

In `onCreate()` of our activity, we find the `EditText` widget and designate the activity itself as being an `OnEditorActionListener` for the `EditText`:

```java
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    search=(EditText) findViewById(R.id.search);
    search.setOnEditorActionListener(this);
}
```

That means when the user presses `<Enter>`, we will get control in an `onEditorAction()` method. There, we pass the search text to a private `searchFor()` method, plus ensure that the input method editor is hidden (if one was used to fill in the search text):
The `searchFor()` method is where the formatting is applied to our search text:

```java
private void searchFor(String text) {
    TextView prose = (TextView) findViewById(R.id.prose);
    Spannable raw = new SpannableString(prose.getText());
    BackgroundColorSpan[] spans = raw.getSpans(0, raw.length(), BackgroundColorSpan.class);
    for (BackgroundColorSpan span : spans) {
        raw.removeSpan(span);
    }
    int index = TextUtils.indexOf(raw, text);
    while (index >= 0) {
        raw.setSpan(new BackgroundColorSpan(0xFF8B008B), index, index + text.length(), Spanned.SPAN_EXCLUSIVE_EXCLUSIVE);
        index = TextUtils.indexOf(raw, text, index + text.length());
    }
    prose.setText(raw);
}
```

First, we get a `Spannable` object out of the `TextView`. While an `EditText` returns an `Editable` from `getText()`, `getText()` on a `TextView` returns a `CharSequence`. In particular, the first time we execute `searchFor()`, `getText()` will return a `SpannedString`, as that is what a string resource turns into. However, that is not modifiable, so we convert it into a `SpannableString` so we can apply formatting to it.
An optimization would be to see if `getText()` returns something implementing `Spannable` and then just using it directly.

We want to highlight the search terms using a `BackgroundColorSpan`. However, that means we first need to get rid of any existing `BackgroundColorSpan` objects applied to the prose from a previous search — otherwise, we would keep highlighting more and more of the prose. So, we use `getSpans()` to find all `BackgroundColorSpan` objects anywhere in the prose (from index 0 through the length of the text). For each that we find, we call `removeSpan()` to get rid of it from our `Spannable`.

Then, we use `indexOf()` on `TextUtils` to find the first occurrence of whatever the user typed into the `EditText`. If we find it, we create a new `BackgroundColorSpan` and apply it to the matching portion of the prose using `setSpan()`. The last parameter to `setSpan()` is a flag, indicating what should happen if text is inserted at either the starting or ending point. In our case, the text itself is remaining constant, so the flag does not matter much — here, we use `SPAN_EXCLUSIVE_EXCLUSIVE`, which would mean that the span would not cover any text inserted at the starting or ending point of the span.

We then continue using `indexOf()` to find any remaining occurrences of the search text. Once we are done modifying our `Spannable`, we put it into the `TextView` via `setText()`.

---

**1665**
The result is that all matching substrings are highlighted in a purple/magenta shade:

![Figure 529: The RichTextSearch sample, after searching on “can”](image)

### Saving Rich Text

SpannableString and SpannedString are not Serializable. There is no built-in way to persist them directly.

However, Html.toHtml() will convert a Spanned object into corresponding HTML, for all CharacterStyle and ParagraphStyle objects that can be readily converted into HTML. You can then persist the resulting HTML any place you would persist a String (e.g., database column).

In principle, you could create other similar conversion code, such as something to take a Spanned and return the corresponding Markdown source.

### Manipulating Rich Text

The TextUtils class has many utility methods that manipulate a CharSequence, to allow you to do things that you might ordinarily have done just with methods on
String. These utility methods will work with any CharSequence, including SpannedString and SpannableString.

Some are specifically aimed at Spanned objects, such as copySpansFrom() (to apply formatting from one CharSequence onto another). Some are clones of String equivalents, such as split(), join(), and substring(). Yet others are designed for developers using the Canvas 2D drawing API, such as ellipsize() and commaEllipsize() for intelligently truncating messages.
Users like things that move. Or fade, spin, or otherwise offer a dynamic experience.

Much of the time, such animations are handled for us by the framework. We do not have to worry about sliding rows in a ListView when the user scrolls, or as the user pans around a ViewPager, and so forth.

However, sometimes, we will need to add our own animations, where we want effects that either are not provided by the framework innately or are simply different (e.g., want something to slide off the bottom of the screen, rather than off the left edge).

Android had an animation framework back in the beginning, one that is still available for you today. However, Android 3.0 introduced a new animator framework that is going to be Android’s primary focus for animated effects going forward. Many, but not all, of the animator framework capabilities are available to us as developers via a backport.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Also, you should read the chapter on custom views, to be able to make sense of one of the samples.

ViewPropertyAnimator

Let’s say that you want to fade out a widget, instead of simply setting its visibility to INVISIBLE or GONE.
For a widget whose name is v, on API Level 11 or higher, that is as simple as:

```
v.animate().alpha(0);
```

Here, “alpha” refers to the “alpha channel”. An alpha of 1 is normal opacity, while an alpha of 0 is completely transparent, with values in between representing various levels of translucence.

That may seem rather simple. The good news is, it really is that easy. Of course, there is a lot more you can do here, and you might have to worry about supporting older Android versions, and we need to think about things other than fading widgets in and out, and so forth.

First, though, let’s consider what is really going on when we call `animate()` on a widget on API Level 11+.

**Native Implementation**

The call to `animate()` returns an instance of `ViewPropertyAnimator`. This object allows us to build up a description of an animation to be performed, such as calling `alpha()` to change the alpha channel value. `ViewPropertyAnimator` uses a so-called fluent interface, much like the various builder classes (e.g., `Notification.Builder`) — calling a method on a `ViewPropertyAnimator()` usually returns the `ViewPropertyAnimator` itself. This allows you to build up an animation via a chained series of method calls, starting with that call to `animate()` on the widget.

You will note that we do not end the chain of method calls with something like a `start()` method. `ViewPropertyAnimator` will automatically arrange to start the animation once we return control of the main application thread back to the framework. Hence, we do not have to explicitly start the animation.

You will also notice that we did not indicate any particulars about how the animation should be accomplished, beyond stating the ending alpha channel value of 0. `ViewPropertyAnimator` will use some standard defaults for the animation, such as a default duration, to determine how quickly Android changes the alpha value from its starting point to 0. Most of those particulars can be overridden from their defaults via additional methods called on our `ViewPropertyAnimator`, such as `setDuration()` to provide a duration in milliseconds.

There are four standard animations that `ViewPropertyAnimator` can perform:
1. Changes in alpha channel values, for fading widgets in and out
2. Changes in widget position, by altering the X and Y values of the upper-left corner of the widget, from wherever on the screen it used to be to some new value
3. Changes in the widget’s rotation, around any of the three axes
4. Changes in the widget’s size, where Android can scale the widget by some percentage to expand or shrink it

We will see an example of changing a widget’s position, using the `translationXBy()` method, later in this chapter.

You are welcome to use more than one animation effect simultaneously, such as using both `alpha()` and `translationXBy()` to slide a widget horizontally and have it fade in or out.

There are other aspects of the animation that you can control. By default, the animation happens linearly — if we are sliding 500 pixels in 500ms, the widget will move evenly at 1 pixel/ms. However, you can specify a different “interpolator” to override that default linear behavior (e.g., start slow and accelerate as the animation proceeds). You can attach a listener object to find out about when the animation starts and ends. And, you can specify `withLayer()` to indicate that Android should try to more aggressively use hardware acceleration for an animation, a concept that we will get into in greater detail later in this chapter.

To see this in action, take a look at the `Animation/AnimatorFade` sample app.

The app consists of a single activity (MainActivity). It uses a layout that is dominated by a single TextView widget, whose ID is `fadee`:

```xml
<RelativeLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <TextView
        android:id="@+id/fadee"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerHorizontal="true"
        android:layout_centerVertical="true"
        android:text="@string/fading_out"
        android:textAppearance="?android:attr/textAppearanceLarge"
        tools:context=".MainActivity"/>
</RelativeLayout>
```
In `onCreate()`, we load up the layout and get our hands on the `fadee` widget:

```java
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);
    fadee=(TextView)findViewById(R.id.fadee);
}
```

MainActivity itself implements `Runnable`, and our `run()` method will perform some animated effects:

```java
@Override
public void run() {
    if (fadingOut) {
        fadee.animate().alpha(0).setDuration(PERIOD);
        fadee.setText(R.string.fading_out);
    } else {
        fadee.animate().alpha(1).setDuration(PERIOD);
        fadee.setText(R.string.coming_back);
    }
    fadingOut=!fadingOut;
    fadee.postDelayed(this, PERIOD);
}
```

Specifically, we use `ViewPropertyAnimator` to fade out the `TextView` over a certain period (`fadee.animate().alpha(0).setDuration(PERIOD);`) and set its caption to a value indicating that we are fading out. If we are to be fading back in, we perform the opposite animation and set the caption to a different value. We then flip the `fadingOut` boolean for the next pass and use `postDelayed()` to reschedule ourselves to run after the period has elapsed.

To complete the process, we `run()` our code initially in `onStart()` and cancel the
The result is that the TextView smoothly fades out and in, alternating captions as it goes.

However, it would be really unpleasant if all this animator goodness worked only on API Level 11+. Fortunately for us, somebody wrote a backport.

**Backport Via NineOldAndroids**

Jake Wharton wrote [NineOldAndroids](http://nineoldandroids.com). This is, in effect, a backport of ViewPropertyAnimator and its underpinnings. There are some slight changes in how you use it, because NineOldAndroids is simply a library. It cannot add methods to existing classes (like adding animate() to View), nor can it add capabilities that the underlying firmware simply lacks. But, it may cover many of your animator needs, even if the name is somewhat inexplicable, and it works going all the way back to API Level 1, ensuring that it will cover any Android release that you care about.

NineOldAndroids is an Android library project. Android Studio users can add a implementation statement to their dependencies closure in build.gradle to pull in com.nineoldandroids:library:... (for some version indicated by ...).

Since NineOldAndroids cannot add animate() to View, the recommended approach is to use a somewhat obscure feature of Java: imported static methods. An import static statement, referencing a particular static method of a class, makes that method available as if it were a static method on the class that you are writing, or as some sort of global function. NineOldAndroids has an animate() method that you
can import this way, so instead of `v.animate()`, you use `animate(v)` to accomplish the same end. Everything else is the same, except perhaps some imports, to reference NineOldAndroids instead of the native classes.

You can see this in the Animation/AnimatorFadeBC sample app.

In addition to having the NineOldAndroids JAR in `libs/`, the only difference between this edition and the previous sample is in how the animation is set up. Instead of lines like:

```java
fadee.animate().alpha(0).setDuration(PERIOD);
```

we have:

```java
animate(fadee).alpha(0).setDuration(PERIOD);
```

This takes advantage of our static import:

```java
import static com.nineoldandroids.view.ViewPropertyAnimator.animate;
```

If the static import makes you queasy, you are welcome to simply import the `com.nineoldandroids.view.ViewPropertyAnimator` class, rather than the static method, and call the `animate()` method on `ViewPropertyAnimator`:

```java
ViewPropertyAnimator.animate(fadee).alpha(0).setDuration(PERIOD);
```

The Foundation: Value and Object Animators

`ViewPropertyAnimator` itself is a layer atop of a more primitive set of animators, known as value and object animators.

A `ValueAnimator` handles the core logic of transitioning some value, from an old to a new value, over a period of time. `ValueAnimator` offers replaceable “interpolators”, which will determine how the values change from start to finish over the animation period (e.g., start slowly, accelerate, then end slowly). `ValueAnimator` also handles the concept of a “repeat mode”, to indicate if the animation should simply happen once, a fixed number of times, or should infinitely repeat (and, in the latter cases, whether it does so always transitioning from start to finish or if it reverses direction on alternate passes, going from finish back to start).

What `ValueAnimator` does not do is actually change anything. It is merely
computing the different values based on time. You can call `getAnimatedValue()` to find out the value at any point in time, or you can call `addUpdateListener()` to register a listener object that will be notified of each change in the value, so that change can be applied somewhere.

Hence, what tends to be a bit more popular is `ObjectAnimator`, a subclass of `ValueAnimator` that automatically applies the new values. `ObjectAnimator` does this by calling a setter method on some object, where you supply the object and the “property name” used to derive the getter and setter method names. For example, if you request a property name of `foo`, `ObjectAnimator` will try to call `getFoo()` and `setFoo()` methods on your supplied object.

As with `ViewPropertyAnimator`, `ValueAnimator` and `ObjectAnimator` are implemented natively in API Level 11 and are available via the NineOldAndroids backport as well.

To see what `ObjectAnimator` looks like in practice, let us examine the `Animation/ObjectAnimator` sample app.

Once again, our activity’s layout is pretty much just a centered `TextView`, here named `word`:

```xml
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <TextView
        android:id="@+id/word"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerHorizontal="true"
        android:layout_centerVertical="true"
        android:textAppearance="?android:attr/textAppearanceLarge"
        tools:context=".MainActivity"/>
</RelativeLayout>
```

The objective of our activity is to iterate through 25 words, showing one at a time in the `TextView`:

```java
package com.commonsware.android.animator.obj;
```
To accomplish this, we use NineOldAndroids version of `ObjectAnimator`, saying that we wish to “animate” the `wordPosition` property of the activity itself, from 0 to 24. We configure the animation to run for 12.5 seconds (i.e., 500ms per word) and to repeat indefinitely by restarting the animation from the beginning on each pass. We
then call start() to kick off the animation.

For this to work, though, we need getWordPosition() and setWordPosition() accessor methods for the theoretical wordPosition property. In our case, the “word position” is simply an integer data member of the activity, which we return in getWordPosition() and update in setWordPosition(). However, we also update the TextView in setWordPosition(), to display the word at that position.

The net effect is that words appear in our TextView, changing on average every 500ms.

**Animating Custom Types**

In the previous section, we animated an int property of an Activity. That works, because Android knows how to compute int values between the start and end position, through simple math.

But, what if we wanted to animate something that is not a simple number? For example, what if we want to animate a Color, or a LatLng from Maps V2, or a TastyTreat class of our own design?

So long as we can perform the calculations, we can animate a type of anything we want, using TypeEvaluator and ofObject() on ObjectAnimator.

A TypeEvaluator is a simple interface, containing a single method that we need to override: evaluate(). However, TypeEvaluator uses generics, and so our implementation will actually be of some concrete class (e.g., a TypeEvaluator of TastyTreat). Our job in evaluate() is to return a value of our designated type (e.g., TastyTreat) given three inputs:

1. The initial value for our animation range, in the form of our designated type
2. The end value for our animation range, in the form of our designated type
3. The fraction along that range that represents how much we have moved from the initial value to the end value

Note that the fraction is not limited to being between 0 and 1, as certain interpolators (e.g., an overshoot interpolator) might result in a fraction being negative (e.g., we overshot past the initial value) or greater than one (e.g., we overshot past the end value).
For example, to have a TypeEvaluator of Color, we might have evaluate() generate a new Color instance based upon applying the fraction to the initial and end red, green, blue, and alpha channels.

To use a TypeEvaluator, instead of ofInt(), ofFloat(), or similar simple factory methods on ObjectAnimator, we use ofObject(). ofObject() takes the object to be animated, the property to be animated, the TypeEvaluator to assist in the actual animation, and the final value of the animation (or, optionally, a series of waypoints to be animated along).

A flavor of ofObject() that takes the property name — akin to the wordPosition ofInt() used in the previous section — has been around since API Level 11. API Level 14 added an ofObject() method that takes a Property value instead of the name of the property. This version has the added benefit of type-safety, as it can ensure that your object to be animated, TypeEvaluator, and final position are all of the same type.

You can see an example of using TypeEvaluator this way in the chapter on Maps V2, as we animate the movement of a map marker from a starting point to an ending point.

**Hardware Acceleration**

Animated effects operate much more smoothly with hardware acceleration. There are two facets to employing hardware acceleration for animations: enabling it overall and directing its use for the animations themselves.

Hardware acceleration is enabled overall on Android devices running Android 4.0 or higher (API Level 14). On Android 3.x, hardware acceleration is available but is disabled by default — use android:hardwareAccelerated="true" in your <application> or <activity> element in the manifest to enable it on those versions. Hardware acceleration for 2D graphics operations like widget animations is not available on older versions of Android.

While this will provide some benefit across the board, you may also wish to consider rendering animated widgets or containers in an off-screen buffer, or “hardware layer”, that then gets applied to the screen via the GPU. In particular, the GPU can apply certain animated transformations to a hardware layer without forcing software to redraw the widgets or containers (e.g., what happens when you invalidate() them). As it turns out, these GPU-enhanced transformations match the ones
supported by ViewPropertyAnimator:

1. Changes in alpha channel values, for fading widgets in and out
2. Changes in widget position, by altering the X and Y values of the upper-left corner of the widget, from wherever on the screen it used to be to some new value
3. Changes in the widget’s rotation, around any of the three axes
4. Changes in the widget’s size, where Android can scale the widget by some percentage to expand or shrink it

By having the widget be rendered in a hardware layer, these ViewPropertyAnimator operations are significantly more efficient than before.

However, since hardware layers take up video memory, generally you do not want to keep a widget or container in a hardware layer indefinitely. Instead, the recommended approach is to have the widget or container be rendered in a hardware layer only while the animation is ongoing, by calling setLayerType() for LAYER_TYPE_HARDWARE before the animation begins, then calling setLayerType() for LAYER_TYPE_NONE (i.e., return to default behavior) when the animation completes. Or, for ViewPropertyAnimator on API Level 16 and higher, use withLayer() in the fluent interface to have it apply the hardware layer automatically just for the animation duration.

We will see examples of using hardware acceleration this way in the next section.

The Three-Fragment Problem

The original tablet implementation of Gmail organized its landscape main activity into two panes, one on the left taking up ~30% of the screen, and one on the right taking up the remainder:

Figure 530: Gmail Fragments (image courtesy of Google and AOSP)
Gmail had a very specific navigation mode in its main activity when viewed in landscape on a tablet, where upon some UI event (e.g., tapping on something in the right-hand area):

- The original left-hand fragment (Fragment A) slid off the screen to the left
- The original right-hand fragment (Fragment B) slid to the left edge of the screen and shrunk to take up the spot vacated by Fragment A
- Another fragment (Fragment C) slid in from the right side of the screen and expanded to take up the spot vacated by Fragment B

And a BACK button press reversed this operation.

This is a bit tricky to set up, leading to the author of this book posting a question on Stack Overflow to get input. Here, we will examine one of the results of that discussion, based in large part on the implementation of the AOSP Email app, which has a similar navigation flow. The other answers on that question may have merit in other scenarios as well.

You can see one approach for implementing the three-pane solution in the Animation/ThreePane sample app.

**The ThreePaneLayout**

The logic to handle the animated effects is encapsulated in a ThreePaneLayout class. It is designed to be used in a layout XML resource where you supply the contents of the three panes, sizing the first two as you want, with the third "pane" having zero width at the outset:

```xml
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/root"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <FrameLayout
        android:id="@+id/left"
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="3"/>

    <FrameLayout
        android:id="@+id/middle"
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="7"/>

    <!-- More layout content...

    ...and here's where you put the third pane. It
    will be show up in the right-hand area, initially
    occupying zero space.

    ...and here's where you put the third pane. It
    will be show up in the right-hand area, initially
    occupying zero space. -->
</com.commonsware.android.anim.threepane.ThreePaneLayout>
```

1680
ThreePaneLayout itself is a subclass of LinearLayout, set up to always be horizontal, regardless of what might be set in the layout XML resource.

```java
public ThreePaneLayout(Context context, AttributeSet attrs) {
    super(context, attrs);
    initSelf();
}

void initSelf() {
    setOrientation(HORIZONTAL);
}
```

When the layout finishes inflating, we grab the three panes (defined as the first three children of the container) and stash them in data members named left, middle, and right, with matching getter methods:

```java
@Override
public void onFinishInflate() {
    super.onFinishInflate();

    left=getChildAt(0);
    middle=getChildAt(1);
    right=getChildAt(2);
}

public View getLeftView() {
    return(left);
}

public View getMiddleView() {
    return(middle);
}

public View getRightView() {
    return(right);
}
```

(ANIMATORS 1681)
The major operational API, from the standpoint of an activity using ThreePaneLayout, is `hideLeft()` and `showLeft()`. `hideLeft()` will switch from showing the left and middle widgets in their original size and position to showing the middle and right widgets wherever left and middle had been originally. `showLeft()` reverses the operation.

The problem is that, initially, we do not know where the widgets are or how big they are, as that should be able to be set from the layout XML resource and are not known until the ThreePaneLayout is actually applied to the screen. Hence, we lazy-retrieve those values in `hideLeft()`, plus remove any weights that had been originally defined, setting the actual pixel widths on the widgets instead:

```java
public void hideLeft() {
    if (leftWidth == -1) {
        leftWidth = left.getWidth();
        middleWidthNormal = middle.getWidth();
        resetWidget(left, leftWidth);
        resetWidget(middle, middleWidthNormal);
        resetWidget(right, middleWidthNormal);
        requestLayout();
    }

    translateWidgets(-1 * leftWidth, left, middle, right);

    ObjectAnimator.ofInt(this, "middleWidth", middleWidthNormal, leftWidth).setDuration(ANIM_DURATION).start();
}
```

The work to change the weights into widths is handled in `resetWidget()`:

```java
private void resetWidget(View v, int width) {
    LinearLayout.LayoutParams p = (LinearLayout.LayoutParams)v.getLayoutParams();
    p.width = width;
    p.weight = 0;
}
```

After the lazy-initialization and widget cleanup, we perform the two animations. `translateWidgets()` will slide each of our three widgets to the left by the width of the left widget, using a `ViewPropertyAnimator` and a hardware layer:
The resize animation — to set the middle size to be what left had been — is handled via an ObjectAnimator, for a theoretical property of `middleWidth` on `ThreePaneLayout`. That is backed by a `setMiddleWidth()` method that adjusts the width property of the middle widget’s LayoutParams and triggers a redraw:

```java
@SuppressWarnings("unused")
private void setMiddleWidth(int value) {
    middle.getLayoutParams().width = value;
    requestLayout();
}
```

The `showLeft()` method simply performs those two animations in reverse:

```java
public void showLeft() {
    translateWidgets(leftWidth, left, middle, right);

    ObjectAnimator.ofInt(this, "middleWidth", leftWidth,
                           middleWidthNormal).setDuration(ANIM_DURATION)
                           .start();
}
```

The sample app uses one activity (`MainActivity`) and one fragment (`SimpleListFragment`) to set up and use the `ThreePaneLayout`. The objective is a UI that roughly mirrors that of the AOSP Email app: a list on the left, a list in the...
middle (whose contents are based on the item chosen in the left list), and
something else on the right (whose contents are based on the item chosen in the
middle list).

SimpleListFragment is used for both lists. Its newInstance() factory method is
handed the list of strings to display. SimpleListFragment just loads those into its
ListView, also setting up CHOICE_MODE_SINGLE for use with the activated style, and
routing all clicks on the list to the MainActivity that hosts the fragment:

```java
package com.commonsware.android.anim.threepane;

import android.app.ListFragment;
import android.os.Bundle;
import android.view.View;
import android.widget.ArrayAdapter;
import android.widget.ListView;
import java.util.ArrayList;
import java.util.Arrays;

public class SimpleListFragment extends ListFragment {
    private static final String KEY_CONTENTS="contents";

    public static SimpleListFragment newInstance(String[] contents) {
        return(newInstance(new ArrayList<String>(Arrays.asList(contents))));
    }

    public static SimpleListFragment newInstance(ArrayList<String> contents) {
        SimpleListFragment result=new SimpleListFragment();
        Bundle args=new Bundle();

        args.putStringArrayList(KEY_CONTENTS, contents);
        result.setArguments(args);

        return(result);
    }

    @Override
    public void onViewCreated(View v, Bundle savedInstanceState) {
        super.onViewCreated(v, savedInstanceState);

        getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
        setContents(getArguments().getStringArrayList(KEY_CONTENTS));
    }

    @Override
    public void onListItemClick(ListView l, View v, int position, long id) {
```
MainActivity populates the left FrameLayout with a SimpleListFragment in onCreate(), if the fragment does not already exist (e.g., from a configuration change). When an item in the left list is clicked, MainActivity populates the middle FrameLayout. When an item in the middle list is clicked, it sets the caption of the right Button and uses hideLeft() to animate that Button onto the screen, hiding the left list. If the user presses BACK, and our left list is not showing, MainActivity calls showLeft() to reverse the animation:

```java
package com.commonsware.android.anim.threepane;

import android.app.Activity;
import android.os.Bundle;
import android.widget.Button;
import java.util.ArrayList;

public class MainActivity extends Activity {
    private static final String KEY_MIDDLE_CONTENTS="middleContents";
    private boolean isLeftShowing=true;
    private SimpleListFragment middleFragment=null;
    private ArrayList<String> middleContents=null;
    private ThreePaneLayout root=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        root=(ThreePaneLayout)findViewById(R.id.root);
    }
}
```

(from Animation/ThreePane/app/src/main/java/com/commonsware/android/anim/threepane/SimpleListFragment.java)
if (getFragmentManager().findFragmentById(R.id.left) == null) {
    getFragmentManager().beginTransaction()
        .add(R.id.left,
             SimpleListFragment.newInstance(items))
        .commit();
}

middleFragment = (SimpleListFragment)getFragmentManager().findFragmentById(R.id.middle);

@Override
public void onBackPressed() {
    if (!isLeftShowing) {
        root.showLeft();
        isLeftShowing = true;
    } else {
        super.onBackPressed();
    }
}

@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putStringArrayList(KEY_MIDDLE_CONTENTS, middleContents);
}

@Override
protected void onRestoreInstanceState(Bundle inState) {
    middleContents = inState.getStringArrayList(KEY_MIDDLE_CONTENTS);
}

void onListItemClick(SimpleListFragment fragment, int position) {
    if (fragment == middleFragment) {
        ((Button)root.getRightView()).setText(middleContents.get(position));

        if (isLeftShowing) {
            root.hideLeft();
            isLeftShowing = false;
        }
    } else {
        middleContents = new ArrayList<String>();

        for (int i=0; i < 20; i++) {
            middleContents.add(items[position] + " "+ i);
        }
    }
}
The Results

If you run this app on a landscape tablet running API Level 11 or higher, you start off with a single list of words on the left:

![Figure 531: ThreePane, As Initially Launched](image)

Clicking on a word brings up a second list, taking up the rest of the screen, with
numbered entries based upon the clicked-upon word:

<table>
<thead>
<tr>
<th>word</th>
<th>consectetur #0</th>
<th>consectetur #1</th>
<th>consectetur #2</th>
<th>consectetur #3</th>
<th>consectetur #4</th>
<th>consectetur #5</th>
<th>consectetur #6</th>
<th>consectetur #7</th>
<th>consectetur #8</th>
<th>consectetur #9</th>
<th>consectetur #10</th>
</tr>
</thead>
<tbody>

*Figure 532: ThreePane, After Clicking a Word*
Clicking on an entry in the second list starts the animation, sliding the first list off to the left, sliding the second list into the space vacated by the first list, and sliding in a “detail view” into the right portion of the screen:

![Image of ThreePane, After Clicking a Numbered Word]

Pressing BACK once will reverse the animation, restoring you to the two-list perspective.

The Backport

The ThreePane sample described above uses the native API Level 11 version of the animator framework and the native implementation of fragments. However, the same approach can work using the Android Support package's version of fragments and NineOldAndroids. You can see this in the Animation/ThreePaneBC sample app.

Besides changing the import statements and adding the NineOldAndroids JAR file, the only other changes of substance were:

- Using `ViewPropertyAnimator.animate(v)` instead of `v.animate()` in `translateWidgets()`
- Conditionally setting the hardware acceleration layers via `setLayerType()` in
translateWidgets() based upon API level, as that method was only added in API Level 11

The smoothness of animations, though, will vary by hardware capabilities. For example, on a first-generation Kindle Fire, running Android 2.3, the backport works but is not especially smooth, while the animations are very smooth on more modern hardware where hardware acceleration can be applied.

The Problems

As we will see in the chapter on “jank”, there is some stutter in the rendering of this app. Fixing it requires removing the animated change in the width of the middle pane, which in turn makes the animation itself look worse. More details on the analysis can be found in the “jank” chapter.
Legacy Animations

Before ViewPropertyAnimator and the rest of the animator framework were added in API Level 11, we had the original Animation base class and specialized animations based upon it, like TranslateAnimation for movement and AlphaAnimation for fades. On the whole, you will want to try to use the animator framework where possible, as the new system is more powerful and efficient than the legacy Animation approach. However, particularly for apps where the NineOldAndroids backport is insufficient, you may wish to use the legacy framework.

After an overview of the role of the animation framework, we go in-depth to animate the movement of a widget across the screen. We then look at alpha animations, for fading widgets in and out. We then see how you can get control during the lifecycle of an animation, how to control the acceleration of animations, and how to group animations together for parallel execution. Finally, we see how the same framework can now be used to control the animation for the switching of activities.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on basic resources and basic widgets. Also, you should read the chapter on custom views.

It’s Not Just For Toons Anymore

Android has a package of classes (android.view.animation) dedicated to animating the movement and behavior of widgets.

They center around an Animation base class that describes what is to be done. Built-
in animations exist to move a widget (TranslateAnimation), change the transparency of a widget (AlphaAnimation), revolve a widget (RotateAnimation), and resize a widget (ScaleAnimation). There is even a way to aggregate animations together into a composite Animation called an AnimationSet. Later sections in this chapter will examine the use of several of these animations.

Given that you have an animation, to apply it, you have two main options:

1. You may be using a container that supports animating its contents, such as a ViewFlipper or TextSwitcher. These are typically subclasses of ViewAnimator and let you define the “in” and “out” animations to apply. For example, with a ViewFlipper, you can specify how it flips between Views in terms of what animation is used to animate “out” the currently-visible View and what animation is used to animate “in” the replacement View.
2. You can simply tell any View to startAnimation(), given the Animation to apply to itself. This is the technique we will be seeing used in the examples in this chapter.

A Quirky Translation

Animation takes some getting used to. Frequently, it takes a fair bit of experimentation to get it all working as you wish. This is particularly true of TranslateAnimation, as not everything about it is intuitive, even to authors of Android books.

Mechanics of Translation

The simple constructor for TranslateAnimation takes four parameters describing how the widget should move: the before and after X offsets from the current position, and the before and after Y offsets from the current position. The Android documentation refers to these as fromXDelta, toXDelta, fromYDelta, and toYDelta.

In Android’s pixel-space, an (X, Y) coordinate of (0, 0) represents the upper-left corner of the screen. Hence, if toXDelta is greater than fromXDelta, the widget will move to the right, if toYDelta is greater than fromYDelta, the widget will move down, and so on.

Imagining a Sliding Panel

Some Android applications employ a sliding panel, one that is off-screen most of the
time but can be called up by the user (e.g., via a menu) when desired. When anchored at the bottom of the screen, you get a container that slides up from the bottom and slides down and out when being removed.

One way to implement such a panel is to have a container (e.g., a `LinearLayout`) whose contents are absent (INVISIBLE) when the panel is closed and is present (VISIBLE) when the drawer is open. If we simply toggled `setVisibility()` using the aforementioned values, though, the panel would wink open and closed immediately, without any sort of animation. So, instead, we want to:

1. Make the panel visible and animate it up from the bottom of the screen when we open the panel
2. Animate it down to the bottom of the screen and make the panel invisible when we close the panel

**The Aftermath**

This brings up a key point with respect to `TranslateAnimation`: the animation temporarily moves the widget, but if you want the widget to stay where it is when the animation is over, you have to handle that yourself. Otherwise, the widget will snap back to its original position when the animation completes.

In the case of the panel opening, we handle that via the transition from INVISIBLE to VISIBLE. Technically speaking, the panel is always “open”, in that we are not, in the end, changing its position. But when the body of the panel is INVISIBLE, it takes up no space on the screen; when we make it VISIBLE, it takes up whatever space it is supposed to.

Later in this chapter, we will cover how to use animation listeners to accomplish this end for closing the panel.

**Introducing SlidingPanel**

With all that said, turn your attention to the [Animation/SlidingPanel] sample project and, in particular, the SlidingPanel class.

This class implements a layout that works as a panel, anchored to the bottom of the screen. A `toggle()` method can be called by the activity to hide or show the panel. The panel itself is a `LinearLayout`, so you can put whatever contents you want in there.
We use two flavors of `TranslateAnimation`, one for opening the panel and one for closing it.

Here is the opening animation:

```java
anim = new TranslateAnimation(0.0f, 0.0f,
                             getHeight(),
                             0.0f);
```

(From `Animation/SlidingPanel/app/src/main/java/com/commonsware/android/anim/SlidingPanel.java`)

Our `fromXDelta` and `toXDelta` are both 0, since we are not shifting the panel’s position along the horizontal axis. Our `fromYDelta` is the panel’s height according to its layout parameters (representing how big we want the panel to be), because we want the panel to start the animation at the bottom of the screen; our `toYDelta` is 0 because we want the panel to be at its “natural” open position at the end of the animation.

Conversely, here is the closing animation:

```java
anim = new TranslateAnimation(0.0f, 0.0f, 0.0f,
                             getHeight());
```

(From `Animation/SlidingPanel/app/src/main/java/com/commonsware/android/anim/SlidingPanel.java`)

It has the same basic structure, except the Y values are reversed, since we want the panel to start open and animate to a closed position.
The result is a container that can be closed:

Figure 534: The SlidingPanel sample application, with the panel closed
... or open, in this case toggled via a menu choice in the SlidingPanelDemo activity:

![Figure 535: The SlidingPanel sample application, with the panel open](image)

**Using the Animation**

When setting up an animation, you also need to indicate how long the animation should take. This is done by calling `setDuration()` on the animation, providing the desired length of time in milliseconds.

When we are ready with the animation, we simply call `startAnimation()` on the SlidingPanel itself, causing it to move as specified by the `TranslateAnimation` instance.

**Fading To Black. Or Some Other Color.**

`AlphaAnimation` allows you to fade a widget in or out by making it less or more transparent. The greater the transparency, the more the widget appears to be “fading”.

1696
**Alpha Numbers**

You may be used to alpha channels, when used in #AARRGGBB color notation, or perhaps when working with alpha-capable image formats like PNG.

Similarly, `AlphaAnimation` allows you to change the alpha channel for an entire widget, from fully-solid to fully-transparent.

In Android, a float value of 1.0 indicates a fully-solid widget, while a value of 0.0 indicates a fully-transparent widget. Values in between, of course, represent various amounts of transparency.

Hence, it is common for an `AlphaAnimation` to either start at 1.0 and smoothly change the alpha to 0.0 (a fade) or vice versa.

**Animations in XML**

With `TranslateAnimation`, we showed how to construct the animation in Java source code. One can also create animation resources, which define the animations using XML. This is similar to the process for defining layouts, albeit much simpler.

For example, there is a second animation project, `Animation/SlidingPanelEx`, which demonstrates a panel that fades out as it is closed. In there, you will find a `res/anim/` directory, which is where animation resources should reside. In there, you will find `fade.xml`:

```xml
<?xml version="1.0" encoding="utf-8"?>
<alpha
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:fromAlpha="1.0"
    android:toAlpha="0.0" />
```

(from `Animation/SlidingPanelEx/app/src/main/res/anim/fade.xml`)

The name of the root element indicates the type of animation (in this case, alpha for an `AlphaAnimation`). The attributes specify the characteristics of the animation, in this case a fade from 1.0 to 0.0 on the alpha channel.

This XML is the same as calling `new AlphaAnimation(1.0f, 0.0f)` in Java.

**Using XML Animations**

To make use of XML-defined animations, you need to inflate them, much as you
might inflate a View or Menu resource. This is accomplished by using the loadAnimation() static method on the AnimationUtils class, seen here in our SlidingPanel constructor:

```java
public SlidingPanel(final Context ctxt, AttributeSet attrs) {
    super(ctxt, attrs);

    TypedArray a = ctxt.obtainStyledAttributes(attrs, 
        R.styleable.SlidingPanel, 
        0, 0);

    speed = a.getInt(R.styleable.SlidingPanel_speed, 300);
    a.recycle();

    fadeOut = AnimationUtils.loadAnimation(ctxt, R.anim.fade);
}
```

Here, we are loading our fade animation, given a Context. This is being put into an Animation variable, so we neither know nor care that this particular XML that we are loading defines an AlphaAnimation instead of, say, a RotateAnimation.

### When It’s All Said And Done

Sometimes, you need to take action when an animation completes.

For example, when we close the panel, we want to use a TranslationAnimation to slide it down from the open position to closed... then keep it closed. With the system used in SlidingPanel, keeping the panel closed is a matter of calling setVisibility() on the contents with INVISIBLE.

However, you cannot do that when the animation begins; otherwise, the panel is gone by the time you try to animate its motion.

Instead, you need to arrange to have it become invisible when the animation ends. To do that, you use an animation listener.

An animation listener is simply an instance of the AnimationListener interface, provided to an animation via setAnimationListener(). The listener will be invoked when the animation starts, ends, or repeats (the latter courtesy of CycleInterpolator, discussed later in this chapter). You can put logic in the
onAnimationEnd() callback in the listener to take action when the animation finishes.

For example, here is the AnimationListener for SlidingPanel:

```java
Animation.AnimationListener collapseListener = new Animation.AnimationListener()
{
    public void onAnimationEnd(Animation animation) {
        setVisibility(View.INVISIBLE);
    }

    public void onAnimationRepeat(Animation animation) {
        // not needed
    }

    public void onAnimationStart(Animation animation) {
        // not needed
    }
};
```

(from Animation/SlidingPanel/app/src/main/java/com/commonsware/android/anim/SlidingPanel.java)

All we do is set our content's visibility to be INVISIBLE, thereby closing the panel.

**Loose Fill**

You will see attributes, available on Animation, named android:fillEnabled and android:fillAfter. Reading those, you may think that you can dispense with the AnimationListener and just use those to arrange to have your widget wind up being “permanently” in the state represented by the end of the animation. All you would have to do is set each of those to true in your animation XML (or the equivalent in Java), and you would be set.

At least for TranslateAnimation, you would be mistaken.

It actually will look like it works — the animated widgets will be drawn in their new location. However, if those widgets are clickable, they will not be clicked in their new location, but rather in their old one. This, of course, is not terribly useful.

Hence, even though it is annoying, you will want to use the AnimationListener techniques described in this chapter.

**Hit The Accelerator**

In addition to the Animation classes themselves, Android also provides a set of Interpolator classes. These provide instructions for how an animation is supposed
to behave during its operating period.

For example, the AccelerateInterpolator indicates that, during the duration of an animation, the rate of change of the animation should begin slowly and accelerate until the end. When applied to a TranslateAnimation, for example, the sliding movement will start out slowly and pick up speed until the movement is complete.

There are several implementations of the Interpolator interface besides AccelerateInterpolator, including:

1. AccelerateDecelerateInterpolator, which starts slowly, picks up speed in the middle, and slows down again at the end
2. DecelerateInterpolator, which starts quickly and slows down towards the end
3. LinearInterpolator, the default, which indicates the animation should proceed smoothly from start to finish
4. CycleInterpolator, which repeats an animation for a number of cycles, following the AccelerateDecelerateInterpolator pattern (slow, then fast, then slow)

To apply an interpolator to an animation, simply call setInterpolator() on the animation with the Interpolator instance, such as the following line from SlidingPanel:

```java
anim.setInterpolator(new AccelerateInterpolator(1.0f));
```

(from Animation/SlidingPanel/app/src/main/java/com/commonsware/android/anim/SlidingPanel.java)

You can also specify one of the stock interpolators via the android:interpolator attribute in your animation XML file.

**Animate. Set. Match.**

For the Animation/SlidingPanelEx project, though, we want the panel to slide open, but also fade when it slides closed. This implies two animations working at the same time (a fade and a slide). Android supports this via the AnimationSet class.

An AnimationSet is itself an Animation implementation. Following the composite design pattern, it simply cascades the major Animation events to each of the animations in the set.
To create a set, just create an AnimationSet instance, add the animations, and configure the set. For example, here is the logic from the SlidingPanel implementation in Animation/SlidingPanelEx:

```java
public void toggle() {
    TranslateAnimation anim=null;
    AnimationSet set=new AnimationSet(true);
    isOpen=!isOpen;
    if (isOpen) {
        setVisibility(View.VISIBLE);
        anim=new TranslateAnimation(0.0f, 0.0f,
                                 getHeight(),
                                 0.0f);
    } else {
        anim=new TranslateAnimation(0.0f, 0.0f, 0.0f,
                                 getHeight());
        anim.setAnimationListener(collapseListener);
        set.addAnimation(fadeOut);
    }
    set.addAnimation(anim);
    set.setDuration(speed);
    set.setInterpolator(new AccelerateInterpolator(1.0f));
    startAnimation(set);
}
```

(From Animation/SlidingPanelEx/app/src/main/java/com/commonsware/android/anim2/SlidingPanel.java)

If the panel is to be opened, we make the contents visible (so we can animate the motion upwards), and create a TranslateAnimation for the upward movement. If the panel is to be closed, we create a TranslateAnimation for the downward movement, but also add a pre-defined AlphaAnimation (fadeOut) to an AnimationSet. In either case, we add the TranslateAnimation to the set, give the set a duration and interpolator, and run the animation.

**Active Animations**

Starting with Android 1.5, users could indicate if they wanted to have inter-activity animations: a slide-in/slide-out effect as they switched from activity to activity. However, at that time, they could merely toggle this setting on or off, and applications had no control over these animations whatsoever.
Starting in Android 2.0, though, developers have a bit more control. Specifically:

1. Developers can call `overridePendingTransition()` on an Activity, typically after calling `startActivity()` to launch another activity or `finish()` to close up the current activity. The `overridePendingTransition()` indicates an in/out animation pair that should be applied as control passes from this activity to the next one, whether that one is being started (`startActivity()`) or is the one previous on the stack (`finish()`).
2. Developers can start an activity via an Intent containing the `FLAG_ACTIVITY_NO_ANIMATION` flag. As the name suggests, this flag requests that animations on the transitions involving this activity be suppressed.

These are prioritized as follows:

- Any call to `overridePendingTransition()` is always taken into account
- Lacking that, `FLAG_ACTIVITY_NO_ANIMATION` will be taken into account
- In the normal case, where neither of the two are used, whatever the user’s preference, via the Settings application, is applied
Many times, our artwork can simply be some PNG or JPEG files, perhaps with different variations in different resource directories by density.

Sometimes, though, we need something more.

In addition to supporting standard PNG and JPEG files, Android has a number of custom drawable resource formats — mostly written in XML — that handle specific scenarios.

For example, you may wish to customize “the background” of a Button, but a Button really has several different background images for different circumstances (normal, pressed, focused, disabled, etc.). Android has a certain type of drawable resource that aggregates other drawable resources, indicating which of those other resources should be used in different circumstances (e.g., for a normal button use X, for a disabled button use Y).

In this chapter, we will explore these non-traditional types of “drawables” and how you can use them within your apps.

**Prerequisites**

Understanding this chapter requires that you have read the core chapters, particularly the ones on basic resources, basic widgets, and vector drawables.

Having read the chapters on animators and legacy animations would be useful.
Where Do These Things Go?

All of the drawables described in this chapter, unless otherwise noted, are density-independent. Hence, they do not normally go in a density-dependent directories like res/drawable-hdpi/. However, that still leaves three possible candidates: res/drawable-nodpi/, res/drawable-anydpi/, and the unadorned res/drawable/.

nodpi: Fallback

A drawable in res/drawable-nodpi/ is valid for any screen density. However, if there is another drawable with the same base name in a density-specific directory, and the device running your app happens to have that screen density, the density-specific resource will be used. As a result, -nodpi becomes a fallback, to be used in cases where you do not have something specific for a density.

For example, suppose that we have res/drawable-nodpi/foo.xml and res/drawable-xxhdpi/foo.png. An -xxhdpi device would use the PNG; all other devices would use the XML.

anydpi: Takeover

A drawable in res/drawable-anydpi/ also is valid for any screen density. However, in this case, the -anydpi variant trumps any density-specific variant.

For example, suppose that we have res/drawable-anydpi/foo.xml and res/drawable-xxhdpi/foo.png. All devices would use the XML, even -xxhdpi devices.

For this reason, often you will see -anydpi used in conjunction with other qualifiers. A popular one will be -v21, to restrict the resources to be used on API Level 21+ devices.

No Qualifier: Just Say “WTF?”

res/drawable/ is a synonym for res/drawable-mdpi/, for backwards compatibility with really old Android apps, written before we had density-specific resources. Hence, res/drawable/ is not really an appropriate choice for density-independent drawables.

Alas, Android Studio may put some drawables here, for uncertain reasons.
So long as there are no other resources with the same basename, the choice made by Android Studio’s developers is unlikely to cause any harm.

**ColorDrawable**

The simplest XML drawable format, by far, is for ColorDrawable. Not surprisingly, this defines a Drawable that is a solid color.

So, you can have a res/drawable/thing.xml file, containing something like this:

```xml
<color xmlns:android="http://schemas.android.com/apk/res/android"
       android:color="#80FF00FF"/>
```

From there, you can use @drawable/thing or R.drawable.thing in the same places that you would use any other drawable resource.

Note that a ColorDrawable is different than a color resource. A color resource (e.g., res/values/colors.xml) specifies a color. A ColorDrawable resource defines a Drawable of a color. A ColorDrawable resource is welcome to reference a color defined by a color resource, though:

```xml
<color xmlns:android="http://schemas.android.com/apk/res/android"
       android:color="@color/primary_dark"/>
```

**AnimationDrawable**

The original way of doing animation on the Web was via the animated GIF. An individual GIF file could contain many frames, and the browser would switch between those frames to display a basic animated effect. This was used by Web designers for things both good (animated progress “spinners”) and bad (“hit the monkey” ad banners).

Android, on the whole, does not support animated GIF files, certainly not as regular images for use with widgets like ImageView.

However, there are times where having this sort of frame-by-frame animation would be useful. For example, in another chapter, we will look at ProgressBar, which is Android’s primary way of demonstrating progress of background work. You may wish to customize the “spinning wheel” image that Android uses by default, to match your app’s color scheme, or to spin your company logo, or whatever. On the
Web, particularly on older browsers, you might use an animated GIF for that. On Android, you still could, though it would require a third-party library or some fairly heavyweight solutions (e.g., WebView, Movie).

Another possibility is to use an AnimationDrawable. AnimationDrawable has the net effect of an animated GIF:

- You define a series of images that serve as the frames of the animation
- You define how long each of those images should be on the screen
- You define whether the animation should loop back to the beginning after it reaches the end or not

However, rather than encoding all of this in an animated GIF, you instead encode this information in an XML file, stored as a drawable resource.

XML-encoded drawable resources are typically stored in a drawable directory that does not contain density information, such as res/drawable/. That is because the XML-encoded drawable resources are density-invariant: they behave the same regardless of density. Those, like the AnimationDrawable, that refer to other images might well refer to other images that are stored in density-dependent resource directories, but the XML-encoded drawable itself is independent of density.

An AnimationDrawable is defined as in XML with a root <animation-list> element, containing a series of <item> elements for each frame:

```xml
<animation-list xmlns:android="http://schemas.android.com/apk/res/android"
    android:oneshot="true">
    <item android:drawable="@drawable/frame1" android:duration="250" />
    <item android:drawable="@drawable/frame2" android:duration="250" />
    <item android:drawable="@drawable/frame3" android:duration="250" />
    <item android:drawable="@drawable/frame4" android:duration="250" />
</animation-list>
```

The root <animation-list> element can have an android:oneshot attribute, indicating whether the animation should repeat after displaying the last frame (false) or stop (true).

The <item> elements have android:drawable attributes pointing to the individual images for the individual frames. Usually these frames are PNG or JPEG files, but you refer to them as drawable resources, using @drawable syntax, so Android can find the right image based upon the density (or other characteristics) of the current device. The <item> elements also need an android:duration attribute, specifying
the time in milliseconds that this frame should be on the screen. While the above example has all durations the same, that is not required.

For example, the Android OS uses AnimationDrawable resources in a few places. One is for the download icon used in a Notification for use with DownloadManager and similar situations. That drawable resource – stat_sys_download.xml — looks like this:

```xml
<?xml version="1.0" encoding="utf-8"?>
<!--
/* /device/apps/common/res/drawable/status_icon_background.xml
** Copyright 2008, The Android Open Source Project
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
** http://www.apache.org/licenses/LICENSE-2.0
** Unless required by applicable law or agreed to in writing, software
** distributed under the License is distributed on an "AS IS" BASIS,
** WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
** See the License for the specific language governing permissions and
** limitations under the License.
*/
<animation-list
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:oneshot="false">
    <item android:drawable="@drawable/stat_sys_download_anim0" android:duration="200"/>
    <item android:drawable="@drawable/stat_sys_download_anim1" android:duration="200"/>
    <item android:drawable="@drawable/stat_sys_download_anim2" android:duration="200"/>
    <item android:drawable="@drawable/stat_sys_download_anim3" android:duration="200"/>
    <item android:drawable="@drawable/stat_sys_download_anim4" android:duration="200"/>
    <item android:drawable="@drawable/stat_sys_download_anim5" android:duration="200"/>
</animation-list>
```

Here, we have a repeating animation (android:oneshot="false"), consisting of six frames, each on the screen for 200 milliseconds.
By specifying an AnimationDrawable in your Notification for its icon, you too can have this sort of animated effect. Of course, the animation is “fire and forget”: other than by removing or replacing the Notification, you cannot affect the animation in any other way.

**Animated GIF Conversion**

It may be that you have an animated GIF that you would like to use as the basis for your AnimationDrawable. If you have passing familiarity with Ruby, the author of this book has published a Ruby script, named gif2animdraw, that automates the conversion.

To use gif2animdraw, in addition to the script itself and a Ruby interpreter, you will need the RMagick, slop, and builder gems. Note that RMagick, in turn, will require ImageMagick libraries and therefore is a bit more complicated to install than is your ordinary gem.

On Linux environments, you can also chmod the script to run it directly; otherwise, you would run it via the ruby command.

The script takes four command-line switches:

- `-i` should point to the GIF file to be converted
- `-o` should point to the root output directory, which typically would be a project's res/ directory
- `-d` should have, as a value, one of the Android density bucket names (e.g., hdpi); this will be used as the density for the frames of the GIF
- Optionally, include `--oneshot` to indicate that this should be a one-shot animation, not a repeating one

The results will be:

- A drawable/ directory underneath your supplied root, containing a file with the same name as the GIF file, but with a .xml extension, representing the AnimationDrawable itself
- A drawable-XXXX/ directory, where XXXX is your stated density, containing each frame of the animated GIF, as a PNG file, with a sequentially numbered filename based on the GIF’s filename
StateListDrawable

Another XML-defined drawable resource, the StateListDrawable, is key if you want to have different images when widgets are in different states.

As outlined in the introduction to this chapter, what makes a Button visually be a Button is its background. To handle different looks for the Button background for different states (normal, pressed, disabled, etc.), the standard Button background is a StateListDrawable, one that looks something like this:

```xml
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project
Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at
   http://www.apache.org/licenses/LICENSE-2.0
Unless required by applicable law or agreed to in writing, software
distributed under the License is distributed on an "AS IS" BASIS,
WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
See the License for the specific language governing permissions and
limitations under the License.-->  
<selector xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:state_window_focused="false" android:state_enabled="true"
          android:drawable="@drawable/btn_default_normal" />
    <item android:state_window_focused="false" android:state_enabled="false"
          android:drawable="@drawable/btn_default_normal_disable" />
    <item android:state_pressed="true"
          android:drawable="@drawable/btn_default_pressed" />
    <item android:state_focused="true" android:state_enabled="true"
          android:drawable="@drawable/btn_default_selected" />
    <item android:state_enabled="true"
          android:drawable="@drawable/btn_default_normal" />
    <item android:state_focused="true"
          android:drawable="@drawable/btn_default_normal_disable_focused" />
    <item android:drawable="@drawable/btn_default_normal_disable" />
</selector>
```

The XML has a <selector> root element, indicating this is a StateListDrawable. The <item> elements inside the root describe what Drawable resource should be
used if the StateListDrawable is being used in some state. For example, if the “window” (think activity or dialog) does not have the focus (android:state_window_focused="false") and the Button is enabled (android:state_enabled="true"), then we use the @drawable/btn_default_normal Drawable resource. That resource, as it turns out, is a nine-patch PNG file, described later in this chapter.

Android applies each rule in turn, top-down, to find the Drawable to use for a given state of the StateListDrawable. The last rule has no android:state_* attributes, meaning it is the overall default image to use if none of the other rules match.

So, if you want to change the background of a Button, you need to:

• Copy the above resource, found in your Android SDK as res/drawable/btn_default.xml inside any of the platforms/ directories, into your project
• Copy each of the Button state nine-patch images into your project
• Modify whichever of those nine-patch images you want, to affect the visual change you seek
• If need be, tweak the states and images defined in the StateListDrawable XML you copied
• Reference the local StateListDrawable as the background for your Button

The backgrounds of most widgets that have backgrounds by default will use a StateListDrawable. Searching a platform version's res/drawable/ directory for XML files containing <selector> elements comes up with a rather long list.

**ColorStateList**

A ColorStateList is analogous to a StateListDrawable, in that it defines states and identifies what should be used for a given state. Whereas StateListDrawable ties states to drawables, ColorStateList ties states to colors. This allows you to, say, change the color of some text based upon whether that text is drawn in a widget that is being pressed, or has the focus, or is disabled. If you tailor the background of a text-based widget using a StateListDrawable, you may well wind up tailoring the foreground text using a ColorStateList.

While this chapter mentions ColorStateList, technically a ColorStateList is not a Drawable. You do not use it in methods that take drawables or in widget XML attributes that take drawables. Rather, there are other methods and other attributes that take a ColorStateList, such as android:textColor.
Similarly, while you can define a ColorStateList in XML, you do not do so in a res/drawable/ resource directory, but rather a res/color/ resource directory. Beyond that, though, a ColorStateList XML resource looks a lot like a StateListDrawable XML resource, such as this definition of @android:color/primary_text_dark from Android 4.4:

```xml
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project
Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at
http://www.apache.org/licenses/LICENSE-2.0

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License. -->

<selector xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:state_enabled="false" android:color="@android:color/bright_foreground_dark_disabled"/>
    <item android:state_window_focused="false" android:color="@android:color/bright_foreground_dark"/>
    <item android:state_pressed="true" android:color="@android:color/bright_foreground_dark_inverse"/>
    <item android:state_selected="true" android:color="@android:color/bright_foreground_dark_inverse"/>
    <item android:state_activated="true" android:color="@android:color/bright_foreground_dark_inverse"/>
    <item android:color="@android:color/bright_foreground_dark"/> <!-- not selected -->
</selector>
```

Based upon the state, the ColorStateList pulls in a separate resource to define the actual color. Those colors, in turn, are defined via <color> elements in res/values/colors.xml as color resources, or are pulled in from system-defined colors (@android:color/... syntax):

```xml
<color name="background_dark">#ff000000</color>
<color name="background_light">#ffffffff</color>
<color name="bright_foreground_dark">@android:color/background_light</color>
<color name="bright_foreground_light">@android:color/background_dark</color>
```
LayerDrawable

A LayerDrawable basically stacks a bunch of other drawables on top of each other. Later drawables are drawn on top of earlier drawables, much as later children of a RelativeLayout are drawn on top of earlier children.

Typically, you will create a LayerDrawable via a <layer-list> XML drawable resource.

For example, a ToggleButton widget has a LayerDrawable as its background:

```xml
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project
Licensed under the Apache License, Version 2.0 (the "License);
you may not use this file except in compliance with the License.
You may obtain a copy of the License at
   http://www.apache.org/licenses/LICENSE-2.0

Unless required by applicable law or agreed to in writing, software
distributed under the License is distributed on an "AS IS" BASIS,
WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
See the License for the specific language governing permissions and
limitations under the License. -->

<layer-list xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:id="@+android:id/background" android:drawable="@android:drawable/btn_default_small"/>
    <item android:id="@+android:id/toggle" android:drawable="@android:drawable/btn_toggle"/>
</layer-list>
```

This LayerDrawable draws two images on top of each other. One is a standard small button background (@android:drawable/btn_default_small). The other is the actual face of the toggle itself — a StateListDrawable that uses different images for
checked and unchecked states.

In the `<layer-list>`, you can have several `<item>` elements. Each `<item>` element usually will need an `android:drawable` attribute, pointing to the drawable that should be drawn. Optionally, you can assign ID values to the items via `android:id` attributes, much like you would do for widgets in a layout XML resource. Later on, you can call `findDrawableByLayerId()` on the `LayerDrawable` to retrieve an individual `Drawable` representing the layer, given its `android:id` value.

There are also `android:left`, `android:right`, `android:top`, and `android:bottom` attributes, which you can use to provide dimension values to offset an image within the layered set. For example, you could use `android:left` to inset one of the layers by a certain number of pixels (or dp or whatever).

By default, the layers in the `LayerDrawable` are scaled to fit the size of whatever `View` is holding them (e.g., the size of the `ToggleButton` using the `LayerDrawable` as a background). To prevent this, you can skip the `android:drawable` attribute, and instead nest a `<bitmap>` element inside the `<item>`, where you can provide an `android:gravity` attribute to control how the image should be handled relative to its containing `View`. We will get more into nested `<bitmap>` elements later in this chapter.

**TransitionDrawable**

A TransitionDrawable is a LayerDrawable with one added feature: for a two-layer drawable, it can smoothly transition from showing one layer to another on top.

For example, you may have noticed that when you tap-and-hold on a row in a `ListView` that the selector highlight has an animated effect, slowly shifting colors from the color used for a simple click to one signifying that you have long-clicked the row. Android accomplishes this via a TransitionDrawable, set up as a `<transition>` XML drawable resource:

```xml
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project
Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at
http://www.apache.org/licenses/LICENSE-2.0

<transition>
```
CUSTOM DRAWABLES

The TransitionDrawable object has a startTransition() method that you can use, that will have Android smoothly switch from the first drawable to the second. You specify the duration of the transition as a number of milliseconds passed to startTransition(). There are also options to reverse the transition, set up more of a cross-fade effect, and the like.

LevelListDrawable

A LevelListDrawable is similar in some respects to a StateListDrawable, insofar as one specific item from the “list drawable” will be displayed based upon certain conditions. In the case of StateListDrawable, the conditions are based upon the state of the widget using the drawable (e.g., checked, pressed, disabled). In the case of LevelListDrawable, it is merely an integer level.

For example, the status or system bar of your average Android device has an icon indicating the battery charge level. That is actually implemented as a LevelListDrawable, via an XML resource containing a root <level-list> element:

```xml
<?xml version="1.0" encoding="utf-8"?>
<!-- //device/apps/common/res/drawable/stat_sys_battery.xml
** Copyright 2007, The Android Open Source Project
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
** http://www.apache.org/licenses/LICENSE-2.0
** Unless required by applicable law or agreed to in writing, software
** distributed under the License is distributed on an "AS IS" BASIS,
```
This LevelListDrawable has eight items, whose android:drawable attributes point to specific other drawable resources (in this case, standard PNG files with different implementations for different densities). Each <item> has an android:maxLevel value. When someone calls setLevel() on the Drawable or setImageLevel() on the ImageView, Android will choose the item with the lowest maxLevel that meets or exceeds the requested level, and show that. In the case of the battery icon, when the battery level changes, the status bar picks up that change and calls setImageLevel() with the battery charge percentage (expressed as an integer from 0-100) — that, in turn, triggers the right PNG file to be displayed.

Another use of LevelListDrawable is with a RemoteViews, such as for an app widget. The setImageLevel() method is “remotable”, despite not being directly part of the RemoteViews API. Hence, given that you use a LevelListDrawable in your app widget’s layout, you should be able to use setInt() with a method name of "setImageLevel" to have the app widget update to display the proper image.

ScaleDrawable and ClipDrawable

A ScaleDrawable does pretty much what its name suggests: it scales another
drawable. A ClipDrawable does pretty much what its name suggests: it clips another drawable.

How they do this, and how you control it, requires a bit more explanation.

Like LevelListDrawable, ScaleDrawable and ClipDrawable leverage the setLevel() method on Drawable (or the setImageLevel() method on ImageView). Whereas LevelListDrawable uses this to choose an individual image out of a set of possible images, ScaleDrawable and ClipDrawable use the level to control how much an image should be scaled or clipped. For this, they support a range of levels from 0 to 10000.

**Scaling**

For a level of 0, ScaleDrawable will not draw anything. For a level from 1 to 10000, ScaleDrawable will scale an image from a configurable minimum size to the bounds of the View to which the drawable is applied.

The amount of scaling is determined by android:scaleHeight and android:scaleWidth attributes:

```xml
<scale
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:drawable="@android:drawable/btn_default"
    android:scaleGravity="left|top"
    android:scaleHeight="50%"
    android:scaleWidth="50%"/>
```

(from Drawable/ScaleClip/app/src/main/res/drawable/scale.xml)

The above ScaleDrawable (denoted by the <scale> root element) says that we should scale both height and width of the underlying drawable to 50% of the available space for the drawable, when the level is at its maximum (10000).

Note that you do not have to scale along both dimensions. If, for example, you kept android:scaleWidth but deleted android:scaleHeight, setImageLevel() would control the scaled width of the underlying image (provided via android:drawable) but not the height.

The android:scaleGravity attribute indicates where the scaled image should reside within the available space (the 10000 level, determined by the bounds of the View to which the drawable is applied). The value shown above, center, keeps the image...
centered within the available space, and shrinks or expands it around the center. A value of `left|top` would keep the image in the upper-left corner of the space, having the visual effect of moving the lower-right corner based upon the supplied level.

**Clipping**

Scaling proportionally reduces the height and/or width of an image. Clipping, on the other hand, chops off part of the height or width of the image.

```xml
<clip xmlns:android="http://schemas.android.com/apk/res/android"
    android:clipOrientation="horizontal"
    android:drawable="@drawable/btn_default_normal"
    android:gravity="left"/>
```

In this sample `ClipDrawable` (indicated by the `<clip>` root element), we are going to allow the level to chop off part of the image indicated by the `android:drawable` attribute. Our `android:clipOrientation`, set to `horizontal`, means we are going to chop off part of the width (`vertical` would have us chop off part of the height). The amount that is going to be chopped off is the level you supply (e.g., `setImageLevel()`) divided by 10000. Hence, a level of 5000 will chop off 0.5 (a.k.a., 50%) of the image.

Where in the image the clipping occurs is determined by the `android:gravity` attribute. An `android:clipOrientation` of `horizontal` and an `android:gravity` of `left`, as in the sample drawable above, means that the left side of the image is retained, and the image will be clipped on the right. Specifying `right` instead of `left` would reverse that, clipping the image from the right, while `center` would clip equally from both sides. There are other gravity values as well, such as `top` and `bottom` values to be used with a `vertical` orientation.

**Seeing It In Action**

To see these effects, take a look at the [Drawable/ScaleClip](Drawable/ScaleClip) sample project. This is derived from [an earlier example](an earlier example) showing how to use ViewPager with PagerTabStrip. In that example, we had 10 tabs, each being a large EditText widget. In this example, we have 2 tabs, “Scale” and “Clip”, both using the same layout:
This is simply a 150dp square ImageView towards the top of the screen and a SeekBar towards the bottom of the screen. The SeekBar will be used to control the level applied to a ScaleDrawable and ClipDrawable, which is why we have android:max set to 10000. We also have our “progress” (original SeekBar value) set to 10000, so the bar’s thumb will be fully slid over to the right at the outset.

The fragments that we will use for the tabs both inherit from a common abstract FragmentBase class:

```java
package com.commonsware.android.scaleclip;

import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import android.widget.SeekBar;

abstract public class FragmentBase extends Fragment implements SeekBar.OnSeekBarChangeListener {
  abstract void setBackgroundImage(ImageView image);
```
In onCreateView(), we inflate the above layout file, hook up the fragment itself to be the listener for SeekBar change events, call the subclass’ setImageBackground() method to populate the ImageView with an image, and set the ImageView’s level to be the initial value of the SeekBar. When the SeekBar value changes, our onProgressChanged() method will adjust the level.

The concrete subclasses — ScaleFragment and ClipFragment — simply populate the ImageView with the ScaleDrawable and ClipDrawable resources shown earlier in

---

**CUSTOM DRAWABLES**

```java
private ImageView image=null;

@Override
public View onCreateView(LayoutInflater inflater, ViewGroup container, Bundle savedInstanceState) {
    setRetainInstance(true);

    View result=inflater.inflate(R.layout.scaleclip, container, false);
   SeekBar bar=((SeekBar)result.findViewById(R.id.level));

    bar.setOnSeekBarChangeListener(this);
    image=(ImageView)result.findViewById(R.id.image);
    setImageBackground(image);
    image.setImageLevel(bar.getProgress());

    return(result);
}

@Override
public void onProgressChanged(SeekBar seekBar, int progress, boolean fromUser) {
    image.setImageLevel(progress);
}

@Override
public void onStartTrackingTouch(SeekBar seekBar) {
    // no-op
}

@Override
public void onStopTrackingTouch(SeekBar seekBar) {
    // no-op
}
```

(from Drawable/ScaleClip/app/src/main/java/com/commonsware/android/scaleclip/FragmentBase.java)
Those two drawables based their scaling and clipping on `res/drawable-xdpi/btn_default_normal.9.png`. This is a slightly-modified copy of the default button background, and is a nine-patch PNG file. We will discuss nine-patch PNG files later in this chapter — suffice it to say for now that it is a PNG file with rules about how it should be stretched.
Our scale tab starts off showing the full image:

*Figure 536: ScaleDrawable, Level of 10000*
CUSTOM DRAWABLES

As we start sliding the SeekBar thumb to the left, the image shrinks progressively:

*Figure 537: ScaleDrawable, Level of Approximately 5000*
CUSTOM DRAWABLES

It eventually tends towards the 50% level specified in our android:scaleHeight and android:scaleWidth values:

![ScaleDrawable](image)

*Figure 538: ScaleDrawable, Level of Approximately 100*

Sliding it all the way to the left, though, causes the image to vanish.
The ClipDrawable starts off looking much like the ScaleDrawable:

Figure 539: ClipDrawable, Level of 10000
As we slide the SeekBar to the left, the right side of the image gets clipped:

![Figure 540: ClipDrawable, Level of Approximately 5000](image)

**InsetDrawable**

An InsetDrawable allows you to apply insets on any side (or all sides) of some other drawable resource. The use case cited in the documentation is “This is used when a View needs a background that is smaller than the View’s actual bounds”. However, at the present time, nothing in the Android open source code uses this particular type of resource, or even the Java class.

In principle, though, you could have an XML drawable resource that looked like this:

```xml
<?xml version="1.0" encoding="utf-8"?>
<inset xmlns:android="http://schemas.android.com/apk/res/android"
    android:drawable="@drawable/something_or_another"
    android:insetLeft="20dp"
    android:insetTop="10dp"/>
```

When used as the background for some View, for example, Android would pull in the something_or_another resource and effectively add 20dp of left margin and 10dp...
CUSTOM DRAWABLES

of top margin on the background when calculating its size and drawing it on the screen.

ShapeDrawable

ShapeDrawable is the original approach to implementing limited vector art on Android. It gives you what amounts to a very tiny subset of SVG, for creating simple vector art shapes.

The root element of a ShapeDrawable resource is <shape>, which may have child elements, along with attributes, to configure what gets rendered on the screen when the drawable is applied.

This section will review the elements and attributes available to you, with sample drawables (and screenshots) culled from the Drawable/Shape sample project.

This is a “sampler” project, designed to depict a number of ShapeDrawables. To accomplish this, we will use action bar tabs. Our activity (MainActivity) has a pair of static int arrays, one pointing at string resources to use for tab captions, the other pointing at corresponding drawable resources:

```java
package com.commonsware.android.shape;

import android.app.ActionBar;
import android.app.ActionBar.Tab;
import android.app.ActionBar.TabListener;
import android.app.Activity;
import android.app.FragmentTransaction;
import android.os.Bundle;
import android.widget.ImageView;

public class MainActivity extends Activity implements TabListener {
    private static final int TABS[] = { R.string.solid, R.string.gradient,
                                       R.string.border, R.string.rounded, R.string.ring,
                                       R.string.layered };,
    private static final int DRAWABLES[] = { R.drawable.rectangle,
                                            R.drawable.gradient, R.drawable.border, R.drawable.rounded,
                                            R.drawable.ring, R.drawable.layered };
    private ImageView image=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);
    }
}
```

1726
In `onCreate()`, we toggle the ActionBar into tab-navigation mode, then iterate over the arrays and add one tab per element.

Our layout is an ImageView, named `image`, centered on the screen, taking up 80% of the horizontal space, plus has 20dp of top and bottom margin:
In our activity’s `onTabSelected()` — implemented because the activity is the TabListener for our tabs — we get the position of our tab and fill in the appropriate drawable into the `ImageView`.

Given that, let’s take a look at how to construct a `ShapeDrawable`, along with some sample drawables.

**<shape>**

Your root element, not surprisingly, is `<shape>`.

The primary thing that you will define on the `<shape>` element is the redundantly-named `android:shape` attribute, to define what sort of shape you want:

- line (a shape with no interior)
- oval (also for ellipses)
- rectangle (including rounded rectangles)
- ring (for partially-filled circles)

There are some other attributes available on `<shape>` for a `ring`, which we will examine later in this chapter.

**<solid>**

Your shape will usually require some sort of fill, to say what color goes in the shape. There are two types of fills: solid and gradient.

For a solid fill, add a `<solid>` child element to the `<shape>`, with an `android:color` attribute indicating what color to use. As with most places in Android, this can either be a literal color or a reference to a color resource.
So, for example, we can specify a solid red rectangle as:

```xml
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
        android:shape="rectangle">
    <solid android:color="#FFAA0000"/>
</shape>
```

This gives us the following visual result:

![ShapeDrawable, Solid Red Rectangle](from Drawable/Shape/app/src/main/res/drawable/rectangle.xml)

Your alternative fill is a gradient. The nice thing about gradients with ShapeDrawable is that they are generated at runtime from the specifications in the ShapeDrawable, and therefore will be smooth. Gradients that appear in PNG files and the like, if stretched, will tend to have a banding effect.

Gradient fills are defined via a `<gradient>` child element of the `<shape>` element.
The simplest way to set up a gradient is to use three attributes:

- `android:startColor` and `android:endColor`, to specify the starting and ending colors of the gradient, respectively, and
- `android:angle`, to specify what direction the gradient “flows” in

The angle must be a multiple of 45 degrees. 0 degrees is left-to-right, 90 degrees is bottom-to-top, 180 degrees is right-to-left, and 270 degrees is top-to-bottom.

So, for example, we could change our rectangle to have a gradient fill, from red to blue, with red at the top, via:

```xml
<shape xmlns:android="http://schemas.android.com/apk/res/android"
       android:shape="rectangle">
  <gradient
      android:angle="270"
      android:endColor="#FF0000FF"
      android:startColor="#FFFF0000"/>
</shape>
```

(from Drawable/Shape/app/src/main/res/drawable/gradient.xml)
That gives us:

![ShapeDrawable, Gradient Fill Rectangle](image)

`Figure 542: ShapeDrawable, Gradient Fill Rectangle`

We will examine some other gradient options in the section on rings, [later in this chapter](#).

**<stroke>**

If you want a separate color for a border around your shape, you can use the `<stroke>` element, as a child of the `<shape>` element, to configure one.

There are four attributes that you can declare. The two that you will probably always use are `android:color` (to indicate the color of the border) and `android:width` (to indicate the thickness of the border). By default, using just those two will give you a solid line around the edge of your shape.

If you would prefer a dashed border, you can add in `android:dashWidth` (to indicate how long each dash segment should be) and `android:dashGap` (to indicate how long the gaps between dash segments should be).

So, for example, we can add a dashed border to our gradient rectangle via a suitable
<stroke> element:

```xml
<shape xmlns:android="http://schemas.android.com/apk/res/android"
      android:shape="rectangle">

  <gradient
    android:angle="270"
    android:endColor="#FF0000FF"
    android:startColor="#FFFF0000"/>

  <stroke
    android:width="2dp"
    android:dashGap="4dp"
    android:dashWidth="20dp"
    android:color="#FF000000"/>

</shape>
```

(from Drawable/Shape/app/src/main/res/drawable/border.xml)

This gives us:

![ShapeDrawable, Gradient Fill Rectangle with Dashed Border](image)

*Figure 543: ShapeDrawable, Gradient Fill Rectangle with Dashed Border*
CUSTOM DRAWABLES

<corners>
If we are implementing a rectangle shape, but we really want it to be a rounded rectangle, we can add a <corners> element as a child of the <shape> element. You can specify the radius to apply to the corners, either for all corners (e.g., android:radius), or for individual corners (e.g., android:topLeftRadius). Here, “radius” basically means the size of the circle that should implement the corner, where a radius of 0dp would indicate the default square corner.

So, if we wanted to add rounded corners to our gradient-filled, dash-outlined rectangle, we could use this:

```xml
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
        android:shape="rectangle">
    <gradient
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFF0000"/>
    <stroke
        android:dashGap="4dp"
        android:dashWidth="20dp"
        android:width="2dp"
        android:color="#FF000000"/>
    <corners android:radius="8dp"/>
</shape>
```

(from Drawable/Shape/app/src/main/res/drawable/rounded.xml)
This gives us the following:

![Figure 544: ShapeDrawable, Gradient Fill Rounded Rectangle with Dashed Border](image_url)

**<padding> and <size>**

There are also `<padding>` and `<size>` elements that you can add, that specify padding to put on the various sizes and the overall size of the drawable. More often than not, you would actually handle this on the `ImageView` or other widget that is using your drawable, but if you would prefer to define those things in the drawable itself, you are welcome to do so.

**Put a Ring On It**

Rings are a bit more complicated, in large part because they are not completely filled. With a ring, the “fill” is filling what goes in the ring itself, not the “hole” in the center of the ring. This means that we need to teach Android more about how that “hole” is supposed to be set up.

To do that, we need to provide two pieces of information:

1. How big the inner radius should be, where by “inner radius” Android means
“the radius of the hole”

2. How thick the ring should be

The ring will then be drawn based upon that inner radius and thickness.

You might wonder, “well, where does the size of the actual drawable come into play?” After all, if we specify an inner radius of 20dp and a thickness of 10dp, that would give us an outer radius of 30dp, for a total width of 60dp... regardless of how big the actual drawable is.

And that is completely correct.

However, for both the inner radius and the thickness, you have two choices of how to specify their values:

1. As actual sizes (dimensions or references to dimension resources)
2. As ratios to the overall drawable width (defined by `<size>` or the widget that is using the drawable)

This gives us four total attributes to choose from, to be placed on the `<shape>` element for ring drawables:

1. android:innerRadius
2. android:innerRadiusRatio
3. android:thickness
4. android:thicknessRatio

Therefore, if you want the ring’s size to be based on the size of the drawable, you would use innerRadiusRatio, thicknessRatio, or both.

The other thing about rings is that they are round. Hence, a default linear gradient fill — going from one side of the drawable to another – may not be what you really want. You can control the type of gradient fill to use via the android:type attribute on the `<gradient>` element. There are three possible values:

1. linear (the default behavior)
2. radial, where the gradient starts from the center (or another point that you define) and changes color from that center to the edges
3. sweep, where the gradient revolves clockwise in a circle, starting from whatever android:angle you specify (or 0, meaning “east”, as the default)
So, for example, take a look at the following `ShapeDrawable`:

```xml
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:innerRadiusRatio="3"
    android:shape="ring"
    android:thickness="15dp"
    android:useLevel="false">

    <gradient
        android:centerColor="#4c737373"
        android:endColor="#ff9933CC"
        android:startColor="#4c737373"
        android:type="sweep"/>

</shape>
```

(from `Drawable/Shape/app/src/main/res/drawable/ring.xml`)

Here, we:

- Declare that our shape is a ring
- Indicate that the distance between the inner radius and the outer radius of the ring should be 15dp
- Indicate that there is a 3:1 ratio between the width of the image and the radius of the “hole” in the ring
- Indicate that the fill should be a gradient that sweeps clockwise from the default angle of 0
- Indicate that the first half of the gradient (start to center) should remain a constant color
- Indicate that the second half of the gradient (center to end) should change color from gray to purple

We also have `android:useLevel="false"` in the `<shape>` element. For unknown reasons, this is required for rings but not for other types of shapes.
This gives us:

![Figure 545: ShapeDrawable, Ring with Gradient Fill](image)

**BitmapDrawable**

Having an XML drawable format named BitmapDrawable may seem like a contradiction in terms. However, BitmapDrawable is not an XML representation of a bitmap, but rather an XML representation of operations to perform on an actual bitmap.

The big thing that BitmapDrawable offers is android:tileMode, which turns a single bitmap into a repeating bitmap. The bitmap is tiled, horizontally and vertically, using a tiling mode that you specify.

This is demonstrated in the [Drawable/TileMode](#) sample project.

Our activity’s layout is just a LinearLayout, set to fill the screen:

```xml
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/widget"
```
Our activity populates action bar tabs, where it applies a particular background image to the LinearLayout (known as R.id.widget) based on the selected tab:

```java
package com.commonsware.android.tilemode;

import android.app.ActionBar;
import android.app.ActionBar.Tab;
import android.app.ActionBar.TabListener;
import android.app.Activity;
import android.app.FragmentTransaction;
import android.os.Bundle;
import android.view.View;

public class MainActivity extends Activity implements TabListener {
    private static final int TABS[] = { R.string._default, R.string.clamp,
        R.string.repeat, R.string.mirror};
    private static final int DRAWABLES[] = { R.drawable._default,
        R.drawable.clamp, R.drawable.repeat, R.drawable.mirror};
    private View widget = null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        widget = findViewById(R.id.widget);

        ActionBar bar = getActionBar();
        bar.setNavigationMode(ActionBar.NAVIGATION_MODE_TABS);

        for (int i=0; i < TABS.length; i++) {
            bar.addTab(bar.newTab().setText(getString(TABS[i]))
                .setTabListener(this));
        }
    }

    @Override
    public void onTabSelected(Tab tab, FragmentTransaction ft) {
        widget.setBackgroundResource(DRAWABLES[tab.getPosition()]);
    }
}
```
CUSTOM DRAWABLES

@Override
public void onTabUnselected(Tab tab, FragmentTransaction ft) {
    // no-op
}

@Override
public void onTabReselected(Tab tab, FragmentTransaction ft) {
    // no-op
}

(from Drawable/TileMode/app/src/main/java/com/commonsware/android/tilemode/MainActivity.java)

The res/drawable/_default.xml resource, used on the first tab, is an unadorned BitmapDrawable resource, where our <bitmap> element simply has an android:src attribute pointing to a bitmap to be used for this BitmapDrawable:

<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
    android:src="@drawable/hatch"/>

(from Drawable/TileMode/app/src/main/res/drawable/_default.xml)
Since we have not specified a tile mode, the image is stretched to fill the size of our LinearLayout when serving as its background:

![Figure 546: BitmapDrawable, Without android:tileMode](from Drawable/TileMode/app/src/main/res/drawable/clamp.xml)

The res/drawable/clamp.xml resource, used on the second tab, adds android:tileMode="clamp":

```xml
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
    android:src="@drawable/hatch"
    android:tileMode="clamp"/>
```

(from Drawable/TileMode/app/src/main/res/drawable/clamp.xml)
This causes the right-most column of pixels and the bottom-most row of pixels to be repeated to fill the available space:

![Figure 547: BitmapDrawable, Clamped](image)
Zooming in on the upper-left portion of our LinearLayout demonstrates this:

![Figure 548: Portion of BitmapDrawable, Clamped](from Drawable/TileMode/app/src/main/res/drawable/repeat.xml)

The res/drawable/repeat.xml resource, used on the third tab, employs android:tileMode="repeat":

```xml
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
    android:src="@drawable/hatch"
    android:tileMode="repeat"/>
```

(from Drawable/TileMode/app/src/main/res/drawable/repeat.xml)
Here, the image is simply repeated *in toto* to fill the available space, rather than only its lower-right edges:

*Figure 549: BitmapDrawable, Repeated*
Zooming in on an arbitrary chunk of the LinearLayout shows this effect:

Figure 550: Portion of BitmapDrawable, Repeated

The res/drawable/mirror.xml resource, used on the fourth tab, uses android:tileMode="mirror":

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
    android:src="@drawable/hatch"
    android:tileMode="mirror"/>
```

(from Drawable/TileMode/app/src/main/res/drawable/mirror.xml)
Here, the image is repeated, but alternately mirrored along the repeating axis. So, it is flipped horizontally for each repeat along the horizontal axis, and it is flipped vertically for each repeat along the vertical axis:

![BitmapDrawable, Mirrored](image1)

*Figure 551: BitmapDrawable, Mirrored*

Zooming in on an arbitrary chunk of the `LinearLayout` shows this effect:

![Portion of BitmapDrawable, Mirrored](image2)

*Figure 552: Portion of BitmapDrawable, Mirrored*
Composite Drawables

Let’s say that we wanted to have a pair of ShapeDrawable images, one superimposed on another. Since a single ShapeDrawable defines only one shape, we would need something else to assist with stacking the images.

One possibility would be to use a LayerDrawable, creating three total resources:

1. The first ShapeDrawable, in its own resource file
2. The second ShapeDrawable, in its own resource file
3. The LayerDrawable, holding references to the two ShapeDrawable resources

And this will certainly work. But you have an alternative: put all of it into a single drawable resource.

An android:drawable attribute in an <item> element can be replaced by child elements representing another drawable structure. Hence, rather than having a LayerDrawable with two <item> elements pointing to other drawable resources, we could have those same <item> elements contain the other drawable XML structures, and thereby cut our number of files from 3 to 1.

For example, we could have something like this:

```xml
<?xml version="1.0" encoding="utf-8"?>
<layer-list xmlns:android="http://schemas.android.com/apk/res/android">
  <item>
    <shape android:shape="rectangle">
      <gradient>
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFF0000"/>
      <stroke>
        android:dashGap="4dp"
        android:dashWidth="20dp"
        android:width="2dp"
        android:color="#FF000000"/>
      <corners android:radius="8dp"/>
    </shape>
  </item>
</layer-list>
```
This is a LayerDrawable, layering two ShapeDrawable structures. The first ShapeDrawable is our dash-bordered, gradient-filled, rounded rectangle from before. The second ShapeDrawable is a ring with a simple gradient sweep fill, from black to white.

This gives us:

```
<item>
  <shape>
    <gradient
      android:endColor="#FFFFFF"
      android:startColor="#ff000000"
      android:type="sweep"/>
    <gradient
      android:endColor="#FFFFFFFF"
      android:startColor="#ff000000"
      android:type="sweep"/>
  </shape>
</item>
</layer-list>
```

(from Drawable/Shape/app/src/main/res/drawable/layered.xml)

**Figure 553: Composite Drawable**
Hence, any of the drawable XML structures other than ShapeDrawable can, in their <item> elements, hold any drawable XML structure, instead of pointing to another separate resource.

Android uses this trick as well. For example, the stock ProgressBar image is based off of a LayerDrawable wrapped around three ShapeDrawable structures:

```xml
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project
Licensed under the Apache License, Version 2.0 (the "License");
you may not use this file except in compliance with the License.
You may obtain a copy of the License at
   http://www.apache.org/licenses/LICENSE-2.0
-->
<layer-list xmlns:android="http://schemas.android.com/apk/res/android">
  <item android:id="@android:id/background">
    <shape>
      <corners android:radius="5dip" />
      <gradient
        android:startColor="#ff9d9e9d"
        android:centerColor="#ff5a5d5a"
        android:centerY="0.75"
        android:endColor="#ff747674"
        android:angle="270"
      />
    </shape>
  </item>
  <item android:id="@android:id/secondaryProgress">
    <clip>
      <shape>
        <corners android:radius="5dip" />
        <gradient
          android:startColor="#80ffd300"
          android:centerColor="#80ff6b00"
          android:centerY="0.75"
          android:endColor="#a0ffcb00"
        />
      </shape>
    </clip>
  </item>
</layer-list>
```
We will get into how this works with a `ProgressBar` in a separate chapter.

**A Stitch In Time Saves Nine**

Most of the types of non-traditional drawable resources you can create in Android are described in XML... but not all.

As you read through the Android documentation, you no doubt ran into references to “nine-patch” or “9-patch” and wondered what Android had to do with quilting. Rest assured, you will not need to take up needlework to be an effective Android developer.

If, however, you are looking to create backgrounds for resizable widgets, like a `Button`, you may wish to work with nine-patch images.

As the Android documentation states, a nine-patch is “a PNG image in which you define stretchable sections that Android will resize to fit the object at display time to accommodate variable sized sections, such as text strings”. By using a specially-created PNG file, Android can avoid trying to use vector-based formats (e.g., `ShapeDrawable`) and their associated overhead when trying to create a background.
at runtime. Yet, at the same time, Android can still resize the background to handle whatever you want to put inside of it, such as the text of a Button.

In this section, we will cover some of the basics of nine-patch graphics, including how to customize and apply them to your own Android layouts.

Note that nine-patch PNG files, while they provide stretching rules, are still somewhat dependent upon density. You may wish to have different versions of your nine-patch PNG files for different densities, and therefore these images should be put in density-specific resource directories (e.g., res/drawable-hdpi/).

The Name and the Border

Nine-patch graphics are PNG files whose names end in .9.png. This means they can be edited using normal graphics tools, but Android knows to apply nine-patch rules to their use.

What makes a nine-patch graphic different than an ordinary PNG is a one-pixel-wide border surrounding the image. When drawn, Android will remove that border, showing only the stretched rendition of what lies inside the border. The border is used as a control channel, providing instructions to Android for how to deal with stretching the image to fit its contents.

Padding and the Box

Along the right and bottom sides, you can draw one-pixel-wide black lines to indicate the “padding box”. Android will stretch the image such that the contents of the widget will fit inside that padding box.
For example, suppose we are using a nine-patch as the background of a Button. When you set the text to appear in the button (e.g., “Hello, world!”), Android will compute the size of that text, in terms of width and height in pixels. Then, it will stretch the nine-patch image such that the text will reside inside the padding box. What lies outside the padding box forms the border of the button, typically a rounded rectangle of some form.

Figure 554: The padding box, as shown by a set of control lines to the right and bottom of the stretchable image

Stretch Zones

To tell Android where on the image to actually do the stretching, draw one-pixel-wide black lines on the top and left sides of the image. Android will scale the graphic only in those areas — areas outside the stretch zones are not stretched.
Perhaps the most common pattern is the center-stretch, where the middle portions of the image on both axes are considered stretchable, but the edges are not:

![Stretch Zones Diagram](image)

*Figure 555: The stretch zones, as shown by a set of control lines to the left and top of the stretchable image*

Here, the stretch zones will be stretched just enough for the contents to fit in the padding box. The edges of the graphic are left unstretched.

Some additional rules to bear in mind:

1. If you have multiple discrete stretch zones along an axis (e.g., two zones separated by whitespace), Android will stretch both of them but keep them in their current proportions. So, if the first zone is twice as wide as the second zone in the original graphic, the first zone will be twice as wide as the second zone in the stretched graphic.
2. If you leave out the control lines for the padding box, it is assumed that the padding box and the stretch zones are one and the same.

**Tooling**

Android Studio has a nine-patch PNG editor, based on the now-discontinued

**CUSTOM DRAWABLES**

Perhaps the most common pattern is the center-stretch, where the middle portions of the image on both axes are considered stretchable, but the edges are not:

![Stretch Zones Diagram](image)

*Figure 555: The stretch zones, as shown by a set of control lines to the left and top of the stretchable image*

Here, the stretch zones will be stretched just enough for the contents to fit in the padding box. The edges of the graphic are left unstretched.

Some additional rules to bear in mind:

1. If you have multiple discrete stretch zones along an axis (e.g., two zones separated by whitespace), Android will stretch both of them but keep them in their current proportions. So, if the first zone is twice as wide as the second zone in the original graphic, the first zone will be twice as wide as the second zone in the stretched graphic.
2. If you leave out the control lines for the padding box, it is assumed that the padding box and the stretch zones are one and the same.

**Tooling**

Android Studio has a nine-patch PNG editor, based on the now-discontinued
draw9patch utility used previously by Android app developers. To work with this tool:

- If you have a regular PNG that you want to convert into a nine-patch PNG, right-click over it and choose “Create 9-patch file” from the context menu
- If you already have a nine-patch PNG (with the .9.png extension), or you created one using “Create 9-patch file”, just double-click on the image to bring it up in a nine-patch editor

![Android Studio, Editing a Nine-Patch PNG](image)

While a regular graphics editor would allow you to draw any color on any pixel, the nine-patch editor limits you to drawing or erasing pixels in the control area:

- Set a pixel (making it black) by clicking on it
- Clear a pixel by shift-clicking on it

If you attempt to draw inside the main image area itself, you will be blocked.

On the right, you will see samples of the image in various stretched sizes, so you can see the impact as you change the stretchable zones and padding box.
CUSTOM DRAWABLES

While this is convenient for working with the nine-patch nature of the image, you will still need some other graphics editor to create or modify the body of the image itself. For example, the image shown above, from the Drawable/NinePatch project, is a modified version of a nine-patch graphic from the SDK’s ApiDemos, where the GIMP was used to add the neon green stripe across the bottom portion of the image.

Using Nine-Patch Images

Nine-patch images are most commonly used as backgrounds, as illustrated by the following layout from the Drawable/NinePatch sample project:

```xml
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <TableLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:stretchColumns="1">
        <TableRow
            android:layout_width="match_parent"
            android:layout_height="wrap_content">
            <TextView
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:layout_gravity="center_vertical"
                android:text="Horizontal:" />
            <SeekBar
                android:id="@+id/horizontal"
                android:layout_width="match_parent"
                android:layout_height="wrap_content" />
        </TableRow>
        <TableRow
            android:layout_width="match_parent"
            android:layout_height="wrap_content">
            <TextView
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:layout_gravity="center_vertical"
                android:text="Vertical:" />
        </TableRow>
    </TableLayout>
</LinearLayout>
```
Here, we have two SeekBar widgets, labeled for the horizontal and vertical axes, plus a Button set up with our nine-patch graphic as its background (android:background = "@drawable/button").

The NinePatchDemo activity then uses the two SeekBar widgets to let the user control how large the button should be drawn on-screen, starting from an initial size of 64px square:

```java
package com.commonsware.android.ninepatch;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.LinearLayout;
import android.widget.SeekBar;

public class NinePatchDemo extends Activity {
  SeekBar horizontal=null;
  SeekBar vertical=null;
  View thingToResize=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
  }

  public void onResize() {
    // change size of button
  }

  public void onHorizontalChange(int level) {
    horizontal.setProgress(level);
  }

  public void onVerticalChange(int level) {
    vertical.setProgress(level);
  }
}
```
thingToResize = findViewById(R.id.resize);
horizontal = (SeekBar) findViewById(R.id.horizontal);
vertical = (SeekBar) findViewById(R.id.vertical);
horizontal.setMax(144); // 240 less 96 starting size
vertical.setMax(144); // keep it square @ max
horizontal.setOnSeekBarChangeListener(h);
vertical.setOnSeekBarChangeListener(v);
}
SeekBar.OnSeekBarChangeListener h = new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar,
        int progress, boolean fromTouch) {
        ViewGroup.LayoutParams old = thingToResize.getLayoutParams();
        ViewGroup.LayoutParams current = new LinearLayout.LayoutParams(64 + progress,
            old.height);

        thingToResize.setLayoutParams(current);
    }

    public void onStartTrackingTouch(SeekBar seekBar) {
        // unused
    }

    public void onStopTrackingTouch(SeekBar seekBar) {
        // unused
    }
};
SeekBar.OnSeekBarChangeListener v = new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar,
        int progress, boolean fromTouch) {
        ViewGroup.LayoutParams old = thingToResize.getLayoutParams();
        ViewGroup.LayoutParams current = new LinearLayout.LayoutParams(old.width,
            64 + progress);

        thingToResize.setLayoutParams(current);
    }

    public void onStartTrackingTouch(SeekBar seekBar) {
        // unused
    }

    public void onStopTrackingTouch(SeekBar seekBar) {
        // unused
    }
};

(from Drawable/NinePatch/app/src/main/java/com/commonsware/android/ninepatch/NinePatchDemo.java)
CUSTOM DRAWABLES

The result is an application that can be used much like the right pane of `draw9patch`, to see how the nine-patch graphic looks on an actual device or emulator in various sizes:

Figure 557: The NinePatch sample project, in its initial state
Figure 558: The NinePatch sample project, after making it bigger horizontally
Figure 559: The NinePatch sample application, after making it bigger in both dimensions
One of Google’s most popular services — after search, of course – is Google Maps, where you can find everything from the nearest pizza parlor to directions from New York City to San Francisco (only 2,905 miles!) to street views and satellite imagery.

Android has had mapping capability from the beginning, with an API available to us as developers to bake maps into our apps. However, as we will see shortly, that original API was getting a bit stale.

In December 2012, Google released a long-awaited update to the mapping capabilities available to Android app developers. The original mapping solution, now known as the Maps V1, worked but had serious limitations. The new mapping solution, known as Maps V2, offers greater power and greater ease of handling common situations, though it too has its rough edges.

**Prerequisites**

Understanding this chapter requires that you have read the core chapters, along with the chapter on drawables. Also, one of the samples involves location tracking, and another of the samples involves the use of the animator framework.

One section involves the use of Picasso, covered in the chapter on Internet access.

This chapter also makes the occasional reference back to Maps V1 for comparisons, mostly for the benefit of developers already familiar with Maps V1 and looking to migrate to Maps V2. However, prior experience with Maps V1 is not necessary to understand this chapter.
A Brief History of Mapping on Android

Back in the dawn of Android, we were given the Maps SDK add-on. This would allow us to load a firmware-hosted mapping library into our applications, then embed maps into our activities, by means of a `MapView` widget.

And it worked.

More importantly, from the standpoint of users, the results from our apps were visually indistinguishable from the built-in Maps application available on devices that had the Maps SDK add-on.

This was the case through most of 2009. Eventually, though, the Google Maps team wanted to update the Maps application... but, for whatever reason, the decision was made to not update the Maps SDK add-on as well. At this point, the Google Maps team effectively forked the Maps SDK add-on, causing the Maps application to diverge from what other Android app developers could deliver. Over time, this feature gap became quite pronounced.

The release of Android 3.0 in early 2011 compounded the problems. Now, we needed to consider using fragments to help manage our code and deliver solutions to all screen sizes. Alas, while we could add maps to our fragments, we could only do so on API Level 11 or higher — the fragments backport from the Android Support package did not work with the Maps SDK add-on.

The release of Maps V2 helped all of this significantly. Now we have proper map support for native and backported versions of the fragment framework. We also have a look and feel that is closer to what the Maps application itself supports. While we still cannot reach feature parity with the Maps application, our SDK apps can at least look like they belong on the same device as the Maps application.

More importantly, as of the time of this writing, Maps V1 is no longer an option for new developers. Those who already have Maps V1 API keys can use Maps V1, but no new Maps V1 API keys are being offered. That leaves you with either using Maps V2 or some alternative mapping solution.

Where You Can Use Maps V2

Many devices will be able to use Maps V2... but not all. Notably:
• Devices need to support OpenGL ES 2.0+, to handle the new vector-based tiles that Maps V2 uses. Over 99% of Android devices in use today that support the Play Store (or its “Android Market” predecessor) also support OpenGL ES 2.0+.
• Devices will need an update to the Play Services Framework that accompanies the Play Store. Devices that do not have the Play Store — either because they are forever stuck on the old Android Market or, like the Kindle Fire, never had Play Store support in the first place — will be unable to use Maps V2.

Later in this chapter, we will look at other mapping libraries that you could use instead of either of Google’s mapping solutions.

Licensing Terms for Maps V2

As with the original Maps SDK add-on, to use Maps V2, you must agree to a terms of service agreement to be authorized to embed Google Maps within your application. If you intend to use Maps V2, you should review these terms closely, as they place many restrictions on developers. The most notorious of these is that you cannot use Maps V2 to create an application that offers “real time navigation or route guidance, including but not limited to turn-by-turn route guidance that is synchronized to the position of a user’s sensor-enabled device.”

If you find these terms to be an issue for your application, you may need to consider alternative mapping solutions.

What You Need to Start

If you wish to use Maps V2 in one or more of your Android applications, this section will outline what you need to get started.

Your Signing Key Fingerprint(s)

As with the legacy Maps SDK add-on, you will need fingerprints of your app signing keys, to tie your apps to your Google account and the API keys you will be generating. However, unlike the legacy Maps SDK add-on, the fingerprints you will be using will be created using the SHA-1 hash algorithm, rather than MD5.

First, you will need to know where the keystore is for your signing key. For a
production keystore that you created yourself for your production apps, you should know where it is located already. For the debug keystore, used by default during development, the location is dependent upon operating system:

- macOS and Linux: `~/.android/debug.keystore`
- Windows XP: `C:\Documents and Settings\$USER\.android\debug.keystore`
- Windows Vista and Windows 7: `C:\Users\$USER\.android\debug.keystore`

(where $USER is your Windows user name)

You will then need to run the `keytool` command, to dump information related to this keystore. The `keytool` command is in your Java SDK, not the Android SDK. You will need to run this from a command line (e.g., Command Prompt in Windows). The specific command to run is:

```
keytool -list -v -keystore ... -alias androiddebugkey -storepass android -keypass android
```

where the `...` is replaced by the path to your debug keystore, enclosed in quotation marks if the path contains spaces. For your production keystore, you would supply your own alias and passwords.

This should emit output akin to:

```
Alias name: androiddebugkey
Creation date: Aug 7, 2011
Entry type: PrivateKeyEntry
Certificate chain length: 1
Certificate<1>:
  Owner: CN=Android Debug, O=Android, C=US
  Issuer: CN=Android Debug, O=Android, C=US
  Serial number: 4e3f2684
  Valid from: Sun Aug 07 19:57:56 EDT 2011 until: Tue Jul 30 19:57:56 EDT 2041
  Certificate fingerprints:
    Signature algorithm name: SHA1withRSA
    Version: 3
```

You will need to make note of the SHA1 entry (see third line from the bottom of the above sample).
**Your Google Account**

To sign up for an API key, you need a Google account. Ideally, this account would be the same one you intend to use for submitting apps to the Play Store (if, indeed, you intend to do so).

**Your API Key**

Given that you are logged into the aforementioned Google account, you can visit the Google Cloud Console to request access to the Maps V2 API. They have a tendency to keep changing this set of pages, but these instructions were good as of late February 2014:

- Create a project via the “Create project” option, if you have not done so already for something else (e.g., GCM)
- Open your project, then select “APIs & auth” from the left navigation bar, and in there select “APIs”
- Sift through the various APIs until you find “Google Maps Android API v2”, then toggle that on
- Agree to the Terms of Service that appears when you try to toggle on Maps V2 access
- Click “Credentials” in the left navigation bar
- Click the “CREATE NEW KEY” button
- In the popup dialog, choose “Android key”
- In the fields that appear once you chose “Android key”, fill in your app’s package name and your SHA1 fingerprint, then click the “Create” button

This will give you an “API key” that you will need for your application.

If you wish to have more than one app use Maps V2, you can click “Edit allowed Android applications” for a key, to return to the dialog where you can paste in another SHA1 fingerprint and package name, separated by a semicolon. Or, if you prefer, you can create new keys for each application.

For apps that are in (or going to) production, you will need to supply both the debug and production SHA1 fingerprints with your package name. By doing this on the same key, you will use the same API key string for both debug and production builds, which simplifies things a fair bit over the separate API keys you would have used with the legacy Maps SDK add-on.

Also note that a single API key seems to only support a few fingerprint/package
pairs. If you try adding a new pair, and the form ignores you, you will need to set up a separate API key for additional pairs.

**The Play Services Library**

You also need to set up the Google Play Services library for use with your app.

While this used to be published via a separate “Google Repository” that you had to download to your development machine, nowadays, it is part of Google’s overall public Maven repository, the one that google() points to in your build.gradle files. Most likely, your project is already set up to use this repository.

If so, all you need to do is add a dependency on com.google.android.gms:play-services-maps for some likely version (e.g., com.google.android.gms:play-services-maps:15.0.1) to your dependencies closure.

Note, though, that starting with version 10.x, the minSdkVersion imposed by the Play Services libraries is 14. If your desired minSdkVersion is lower than that, you will need to remain on older versions of the Play Services libraries.

**The Book Samples… And You!**

If you wish to try to run the book samples outlined in this chapter, you will need to replace the Maps V2 API key in the manifest with your own.

**Setting Up a Basic Map**

With that preparation work completed, now you can start working on projects that use the Maps V2 API. In this section, we will review the MapsV2/Basic sample project, which simply brings up a Maps V2 map of the world.

**The Dependency**

Android Studio users need an entry in their top-level dependencies closure to pull in the Play Services SDK artifact:

```groovy
dependencies {
    implementation 'com.android.support:support-v4:27.1.1'
    implementation 'com.google.android.gms:play-services-maps:15.0.1'
}
```
The Project Setup and the Manifest

This project uses Maps V2, and so it has a reference to that library project.

Our manifest file is fairly traditional, though there are a number of elements in it that are required by Maps V2:

```xml
<?xml version="1.0" encoding="utf-8"?>
<manifest
    package="com.commonsware.android.mapsv2.basic"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-permission
        android:name="android.permission.WRITE_EXTERNAL_STORAGE"
        android:maxSdkVersion="22" />

    <uses-feature
        android:glEsVersion="0x00020000"
        android:required="false" />

    <application
        android:allowBackup="false"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name="MainActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN" />
                <category android:name="android.intent.category.LAUNCHER" />
            </intent-filter>
        </activity>

        <meta-data
            android:name="com.google.android.maps.v2.API_KEY"
            android:value="AIzaSyC4iyT46cB00IdKGCy5EmAxKSUcO20y8" />

        <meta-data
            android:name="com.google.android.gms.version"
            android:value="@integer/google_play_services_version" />
    </application>
</manifest>
```
Specifically:

- We need the WRITE_EXTERNAL_STORAGE permissions, but only on Android 5.1 and below, so we can use android:maxSdkVersion="22" to only request that permission on older devices.
- We need a <meta-data> element, with a name of com.google.android.maps.v2.API_KEY, whose value is the API key we got from the Google APIs Console for use with this particular package name.
- We can have a second <meta-data> element, with a name of com.google.android.gms.version, with a value of the @integer/google_play_services_version (an integer resource supplied by the Play Services SDK library project). Starting with version 8.1.0 of the Maps V2 library, this element is not essential, as it will be added automatically to our manifest via the manifest merger process. However, code written for older versions of Maps V2 than 8.1.0 will need the element, and there is no particular harm in having it.

We also should include a <uses-feature> element for OpenGL ES 2.0. If your app absolutely must be able to run Maps V2, have android:required="true" (or drop the android:required attribute entirely, as true is the default), which will force devices to have OpenGL ES 2.0 to run your app. If your app will gracefully degrade for devices incapable of running Maps V2, use android:required="false", as is shown in the sample.

Beyond those items, everything else in this project is based on what the app needs, more so than what Maps V2 needs. Note, though, that the Play Services SDK library project will add additional items to our manifest, notably requests for a few other permissions, like INTERNET. Also note that we used to need to define and use a custom permission, based upon our app's package name and ending in MAPS_RECEIVE. This is not required as of Play Services 3.1.59 and the “rev 8” release of the Play Services SDK.

**The Play Services Detection**

In the fullness of time, all devices that are capable of using Maps V2 will already have the on-device portion of this logic, known as the “Google Play services” app.
However, it is entirely possible, in the short term, that you will encounter devices that are capable of using Maps V2 (e.g., they have OpenGL ES 2.0 or higher), but do not have the “Google Play services” app from the Play Store, and therefore you cannot actually use Maps V2 in your app.

This is a departure from the Maps V1 approach, where either the device shipped with maps capability, or it did not, and nothing (legally) could be done to change that state.

To determine whether or not the Maps V2 API is available to you, the best option is to call the isGooglePlayServicesAvailable() static method on the GooglePlayServicesUtil utility class supplied by the Play Services library. This will return an int, with a value of ConnectionResult.SUCCESS if Maps V2 can be used right away.

Actually assisting the user to get Maps V2 set up all the way is conceivable but is also bug-riddled and annoying. The MapsV2/Basic sample app has an AbstractMapActivity base class that is designed to hide most of this annoyance from you. If you wish to know the details of how this works, we will cover it later in this chapter.

The Fragment and Activity

Our main activity — MainActivity — extends from the aforementioned AbstractMapActivity and simply overrides onCreate(), as most activities do:

```java
package com.commonsware.android.mapsv2.basic;

import android.os.Bundle;

public class MainActivity extends AbstractMapActivity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (readyToGo()) {
            setContentView(R.layout.activity_main);
        }
    }
}
```

(from MapsV2/Basic/app/src/main/java/com/commonsware/android/mapsv2/basic/MainActivity.java)
We call `setContentView()` to load up the `activity_main` layout resource:

```xml
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/map"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  class="com.google.android.gms.maps.SupportMapFragment"/>
```

(from MapsV2/Basic/app/src/main/res/layout/activity_main.xml)

That resource, in turn, has a `<fragment>` element pointing to a `com.google.android.gms.maps.SupportMapFragment` class supplied by the Play Services library. This is a fragment that knows how to display a Maps V2 map. There is a corresponding `com.google.android.gms.maps.MapFragment` class based on the native `Fragment` class.

You will notice, though, that we only call `setContentView()` if a `readyToGo()` method returns true. The `readyToGo()` method is supplied by the `AbstractMapActivity` class and returns true if we are safe to go ahead and use Maps V2, false otherwise. In the false case, `AbstractMapActivity` will be taking care of trying to get Maps V2 going, and we need do nothing further.
The Result

When you run the app, assuming that Maps V2 is ready for use, you will get a basic map showing a good-sized chunk of the planet:

![Maps V2 Map, as Initially Viewed](image)

If your Maps V2 API key is incorrect, or you do not have this app's package name set up for that key in the Google APIs Console, you will get an “Authorization failure” error message in Logcat, and you will get a blank map, akin to the behavior seen in Maps V1 when you had an invalid android:apiKey attribute on the MapView.

Playing with the Map

Showing a map of a good-sized chunk of the planet is nice, and it is entirely possible that is precisely what you wanted to show the user. If, on the other hand, you wanted to show the user something else — another location, a closer look, etc. — you will need to further configure your map, via a GoogleMap object.

To see how this is done, take a look at the MapsV2/NooYawk sample application. This is a clone of MapsV2/Basic that adds in logic to center and zoom the map over a
portion of New York City.

The `onCreate()` method of the revised `MapActivity` is now a bit more involved:

```java
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    if (readyToGo()) {
        setContentView(R.layout.activity_main);
        SupportMapFragment mapFrag = (SupportMapFragment) getSupportFragmentManager().findFragmentById(R.id.map);
        if (savedInstanceState == null) {
            mapFrag.getMapAsync(this);
        }
    }
}
```

(from MapsV2/NooYawk/app/src/main/java/com/commonsware/android/mapsv2/nooyawk/MainActivity.java)

After calling `setContentView()`, we can retrieve our `SupportMapFragment` via `findFragmentById()`, no different than any other static fragment.

Then, if `savedInstanceState` is null — meaning that the activity is not being recreated, but instead is being created from scratch — we call `getMapAsync()` on the `SupportMapFragment`. This triggers some asynchronous work to set up a `GoogleMap` object. `getMapAsync()` takes an implementation of `OnMapReadyCallback` as a parameter. In this case, `OnMapReadyCallback` is implemented on the activity itself.

That `GoogleMap` object will then be delivered to us in `onMapReady()`. Most of our work in configuring the map will be accomplished by calling methods on this `GoogleMap` object:

```java
@Override
public void onMapReady(GoogleMap map) {
    CameraUpdate center = CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044, -73.98180484771729));
    CameraUpdate zoom = CameraUpdateFactory.zoomTo(15);
    map.moveCamera(center);
    map.animateCamera(zoom);
}
```

(from MapsV2/NooYawk/app/src/main/java/com/commonsware/android/mapsv2/nooyawk/MainActivity.java)

To change where the map is centered, we can create a `CameraUpdate` object from the
CameraUpdateFactory ("camera" in this case referring to the position of the user's virtual eyes with respect to the surface of the Earth). The newLatLng() factory method on CameraUpdateFactory will give us a CameraUpdate object that can re-center the map over a supplied latitude and longitude. Those coordinates are encapsulated in a LatLng object and are maintained as decimal degrees as Java float or double values (as opposed to the Maps V1 GeoPoint, which used integer microdegrees).

To change the zoom level of the map, we need another CameraUpdate object, this time from the zoomTo() factory method on CameraUpdateFactory. As with Maps V1, the zoom levels start at 1 and zoom in by powers of two. As you will see, a value of 15 gives you a nice block-level view of a city like New York City.

To actually apply these changes to the map, we have two methods on GoogleMap:

1. moveCamera() will perform a "smash cut" and immediately change the map based upon the supplied CameraUpdate
2. animateCamera() will smoothly animate the map from its original state to the new state supplied by the CameraUpdate
In our case, we immediately shift to the proper position, but then zoom in from the default zoom level to 15, giving us a map centered over Columbus Circle, in the southwest corner of Central Park in Manhattan:

![Figure 561: Maps V2 Centered Over Columbus Circle, New York City](image)

Note that you might want to do both actions simultaneously, rather than have one be animated and one not as in this sample. In that case, you can manually create a CameraPosition object that describes the desired center, zoom, etc., then use the newCameraPosition() method on CameraUpdateFactory to get a CameraUpdate instance that will apply all of those changes.

### Map Tiles

The map, by default, shows the normal tile set. setMapType() on the GoogleMap allows you to switch to satellite, hybrid (satellite view plus place labels), or terrain tile sets.

### Placing Simple Markers

For markers — push-pins and the like — you simply hand markers to the GoogleMap
for display, as is illustrated in the MapsV2/Markers sample application. This is a clone of MapsV2/NooYawk, with four markers for four landmarks within Manhattan.

Our onCreate() method on MainActivity now always invokes getMapAsync(), not just when the activity is first created. However, we still check savedInstanceState and set a new needsInit boolean data member to true if savedInstanceState is null:

```java
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    if (readyToGo()) {
        setContentView(R.layout.activity_main);
        SupportMapFragment mapFrag =
            (SupportMapFragment)getSupportFragmentManager().findFragmentById(R.id.map);
        if (savedInstanceState == null) {
            needsInit = true;
        }
        mapFrag.getMapAsync(this);
    }
}
```

(from MapsV2/Markers/app/src/main/java/com/commonsware/android/mapsv2/markers/MainActivity.java)

Our onMapReady() method performs the camera adjustments if needsInit is true. It also has four additional statements – calls to a private addMarker() method to define the four landmarks:

```java
@Override
public void onMapReady(GoogleMap map) {
    if (needsInit) {
        CameraUpdate center =
            CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
                                                        -73.98180484771729));
        CameraUpdate zoom = CameraUpdateFactory.zoomTo(15);
        map.moveCamera(center);
        map.animateCamera(zoom);
    }
    addMarker(map, 40.748963847316034, -73.96807193756104,
              R.string.un, R.string.united_nations);
    addMarker(map, 40.76866299974387, -73.98268461227417,
              R.string.lincoln_center,
              R.string.lincoln_center_snippet);
    addMarker(map, 40.765136435316755, -73.97989511489868,
              R.string.washington_monument,
              R.string.washington_monument_snippet);
    addMarker(map, 40.641553738000001, -73.981647460000001,
              R.string.union_station,
              R.string.union_station_snippet);
}
```

1775
The `addMarker()` method on our `MainActivity` adds markers by creating a `MarkerOptions` object and passing it to the `addMarker()` on `GoogleMap`. `MarkerOptions` offers a so-called “fluent” interface, with a series of methods to affect one aspect of the `MarkerOptions`, each of which returns the `MarkerOptions` object itself. That way, configuring a `MarkerOptions` is a chained series of method calls:

```java
private void addMarker(GoogleMap map, double lat, double lon,
                        int title, int snippet) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon)).
                       title(getString(title)).
                       snippet(getString(snippet)));
}
```

Here, we:

- Set the `position()` of the marker, in the form of another `LatLng` object
- Set the `title()` and `snippet()` of the marker to be a pair of strings loaded from string resources

We will see other methods available on `MarkerOptions` in upcoming sections of this chapter.

`addMarker()` on `GoogleMap` returns an actual `Marker` object, which we could hold onto to change certain aspects of it later on (e.g., its title). In the case of this sample, we ignore this.

Now, you may be wondering why we set up the markers on every `onMapReady()` invocation, not just in the `needsInit` block. That is because while a `SupportMapFragment` retains its camera information (center, zoom, etc.) on a configuration change, it does not retain its markers. Hence, we need to re-establish the markers in all calls to `onCreate()`, not just the very first one.
With no other changes, we get a version of the map that shows markers at our designated locations:

*Figure 562: Maps V2 with Two Markers*
Initially, we only see two markers, as the other two are outside the current center position and zoom level of the map. If the user changes the center or zoom, markers will come and go as needed:

![Figure 563: Maps V2 with All Four Markers](image)

We do not need to worry about managing the markers ourselves, so long as the GoogleMap performance is adequate. It is likely that dumping 10,000 markers into a GoogleMap will still result in sluggish responses, though, so you may need to add and remove markers yourself based upon what portion of the world the user happens to be examining in the map at the moment.

**Seeing All the Markers**

When you add markers to a map, there is no guarantee that the markers will be visible given the map’s current center position and zoom level. In fact, it is entirely possible that you add a bunch of markers and *none* are visible, so the user may not realize that the markers were added.

There is a way that you can center and zoom the map to show some set of markers, based on their positions. You get to choose the markers: all of them, the four nearest
markers, etc.

We can see how this works in the MapsV2/Bounds sample application. This is a clone of MapsV2/Markers from the previous section, with reworked code to show all four markers when the map is first displayed.

The key to making this work is a LatLngBounds object. This represents a bounding box that contains all LatLng locations handed to the LatLngBounds. To build up a LatLngBounds, you can use the LatLngBounds.Builder class. So, our revised MainActivity has a LatLngBounds.Builder private data member:

```java
private LatLngBounds.Builder builder = new LatLngBounds.Builder();
```

Our revised addMarker() method adds the LatLng values from our markers as they are added to the map:

```java
private void addMarker(GoogleMap map, double lat, double lon,
                        int title, int snippet) {
    Marker marker =
        map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                      .title(getString(title))
                      .snippet(getString(snippet)));

    builder.include(marker.getPosition());
}
```

Finally, the revised onMapReady() moves the CameraUpdateFactory work until after all four of the addMarker() calls and changes it a bit:

```java
@Override
public void onMapReady(final GoogleMap map) {
    addMarker(map, 40.748963847316034, -73.96807193756104,
               R.string.un, R.string.united_nations);
    addMarker(map, 40.76866299974387, -73.98268461227417,
               R.string.lincoln_center,
               R.string.lincoln_center_snippet);
    addMarker(map, 40.765136435316755, -73.97989511489868,
               R.string.carnegie_hall,
               R.string.practice_x3);
    addMarker(map, 40.70686417491799, -74.01572942733765,
               R.string.downtown_club,
               R.string.heisman_trophy);

    if (needsInit) {
```
Specifically, we:

- Ask the LatLngBounds.Builder to build() the LatLngBounds
- Pass that to the newLatLngBounds() method on CameraUpdateFactory, along with an inset value in pixels (all LatLng locations will be that many pixels in from the edges, or more)
- Use moveCamera() to center and zoom the map based upon the resulting CameraUpdate

All of this is done in a Runnable which we post() to a View (here, the FrameLayout of our activity supplied by Android as android.R.id.content). GoogleMap cannot ensure that all of our markers are visible until it knows how big the map is, and that is not known until the map is rendered to the screen. post() will add our work to the end of the main application thread’s work queue. The Runnable will not be run until after the map is on the screen, at which time the CameraUpdate can work.
Flattening and Rotating Markers

Markers, by default, appear to be “push pins” pressed into the surface of the map. This is not necessarily obvious with the default top-down perspective of the map camera. But, if you use a two-finger vertical swiping gesture, you can change the camera tilt, and that will illustrate the “push pin” effect a bit better:

![Figure 564: Maps V2 with Markers, Viewed on a Tilt](image)

However, you have options for flat markers and rotated markers.
A flat marker is one that is flat on the map. In other words, rather than theoretically rising out of the Z axis of the map, the marker is kept on the X-Y plane:

Figure 565: Maps V2 with Markers, One Normal, One Flat
It is also possible to rotate a marker. The flat marker in the previous screenshot is rotated 90 degrees from its normal “bulb on the north side” orientation. The following screenshot shows another flat marker, rotated 270 degrees from normal:

![Figure 566: Maps V2 with Markers, Flat and Rotated](image)

These features can be handy for providing pointers in a particular direction, such as indicating not only the location to make a turn, but what direction to turn at that location.

These capabilities are courtesy of `flat()` and `rotation()` methods on `MarkerOptions`, plus corresponding getters and setters on `Marker` itself. To see how this works, let’s examine the `MapsV2/FlatMarkers` sample application. This is a clone of `MapsV2/Markers`, with markers applied using different values for `flat()` and `rotation()`.

Specifically, our own `addMarker()` helper method now takes and applies a boolean parameter for `flat` (true means it is flat, false means normal behavior), as well as a float parameter for `rotation` (a value between 0 and 360 for the rotation off the default in degrees):

```java
private void addMarker(GoogleMap map, double lat, double lon,
                       int title, int snippet, boolean flat,
                       float rotation) {
```
Mapping with Maps V2

```java
map.addMarker(new MarkerOptions().position(newLatLng(lat, lon)).
            .title(getString(title)).
            .snippet(getString(snippet)).
            .flat(flat).rotation(rotation));
```

(from MapsV2/FlatMarkers/app/src/main/java/com/commonsware/android/mapsV2/flatmarkers/MainActivity.java)

When we call `addMarker()`, we supply corresponding values:

```java
addMarker(map, 40.748963847316034, -73.96807193756104,
          R.string.un, R.string.united_nations, false, 180);
addMarker(map, 40.76866299974387, -73.98268461227417,
          R.string.lincoln_center,
          R.string.lincoln_center_snippet, false, 0);
addMarker(map, 40.765136435316755, -73.97989511489868,
          R.string.carnegie_hall, R.string.practice_x3, true, 90);
addMarker(map, 40.70686417491799, -74.01572942733765,
          R.string.downtown_club, R.string.heisman_trophy, true,
          270);
```

(from MapsV2/FlatMarkers/app/src/main/java/com/commonsware/android/mapsV2/flatmarkers/MainActivity.java)
Sprucing Up Your “Info Windows”

If the user taps on one of the markers from the preceding sample, Android will automatically display a popup, known as an “info window”:

![Figure 567: Maps V2 with Default Info Window](image)

You can tailor that “info window” if desired, either replacing just the interior portion (leaving the bounding border with its caret intact) or replacing the entire window. However, in the interests of memory conservation, you do not hand new View widgets to the MarkerOptions object. Instead, you can provide an adapter that will be called when info windows (or their contents) are required.

To see how this works, we can examine the MapsV2/Popups sample application. This is a clone of MapsV2/Markers, where we are using our own layout file for the contents of the info windows, from the popup.xml layout resource:

```xml
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
android:layout_width="match_parent"
android:layout_height="wrap_content"
android:orientation="horizontal">
```

1785
Here, we will show the title and snippet in our own chosen font size and weight, plus show the launcher icon on the left.

To use this layout, we must create an `InfoWindowAdapter` implementation — in the case of this sample project, that is found in the `PopupAdapter` class:

```java
package com.commonsware.android.mapsv2.popups;

import android.annotation.SuppressLint;
import android.view.LayoutInflater;
import android.view.View;
import android.widget.TextView;
import com.google.android.gms.maps.GoogleMap.InfoWindowAdapter;
import com.google.android.gms.maps.model.Marker;
```
When an info window is to be displayed, Android will first call `getInfoWindow()` on our `InfoWindowAdapter`, passing in the `Marker` whose info window is needed. If we return a `View` here, that will be used for the entire info window. If, instead, we return `null`, Android will call `getInfoContents()`, passing in the same `Marker` object. If we return a `View` here, Android will use that as the “body” of the info window, with Android supplying the border. If we return `null`, the default info window is displayed. This way, we can conditionally do any of the three possibilities (replace the window, replace the contents, or accept the default).

In our case, `getInfoContents()` will inflate the `popup.xml` layout and populate the two `TextView` widgets with the title and snippet from the `Marker`. However, we cache the inflated layout and reuse it on the second and subsequent calls to `getInfoContents()`. Despite the “adapter” name conjuring up visions of
ListAdapter and having multiple outstanding views, InfoWindowAdapter will only ever use one View at a time. Hence, rather than inflate our layout each time we need to show the info window, we can safely reuse the previously-used View.

Then, we just need to tell the GoogleMap to use our InfoWindowAdapter, via a call to setInfoWindowAdapter(), such as this statement from onMapReady() of our new edition of MainActivity:

```java
map.setInfoWindowAdapter(new PopupAdapter(getLayoutInflater()));
```

(from MapsV2/Popups/app/src/main/java/com/commonsware/android/maps2/popups/MainActivity.java)

Now, when the user taps on a marker, they will get our customized info window:

![Figure 568: Maps V2 with Customized Info Window](image)

We can also call setOnInfoWindowClickListener() on our GoogleMap, passing in an implementation of the OnInfoWindowClickListener interface, to find out when the user taps on the info window. In the case of MainActivity, we set up the activity itself to implement that interface and be the listener:

```java
map.setOnInfoWindowClickListener(this);
```

(from MapsV2/Popups/app/src/main/java/com/commonsware/android/maps2/popups/MainActivity.java)

This requires us to implement an onInfoWindowClick() method, where we are passed the Marker representing the tapped-upon info window: 1788
@Override
public void onInfoWindowClick(Marker marker) {
    Toast.makeText(this, marker.getTitle(), Toast.LENGTH_LONG).show();
}

(from MapsV2/Popups/app/src/main/java/com/commonsware/android/mapsv2/popups/MainActivity.java)

Here, we just display a Toast with the title of the Marker when the user taps an info window:

![Figure 569: Maps V2 with Toast Triggered by Tap on Info Window](image)

Note that, according to the documentation, you can only find out about taps on the entire info window. Indeed, if you try setting up click listeners on the widgets in your custom layout, you will find that they are not called. This is because the View you return for the info window is converted into a Bitmap, which is then displayed. Presumably, this is to steer developers in the direction of making larger tap targets, rather than expecting users to tap tiny elements within an info window. On the other hand, if your design calls for a large info window containing several navigation options, you will need to either re-think your design or avoid the info window system. We will see how to find out about taps on markers more directly later in this chapter.
Images and Your Info Window

The Bitmap approach that Maps V2 uses for the info window introduces an additional challenge: updating the info window itself. Normally, we would just update the individual widgets in the info window, the way we might update widgets in an already-visible row in a ListView. However, that is not an option here, as our widgets are discarded almost immediately.

One particular occurrence of this problem comes when you want to show an image in the info window. If the image is a resource, or is already in memory, showing it is not a big problem, as you can just populate your ImageView in your info window with it. However, if the image is a file (or, worse, needs to be downloaded), you want to load the image asynchronously. However, if you kick off some background thread, like an AsyncTask, to retrieve the image, you will return from your InfoWindowAdapter method long before the task is complete. Your info window will show whatever placeholder image you used; the image you loaded will never be seen, even if you update your original ImageView.

There are two solutions to this problem.

The best solution, by far, is to have the images before you need them, wherever possible. For example, if you are showing a map with 25 markers, for which you need 25 thumbnail images, start downloading those images while you are showing the map. With luck, at the point in time when the user taps on a marker to show the info window, you will have your image already.

However, this approach will not work well if:

- You need a ridiculous number of images, or
- You need images, but they need to be downloaded full-sized and turned into thumbnails locally, as that might consume quite a bit of bandwidth, or
- Your last name is Murphy, and therefore the user taps on an info window before you have had a chance to prepare its image.

The workaround is to make note of the Marker the user tapped upon to open its info window, then call showInfoWindow() on that Marker to cause the info window to be redisplayed once you have your image, triggering calls to your InfoWindowAdapter. There, you can see that your image cache includes the image that you need, and you can apply it to the info window.
The problem here is that it is possible that the user tapped on another marker, after the first one, while you were busily fetching and loading the image. Hence, rather than blindly calling `showInfoWindow()` on the Marker, you should call `isInfoWindowShown()` first, and only call `showInfoWindow()` to force the refresh if `isInfoWindowShown()` returns true. Otherwise, some other marker’s info window is shown. The user is not expecting this earlier info window to somehow magically reappear.

All of this is a pain. It can be made a bit less of a pain by use of an image fetching-and-caching library like [Picasso](http://square.github.io/picasso/). We can see how this can be applied by looking at the [MapsV2/ImagePopups](https://github.com/mapbox/mobile-sdk-android/tree/master/MappingsV2/ImagePopups) sample application. This is a clone of [MapsV2/Popups](https://github.com/mapbox/mobile-sdk-android/tree/master/MappingsV2/Popups), with some additions to handle lazy-populating an info window based upon a downloaded image.

First, since we are going to be generating some thumbnails based on downloaded imagery, it helps to establish a fixed-size `ImageView` for our icon. So, this project has a pair of dimension resources, for the image height and width:

```xml
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <dimen name="icon_width">96dp</dimen>
    <dimen name="icon_height">64dp</dimen>
</resources>
```

Those are then used in a revised version of the popup layout resource:

```xml
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">
    <ImageView
        android:id="@+id/icon"
        android:layout_width="@dimen/icon_width"
        android:layout_height="@dimen/icon_height"
        android:padding="2dp"
        android:src="@drawable/ic_launcher"
        android:contentDescription="@string/icon"/>
    <LinearLayout
        android:layout_width="match_parent"/>
</LinearLayout>
```

1791
We need some way of keeping track of what images should be used for each marker. This is somewhat annoying to implement, as we cannot subclass Marker, since it is marked as final and cannot be extended. However, we can use getId() on a Marker to obtain a unique ID, and we can use that as the key to additional model data. We will examine variations on this technique later in this chapter. For now, this sample gets away with a simple HashMap, mapping the string ID of a Marker to a Uri representing an image to be shown for that Marker’s info window:

```java
private HashMap<String, Uri> images = new HashMap<String, Uri>();
```

Our private addMarker() method now takes a String name of an image, and it adds a Uri pointing to that image to the HashMap, keyed by the ID of the generated Marker:

```java
private void addMarker(GoogleMap map, double lat, double lon,
                       int title, int snippet, String image) {
    Marker marker =
        map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                       .title(getString(title))
                       .snippet(getString(snippet)));
    if (image != null) {
```
For three of our markers, we pass in actual filenames; for a fourth, null is used, indicating that there is no suitable image for use:

```
for (int i = 0; i < markers.size(); i++) {
    addMarker(map, markers.get(i).getLatitude(), markers.get(i).getLongitude(),
              R.string.un, R.string.united_nations, "UN_HQ.jpg");
    addMarker(map, markers.get(i).getLatitude(), markers.get(i).getLongitude(),
              R.string.lincoln_center, R.string.lincoln_center_snippet, "Avery_Fisher_Hall.jpg");
    addMarker(map, markers.get(i).getLatitude(), markers.get(i).getLongitude(),
              R.string.carnegie_hall, R.string.practice_x3, "Carnegie_Hall.jpg");
    addMarker(map, markers.get(i).getLatitude(), markers.get(i).getLongitude(),
              R.string.downtown_club, R.string.heisman_trophy, null);
}
```

Note that the three images being used in this chapter come from Wikipedia. One is public domain, the others are licensed under the Creative Commons Attribution 1.0 license. Those two are a picture of Avery Fisher Hall, part of the Lincoln Center for the Performing Arts (courtesy of Geographer) and the other is a picture of the United Nations building (courtesy of WorldIslandInfo).

The PopupAdapter needs access to these images. It will also need access to a Context, for use with Picasso. So, PopupAdapter now has data members for these, which are passed into a revised version of its constructor by MainActivity. That constructor not only holds onto the new objects, but it retrieves the values of the dimension resources for our images, converted by Android into pixels for the screen density of the device that we are running on:

```
PopupAdapter(Context ctxt, LayoutInflater inflater, HashMap<String, Uri> images) {
    this.ctxt=ctxt;
    this.inflater=inflater;
    this.images=images;

    iconWidth=
        ctxt.getResources().getDimensionPixelSize(R.dimen.icon_width);
```
The revised `getInfoContents()` method is significantly more complicated than was its predecessor:

```java
@SuppressLint("InflateParams")
@Override
public View getInfoContents(Marker marker) {
    if (popup == null) {
        popup=inflater.inflate(R.layout.popup, null);
    }

    if (lastMarker == null
            || !lastMarker.getId().equals(marker.getId())) {
        lastMarker=marker;

        TextView tv=(TextView)popup.findViewById(R.id.title);
        tv.setText(marker.getTitle());
        tv=(TextView)popup.findViewById(R.id.snippet);
        tv.setText(marker.getSnippet());

        Uri image=images.get(marker.getId());
        ImageView icon=(ImageView)popup.findViewById(R.id.icon);

        if (image == null) {
            icon.setVisibility(View.GONE);
        } else {
            icon.setVisibility(View.VISIBLE);
            Picasso.with(ctxt).load(image).resize(iconWidth, iconHeight)
                .centerCrop().noFade()
                .placeholder(R.drawable.placeholder)
                .into(icon, new MarkerCallback(marker));
        }
    }

    return(popup);
}
```

We track the last `Marker` that we have processed in a `lastMarker` data member.
Initially, of course, that will be `null`. If it is, or if the `Marker` passed into `getInfoContents()` is a different one (based on the `getId()` value), then we populate the popup view. This includes fetching the `Uri` from the `HashMap` of `Uri` values (given the `Marker` ID). If there is no `Uri`, `getInfoContents()` marks the `ImageView` as `GONE`, so it will not take up space in the popup. If, however, there is an `image Uri`, `getInfoContents()` asks Picasso to “do its thing”:

- Load the image from the `Uri`
- Resize the image to be the desired dimensions for the `ImageView`, center-cropping to keep the right aspect ratio
- Skip the fade-in animation that is normally applied when Picasso populates an `ImageView` (as the Maps V2 Bitmap is generated before the animation completes, resulting in a washed-out image)
- Use a particular placeholder drawable resource while the image is loading
- Populate the `ImageView` with the results, specifying a `MarkerCallback` to be notified of the results

`MarkerCallback`, as an implementation of Picasso’s `Callback` interface, needs `onError()` and `onSuccess()` methods. `onError()` just dumps a message to Logcat, while `onSuccess()` refreshes the info window, via a call to `showInfoWindow()` on the `Marker`, if that info window is still showing:

```java
static class MarkerCallback implements Callback {
    Marker marker = null;

    MarkerCallback(Marker marker) {
        this.marker = marker;
    }

    @Override
    public void onError() {
        Log.e(getClass().getSimpleName(), "Error loading thumbnail!");
    }

    @Override
    public void onSuccess() {
        if (marker != null && marker.isInfoWindowShown()) {
            marker.showInfoWindow();
        }
    }
}
```

(from MapsV2/ImagePopups/app/src/main/java/com/commonsware/android/mapsv2/imagepopups/PopupAdapter.java)
If you run this sample app, you will see the popup with a placeholder image at first, quickly being replaced by the thumbnail supplied by Picasso:

![Image of a map showing locations like Lincoln Center and Time Warner Center.](image.png)

*Figure 570: Maps V2 with Popup and Thumbnail*

**Setting the Marker Icon**

Maps V2 includes a stock marker icon that looks a lot like the standard Google Maps marker. You have three major choices for what to use for your own markers:

1. Stick with the stock icon, which is the default behavior
2. Change the stock icon to a different hue
3. Replace the stock icon with your own from an asset, resource, file, or in-memory Bitmap

To indicate that you want a different icon than the stock one, use the `icon()` method on the `MarkerOptions` fluent interface. This takes a `BitmapDescriptor`, which you get from one of a series of static methods on the `BitmapDescriptorFactory` class.

For example, you might have a revised version of the `addMarker()` method of
MainActivity that took a hue — a value from 0 to 360 representing different colors along a color wheel. 0 represents red, 120 represents green, and 240 represents blue, with different shades in between. There is a series of HUE_ constants defined on BitmapDescriptorFactory, plus a defaultMarker() method that takes a hue as a parameter and returns a BitmapDescriptor that will use the stock icon, colored to the specified hue:

```java
private void addMarker(GoogleMap map, double lat, double lon,
                      int title, int snippet, int hue) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                   .title(getString(title))
                   .snippet(getString(snippet))
                   .icon(BitmapDescriptorFactory.defaultMarker(hue)));
}
```

(from MapsV2/Taps/app/src/main/java/com/commonsware/android/maps2/taps/MainActivity.java)

This could then be used to give you different colors per marker, or by category of marker, etc.:

![Map with different marker colors](image)

*Figure 571: Maps V2 with Alternate Marker Hues*

Note that you can modify the icon at runtime via the setIcon() method on the Marker returned by addMarker() method on GoogleMap.
However, you cannot draw the marker directly yourself, the way you might have with Maps V1. What you can do is draw to a Bitmap-backed Canvas object, then use the resulting Bitmap with BitmapFactoryDescriptor and its fromBitmap() factory method.

**Responding to Taps**

Perhaps we would like to find out when a user taps on one of our markers, instead of displaying an info window. Maybe we want to have some other UI response to that tap in our app.

To do that, simply create an implementation of the OnMarkerClickListener interface and attach it to the GoogleMap via setOnMarkerClickListener(). You will then be called with onMarkerClick() when the user taps on a marker, and you are passed the Marker object in question. If you return true, you are indicating that you are handling the event; returning false means that default handling (the info window) should be done.

You can see this, plus the multi-colored markers, in the MapsV2/Taps sample application. This takes MapsV2/Popups and adds a Toast when the user taps a marker, in addition to displaying the info window:

```java
@Override
public boolean onMarkerClick(Marker marker) {
    Toast.makeText(this, marker.getTitle(), Toast.LENGTH_LONG).show();

    return(false);
}
```
Our call to `setOnMarkerClickListener()` is up in the `onMapReady()` method of `MainActivity`:

```java
map.setOnMarkerClickListener(this);
```

### Dragging Markers

By default, markers are not draggable. But, if you call `draggable(true)` on your `MarkerOptions` when creating the marker — or call `setDraggable(true)` on the `Marker` later on — Android will automatically support drag-and-drop. The user can tap-and-hold on the marker to enable drag mode, then slide the marker around the map.

Note that at the present time, this functionality is a little odd. When you tap-and-hold the marker, with drag mode enabled, the marker initially jumps away from its original position. The user can reposition the marker to any desired location, and
the marker will seem to “drop” where the user requests. Why the marker makes the sudden shift at the outset, using the default marker settings, is unclear.

Of course, your code may need to know about drag-and-drop events, such as to update your own data model to reflect the newly-chosen location. You can register an `OnMarkerDragListener` that will be notified of the start of the drag, where the marker slides during the drag, and where the marker is dropped at the end of the drag.

You can see all of this in the `MapsV2/Drag` sample application, which is a clone of `MapsV2/Popup` with drag-and-drop enabled.

To enable drag-and-drop, we just chain `draggable(true)` onto the series of calls on our `MarkerOptions` when creating the markers:

```java
private void addMarker(GoogleMap map, double lat, double lon,
                       int title, int snippet) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                  .title(getString(title))
                  .snippet(getString(snippet))
                  .draggable(true));
}
```

We also register `MainActivity` as being the drag listener, up in `onMapReady()`:

```java
map.setOnMarkerDragListener(this);
```

That requires `MainActivity` to implement `OnMarkerDragListener`, which in turn requires three methods to be defined: `onMarkerDragStart()`, `onMarkerDrag()`, and `onMarkerDragEnd()`:

```java
@Override
public void onMarkerDragStart(Marker marker) {
    LatLng position = marker.getPosition();

    Log.d(getClass().getSimpleName(), String.format("Drag from %f:%f",
                                                      position.latitude,
                                                      position.longitude));
}
```

```java
@Override
```
Here, we just dump the information about the new marker position in Logcat.

So, if you run this app and drag-and-drop a marker, you will see output in Logcat akin to:

```
12-19 13:10:36.442: D/MainActivity(22510): Drag from 40.770876:-73.982499
12-19 13:10:36.892: D/MainActivity(22510): Dragging to 40.770876:-73.981593
12-19 13:10:36.912: D/MainActivity(22510): Dragging to 40.770795:-73.981352
12-19 13:10:36.932: D/MainActivity(22510): Dragging to 40.770754:-73.981141
...
12-19 13:10:38.292: D/MainActivity(22510): Dragging to 40.769596:-73.983615
12-19 13:10:38.372: D/MainActivity(22510): Dragged to 40.769596:-73.983615
```

The actual list of events was much longer, as onMarkerDrag() is called a lot, so the ... in the Logcat entries above reflect another 50 or so lines for a drag-and-drop that took a couple of seconds.

Also, up in onCreate(), we retain our SupportMapFragment across configuration changes via setRetainInstance(true):

```
mapFrag.setRetainInstance(true);
```

Retaining the fragment instance causes the fragment to keep our markers in their
moved positions, rather than resetting them to their original positions.

The “Final” Limitations

In Maps V2, not only do you not create Marker objects directly yourself, but Marker is marked as final and cannot be extended. Hence, you cannot use a Marker directly to hold model data.

However, Marker does have getId(), an immutable identifier for the Marker. We can use that as a key for a HashMap that allows us to get at additional model data associated with the Marker.

You can see this approach in the MapsV2/Models sample application, which is a clone of MapsV2/Popup where we use the ID in just this fashion.

Our simplified model is merely the data we poured into our Marker objects in the original MapsV2/Popup project:

```java
package com.commonsware.android.mapsv2.model;

import android.content.Context;

public class Model {
  String title;
  String snippet;
  double lat;
  double lon;

  Model(Context ctxt, double lat, double lon, int title, int snippet) {
    this.title=ctxt.getString(title);
    this.snippet=ctxt.getString(snippet);
    this.lat=lat;
    this.lon=lon;
  }

  String getTitle() {
    return(title);
  }

  String getSnippet() {
    return(snippet);
  }
}
```
Our activity holds onto a HashMap of these Model objects, with the map keyed by the Marker ID (a String):

```java
private HashMap<String, Model> models = new HashMap<String, Model>();
```

Of course, a real application would have a much more elaborate setup than this.

We then arrange to populate our map with Marker objects created from our Model objects, moving the add-the-markers-to-the-map logic to an addMarkers() method:

```java
private void addMarkers(GoogleMap map) {
    Model model =
        new Model(this, 40.748963847316034, -73.96807193756104,
                R.string.un, R.string.united_nations);
    models.put(addMarkerForModel(map, model).getId(), model);

    model =
        new Model(this, 40.76866299974387, -73.98268461227417,
                R.string.lincoln_center,
                R.string.lincoln_center_snippet);
    models.put(addMarkerForModel(map, model).getId(), model);

    model =
        new Model(this, 40.765136435316755, -73.97989511489868,
                R.string.carnegie_hall,
                R.string.practice_x3);
    models.put(addMarkerForModel(map, model).getId(), model);

    model =
        new Model(this, 40.70686417491799, -74.01572942733765,
                R.string.downtown_club,
                R.string.heisman_trophy);
    models.put(addMarkerForModel(map, model).getId(), model);
}
```
private Marker addMarkerForModel(GoogleMap map, Model model) {
    LatLng position =
        new LatLng(model.getLatitude(), model.getLongitude());

    return (map.addMarker(new MarkerOptions().position(position)
                               .title(model.getTitle())
                               .snippet(model.getSnippet())));
}

Notice that addMarkerForModel() returns the Marker, and we use getId() on that Marker as the key when adding a Model to the HashMap.

Our PopupAdapter gets the data for the info window from the Model (though, in truth, in this case, it could have gotten the data from the Marker itself, since we did not add more information to the info window):

import android.view.LayoutInflater;
import android.view.View;
import android.widget.TextView;
import java.util.HashMap;
import com.google.android.gms.maps.GoogleMap.InfoWindowAdapter;
import com.google.android.gms.maps.model.Marker;

class PopupAdapter implements InfoWindowAdapter {
    LayoutInflater inflater = null;
    HashMap<String, Model> models = null;

    PopupAdapter(LayoutInflater inflater, HashMap<String, Model> models) {
        this.inflater = inflater;
        this.models = models;
    }

    @Override
    public View getInfoWindow(Marker marker) {
        return (null);
    }

    @Override
    public View getInfoContents(Marker marker) {
        View popup = inflater.inflate(R.layout.popup, null);

        TextView tv = (TextView) popup.findViewById(R.id.title);
        
        return (popup);
    }
}
Visually, this is indistinguishable from the original MapsV2/Popups project. Of course, a real app would have more complex models, perhaps containing more discrete information for a more complex info window.

### A Bit More About IPC

IPC is not only a problem in terms of disappearing Marker objects.

If you run a Maps V2 app under Traceview, to see what methods get called and how much time everything takes, you will see that many, many operations with GoogleMap do little in your process, but instead make synchronous calls to a Play Services process to do the real work. You need to avoid manipulating your GoogleMap in time-sensitive portions of your code.

### Finding the User

It is often useful to help point out to the user their current location. That is a matter of adding a suitable location permission (e.g., ACCESS_FINE_LOCATION) and calling setMyLocationEnabled(true) on your GoogleMap. This activates a layer that will highlight their location, with the user having an option of having the “camera” (i.e., their perspective on the map) reposition itself to their location and move as they move. This latter capability is activated by a small icon in the upper right of the map.

There does not appear to be a way to force camera tracking of the user’s position — you are reliant upon the user tapping that icon. You also have no control over the nature of the location provider that is used.

However, there is a workaround for this, proposed in a Stack Overflow answer — provide your own location data and update the camera yourself, by means of setLocationSource(). setLocationSource() lets you push locations to the

```java
tv.setText(models.get(marker.getId()).getTitle());
tv=(TextView)popup.findViewById(R.id.snippet);
tv.setText(models.get(marker.getId()).getSnippet());

return popup;
}
```
GoogleMap, making other adjustments (e.g., camera position) along the way.

You can see this in operation in the MapsV2/Location sample application, which is based on MapsV2/Popup but with a variety of changes to deal with location tracking. A lot of that has to do with the runtime permissions system on Android 6.0+, as we need permission from the user to be able to work with the device location.

Dealing with the Runtime Permission

onCreate() of MainActivity now looks radically different:

```java
@Override
protected void onCreate(Bundle state) {
    super.onCreate(state);

    if (state==null) {
        needsInit=true;
    } else {
        isInPermission=state.getBoolean(STATE_IN_PERMISSION, false);
        autoFollow=state.getBoolean(STATE_AUTO_FOLLOW, true);
    }

    onCreateForRealz(canGetLocation());
}
```

(from MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java)

Most of the original business logic from onCreate() has been moved into onCreateForRealz(). That method takes a boolean parameter, indicating whether or not we have permission to access the user's location. Here, we get that from a canGetLocation() method that, in turn, uses ContextCompat.checkSelfPermission() to see if we hold ACCESS_FINE_LOCATION:

```java
private boolean canGetLocation() {
    return ContextCompat.checkSelfPermission(this,
            Manifest.permission.ACCESS_FINE_LOCATION)==
            PackageManager.PERMISSION_GRANTED);
}
```

(from MapsV2/Location/app/src/main/java/com/commonsware/android/mapsv2/location/MainActivity.java)

If we can work with locations, onCreateForRealz() will do what onCreate() used to do: call readyToGo() and, if we are ready to go, bring up the map:
If we do not have access to the user’s location, this particular sample app is not that interesting, so we will ask the user for permission, via a call to ActivityCompat.requestPermissions(). This will eventually trigger a call to onRequestPermissionsResult():

```java
@Override
class MainActivity {  
public void onRequestPermissionsResult(int requestCode,  
String[] permissions,  
int[] grantResults) {
    isInPermission=false;
    if (requestCode==REQUEST_PERMS) {  
        if (canGetLocation()) {  
            onCreateForRealz(true);
        }  
        else {  
            finish(); // denied permission, so we're done
        }
    }
}
```

Here, if we can now get the location, we go ahead and run through onCreateForRealz() again, to initialize the map. If, however, the user denied us the right to access the location, we finish() and exit the activity outright.

Throughout this code, you have seen references to an isInPermission field. This
tracks whether or not we are in the middle of requesting a permission:

- It is initialized to false in the activity
- It is set to true just before calling requestPermissions(
- It is set back to false in onRequestPermissionsResult() 
- It is saved across configuration changes via onSaveInstanceState() and is retrieved from that state in onCreate():

```java
@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putBoolean(STATE_IN_PERMISSION, isInPermission);
    outState.putBoolean(STATE_AUTO_FOLLOW, autoFollow);
}
```

(where STATE_IN_PERMISSION is a static final String to use as a key for the Bundle value)

This allows us to check whether or not we are in the middle of requesting permissions already in onCreateForRealz() and avoid popping up the permission-request dialog twice if the user rotates the screen while the first dialog is up, then denies the permission.

**Tracking If We Should Follow the User**

The UI has a checkable overflow item in the action bar, named follow. When checked, we will use LocationManager to move the map camera ourselves to the user’s location. When unchecked, we will show the my-location layer, and the user can manually jump to their current location via the button supplied by that layer.

So, we need to keep track of whether we should be automatically following the user or not.

To that end, we have an autoFollow field, initially set to true, as the action item checkbox initially is checked. We toggle that field as the user checks and unchecks the item:

```java
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);

```
We also call a `follow()` method to update the UI based on the user's choice — we will see that method shortly.

We also hold onto that `autoFollow` value in the saved instance state `Bundle` and restore it when the activity is recreated.

**Showing the My-Location Layer**

Part of what we do in `onMapReady()` is call `setMyLocationEnabled(true)` on the map, which puts a blue dot at the user’s location:

```java
@Override
public void onMapReady(final GoogleMap map) {
    this.map = map;
    if (needsInit) {
        CameraUpdate center =
            CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
                -73.98180484771729));
        CameraUpdate zoom = CameraUpdateFactory.zoomTo(15);
        map.moveCamera(center);
        map.animateCamera(zoom);
    }
    addMarker(map, 40.748963847316034, -73.96807193756104,
```
Part of what `follow()` does is call `setMyLocationButtonEnabled()`, with a suitable boolean value, to toggle whether the “jump to my location” button is shown:

```java
private void follow() {
  if (map!=null && locMgr!=null) {
    if (autoFollow) {
      locMgr.requestLocationUpdates(0L, 0.0f, crit, this, null);
      map.setLocationSource(this);
      map.getUiSettings().setMyLocationButtonEnabled(false);
    } else {
      map.getUiSettings().setMyLocationButtonEnabled(true);
      map.setLocationSource(null);
      locMgr.removeUpdates(this);
    }
  }
}
```

Supplying Location Data

The rest of `follow()` either starts up or stops our request for location data using `LocationManager`, plus setting up our activity as being the source of location data, using `setLocationSource()`.
setLocationSource() takes a LocationSource implementation, and we implement that interface on the activity itself. It therefore needs activate() and deactivate() methods, where we can track a supplied OnLocationChangedListener for us to use:

```java
@Override
public void activate(OnLocationChangedListener listener) {
    this.mapLocationListener = listener;
}
```

```java
@Override
public void deactivate() {
    this.mapLocationListener = null;
}
```

LocationManager will supply our location data to onLocationChanged(). There, we do two things:

1. Forward the location along to the OnLocationChangedListener supplied to our LocationSource, and
2. Update the camera to point at the user’s location

```java
@Override
public void onLocationChanged(Location location) {
    if (mapLocationListener != null) {
        mapLocationListener.onLocationChanged(location);

        LatLng latlng =
            new LatLng(location.getLatitude(), location.getLongitude());
        CameraUpdate cu = CameraUpdateFactory.newLatLng(latlng);

        map.animateCamera(cu);
    }
}
```

The result is that while autoFollow is true, we will find the user’s location and use that to update the map. When autoFollow is false, we let the map itself handle that role, including showing that “jump to my location” button.

## Drawing Lines and Areas

If you wanted to draw on a map in the Maps V1 framework, you created an Overlay
and drew upon it. This forced you to handle low-level drawing work yourself, as you were handed a Canvas object and had to handle all the lines, fills, and so forth yourself.

Maps V2 offers a different approach. Free-form drawing is still conceivable, though it appears to have to be handled in the form of tile overlays instead of map overlays. However, for the simpler cases of drawing lines and areas, Maps V2 has built-in polyline, polygon, and circle support. You tell the GoogleMap what needs to be drawn, and it handles drawing it, both initially and as the map is zoomed or panned. A polyline is a line connecting a series of points; a polygon is a region defined by a series of corners. A circle, from the standpoint of Maps V2, is defined by a center coordinate and a radius.

We can see polylines and polygons on a GoogleMap in the MapsV2/Poly sample application, which is a clone of MapsV2/Popup with two additions:

- A polyline connecting the locations of our four markers
- A polygon enclosing the area of Manhattan known as the Garment District (bounded by 34th Street, 42nd Street, Fifth Avenue, and Ninth Avenue)

To draw those, we simply add a few lines to onMapReady() of MainActivity:

```java
PolylineOptions line = new PolylineOptions().add(new LatLng(40.70686417491799, -74.01572942733765),
    new LatLng(40.76866299974387, -73.98268461227417),
    new LatLng(40.765136435316755, -73.97989511489868),
    new LatLng(40.748963847316034, -73.96807193756104));
map.addPolyline(line);

PolygonOptions area = new PolygonOptions().add(new LatLng(40.748429, -73.984573),
    new LatLng(40.753393, -73.996311),
    new LatLng(40.758393, -73.992705),
    new LatLng(40.753484, -73.980882));
map.addPolygon(area);
```

(from MapsV2/Poly/app/src/main/java/com/commonsware/android/mapsv2/poly/MainActivity.java)
The API for adding polylines and polygons is reminiscent of the API for adding markers: define an `...Options` object with the characteristics of the item to be drawn, then call an `add...()` method on `GoogleMap` to add the item.

So, to add a polyline, we create a `PolylineOptions` object. Using its fluent interface, we `add()` a series of `LatLng` objects, representing the points to be connected by the line. We also specify the line width in `pixels` via `width()` and the color of the line via `color()`. If we had several lines that might overlap, we could specify the `zIndex()`, where higher indexes indicate lines to be drawn over the top of lines with lower indexes. We add the polyline to the map by passing our `PolylineOptions` to `addPolyline()` on `GoogleMap`.

This gives us a line connecting the four markers, with `GoogleMap` handling the details of where the line should be drawn on the screen given the current map center and zoom levels:

![Figure 573: Maps V2 with Polyline](image)

Note that the polyline is drawn using a flat Mercator projection by default. For most maps, that is perfectly fine. If your map will be showing countries and continents, rather than city blocks, you might want to call `geodesic(true)` on the `PolylineOptions`, to have the line drawn on a geodesic curve, reflecting the
spherical nature of the Earth (dissenting opinions on that notwithstanding).

Similarly, we create a PolygonOptions object, configure it, and pass it to addPolygon for our Garment District box. The add() method on PolygonOptions will take the corners of our polygon, automatically enclosing that region. We also specify the strokeColor(). We could have specified a fillColor() (default is transparent), strokeWidth() (default is 10 pixels), zIndex(), and geodesic().

If we run the app and pan the map down to the south a bit, we see our polygon:

![Figure 574: Maps V2 with Polyline and Polygon](image)

As with the polyline, Android automatically handles drawing what is needed based on map center and zoom levels.

Note that, as with markers, we need to re-add the polylines and polygons after a configuration change, as the GoogleMap does not retain that information.

**Gestures and Controls**

By default, standard gestures and controls are enabled on your map:
• The user can change zoom level either by + and - buttons or via “pinch-to-zoom” gestures
• The user can change the center of the map via simple swipe gestures
• The user can change the camera tilt via two-finger vertical swipes, so instead of a traditional top-down perspective, the user can see things on an angle
• The user can change the orientation of the map via a two-finger rotating swipe, to change the typical “north is to the top of the map” to some other orientation

You can obtain a UiSettings object from your GoogleMap via getUiSettings() to disable these features, if desired:

- setRotateGesturesEnabled()
- setScrollGesturesEnabled() (for panning the map)
- setTiltGesturesEnabled()
- setZoomControlsEnabled() (for the + and - buttons)
- setZoomGesturesEnabled() (for pinch-to-zoom)

There is also setAllGesturesEnabled() to toggle on or off all gesture-based map control. This is roughly analogous to the android:clickable attribute on the Maps V1 edition of MapView.

There is also setCompassEnabled(), to indicate if a compass should be shown if the user changes the map orientation via a rotate gesture.

**Tracking Camera Changes**

If you have gestures enabled, the user can change the perspective of the map, referred to as changing the camera position. You may need to know about these changes, to perform various operations in your app based upon what is presently visible on the screen.

Originally, to find out when the camera position changes, you could call setOnCameraChangeListener() on the GoogleMap, supplying an implementation of OnCameraChangeListener, which would be called with onCameraChange() as the user pans, zooms, or tilts the map. This approach was deprecated and replaced with a series of listeners:

- OnCameraMoveStartedListener, invoked when the user starts moving the map
• `OnCameraMoveListener`, invoked when the user continues moving the map after having originally started moving it, all in one gesture
• `OnCameraIdleListener`, invoked when the user stops moving the map (e.g., lifts up their finger or stylus)
• `OnCameraMoveCanceledListener`, invoked if you do something programmatically to interrupt the camera movement

To see how this works, we can take a quick peek at the MapsV2/Camera sample application, which is a clone of MapsV2/Popup with camera position tracking enabled.

Late in `onMapReady()` of `MainActivity`, we call a series of setter methods on the `GoogleMap` to associate `MainActivity` itself as the listener for these events:

```java
map.setOnCameraMoveStartedListener(this);
map.setOnCameraMoveListener(this);
map.setOnCameraMoveCanceledListener(this);
map.setOnCameraIdleListener(this);
```

(from MapsV2/Camera/app/src/main/java/com/commonsware/android/mapsv2/camera/MainActivity.java)

This requires `MainActivity` to implement all four of those listener interfaces:

```java
public class MainActivity extends AbstractMapActivity implements
OnMapReadyCallback, OnInfoWindowClickListener,
OnCameraMoveStartedListener,
OnCameraMoveListener,
OnCameraMoveCanceledListener,
OnCameraIdleListener {
```

(from MapsV2/Camera/app/src/main/java/com/commonsware/android/mapsv2/camera/MainActivity.java)

And, this requires `MainActivity` to implement the callback method for each of those listeners:
### Mapping with Maps V2

<td>OnCameraMoveCanceledListener</td>
<td>onCameraMoveCanceled()</td>
</tr>
</tbody>
</table>

```java
@Override
public void onCameraIdle() {
    CameraPosition position = map.getCameraPosition();

    Log.d("onCameraIdle",
        String.format("lat: %f, lon: %f, zoom: %f, tilt: %f",
            position.target.latitude,
            position.target.longitude, position.zoom,
            position.tilt));
}

@Override
public void onCameraMoveCanceled() {
    CameraPosition position = map.getCameraPosition();

    Log.d("onCameraMoveCanceled",
        String.format("lat: %f, lon: %f, zoom: %f, tilt: %f",
            position.target.latitude,
            position.target.longitude, position.zoom,
            position.tilt));
}

@Override
public void onCameraMove() {
    CameraPosition position = map.getCameraPosition();

    Log.d("onCameraMove",
        String.format("lat: %f, lon: %f, zoom: %f, tilt: %f",
            position.target.latitude,
            position.target.longitude, position.zoom,
            position.tilt));
}

@Override
public void onCameraMoveStarted(int i) {
```
Here, we just log a message to Logcat on each camera position change, logging:

• the latitude and longitude of the map center, obtained from the target LatLng data member of the CameraPosition object supplied to onCameraChange(),
• the zoom level of the map, from the zoom data member of CameraPosition, and
• the tilt of the map, in degrees, from the tilt data member of CameraPosition

As a result, if you run this app and play around with the various gestures, you get a series of Logcat messages with the results:

Note that onCameraMoveStarted() will be invoked for three reasons:

1. The user started panning, tilting, or rotating the map, or used a pinch-to-zoom gesture
2. The user did something else that triggered a camera change, such as tapping the “my location” button to move the camera to their current location
3. You did something programmatically to change the camera position
The parameter passed into `onCameraMoveStarted()` will contain a reason code (e.g., `REASON_GESTURE`) to help you distinguish these cases, if that level of detail is needed by your app.

**Maps in Fragments and Pagers**

One key limitation of Maps V1 was that you could only have one `MapView` instance per process. Presumably, the proprietary code at the heart of the Maps SDK add-on used static data members for some state management, ones that would get messed up if there were two or more `MapView` widgets in active use.

Fortunately, Maps V2 gets rid of this restriction. You are welcome to have multiple `SupportMapFragment` objects if that makes sense. Maps are relatively memory-intensive, so you should not be planning on having dozens or hundreds of them in use at a time, but you can have more than one.

To showcase this, the [MapsV2/Pager](MapsV2/Pager) sample application hosts 10 `SupportMapFragment` instances as pages in a `ViewPager`. The bulk of the application is a clone of one of the `ViewPager` samples from [the chapter on ViewPager](#).

Having maps in a `ViewPager` presents a bit of a problem, in terms of interpreting horizontal swipe events. Normally, `ViewPager` handles those itself. However, that would mean that the user cannot pan the map horizontally, which makes using the map somewhat challenging. In this sample, we will augment the `ViewPager` with logic to allow horizontal swiping on the maps and on the tab strip.

Our activity inflates a layout that contains our `ViewPager` along with a `PagerTabStrip`:

```xml
<?xml version="1.0" encoding="utf-8"?>
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <android.support.v4.view.PagerTabStrip
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_gravity="top"/>

</com.commonsware.android.mapsv2.pager.MapAwarePager>
```

(from [MapsV2/Pager/app/src/main/res/layout/activity_main.xml](MapsV2/Pager/app/src/main/res/layout/activity_main.xml))
However, you will note that this is not `ViewPager`, but rather `MapAwarePager`, a custom subclass of `ViewPager` that we will examine shortly.

`MainActivity` then populates the `MapAwarePager` with an instance of a `MapPageAdapter`:

```
package com.commonsware.android.mapsv2.pager;

import android.os.Bundle;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;

public class MainActivity extends AbstractMapActivity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (readyToGo()) {
            setContentView(R.layout.activity_main);

            ViewPager pager = findViewById(R.id.pager);

            pager.setAdapter(buildAdapter());
        }
    }

    private PagerAdapter buildAdapter() {
        return new MapPageAdapter(this, getSupportFragmentManager());
    }
}
```

MapPageAdapter is a `FragmentStatePagerAdapter`, not a `FragmentPagerAdapter`. This means that as the user swipes through our `ViewPager`, the adapter has the right to discard old fragments when it creates new ones. This helps reduce the overall memory footprint of our activity.

```
package com.commonsware.android.mapsv2.pager;

import android.content.Context;
import android.support.v4.app.Fragment;
import android.support.v4.app.FragmentManager;
import android.support.v4.app.FragmentStatePagerAdapter;

public class MapPageAdapter extends FragmentStatePagerAdapter {
    Context ctxt = null;
}
```
MapPageAdapter declares that there should be ten pages (in `getCount()`) and returns an instance of PageMapFragment for each page. PageMapFragment is a subclass of SupportMapFragment, and so is responsible for displaying our map:

```java
package com.commonsware.android.mapsv2.pager;
import android.os.Bundle;
import android.view.View;
import com.google.android.gms.maps.CameraUpdate;
import com.google.android.gms.maps.CameraUpdateFactory;
import com.google.android.gms.maps.GoogleMap;
import com.google.android.gms.maps.OnMapReadyCallback;
import com.google.android.gms.maps.SupportMapFragment;
import com.google.android.gms.maps.model.LatLng;
import com.google.android.gms.maps.model.MarkerOptions;
public class PageMapFragment extends SupportMapFragment implements OnMapReadyCallback {
  private boolean needsInit=false;
  @Override
  public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);
    if (savedInstanceState == null) {
      needsInit=true;
    }
    getMapAsync(this);
  }
  @Override
  public void onMapReady(final GoogleMap map) {
    if (needsInit) {
      CameraUpdate center = CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
```
If we simply wanted to display an unconfigured map, we could just have `MapPageAdapter` create and return instances of `SupportMapFragment` directly. If we want to configure our map, though, we need to get control when the `GoogleMap` object is ready for use. One way to do that is to extend `SupportMapFragment` and override `onViewCreated()` and call `getMapAsync()` there to begin the whole get-the-`GoogleMap`-loaded process. In `onMapReady()`, we can then go ahead and configure the map much as we have done in previous examples, just from within the fragment itself rather than from the hosting activity.

`MapAwarePager` overrides one key method of `ViewPager`: `canScroll()`:

```java
package com.commonsware.android.mapsv2.pager;

import android.content.Context;
import android.support.v4.viewPager.PagerTabStrip;
import android.support.v4.view.ViewPager;
import android.util.AttributeSet;
import android.view.SurfaceView;
import android.view.View;

public class MapAwarePager extends ViewPager {
    public MapAwarePager(Context context, AttributeSet attrs) {
        super(context, attrs);
    }
}
```

(from MapsV2/Pager/src/main/java/com/commonsware/android/mapsv2/pager/PageMapFragment.java)
canScroll() should return true if the View (and specifically the supplied X and Y coordinates within that View) can be scrolled horizontally, false otherwise. In our case, we want to say that the map and the tab strip are each scrollable horizontally. As it turns out, the passed-in View for our SupportMapFragment will be the map if it is a subclass of SurfaceView (determined by trial and error on the author's part, with hopes for a more authoritative solution in a future edition of the Maps V2 API). So, if the passed-in View is either a SurfaceView or a PagerTabStrip, we return true, otherwise we default to normal logic.
The result is a series of independent maps, one per page:

![Multiple Maps V2 Maps in a ViewPager](image)

**Figure 575: Multiple Maps V2 Maps in a ViewPager**

Each map is independent: if the user pans or zooms one map, that has no impact on any of the other pages. Panning the maps horizontally works; to move between pages, use the tab strip.

**Animating Marker Movement**

Markers, by default, are static, unless you make them be draggable, and then only the user can drag them.

However, you are welcome to update the position of a Marker at any point, by calling `setPosition()` and supplying a new `LatLng`. The Marker then will jump to that position.

But what if you want to animate the movement of a Marker from its current position to a new one? Maps V2 does not offer anything “out of the box” for implementing this, but Google demonstrated approaches for this in a [“DevBytes” video](https://www.youtube.com/watch?v=example) and related [bit of code in a GitHub Gist](https://gist.github.com/example). This section will cover the technique appropriate for API Level 14+, including a full working sample (the Gist shows code but not its usage).
Problem #1: Animating a LatLng

The position of a Marker is a LatLng, as we have seen previously. LatLng is not a simple number, and so the animator framework needs our assistance to animate them. Specifically, we need a TypeEvaluator for LatLng, with our evaluate() method taking the initial and end positions and computing another LatLng representing the fraction position between those other positions. This concept was introduced back in the chapter on the animator framework.

A simple approach to computing the fractional LatLng would be to apply the fraction to the latitude and the longitude as Java double values:

```java
LatLng interpolate(float fraction, LatLng initial, LatLng end) {
    double lat = (end.latitude - initial.latitude) * fraction + initial.latitude;
    double lng = (end.longitude - initial.longitude) * fraction + initial.longitude;
    return new LatLng(lat, lng);
}
```

That would work reasonably well for fairly close points, such as animating a marker within a city. However, animating markers across longer distances means that we have to take into account some geographic realities that a simple calculation will miss.

Problem #2: The Earth Is Not Flat (Really!)

One bit of reality is that the Earth is round. The above calculation assumes that the Earth is flat. Calculating “great circle” positions requires a fair bit of spherical trigonometry, known to cause loss of hair in software developers.

Hence, ideally, we will use somebody’s existing debugged algorithm for that.

Problem #3: 180 Equals –180, At Least For Longitude

The other problem is that longitudes wrap around, as 180 degrees longitude is equivalent to –180 degrees longitude, and longitudinal values are considered to be between 180 and –180. In cases where we would not cross 180 degrees longitude, this is not an issue. However, a simple calculation might miss this and wind up having our animation “take the long way” (e.g., animating from –175 degrees longitude to 175 degrees longitude by going 350 degrees around the Earth, rather than just 10 degrees and crossing the International Date Line).
Introducing Some Googly Assistance

Google themselves have released a utility library for Maps V2. It offers polyline and polygon decoding, primarily for interoperability with other location-related Google services like the Google Directions API. The SphericalUtil class handles all of the nasty math for computing distances along the surface of the Earth and related calculations. It also offers BubbleIconFactory, which makes it easy to create marker icons that look a bit like info windows (complete with border and caret) wrapping around a bit of text or an icon.

In our case, we can use SphericalUtil to handle Problem #2 and Problem #3, interpolating the location between two LatLng values, taking the curvature of the Earth and longitude idiosyncrasies into account.

Seeing This in Action

The MapsV2/Animator sample project is a modified version of the MapsV2/Markers project, adding in the notion of animating a marker from its original position (Lincoln Center) to a new position (Penn Station) within Manhattan.

Since we want to use the Google map utility library, we need to add it as a dependency. Android Studio users can simply add implementation 'com.google.maps.android:android-maps-utils:0.3.4' (or a higher version) to the dependencies closure.

We need to know where our starting and ending position for the animation will be, in terms of LatLng objects. Since those have no dependencies upon a Context or anything, we can simply declare them as static final values:

```java
private static final LatLng PENN_STATION=new LatLng(40.749972, -73.992319);
private static final LatLng LINCOLN_CENTER=
    new LatLng(40.76866299974387, -73.98268461227417);
```

(from MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java)

We will also need the actual Marker object created when we add our starting position (LINCOLN_CENTER) to the map. So far, we have ignored the Marker returned by addMarker() on GoogleMap, but now we need that. So, our own addMarker() method now returns this value:

```java
private Marker addMarker(GoogleMap map, double lat, double lon,
```

1826
We also now have a `markerToAnimate` data member of the activity, for our `Marker`, which we populate from our modified `addMarker()` method:

```java
addMarker(map, 40.748963847316034, -73.96807193756104,
          R.string.un, R.string.united_nations);
markerToAnimate=
  addMarker(map, LINCOLN_CENTER.latitude,
            LINCOLN_CENTER.longitude, R.string.lincoln_center,
            R.string.lincoln_center_snippet);
addMarker(map, 40.765136435316755, -73.97989511489868,
          R.string.carnegie_hall, R.string.practice_x3);
addMarker(map, 40.70686417491799, -74.01572942733765,
          R.string.downtown_club, R.string.heisman_trophy);
```

To make the sample work repeatedly, it would be nice to support bi-directional animation, starting with animating from Lincoln Center to Penn Station, then reversing the animation to go back to Lincoln Center. That means that we need to know, for any particular animation, where the end position should be. So, we track a `LatLng` for the next end position, surprisingly named `nextAnimationEnd`, initializing it to be `PENN_STATION` (since we are starting at the outset at `LINCOLN_CENTER`):

```java
private LatLng nextAnimationEnd=PENN_STATION;
```

Next, we need to give the user a means of actually requesting the animation to run. To do that, we define a new menu XML resource for an `animate` menu item (using the directions icon for lack of a better handy icon):

```xml
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/animate"
    android:icon="@android:drawable/ic_menu_directions"
    android:showAsAction="ifRoom"
  />
</menu>
```
We then load that menu resource in an overridden `onCreateOptionsMenu()` and direct the click event to an `animateMarker()` method in `onOptionsItemSelected()`:

```java
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.animate, menu);
    return (super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.animate) {
        animateMarker();
        return (true);
    }
    return (super.onOptionsItemSelected(item));
}
```

In `animateMarker()`, we need to do two things:

1. Actually run the animation
2. Ensure that the camera position is such that the animation will actually be visible, as it is pointless to animate a marker between two points if the currently-viewed portion of the map does not show those points

To handle the camera position, we need to use `moveCamera()` with a `CameraUpdate` from `CameraUpdateFactory`, as we used to set the initial camera position and zoom level. To handle the case where we want one or more points to be visible, we can use the `newLatLngBounds()` method on `CameraUpdateFactory`. This takes a `LatLngBounds` describing the area that needs to be visible, plus a padding amount in pixels for where that area should be inset within the map.

Of course, this implies that we have a `LatLngBounds`. 

1828
Since LatLngBounds also does not depend upon a Context or much of anything, we can define one of those as a static final data member, using a LatLngBounds.Builder instance:

```java
private static final LatLngBounds bounds =
    new LatLngBounds.Builder().include(LINCOLN_CENTER)
    .include(PENN_STATION).build();
```

A LatLngBounds.Builder takes one or more LatLng objects — passed in via include() — then constructs a LatLngBounds that encompasses all of those points via build().

Our animateMarker() method then starts off by using moveCamera() to reset the camera to show that defined region:

```java
private void animateMarker() {
    map.moveCamera(CameraUpdateFactory.newLatLngBounds(bounds, 48));

    Property<? extends Marker, LatLng> property =
        Property.of(Marker.class, LatLng.class, "position");
    ObjectAnimator animator =
        ObjectAnimator.ofObject(markerToAnimate, property,
            new LatLngEvaluator(), nextAnimationEnd);
    animator.setDuration(2000);
    animator.start();

    if (nextAnimationEnd == LINCOLN_CENTER) {
        nextAnimationEnd = PENN_STATION;
    } else {
        nextAnimationEnd = LINCOLN_CENTER;
    }
}
```

Then, we need to set up the animation. To do this, we will use the object animator framework, specifically an ObjectAnimator. We know the Marker that we want to animate (markerToAnimate) and we know where we want to animate it to (nextAnimationEnd). What we need is to indicate the property to animate on this object, plus provide help to actually animate a LatLng.

To specify the property, we could just pass in the name of the property ("position").
However, in animateMarker(), we set up a Property object via the static of() factory method. This makes our use of ofObject() more type-safe, as Property will help enforce that we are animating a Marker using LatLng values.

To animate LatLng values, we need a TypeEvaluator for LatLng, here defined as a static inner class named LatLngEvaluator:

```java
private static class LatLngEvaluator implements TypeEvaluator<LatLng> {
    @Override
    public LatLng evaluate(float fraction, LatLng startValue, LatLng endValue) {
        return SphericalUtil.interpolate(startValue, endValue, fraction);
    }
}
```

(from MapsV2/Animator/app/src/main/java/com/commonsware/android/mapsv2/animator/MainActivity.java)

Our evaluate() method turns around and calls the static interpolate() method on SphericalUtil, supplied by Google's map utility library. interpolate() handles all the nasty spherical trigonometry and stuff, so we do not have to.

We then set the duration of the animation to be two seconds, and start the animation.

Finally, to reverse the animation for the next request, animateMarker() resets the value of nextAnimationEnd to be PENN_STATION or LINCOLN_CENTER, wherever we will animate to next.

**Honoring Traffic Rules, Like “Drive Only On Streets”**

You will notice that our animation ignores other aspects of reality, such as buildings that might be in the way. Sometimes, that is appropriate, such as animating the movement of:

- a bird
- a plane
- a costumed superhero with independent flight capability

Sometimes, though, we need to take into account those obstacles, such as animating the movement of:

- a pedestrian
- a car
• a costumed superhero “flying” by means of swinging between buildings using dynamically-generated cables of either natural or synthetic origin

However, to do this implies that we know where the obstacles are. Or, more accurately, we would need to animate the marker along known good waypoints, such as streets.

The animation would not be especially difficult, as ofObject() can take a series of waypoints. However, we would need to find those waypoints, and there is nothing in Maps V2 itself that supplies this data.

Maps, of the Indoor Variety

The good news is that Maps V2 supports Google’s indoor maps, for those venues for which Google has indoor map data.

The bad news is that for some reason, only one map at a time supports indoor maps. The default will be that the first map you create will support indoor maps, and others will not.

To see if a given map offers indoor map capability, you can call isIndoorEnabled() on GoogleMap. To toggle this capability, call setIndoorEnabled().

Taking a Snapshot of a Map

Once a map is drawn, you can take a snapshot of it, converting the viewed map into a Bitmap object. This is designed to take an image of the map and use it in places where a SupportMapFragment, or even a MapView, cannot go, such as:

• Things tied to a RemoteViews, such as a custom Notification
• Thumbnails of maps, for an app that allows users to manipulate several maps at once

The GoogleMap object has two flavors of a snapshot() method. Both take a SnapshotReadyCallback object. You will need to supply an instance of something implementing the SnapshotReadyCallback interface, overriding onSnapshotReady(), where you will receive your Bitmap.

One flavor of snapshot() takes just the SnapshotReadyCallback; the other also takes a Bitmap of the proper dimensions, such as a previous snapshot Bitmap that you
want to recycle. Using the latter snapshot() is recommended where possible, so you do not need to allocate new Bitmap objects on each snapshot() call.

Note that snapshot() will only work once the map is actually rendered. So, for example, calling snapshot() from onCreate() of your activity will fail, because the map has not been rendered yet. snapshot() is designed to be called based upon user input, either to manually capture a snapshot or based on navigation (e.g., tapping on a ListView item triggers saving a snapshot of the current map as a thumbnail before changing the map contents).

Also, the documentation for snapshot() contains the following:

**Note:** Images of the map must not be transmitted to your servers, or otherwise used outside of the application. If you need to send a map to another application or user, send data that allows them to reconstruct the map for the new user instead of a snapshot.

As this statement may be tied to the terms and conditions of your use of Maps V2, you should talk with qualified legal counsel before:

- Saving a snapshot to external storage
- Sharing a snapshot via ACTION_SEND
- Sending a snapshot to your server

or similar operations.

**SupportMapFragment vs. MapView**

So far, all the examples shown in this chapter use SupportMapFragment. In most cases, this is the right thing to use.

However, there may be places where you really want to use a View, rather than a Fragment, for your maps.

The good news is that Maps V2 does have a MapView. SupportMapFragment usually handles creating and managing the MapView for you, but you can, if you wish, avoid SupportMapFragment and manage the MapView yourself.

The biggest limitation is that you need to forward the lifecycle methods from your activity or fragment on to the MapView, calling onCreate(), onResume(), onPause(), onDestroy(), and onSaveInstanceState() on the MapView. Normally,
SupportMapFragment would do that for you, saving you the trouble.

Also note that while MapView is a ViewGroup, you are not allowed to add child widgets to it.

**About That AbstractMapActivity Class…**

Early on, we hand-waved our way past the AbstractMapActivity that all of our MainActivity classes inherit from, and we skirted past the readyToGo() method that we were calling. Also, you may have noticed that our app has an action bar overflow item, that we do not seem to be creating in MainActivity.

Now, it is time to dive into what is going on in our AbstractMapActivity implementations.

The readyToGo() method in AbstractMapActivity is designed to help us determine if Maps V2 is “ready to go” and, if not, to help the user perhaps fix their device such that Maps V2 will work in the future:

```java
protected boolean readyToGo() {
    GoogleApiAvailability checker =
        GoogleApiAvailability.getInstance();

    int status = checker.isGooglePlayServicesAvailable(this);

    if (status == ConnectionResult.SUCCEESS) {
        if (getVersionFromPackageManager(this) >= 2) {
            return true;
        } else {
            Toast.makeText(this, R.string.no_maps, Toast.LENGTH_LONG).show();
            finish();
        }
    } else if (checker.isUserResolvableError(status)) {
        ErrorDialogFragment.newInstance(status)
            .show(getFragmentManager(),
                  TAG_ERROR_DIALOG_FRAGMENT);
    } else {
        Toast.makeText(this, R.string.no_maps, Toast.LENGTH_LONG).show();
        finish();
    }
}
```
Determining the availability of Maps V2 — or anything in the Play Services SDK — is handled through an instance of `GoogleApiAvailability`. You get a singleton instance of this class via its static `getInstance()` method.

First, we call `isGooglePlayServicesAvailable()` method on the `GoogleApiAvailability` singleton. This will return an integer indicating whether Maps V2 is available for our use or not.

If the return value is `ConnectionResult.SUCCESS` — meaning Maps V2 is indeed available to us – we check to see if OpenGL ES is version 2.0 or higher, as we did not require that in the manifest. There are a few ways in Android to check the OpenGL ES version. This sample uses some code from the Compatibility Test Suite (CTS), examining `PackageManager` to determine the major level:

```java
private static int getVersionFromPackageManager(Context context) {
    PackageManager packageManager = context.getPackageManager();
    FeatureInfo[] featureInfos = packageManager.getSystemAvailableFeatures();
    if (featureInfos != null && featureInfos.length > 0) {
        for (FeatureInfo featureInfo : featureInfos) {
            // Null feature name means this feature is the open
            // gl es version feature.
            if (featureInfo.name == null) {
                if (featureInfo.reqGlEsVersion != FeatureInfo.GL_ES_VERSION_UNDEFINED) {
                    return getMajorVersion(featureInfo.reqGlEsVersion);
                }
            }
        }
    }
    return 0;
}
```

(from MapsV2/Basic/app/src/main/java/com/commonsware/android/mapsv2/basic/AbstractMapActivity.java)
If the major version is 2 or higher, we return `true` from `readyToGo()`, so `MainActivity` knows to continue on setting up the map. If the major version is 1, we display a `Toast` — a production-grade app would do something else to let the user know of the problem, most likely.

But, what if `isGooglePlayServicesAvailable()` returns something else?

There are two major possibilities here:

1. The error is something that the user might be able to rectify, such as by downloading the Google Play Services app from the Play Store
2. The error is something that the user cannot recover from

We can distinguish these two cases by calling `isUserResolvableError()` on the `GoogleApiAvailability` singleton, passing in the value we received from `isGooglePlayServicesAvailable()`. This will return `true` if the user might be able to fix the problem, `false` otherwise.

In the `false` case, the user is just out of luck, so we display a `Toast` to alert them of this fact, then `finish()` the activity and return `false`, so `MainActivity` skips over the rest of its work.

In the `true` case, we can display something to the user to prompt them to fix the problem. One way to do that is to use a dialog obtained from Google code, by calling the static `getErrorDialog()` method on a `GoogleApiAvailability` singleton. In our case, we wrap that in a `DialogFragment` named `ErrorDialogFragment`, implemented as a static inner class of `AbstractMapActivity`:

```java
public static class ErrorDialogFragment extends DialogFragment {
    static final String ARG_ERROR_CODE="errorCode";
```
While the code and comments around `getErrorDialog()` suggest that there is some way for us to find out if the user performed actions that fix the problem, this code does not seem to work well in practice. After all, downloading Google Play Services is asynchronous, so even if the user returns to our app, it is entirely likely that Maps V2 is still unavailable. As a result, when the user is done with the dialog, we `finish()` the activity, forcing the user to start it again if and when they are done downloading Google Play Services.

Testing this code requires an older device, one in which the “Google Play services” app can be uninstalled... if it can be installed at all.

As it turns out, not all Android devices support the Play Store, or the Google Play Services by extension. Notably, if the device lacks the Play Store, `isUserRecoverableError()` returns true, even though the user cannot recover from
this situation (except perhaps via a firmware update).

(An earlier problem where `getErrorDialog()` could return `null` even for cases where the error is supposedly user-recoverable has been fixed)

### Helper Libraries for Maps V2

Many developers have been busy writing libraries that help in the development of Maps V2 applications, beyond Google's own utility library mentioned in the section on animating markers.
Perhaps the most expansive of these is the Android Maps Extensions library. The big thing that this library offers is marker clustering, where as the user zooms out, individual markers are replaced by a marker representing a cluster, so you avoid flooding a small area with too many individual markers:

![Figure 576: Map with Many Markers (from Android Maps Extensions demo app)](image)

Figure 576: Map with Many Markers (from Android Maps Extensions demo app)
Figure 577: Same Map with Cluster Markers (from Android Maps Extensions demo app)
This library wraps the Maps V2 classes, allowing the library to offer extensions to the standard Maps V2 API, including:

- Associating your own data with Marker, Polygon, Polyline, and other classes, to tie them back to your models
- Getters to retrieve previously-defined markers, etc.
- Etc.

Another library offering marker clustering is clusterkraf, from Two Toasters.

The clusterkraf library can optionally integrate with Cyril Mottier’s Polaris2 library. His original Polaris library aimed to provide more features to Maps V1; Polaris2 fills a similar role for Maps V2. At this time, Polaris2 is a smaller library, simply because Maps V2 handles much of what Polaris provided. Polaris2, like Android Maps Extensions, wraps the Maps V2 API with its own classes, in lieu of subclassing (since most Maps V2 classes are marked final). Of note, Polaris2 offers \reset{} methods on many of the …Options classes (e.g., MarkerOptions), and offers constants for the minimum and maximum valid latitude and longitude.
Problems with Maps V2 at Runtime

Portions of the logic that powers your Maps V2 SupportMapFragment are supplied by the Google Play Services app. As a result, many operations with Maps V2, such as manipulating markers, require IPC calls between your app and Google Play Services. If those IPC calls are synchronous, they will add a bit of overhead to your app — enough that you will want to avoid them in time-critical pieces of code, tight loops, and the like.

Problems with Maps V2 Deployment

Of course, the key question is: should you be using Maps V2 at all?

Google thinks so, as they have turned off access to new API keys for Maps V1. That makes ongoing development of Maps V1 solutions a bit risky, as you cannot create new API keys for new signing keys, such as if you need to replace your debug keystore.

However, Maps V2 has some deployment limitations at this time. While 99.8+% of Android devices that have the Play Store have the requisite OpenGL ES 2.0+, some devices that have a suitable OpenGL ES version may not have the Play Store or otherwise be unable to get Google Play Services, required for using Maps V2. The isGooglePlayServicesAvailable() approach advocated by Google can help determine this at runtime, though this approach used to have some bugs, and it still cannot always help you recover from this problem.

And, as the next section illustrates, not every Android device supports Maps V2, because not every device supports Google Play Services.
What Non-Compliant Devices Show

If your app tries to bring up Maps V2 on a device that cannot possibly have the Play Services Framework — such as a Kindle Fire — the user will see an error dialog:

![Google Play services error dialog](image)

For those devices, you will need to consider some alternative source of maps.

Mapping Alternatives

Beyond using Maps V2 or Maps V1, you may need to consider other mapping alternatives. The Google mapping APIs are only available on Android devices that have the Maps SDK add-on (Maps V1) or Google Play Services (Maps V2). Not all devices have those. And, the limitations of Maps V2 deployment and the deprecation of Maps V1 may convince you that relying upon Google for maps is not safe at the present time.

The most common native replacement for Google's mapping is OpenStreetMap, which to some extent is “the Wikipedia of maps”. OSMDroid is a library that provides a Maps V1-ish API for embedding OpenStreetMap-based maps into your application.

Another solution is to integrate Web-based Google maps into your app, the same way that you might embed them into your Web site. An activity hosting a WebView can display a Web-based Google Map, for example.

Certain devices may have access to other native mapping solutions. For example, Amazon has published their own maps API for use with the Kindle Fire.
Crafting Your Own Views

One of the classic forms of code reuse is the GUI widget. Since the advent of Microsoft Windows — and, to some extent, even earlier – developers have been creating their own widgets to extend an existing widget set. These range from 16-bit Windows “custom controls” to 32-bit Windows OCX components to the innumerable widgets available for Java Swing and SWT, and beyond. Android lets you craft your own widgets as well, such as extending an existing widget with a new UI or new behaviors.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Pick Your Poison

You have five major options for creating a custom View class.

First, your “custom View class” might really only be custom Drawable resources. Many widgets can adopt a radically different look and feel just with replacement graphics. For example, you might think that these toggle buttons from the Android 2.1 Google Maps application are some fancy custom widget:

![Figure 580: Google Maps navigation toggle buttons](image)
In reality, those are just radio buttons with replacement images.

Second, your custom View class might be a simple subclass of an existing widget, where you override some behaviors or otherwise inject your own logic. Unfortunately, most of the built-in Android widgets are not really designed for this sort of simple subclassing, so you may be disappointed in how well this particular technique works.

Third, your custom View class might be a composite widget — akin to an activity’s contents, complete with layout and such, but encapsulated in its own class. This allows you to create something more elaborate than you will just by tweaking resources. We will see this later in the chapter with ColorMixer.

Fourth, you might want to implement your own layout manager, if your GUI rules do not fit well with RelativeLayout, TableLayout, or other built-in containers. For example, you might want to create a layout manager that more closely mirrors the “box model” approach taken by XUL and Flex, or you might want to create one that mirrors Swing’s FlowLayout (laying widgets out horizontally until there is no more room on the current row, then start a new row).

Finally, you might want to do something totally different, where you need to draw the widget yourself. For example, the ColorMixer widget uses SeekBar widgets to control the mix of red, blue, and green. But, you might create a ColorWheel widget that draws a spectrum gradient, detects touch events, and lets the user pick a color that way.

Some of these techniques are fairly simple; others are fairly complex. All share some common traits, such as widget-defined attributes, that we will see throughout the remainder of this chapter.
Colors, Mixed How You Like Them

The classic way for a user to pick a color in a GUI is to use a color wheel like this one:

![Color Wheel](image)

*Figure 581: Color Wheel*

However, a color wheel like that is difficult to manipulate on a touch screen, particularly a capacitive touchscreen designed for finger input. Fingers are great for gross touch events and lousy for selecting a particular color pixel.
Another approach is to use a mixer, with sliders to control the red, green, and blue values:

![ColorMixer widget](image)

*Figure 582: The ColorMixer widget, inside an activity*

That is the custom widget you will see in this section, based on the code in the Views/ColorMixer sample project.

**The Layout**

ColorMixer is a composite widget, meaning that its contents are created from other widgets and containers. Hence, we can use a layout file to describe what the widget should look like.

The layout to be used for the widget is not that much: three SeekBar widgets (to control the colors), three TextView widgets (to label the colors), and one plain View (the “swatch” on the left that shows what the currently selected color is). Here is the file, found in res/layout/mixer.xml in the Views/ColorMixer project:

```xml
<?xml version="1.0" encoding="utf-8"?>
<merge xmlns:android="http://schemas.android.com/apk/res/android">
    <View android:id="@+id/swatch"/>
</merge>
```
android:layout_width="40dip"
android:layout_height="40dip"
android:layout_alignParentLeft="true"
android:layout_centerVertical="true"
android:layout_marginLeft="4dip"
 />
<TextView android:id="@+id/redLabel"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:layout_alignTop="@id/swatch"
android:layout_toRightOf="@id/swatch"
android:layout_marginLeft="4dip"
android:text="@string/red"
android:textSize="24sp"
 />
<SeekBar android:id="@+id/red"
android:layout_width="match_parent"
android:layout_height="wrap_content"
android:layout_alignTop="@id/redLabel"
android:layout_toRightOf="@id/redLabel"
android:layout_marginLeft="4dip"
android:layout_marginRight="8dip"
 />
<TextView android:id="@+id/greenLabel"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:layout_below="@id/redLabel"
android:layout_toRightOf="@id/swatch"
android:layout_marginLeft="4dip"
android:layout_marginTop="4dip"
android:text="@string/green"
android:textSize="24sp"
 />
<SeekBar android:id="@+id/green"
android:layout_width="match_parent"
android:layout_height="wrap_content"
android:layout_alignTop="@id/greenLabel"
android:layout_toRightOf="@id/greenLabel"
android:layout_marginLeft="4dip"
android:layout_marginRight="8dip"
 />
<TextView android:id="@+id/blueLabel"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:layout_below="@id/greenLabel"
android:layout_toRightOf="@id/swatch"
android:layout_marginLeft="4dip"
android:layout_marginTop="4dip"

One thing that is a bit interesting about this layout, though, is the root element: `<merge>`. A `<merge>` layout is a bag of widgets that can be poured into some other container. The layout rules on the children of `<merge>` are then used in conjunction with whatever container they are added to. As we will see shortly, ColorMixer itself inherits from RelativeLayout, and the children of the `<merge>` element will become children of ColorMixer in Java. Basically, the `<merge>` element is only there because XML files need a single root — otherwise, the `<merge>` element itself is ignored in the layout.

The Attributes

Widgets usually have attributes that you can set in the XML file, such as the android:src attribute you can specify on an ImageButton widget. You can create your own custom attributes that can be used in your custom widget, by creating a res/values/attrs.xml file containing declare-styleable resources to specify them.

For example, here is the attributes file for ColorMixer:

```xml
<resources>
  <declare-styleable name="ColorMixer">
    <attr name="initialColor" format="color" />
  </declare-styleable>
</resources>
```

The declare-styleable element describes what attributes are available on the widget class specified in the name attribute — in our case, ColorMixer. Inside
Crafting Your Own Views

declare-styleable you can have one or more attr elements, each indicating the name of an attribute (e.g., initialColor) and what data format the attribute has (e.g., color). The data type will help with compile-time validation and in getting any supplied values for this attribute parsed into the appropriate type at runtime.

Here, we indicate there is only one attribute: initialColor, which will hold the initial color we want the mixer set to when it first appears.

There are many possible values for the format attribute in an attr element, including:

1. boolean
2. color
3. dimension
4. float
5. fraction
6. integer
7. reference (which means a reference to another resource, such as a Drawable)
8. string

You can even support multiple formats for an attribute, by separating the values with a pipe (e.g., reference|color).

The Class

Our ColorMixer class, a subclass of RelativeLayout, will take those attributes and provide the actual custom widget implementation, for use in activities.

Constructor Flavors

A View has three possible constructors:

1. One takes just a Context, which usually will be an Activity
2. One takes a Context and an AttributeSet, the latter of which represents the attributes supplied via layout XML
3. One takes a Context, an AttributeSet, and the default style to apply to the attributes

If you are expecting to use your custom widget in layout XML files, you will need to implement the second constructor and chain to the superclass. If you want to use
styles with your custom widget when declared in layout XML files, you will need to implement the third constructor and chain to the superclass. If you want developers to create instances of your View class in Java code directly, you probably should implement the first constructor and, again, chain to the superclass.

In the case of ColorMixer, all three constructors are implemented, eventually routing to the three-parameter edition, which initializes our widget. Below, you will see the first two of those constructors, with the third coming up in the next section:

```java
public ColorMixer(Context context) {
    this(context, null);
}

public ColorMixer(Context context, AttributeSet attrs) {
    this(context, attrs, 0);
}
```

(from Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java)

**Using the Attributes**

The ColorMixer has a starting color — after all, the SeekBar widgets and swatch View have to show something. Developers can, if they wish, set that color via a setColor() method:

```java
public void setColor(int color) {
    red.setProgress(Color.red(color));
    green.setProgress(Color.green(color));
    blue.setProgress(Color.blue(color));
    swatch.setBackgroundColor(color);
}
```

(from Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java)

If, however, we want developers to be able to use layout XML, we need to get the value of initialColor out of the supplied AttributeSet. In ColorMixer, this is handled in the three-parameter constructor:

```java
public ColorMixer(Context context, AttributeSet attrs, int defStyle) {
    super(context, attrs, defStyle);
    ((Activity)getContext()).
        getLayoutInflater().
        inflate(R.layout.mixer, this, true);
}
```
There are three steps for getting attribute values:

- Get a `TypedArray` conversion of the `AttributeSet` by calling `obtainStyledAttributes()` on our `Context`, supplying it the `AttributeSet` and the ID of our styleable resource (in this case, `R.styleable.ColorMixer`, since we set the name of the `declare-styleable` element to be `ColorMixer`)
- Use the `TypedArray` to access specific attributes of interest, by calling an appropriate getter (e.g., `getInt()`) with the ID of the specific attribute to fetch (`R.styleable.ColorMixer_initialColor`)
- Recycle the `TypedArray` when done, via a call to `recycle()`, to make the object available to Android for use with other widgets via an object pool (versus creating new instances every time)

Note that the name of any given attribute, from the standpoint of `TypedArray`, is the name of the styleable resource (`R.styleable.ColorMixer`) concatenated with an underscore and the name of the attribute itself (`_initialColor`).
In ColorMixer, we get the attribute and pass it to setColor(). Since getInt() on AttributeSet takes a default value, we supply some stock color that will be used if the developer declined to supply an initialColor attribute.

Also note that our ColorMixer constructor inflates the widget’s layout. In particular, it supplies true as the third parameter to inflate(), meaning that the contents of the layout should be added as children to the ColorMixer itself. When the layout is inflated, the <merge> element is ignored, and the <merge> element’s children are added as children to the ColorMixer.

Saving the State

Similar to activities, a custom View overrides onSaveInstanceState() and onRestoreInstanceState() to persist data as needed, such as to handle a screen orientation change. The biggest difference is that rather than receive a Bundle as a parameter, onSaveInstanceState() must return a Parcelable with its state... including whatever state comes from the parent View.

The simplest way to do that is to return a Bundle, in which we have filled in our state (the chosen color) and the parent class’ state (whatever that may be).

So, for example, here are implementations of onSaveInstanceState() and onRestoreInstanceState() from ColorMixer:

```java
@override
public Parcelable onSaveInstanceState() {
    Bundle state = new Bundle();

    state.putParcelable(SUPERSTATE, super.onSaveInstanceState());
    state.putInt(COLOR, getColor());

    return state;
}

@override
public void onRestoreInstanceState(Parcel ss) {
    Bundle state = (Bundle)ss;

    super.onRestoreInstanceState(state.getParcelable(SUPERSTATE));

    setColor(state.getInt(COLOR));
}
```

(from Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java)
The Rest of the Functionality

ColorMixer defines a callback interface, named OnColorChangedListener:

```
public interface OnColorChangedListener {
    public void onColorChange(int argb);
}
```

(from Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java)

ColorMixer also provides getters and setters for an OnColorChangedListener object:

```
public OnColorChangedListener getOnColorChangedListener() {
    return (listener);
}

public void setOnColorChangedListener(OnColorChangedListener listener) {
    this.listener=listener;
}
```

(from Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java)

The rest of the logic is mostly tied up in the SeekBar handler, which will adjust the swatch based on the new color and invoke the OnColorChangedListener object, if there is one:

```
private SeekBar.OnSeekBarChangeListener onMix=new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar, int progress, boolean fromUser) {
        int color=color;
        swatch.setBackgroundColor(color);
        if (listener!=null) {
            listener.onColorChange(color);
        }
    }

    public void onStartTrackingTouch(SeekBar seekBar) {
        // unused
    }

    public void onStopTrackingTouch(SeekBar seekBar) {
        // unused
    }
};
```

(from Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixer.java)
Seeing It In Use

The project contains a sample activity, ColorMixerDemo, that shows the use of the ColorMixer widget.

The layout for that activity, shown below, can be found in res/layout/main.xml of the Views/ColorMixer project:

```xml
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:mixer="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">
    <TextView android:id="@+id/color"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    <com.commonsware.android.colormixer.ColorMixer
        android:id="@+id/mixer"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        mixer:initialColor="#FFA4C639"/>
</LinearLayout>
```

(from Views/ColorMixer/app/src/main/res/layout/main.xml)

Notice that the root LinearLayout element defines two namespaces, the standard android namespace, and a separate one named mixer. The mixer namespace is given a URL of http://schemas.android.com/apk/res-auto, which indicates to the Android build system to match up mixer attributes with their respective widgets that are supplied via Android library projects.

Our ColorMixer widget is in the layout, with a fully-qualified class name (com.commonsware.android.colormixer.ColorMixer), since ColorMixer is not in the android.widget package. Notice that we can treat our custom widget like any other, giving it a width and height and so on.

The one attribute of our ColorMixer widget that is unusual is mixer:initialColor. initialColor, you may recall, was the name of the attribute we declared in res/values/attrs.xml and retrieve in Java code, to represent the color to start with. The mixer namespace is needed to identify where Android should be pulling the rules
for what sort of values an initialColor attribute can hold. Since our `<attr>` element indicated that the format of initialColor was color, Android will expect to see a color value here, rather than a string or dimension.

The ColorMixerDemo activity is not very elaborate:

```java
package com.commonsware.android.colormixer;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;

public class ColorMixerDemo extends Activity {
    private TextView color=null;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        color=findViewById(R.id.color);

        ColorMixer mixer=findOneViewById(R.id.mixer);

        mixer.setOnColorChangedListener(onColorChange);
    }

    private ColorMixer.OnColorChangedListener onColorChange =
            new ColorMixer.OnColorChangedListener() {
                public void onColorChange(int argb) {
                    color.setText(Integer.toHexString(argb));
                }
            };
}
```

(from Views/ColorMixer/app/src/main/java/com/commonsware/android/colormixer/ColorMixerDemo.java)

It gets access to both the ColorMixer and the TextView in the main layout, then registers an OnColorChangedListener with the ColorMixer. That listener, in turn, puts the value of the color in the TextView, so the user can see the hex value of the color along with the shade itself in the swatch.

**ReverseChronometer: Simply a Custom Subclass**

Sometimes, what you want to achieve only requires a basic subclass of an existing
Crafting Your Own Views

widget (or container), into which you can pour your business logic.

For example, Android has a Chronometer widget, which is used for denoting elapsed time of some operation. It works well, but it only counts up from zero. It cannot be used to display a countdown instead.

But, we can roll a ReverseChronometer that does, simply by subclassing TextView, as seen in the Views/ReverseChronometer sample project:

```java
package com.commonsware.android.revchron;

import android.content.Context;
import android.graphics.Color;
import android.os.SystemClock;
import android.util.AttributeSet;
import android.widget.TextView;

public class ReverseChronometer extends TextView implements Runnable {
    long startTime = 0L;
    long overallDuration = 0L;
    long warningDuration = 0L;

    public ReverseChronometer(Context context, AttributeSet attrs) {
        super(context, attrs);

        reset();
    }

    @Override
    public void run() {
        long elapsedSeconds =
            (SystemClock.elapsedRealtime() - startTime) / 1000;

        if (elapsedSeconds < overallDuration) {
            long remainingSeconds = overallDuration - elapsedSeconds;
            long minutes = remainingSeconds / 60;
            long seconds = remainingSeconds - (60 * minutes);

            setText(String.format("%d:%02d", minutes, seconds));

            if (warningDuration > 0 && remainingSeconds < warningDuration) {
                setTextColor(0xFFFF6600); // orange
            } else {
                setTextColor(Color.BLACK);
            }
        }
    }
}
```
ReverseChronometer is designed to show minutes and seconds remaining from some initial time. In the constructor, by means to a call to a `reset()` method, we set the text of the TextView to show a generic starting point (“-:-”), set its color to black, and note the current time (`SystemClock.elapsedRealtime()`) in a `startTime` data member.

ReverseChronometer also tracks two durations in seconds, with corresponding setter methods:

- `overallDuration` is how long the countdown should run from beginning to end
- `warningDuration` is how far from the end we should change the color of the TextView from black to orange, to hint to the viewer that time is running out

ReverseChronometer implements Runnable, and when its `run()` method is called, it
determines how many seconds have elapsed since that startTime value. Depending on the amount of seconds remaining, we either:

- Just update the text to show the minutes and seconds remaining
- Update the text and set the color to black or orange
- Set the text to “0:00” (time has run out) and set the text color to red

In either of the first two cases, we also call postDelayed() to schedule ourselves to run again in a second, where we can update the TextView contents once more. That continues until somebody calls stop().

As with any custom View, we can reference this in a layout XML resource, fully-qualifying the class name used as the name of our XML element for the widget. And, since we inherit from TextView, we can set any of the attributes that we want on that TextView, in terms of styling the text, positioning it within a parent container, etc.:

```xml
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    tools:context=".MainActivity">

    <com.commonsware.android.revchron.ReverseChronometer
        android:id="@+id/chrono"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerInParent="true"
        android:textSize="50sp"
        android:textStyle="bold"/>

</RelativeLayout>
```

All our activity needs to do is set the durations, then call run() and stop() at appropriate times, such as when the activity is resumed and paused:

```java
package com.commonsware.android.revchron;

import android.app.Activity;
import android.os.Bundle;

public class MainActivity extends Activity {
    private ReverseChronometer chrono=null;
```
```java
@override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    chrono=(ReverseChronometer)findViewById(R.id.chrono);
    chrono.setOverallDuration(90);
    chrono.setWarningDuration(10);
}

@Override
public void onResume() {
    super.onResume();
    chrono.run();
}

@Override
public void onPause() {
    chrono.stop();
    super.onPause();
}
}
```

(from Views/ReverseChronometer/app/src/main/java/com/commonsware/android/revchron/MainActivity.java)
The result is much as you would expect: a countdown of the time remaining:

![Image: ReverseChronometer, Early in Countdown](image)

*Figure 583: ReverseChronometer, Early in Countdown*
CRAFTING YOUR OWN VIEWS

...changing to orange when we are within the warning duration:

![ReverseChronometer, Late in Countdown](image)

*Figure 584: ReverseChronometer, Late in Countdown*
...and changing to red when time has run out:

![ReverseChronometer](image)

*Figure 585: ReverseChronometer, With Complete Time Elapsed*

Of course, much more could be done with this widget, if you chose:

- Support other constructors, beyond the two-argument constructor needed for layout inflation
- Support setting durations and colors via custom XML attributes
- Adding listeners for warning and expired events, so other things can be done at those points in time (e.g., play a sound, vibrate the device)

**AspectLockedFrameLayout: A Custom Container**

You can also craft your own custom container classes, whether inheriting straight from `ViewGroup` to implement your own set of layout rules, or by extending an existing `ViewGroup` to merely augment its functionality.

For example, there may be cases where you want to control the aspect ratio of some set of widgets. This is important when working with preview frames off of the Camera to prevent distortion, for example.
AspectLockedFrameLayout, therefore, is a custom extension of FrameLayout that ensures that its contents are kept within a particular aspect ratio, reducing the height or width of the contents to keep that aspect ratio.

AspectLockedFrameLayout is published as part of the CWAC-Layouts project, with its own GitHub repo. As with many of the CWAC projects, the reusable code is distributed as a JAR and as an Android library project, with a demo/ sub-project illustrating the use of some of the library’s contents.

AspectLockedFrameLayout holds onto two data members:

- A double (aspectRatio) that represents a specific aspect ratio to maintain, initialized to 0.0
- A View (aspectRatioSource) that represents some other widget whose aspect ratio should be matched, initialized to null

AspectLockedFrameLayout has corresponding setters for each:

```java
lockedHeight=(int)(lockedWidth / localRatio + .5);

// Add the padding of the border.
lockedWidth+=hPadding;
lockedHeight+=vPadding;

// Ask children to follow the new preview dimension.
super.onMeasure(MeasureSpec.makeMeasureSpec(lockedWidth,
    MeasureSpec.EXACTLY),
    MeasureSpec.makeMeasureSpec(lockedHeight,
    MeasureSpec.EXACTLY));
```

/**
 * Supplies a View as a source. The AspectLockedFrameLayout will aim to
 * match the aspect ratio of this View. This is a one-time check; if the
 * View changes its aspect ratio later, the AspectLockedFrameLayout will
 * not attempt to match it.
 *
 * @param v some View
 */

The “business logic” of maintaining the aspect ratio comes in onMeasure(). onMeasure() is called on a ViewGroup when it is time for it to determine its actual size, based upon things like the requested height and width and the sizes of its
children. In our case onMeasure() needs to be tweaked to maintain the aspect ratio, assuming that we have an aspect ratio to work with:

```java
public AspectLockedFrameLayout(Context context, AttributeSet attrs) {
    super(context, attrs);
}
```

// from com.android.camera.PreviewFrameLayout, with slight modifications

```java
@Override
protected void onMeasure(int widthSpec, int heightSpec) {
    double localRatio = aspectRatio;
    if (localRatio == 0.0 && aspectRatioSource != null && aspectRatioSource.getHeight() > 0) {
        localRatio = (double)aspectRatioSource.getWidth() / (double)aspectRatioSource.getHeight();
    }
    if (localRatio == 0.0) {
        super.onMeasure(widthSpec, heightSpec);
    } else {
        int lockedWidth = MeasureSpec.getSize(widthSpec);
        int lockedHeight = MeasureSpec.getSize(heightSpec);
        if (lockedWidth == 0 && lockedHeight == 0) {
            throw new IllegalArgumentException("Both width and height cannot be zero -- watch out for scrollable containers");
        }
        // Get the padding of the border background.
        int hPadding = getPaddingLeft() + getPaddingRight();
        int vPadding = getPaddingTop() + getPaddingBottom();
        // Resize the preview frame with correct aspect ratio.
        lockedWidth -= hPadding;
        lockedHeight -= vPadding;
        if (lockedHeight > 0 && (lockedWidth > lockedHeight * localRatio)) {
            lockedWidth = (int)(lockedHeight * localRatio + .5);
        }
    }
```

We start by determining what actually is the desired aspect ratio, held onto in a localRatio local variable. That will be aspectRatio if we do not have an aspectRatioSource that already knows its size, otherwise we will calculate the
aspect ratio from the source. And, if `localRatio` turns out to be 0.0, indicating that we do not have an aspect ratio to maintain, we just chain to the superclass, so `AspectLockedFrameLayout` will behave just like a normal `FrameLayout`.

If we do have an aspect ratio to maintain, we start by determining our requested height and width. `onMeasure()` is passed a pair of “specs” that provides details about our requested size, and we can get the height and width from those by means of the `MeasureSpec` helper class. We remove any horizontal padding — padding is considered to be “outside” the locked area and therefore is ignored in aspect ratio calculations. We then adjust the height or the width, as needed, to maintain the aspect ratio. We add back in the padding, then chain to the superclass with revised height and width “specs” via `MeasureSpec`.

Note that much of this logic was derived from `com.android.camera.PreviewFrameLayout` from the AOSP Camera application, which is used to maintain the aspect ratio of the `SurfaceView` used to display preview frames.

To use an `AspectLockedFrameLayout`, just add it to your layout XML file, with an appropriate child widget/container representing the material that needs to maintain a particular aspect ratio. Since the `AspectLockedFrameLayout` is overriding its natural size, you can use `android:layout_gravity` to control its positioning within some parent widget, such as centering it:

```xml
<FrameLayout
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <com.commonsware.cwac.layouts.AspectLockedFrameLayout
        android:id="@+id/source"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_gravity="center">

    <!-- children go here -->

    </com.commonsware.cwac.layouts.AspectLockedFrameLayout>
</FrameLayout>
```

**Mirror and MirroringFrameLayout: Draw It Yourself**

Another scenario where aspect ratios matter is when you are presenting information on an external display via `Presentation`, as is covered elsewhere in this book.
CRAFTING YOUR OWN VIEWS

Ideally, you fill the external display. And normally this will happen for you automatically, as your Presentation content view should fill the available screen space... assuming that the content has the right aspect ratio, or can be suitably stretched.

One scenario where this might be a problem is if you want the same material shown on both the main display and on the external display. For example, suppose that you are using Presentation to deliver... well... a presentation. The external display is probably some form of video projector, and you will want your slides or other materials shown there. However, it is useful for you to be able to see those same slides and such on the tablet, as typically the projector screen is behind, or to the side of, the presenter. If the presenter has to keep turning around to confirm what is shown on “the big screen”, it can detract from the presentation.

Moreover, you might not only want to show the same material, but have it stem from the same source, on the tablet, for interactivity reasons. Suppose that you want to display a Web page. You might just pop up a WebView in the Presentation. But... how do you scroll? The Presentation offers no touch interface — projector screens do not magically respond to pinch-to-zoom just because we happen to be projecting something onto them from an Android tablet.

In this case, ideally we would like to mirror something. Have the actual widgets shown on the tablet, which can then respond to touch events and the like. At the same time, capture what is shown on the tablet and reproduce it, verbatim, on the Presentation for the audience to see. Now everybody can see the same material, and the presenter can manipulate that material.

But now aspect ratios come into play. We want to fill the Presentation display space, without black bars or stretching or whatever. That only works if our source material — the widgets and containers to be mirrored — have the same aspect ratio as the Presentation’s Display itself.

With that in mind, the CWAC Layouts project also contains two classes to solve this problem:

• MirroringFrameLayout is an AspectLockedFrameLayout that also can mirror its content to...
• Mirror, a View that takes a Bitmap representing the MirroringFrameLayout contents and displays it

Technically, MirroringFrameLayout works with a MirrorSink, an interface that can
receive updates to the content to be mirrored when that content changes. Mirror implements MirrorSink, and you could have other classes implement MirrorSink as well if that made sense for your app. The sections that follow focus on MirroringFrameLayout working with a Mirror, as that is the most likely scenario.

**MirroringFrameLayout**

MirroringFrameLayout extends AspectLockedFrameLayout, so that we can lock the aspect ratio of the to-be-mirrored contents to match the aspect ratio of the Mirror. The Mirror is designed to be projected by the Presentation, and so if the Mirror fills the Presentation's Display, we want our MirroringFrameLayout to match the aspect ratio so the entire Display can indeed be filled.

Of course, a ViewGroup like FrameLayout normally just has its children draw to the screen. In our case, we need to capture what is drawn ourselves, to supply to the Mirror as needed. This is a bit tricky.

```java
package com.commonsware.cwac.layouts;

import android.content.Context;
import android.graphics.Bitmap;
import android.graphics.Canvas;
import android.graphics.Rect;
import android.util.AttributeSet;
import android.view.ViewTreeObserver.OnPreDrawListener;
import android.view.ViewTreeObserver.OnScrollChangedListener;

/**
 * A FrameLayout that locks its aspect ratio (courtesy of AspectLockedFrameLayout)
 * and supplies "screenshots" of its contents to an associated MirrorSink,
 * such as a Mirror.
 *
 * Principally, MirroringFrameLayout and Mirror are designed for use with
 * Android's Presentation system. The MirroringFrameLayout would be part of the
 * UI of the activity on the mobile device, allowing for user interaction. The
 * Mirror would be used in the Presentation to show an audience (e.g., via a
 * projector) what is shown inside the MirroringFrameLayout on the mobile
 * device.
 */
public class MirroringFrameLayout extends AspectLockedFrameLayout implements OnPreDrawListener, OnScrollChangedListener {
    private MirrorSink mirror=null;
    private Bitmap bmp=null;
    private Canvas bmpBackedCanvas=null;
    private Rect rect=new Rect();

    /**
     * @inheritDoc
     */
    public MirroringFrameLayout(Context context) {
        this(context, null);
    }
}
```
public MirroringFrameLayout(Context context, AttributeSet attrs) {
    super(context, attrs);
    setWillNotDraw(false);
}

public void setMirror(MirrorSink mirror) {
    this.mirror = mirror;
    if (mirror != null) {
        setAspectRatioSource(mirror);
    }
}

public void onAttachedToWindow() {
    super.onAttachedToWindow();
    getViewTreeObserver().addOnPreDrawListener(this);
    getViewTreeObserver().addOnScrollChangedListener(this);
}

public void onDetachedFromWindow() {
    super.onDetachedFromWindow();
}

public void draw(Canvas canvas) {
    if (mirror != null) {
        bmp.eraseColor(0);
        super.draw(bmpBackedCanvas);
        getDrawingRect(rect);
        canvas.drawBitmap(bmp, null, rect, null);
        mirror.update(bmp);
    } else {

Our one-argument constructor uses this() to chain to the two-argument constructor. The two-argument constructor calls setWillNotDraw(false) indicating to Android that we want this ViewGroup to participate in the drawing process like a regular View — normally, certain steps in the drawing process are skipped as being
irrelevant to View classes that do not draw anything themselves.

We have a setMirror() method, where the activity or fragment can supply the MirrorSink that is connected to this MirroringFrameLayout. In addition to holding onto the MirrorSink in a mirror data member, we call setAspectRatioSource(), inherited from AspectLockedFrameLayout, so our contents will match the aspect ratio from that source.

MirroringFrameLayout overrides onAttachedToWindow() and onDetachedFromWindow(). As one might guess, these callbacks are called when views are attached and detached from some window. Usually, that window represents an activity, though it could represent a Dialog or a Presentation.

In those callbacks, we connect with the ViewTreeObserver of the MirroringFrameLayout. A ViewTreeObserver is a way to find out about events of a view tree, rooted at some ViewGroup. In our case, we want to find out when children are going to be drawn (addOnPreDrawListener()) and when they are scrolled (addOnScrollChangedListener()).

We override onSizeChanged(). This is called on any View when its size may have changed, either because it is being sized initially when the UI is being set up, or because something else nearby changed size (e.g., its parent) and therefore the size of the View itself may now be different. In our case, we use onSizeChanged() to set up a Bitmap object, sized to match our size, and a Canvas object that wraps around that Bitmap object. As you will see, we will use this Canvas to capture what is being drawn on the screen, for later use by the Mirror.

We also override draw(). This is, in effect, the “entry point” into the logic that causes a View to render itself on the screen, by drawing to a supplied Canvas object. Most View classes do not override draw(), as the real rendering is done in an onDraw() method, as we will see with Mirror later in this chapter. However, in our case, we have to override draw() for one simple reason: we do not want to draw to the Canvas supplied by Android to the draw() method. We want to draw to our own Canvas, backed by that Bitmap.

To that end, if we have a MirrorSink, we:

- Make sure the Bitmap starts off blank by calling eraseColor()
- Chain to the superclass, replacing the Canvas given to us in draw() by our own Bitmap-backed Canvas
- Calculate a Rect object with our size and position, using getDrawingRect()
• Use that Rect and the Bitmap to render the Bitmap to the “real” Canvas supplied to us in draw()
• Call update() on the MirrorSink, to give it the new Bitmap

By rendering our contents to the Bitmap-backed Canvas, instead of the normal one, we capture a copy of the output, in the form of the Bitmap. Since the Bitmap has the same size as the “real” Canvas (courtesy of our onSizeChanged() work), when we draw the Bitmap onto the Canvas, we effectively “color in” the same pixels in the same spots as if we had skipped all of this and left the normal draw() logic alone. But, since we still hold onto our Bitmap, we can use those same pixels elsewhere… such as in our Mirror.

The problem with relying on draw() is that it is not always called when there are changes to widgets within the MirroringFrameLayout. In particular, WebView often does not trigger draw() on the MirroringFrameLayout. That’s where the pre-draw and scroll-changed events from the ViewTreeObserver come into play: they give us more indication that we need to update our Bitmap.

The onPreDraw() method is called when a child of this MirroringFrameLayout is about to be drawn. If we have our MirrorSink, we then either call requestLayout() (if we have no bitmap yet) or invalidate() (if we do), to trigger Android to go through the draw process for the MirroringFrameLayout too, allowing us to update our Bitmap.

The onScrollChanged() method is called when a child of this MirroringFrameLayout has been scrolled. This delegates to onPreDraw(), to run through the same logic to force an update to the Bitmap.

**Mirror**

Mirror extends the base View class, and so it is the most “raw” of all the custom widgets and containers shown so far in this chapter. It has an update() method, used to connect the MirroringFrameLayout from which the Mirror can obtain what it is supposed to display:

```java
package com.commonsware.cwac.layouts;

import android.content.Context;
import android.graphics.Bitmap;
import android.graphics.Canvas;
import android.graphics.Rect;
import android.util.AttributeSet;
```
import android.view.View;

/**
 * A View that implements MirrorSink and renders the supplied bitmaps to its
 * own contents. When connected to a MirroringFrameLayout, Mirror will aim to
 * show the same contents as is in the MirroringFrameLayout, at the same aspect
 * ratio, though possibly at a different size.
 * *
 * Principally, MirroringFrameLayout and Mirror are designed for use with
 * Android's Presentation system. The MirroringFrameLayout would be part of the
 * UI of the activity on the mobile device, allowing for user interaction. The
 * Mirror would be used in the Presentation to show an audience (e.g., via a
 * projector) what is shown inside the MirroringFrameLayout on the mobile
 * device.
 * */
public class Mirror extends View implements MirrorSink {
    private Rect rect = new Rect();
    private Bitmap bmp = null;

    /**
     * @inheritDoc
     */
    public Mirror(Context context) {
        super(context);
    }

    /**
     * @inheritDoc
     */
    public Mirror(Context context, AttributeSet attrs) {
        super(context, attrs);
    }

    /**
     * @inheritDoc
     */
    public Mirror(Context context, AttributeSet attrs, int defStyle) {
        super(context, attrs, defStyle);
    }

    /**
     * @inheritDoc
     */
    @Override
    public void update(Bitmap bmp) {
        this.bmp = bmp;
        invalidate();
    }
}
/**
 * {@inheritdoc}
 */

@Override
protected void onDraw(Canvas canvas) {
    super.onDraw(canvas);

    if (bmp != null) {
        getDrawingRect(rect);

        calcCenter(rect.width(), rect.height(), bmp.getWidth(),
                  bmp.getHeight(), rect);
        canvas.drawBitmap(bmp, null, rect, null);
    }
}

// based upon http://stackoverflow.com/a/14679729/115145

static void calcCenter(int vw, int vh, int iw, int ih, Rect out) {
    double scale =
        Math.min((double)vw / (double)iw, (double)vh / (double)ih);

    int h=(int)(scale * ih);
    int w=(int)(scale * iw);
    int x=((vw - w) >> 1);
    int y=((vh - h) >> 1);

    out.set(x, y, x + w, y + h);
}

The bulk of the “business logic” lies in onDraw(), plus a helper calcCenter() static method.

onDraw() is called on a View when it is time for that widget to actually draw its visual representation onto the supplied Canvas. Different widgets will use different drawing primitive methods offered by Canvas, to draw lines and text and whatnot. In our case, we:

• Calculate a Rect object with our size and position, using getDrawingRect()
• Get the Bitmap object from the MirroringFrameLayout, via a call to getLastBitmap() (which simply returns the Bitmap that the MirroringFrameLayout is using)
• Call calcCenter to adjust our Rect to take into account the fact that our size
may be different than the size of the actual Bitmap
• Call drawBitmap() on our Canvas, to render the Bitmap into the location
specified by the Rect, where drawBitmap() will automatically down-sample
or up-sample the image as needed to fill the necessary space

Usage and Results

Normally, you would use the Mirror in a layout for a Presentation and the
MirroringFrameLayout in an activity that controls the Presentation. However, it is
possible to use both in the same layout file, for light testing. However, please do not
put the Mirror inside of the MirroringFrameLayout, as this is likely to cause a
rupture in the space-time continuum, and you really do not want to be responsible
for that.

So, in the SimpleMirrorActivity from the demo/ sub-project, we use a layout that
has both Mirror and MirroringFrameLayout, with the latter set to mirror a WebView:

```xml
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    tools:context=".SimpleMirrorActivity">
    <FrameLayout
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="1">
        <com.commonsware.cwac.layouts.MirroringFrameLayout
            android:id="@+id/source"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:layout_gravity="center">
            <EditText
                android:id="@+id/editor"
                android:layout_width="match_parent"
                android:layout_height="match_parent"
                android:gravity="left|top"
                android:inputType="textMultiLine"/>
        </com.commonsware.cwac.layouts.MirroringFrameLayout>
    </FrameLayout>
</LinearLayout>
```
In this case, we set the background of the FrameLayout holding our MirroringFrameLayout to green, to show how the MirroringFrameLayout size is changed to maintain our aspect ratio.

(or, perhaps we just like green)

Besides configuring the to-be-mirrored widgets, all you need to do is call setMirror() on the MirroringFrameLayout to enable the mirroring logic:
While the bottom portion is just the `Mirror` and therefore is non-interactive, the top
is the real WebView, which can be scrolled, with the resulting changes reflected in the Mirror in real-time:

![Figure 587: MirroringFrameLayout and Mirror, Showing Scrolled Contents](image)

**Limitations**

MirroringFrameLayout only works for materials drawn in the Java layer, that therefore can be drawn to the Bitmap-backed Canvas. Content *not* drawn in the Java layer will not work with MirroringFrameLayout, notably anything involving a SurfaceView. This not only includes your own SurfaceView widgets, but anything else that depends upon SurfaceView, such as VideoView or the Maps V2 MapView and MapFragment.

Also, the re-sampling done by Mirror is not especially sophisticated and will cause jagged effects, particularly when up-sampling. Ideally, the MirroredFrameLayout will be the same size or larger than the Mirror. This may not always be possible, particularly with a Mirror shown on a 1080p external display, but the closer you can get will improve the output.
Advanced Preferences

We saw SharedPreferences and PreferenceFragment earlier in the book. However, we can have more elaborate preference collection options if we wish, such as a full master-detail implementation like the Settings app sports. There are also many other common attributes on the preference XML elements that we might consider taking advantage of, such as allowing us to automatically enable and disable preferences based upon whether some other preference is checked or unchecked.

In this chapter, we will explore some of these additional capabilities in the world of Android preferences.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on SharedPreferences.

Introducing PreferenceActivity

If you have a fairly simple set of preferences to collect from the user, using a single PreferenceFragment should be sufficient.

On the far other end of the spectrum, Android's Settings app collects a massive amount of preference values from the user. These are spread across a series of groups of preferences, known as preference headers.

While your app may not need to collect as many preferences as does the Settings app, you may need more than what could be collected easily in a single PreferenceFragment. In that case, you can consider adopting the same structure of...
headers-and-fragments that the Settings app uses, by means of a PreferenceActivity.

To see this in action, take a look at the Prefs/FragmentsBC sample project. It is very similar to the original SharedPreferences demo app from before. However, this one arranges to collect a fifth preference value, in a separate PreferenceFragment, and uses PreferenceActivity to allow access to both PreferenceFragment UI structures.

**Defining Your Preference Headers**

In the master-detail approach offered by PreferenceActivity, the “master” list is a collection of preference headers. Typically, you would define these in another XML resource. In the sample project, that is found in res/xml/preference_headers.xml:

```
<preference-headers xmlns:android="http://schemas.android.com/apk/res/android">
  <header android:fragment="com.commonsware.android.preffragsbc.EditPreferences$First" android:summary="@string/header1summary" android:title="@string/header1title">
  </header>
  <header android:fragment="com.commonsware.android.preffragsbc.EditPreferences$Second" android:summary="@string/header2summary" android:title="@string/header2title">
  </header>
</preference-headers>
```

Here, your root element is `<preference-headers>`, containing a series of `<header>` elements. Each `<header>` contains at least three attributes:

1. `android:fragment`, which identifies the Java class implementing the PreferenceFragment to use for this header, as is described in the next section
2. `android:title`, which is a few words identifying this header to the user
3. `android:summary`, which is a short sentence explaining what the user will find inside of this header.

Once again, you may wish to also include `android:summary`, which is a short sentence explaining what the user will find inside of this header.

You can, if you wish, include one or more `<extra>` child elements inside the
ADVANCED PREFERENCES

The <header> element. These values will be put into the “arguments” Bundle that the associated PreferenceFragment can retrieve via getArguments().

Creating Your PreferenceActivity

EditPreferences — which in the original sample app was a regular Activity — is now a PreferenceActivity. It contains little more than the two fragments referenced in the above preference header XML:

```java
package com.commonsware.android.preffragbsc;

import android.os.Bundle;
import android.preference.PreferenceActivity;
import android.preference.PreferenceFragment;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
    @Override
    public void onBuildHeaders(List<Header> target) {
        loadHeadersFromResource(R.xml.preference_headers, target);
    }

    @Override
    protected boolean isValidFragment(String fragmentName) {
        if (First.class.getName().equals(fragmentName) || Second.class.getName().equals(fragmentName)) {
            return(true);
        }

        return(false);
    }

    public static class First extends PreferenceFragment {
        @Override
        public void onCreate(Bundle savedInstanceState) {
            super.onCreate(savedInstanceState);

            addPreferencesFromResource(R.xml.preferences);
        }
    }

    public static class Second extends PreferenceFragment {
        @Override
        public void onCreate(Bundle savedInstanceState) {
            super.onCreate(savedInstanceState);
        }
    }
}
```
onBuildHeaders() is where we supply the preference headers, via a call to loadHeadersFromResource().

We also need to have an isValidFragment() method, that will return true if the supplied fragment name is one we should be showing in this PreferenceActivity, false otherwise. This will only be called on Android 4.4+. However, we need to set up the project build target (e.g., compileSdkVersion in Android Studio) to API Level 19 or higher. Failing to have this method will cause your app to crash on Android 4.4+ devices, when the user tries to bring up one of your PreferenceFragments.

Each PreferenceFragment is then responsible for calling addPreferencesFromResource() to populate its contents. In this case, we now have two such resources: res/xml/preferences.xml (the original, used by First) and res/xml/preferences2.xml (used by Second).
The Results

On a wide enough screen — like that of a Nexus 9 in landscape — we get a master-detail presentation:

![PreferenceActivity UI, on a Landscape Nexus 9](image)

*Figure 588: PreferenceActivity UI, on a Landscape Nexus 9*

Here, we see the first preference fragment already pre-selected, showing its settings. Tapping on the second header will show the other preferences.
On a smaller screen, the master-detail approach means that we see a list of headers first:

![PreferenceActivity UI, on a Portrait Nexus 5](image)

*Figure 589: PreferenceActivity UI, on a Portrait Nexus 5*

Tapping the headers give us access to the individual fragments.

**Intents for Headers or Preferences**

If you have the need to collect some preferences that are beyond what the standard preferences can handle, you have some choices.

One is to create a custom Preference. Extending DialogPreference to create your own Preference implementation is not especially hard. However, it does constrain you to something that can fit in a dialog.

Another option is to specify an `<intent>` element as a child of a `<header>` element. When the user taps on this header, your specified Intent is used with `startActivity()`, giving you a gateway to your own activity for collecting things that are beyond what the preference UI can handle. For example, you could have the following `<header>`:

---

1884
Then, so long as you have an activity with an `<intent-filter>` specifying your desired action (`com.commonsware.android.MY_CUSTOM_ACTION`), that activity will get control when the user taps on the associated header.

**Conditional Headers**

The two-tier, headers-and-preferences approach is fine and helps to organize large rosters of preferences. However, it does tend to steer developers in the direction of displaying headers *all of the time*. For many apps, that is rather pointless, because there are too few preferences to collect to warrant having more than one header.

One alternative approach is to use the headers on larger devices, but skip them on smaller devices. That way, the user does not have to tap past a single-item `ListFragment` just to get to the actual preferences to adjust.

This is a wee bit tricky to implement. However, you have two options for how to accomplish it.

(The author would like to thank Richard Le Mesurier, whose question on this topic spurred the development of this section and its samples)

**Option #1: Do Not Define the Headers**

The basic plan in the first approach is to have smarts in `onBuildHeaders()` to handle this. `onBuildHeaders()` is the callback that Android invokes on our `PreferenceActivity` to let us define the headers to use in the master-detail pattern. If we want to have headers, we would supply them here; if we want to skip the headers, we would instead fall back to the classic (and, admittedly, deprecated) `addPreferencesFromResource()` method to load up some preference XML.

There is an `isMultiPane()` method on `PreferenceActivity`, starting with API Level 11, that will tell you if the activity will render with two fragments (master+detail) or not. In principle, this would be ideal to use. Unfortunately, it does not seem to be designed to be called from `onBuildHeaders()`. Similarly,
addPreferencesFromResource() does not seem to be callable from onBuildHeaders(). Both are due to timing: onBuildHeaders() is called in the middle of the PreferenceActivity onCreate() processing.

So, we have to do some fancy footwork.

By examining the source code to PreferenceActivity, you will see that the logic that drives the single-pane vs. dual-pane UI decision boils down to:

```
onIsHidingHeaders() || !onIsMultiPane()
```

If that expression returns true, we are in single-pane mode; otherwise, we are in dual-pane mode. onIsHidingHeaders() will normally return false, while onIsMultiPane() will return either true or false based upon screen size.

So, we can leverage this information in a PreferenceActivity to conditionally load our headers, as seen in the EditPreferences class in the Prefs/SingleHeader sample project:

```java
package com.commonsware.android.pref1header;

import android.os.Bundle;
import android.preference.PreferenceActivity;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
  private boolean needResource=false;

  @SuppressWarnings("deprecation")
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (needResource) {
      addPreferencesFromResource(R.xml.preferences);
    }
  }

  @Override
  public void onBuildHeaders(List<Header> target) {
    if (onIsHidingHeaders() || !onIsMultiPane()) {
      needResource=true;
    } else {
      loadHeadersFromResource(R.xml.preference_headers, target);
    }
  }
}
```
Here, if we are in dual-pane mode, `onBuildHeaders()` populates the headers as normal. If, though, we are in single-pane mode, we skip that step and make note that we need to do some more work in `onCreate()`.

Then, in `onCreate()`, if we did not load our headers we use the classic `addPreferencesFromResource()` method.

The net result is that on Android 3.0+ tablets, we get the dual-pane, master-detail look with our one header, but on smaller devices (regardless of version), we roll straight to the preferences themselves.

Note that this sample application uses a single PreferenceFragment implementation, named `StockPreferenceFragment`:

```java
package com.commonsware.android.pref1header;

import android.os.Bundle;
import android.preference.PreferenceFragment;

public class StockPreferenceFragment extends PreferenceFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        int res =
            getActivity().getResources()
                .getIdentifier(getArguments().getString("resource"),
                              "xml",
                              getActivity().getPackageName());

        addPreferencesFromResource(res);
    }
}
```

Advanced Preferences

1887
StockPreferenceFragment does what it is supposed to: call addPreferencesFromResource() in onCreate() with the resource ID of the preferences to load. However, rather than hard-coding a resource ID, as we normally would, we look it up at runtime.

The <extra> elements in our preference header XML supply the name of the preference XML to be loaded:

```xml
<preference-headers xmlns:android="http://schemas.android.com/apk/res/android">
  <header>
    android:fragment="com.commonsware.android.pref1header.StockPreferenceFragment"
    android:summary="@string/header1summary"
    android:title="@string/header1title">
      <extra>
        android:name="resource"
        android:value="preferences"/>
    </header>
</preference-headers>
```

(from Prefs/SingleHeader/app/src/main/res/xml/preference_headers.xml)

We get that name via the arguments Bundle (getArguments().getString("resource")).

To look up a resource ID at runtime, we can use the Resources object, available from our activity via a call to getResources(). Resources has a method, getIdentifier(), that will return a resource ID given three pieces of information:

1. The base name of the resource (in our case, the value retrieved from the <extra> element)
2. The type of the resource (e.g., "xml")
3. The package holding the resource (in our case, our own package, retrieved from our activity via getPackageName())

Note that getIdentifier() uses reflection to find this value, and so there is some overhead in the process. Do not use getIdentifier() in a long loop – cache the value instead.

The net is that StockPreferenceFragment loads the preference XML described in the <extra> element, so we do not need to create separate PreferenceFragment implementations per preference header.
Option #2: Go Directly to the Fragment

The advantage of the above approach is that it works with Android’s own logic of whether to display the master-detail fragments or just one at a time. However, that logic — the fact that `onIsHidingHeaders() || !onIsMultiPane()` determines the look of the activity — is not documented, and therefore may change in future Android releases.

Another option is to launch your `PreferenceActivity` in such a way that tells Android to skip showing the headers. This approach is better documented and therefore perhaps more stable. This can also be used in cases where you do want headers sometimes, but at other times you want to route the user to a specific `PreferenceFragment`. The downside is that this technique only works on API Level 11+.

To see how this works, take a look at the Prefs/SingleHeader2 sample project.

Our `EditPreferences` class is the same implementation as in the original sample for this chapter, except that we only load up the single XML resource’s worth of preferences:

```java
package com.commonsware.android.prefs1header;

import android.preference.PreferenceActivity;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
  @Override
  public void onBuildHeaders(List<Header> target) {
    loadHeadersFromResource(R.xml.preference_headers, target);
  }

  @Override
  protected boolean isValidFragment(String fragmentName) {
    return(StockPreferenceFragment.class.getName().equals(fragmentName));
  }
}
```

(From Prefs/SingleHeader2/app/src/main/java/com/commonsware/android/pref1header/EditPreferences.java)

However, there is a change in our main activity (FragmentsDemo). Before, when the user chose the “Settings” action bar overflow item, we would just call `startActivity()` to bring up `EditPreferences`. Now, we delegate that work to an `editPrefs()` method on `FragmentsDemo`, which will have the smarts to control how
we bring up the EditPreferences activity:

```java
private void editPrefs() {
    Intent i = new Intent(this, EditPreferences.class);
    i.putExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT,
               StockPreferenceFragment.class.getName());
    Bundle b = new Bundle();
    b.putString("resource", "preferences");
    i.putExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT_ARGUMENTS, b);
    startActivity(i);
}
```

Here, we will add two extras to our Intent:

- EXTRA_SHOW_FRAGMENT, set to the fully-qualified class name of the PreferenceFragment to be displayed, here obtained by calling getName() on the Class object for StockPreferenceFragment
- EXTRA_SHOW_FRAGMENT_ARGUMENTS, set to a Bundle containing the same values that would ordinarily be loaded from the <extra> elements in the preference header XML resource (in our case, the name of the preference XML resource to load)

Those extras will be automatically handled by PreferenceActivity (on API Level 11+) and will have the effect of directly taking the user to our one-and-only fragment, bypassing the headers.

**Dependent Preferences**

In the Settings app, or in other apps that appear to be using PreferenceFragment-based UIs, you may have noticed that there are times when preferences are disabled. They become enabled when you check a CheckBoxPreference or toggle on a SwitchPreference.

That is handled via the android:dependency attribute on the to-be-disabled preferences. The value of android:dependency is the key of a TwoStatePreference subclass, such as a CheckBoxPreference or a SwitchPreference. The enabled/
disabled state of the preference with the android:dependency attribute depends on the checked state of the named dependency.

For example, the Prefs/Dependency sample project is a clone of the original SharedPreferences demo app with one slight change: all the preferences other than checkbox are now dependent upon checkbox:

```xml
    <CheckBoxPreference
        android:key="checkbox"
        android:summary="@string/pref1summary"
        android:title="@string/pref1title"/>

    <RingtonePreference
        android:dependency="checkbox"
        android:key="ringtone"
        android:showDefault="true"
        android:showSilent="true"
        android:summary="@string/pref2summary"
        android:title="@string/pref2title"/>

    <EditTextPreference
        android:dependency="checkbox"
        android:dialogTitle="@string/dialogtitle"
        android:key="text"
        android:summary="@string/pref3summary"
        android:title="@string/pref3title"/>

    <ListPreference
        android:dependency="checkbox"
        android:dialogTitle="@string/listdialogtitle"
        android:entries="@array/cities"
        android:entryValues="@array/airport_codes"
        android:key="list"
        android:summary="@string/pref4summary"
        android:title="@string/pref4title"/>
</PreferenceScreen>
```

(from Prefs/Dependency/app/src/main/res/xml/preferences.xml)
When you run the project, the dependent preferences are disabled while the checkbox is unchecked:

![Dependent Preferences, Disabled](image)

*Figure 590: Dependent Preferences, Disabled*
Nested Screens

Perhaps you have more preferences than you want to collect on a single screen, but you do not feel that a master-detail presentation is the right structure. Or, perhaps you have lots of preferences to collect, and even collecting preferences into groups by header is insufficient.

Another possibility is to nest preference screens. One screen holds another. On the outer preference screen, the user has a “preference” entry that simply displays the nested screen, as opposed to directly collecting any preferences.

A `<PreferenceScreen>` element in your preference XML can hold another `<PreferenceScreen>` element. That inner `<PreferenceScreen>` can come in one of two forms:

1. Inside the inner `<PreferenceScreen>` you have more preference XML elements. This means there is only one `PreferenceFragment` for the whole
structure (outer `<PreferenceScreen>`, including the inner `<PreferenceScreen>`). However, visually, the user will “drill down” from the outer screen into the inner one by tapping on an entry.

2. The inner `<PreferenceScreen>` has an `android:fragment` attribute, just like a preference header might. This points to a Fragment — typically a `PreferenceFragment` — that will be responsible for the “inner” content. This is a bit more complex to set up, as it requires a couple of fragments. However, it gives you greater flexibility. Plus, it is fairly easy to then switch from using preference headers and the master-detail approach to using nested preference screens, or back again, as you are simply reusing the same `PreferenceFragment` implementations in either case.

The `Prefs/NestedScreens` sample project takes the master-detail approach shown earlier in this chapter and switches it to having a top-level screen and a nested screen. This is accomplished by adding a `<PreferenceScreen>` element to `res/xml/prefs.xml`, pointing to our Second `PreferenceFragment`:

```xml
<PreferenceScreen
    android:fragment="com.commonsware.android.preffragsbc.EditPreferences$Second"
    android:key="unused"
    android:title="@string/nested_title"/>
```

(from `Prefs/NestedScreens/app/src/main/res/xml/preferences.xml`)

Here, the `android:title` (and optional `android:summary`) will be shown on the `outer` screen, as an entry that the user can tap on to get to this inner screen. While in this sample, we are not using `android:key`, in principle you could use this to get at the PreferenceScreen itself to manipulate it at runtime (e.g., disable it).

For this style of `<PreferenceScreen>` to work, the preference XML must be used by a `PreferenceFragment` in a `PreferenceActivity` — you cannot use it with a regular `Activity`. However, just because you use `PreferenceActivity` does not mean that you have to opt into the master-detail structure. We can use the same `onCreate()`, show-the-`PreferenceFragment` approach that we use with a regular `Activity`.

However, there is one big catch: when the user taps on the entry that will launch the inner screen, the Android framework will start another `instance` of our `PreferenceActivity`. It will give us the same `EXTRA_SHOW_FRAGMENT` value as we saw earlier in this chapter. However, `PreferenceActivity` will automatically show that fragment; we do not need to show it ourselves.

But, this means that our `onCreate()` needs to distinguish between the “show the outer screen ourselves” case and the “show the inner screen automatically” case,
which we can do by seeing if EXTRA_SHOW_FRAGMENT exists:

```java
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getIntent().getStringExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT) == null) {
        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content, new First()).commit();
        }
    }
}
```

The result is that we see the outer screen first, containing our entry for the inner screen:

![Figure 592: Nested Preferences, Outer Screen](image-url)
Tapping on that entry brings up the inner, nested, screen:

![Nested Preferences, Inner Screen](image)

**Figure 593: Nested Preferences, Inner Screen**

## Listening to Preference Changes

Sometimes, you may need to take steps when the user interacts with a preference in your PreferenceFragment-based UI.

A common scenario for this comes with the summary. In some cases, is it handy to have the summary reflect the current value of the preference. While some preferences naturally show their value inline (e.g., a CheckBoxPreference), those that extend from DialogPreference only show their value when the user taps on the preference to display the dialog. Putting something in the summary that reflects the value can save the user a click.

However, by default, the summary is static, populated by the android:summary attribute in your preference XML. If you want it to reflect the current preference value, you not only need to be able to set the summary in Java, but to be able to respond when the user changes the value, so you can update the summary again.
ADVANCED PREFERENCES

The Prefs/CustomSubtitle sample project demonstrates how this works. This is yet another clone of the original SharedPreferences demo app. This time, the preference XML is unchanged from the original. However, we have a slightly more elaborate PreferenceFragment implementation:

```java
public static class Prefs extends PreferenceFragment
    implements Preference.OnPreferenceChangeListener {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        addPreferencesFromResource(R.xml.preferences);
        Preference pref=findPreference("text");
        updateSummary(pref,
            pref.getSharedPreferences().getString(pref.getKey(), null));
        pref.setOnPreferenceChangeListener(this);
    }
    @Override
    public boolean onPreferenceChange(Preference pref, Object newValue) {
        updateSummary(pref, newValue.toString());
        return(true);
    }
    private void updateSummary(Preference pref, String value) {
        if (value==null || value.length()==0) {
            pref.setSummary(R.string.msg_missing_text);
        } else {
            pref.setSummary(value);
        }
    }
}
```

(from Prefs/CustomSubtitle/app/src/main/java/com/commonsware/android/preffrag/EditPreferences.java)

In onCreate(), after addPreferencesFromResource(), we call findPreference() to retrieve the Preference object that manages the snippet of UI for a particular preference. The flow here mimics that of setContentView() and findViewById(): first you inflate the resource, then you find the Java object corresponding to some XML element out of that resource. findPreference() takes the key of the preference that you are looking for; in this case, we are looking for the EditTextPreference, whose key is text.
ADVANCED PREFERENCES

We then call a private `updateSummary()` method, which takes the Preference and the current value of that preference and updates the summary. To get the current value, `onCreate()` can ask the Preference for its backing `SharedPreferences` (via `getSharedPreferences()`), then retrieve the value using standard getters (e.g., `getString()`). `updateSummary()` then shows the string representation of the current value, or a canned message if there does not appear to be a current value.

We also register the fragment itself as being the `OnPreferenceChangeListener`, and register the fragment with the preference via `setOnPreferenceChangeListener()`. This means that when the user manipulates this preference, we will be called with `onPreferenceChange()`. This is done before the `SharedPreferences` are updated. Our options are either to return true and have the normal persistence process continue, or return false and manage persistence ourselves (e.g., perform some conversion on the raw value before storing it). In our case, we are just using this to call `updateSummary()` again.

If you install the app and run it, you will not have an existing value for the preference, and so the summary shows a stock message:

![Figure 594: Custom Subtitle Demo, Before Editing Text](image)

After you tap on the `EditTextPreference` and fill in some value in the dialog, the...
When you use SharedPreferences to retrieve a value, you can usually provide a default value along with the key for the value that you want. If there is no preference value for that key, you get the default that you supplied.

A preference in preference XML also has an android:defaultValue attribute. This is, roughly speaking, the preference UI counterpart to that second parameter to the SharedPreferences getters. If the user interacts with the preference, the android:defaultValue value will be presented to the user if there was no preference value stored for that key in the underlying SharedPreferences.

To synchronize these, you can call setDefaultValues() on the PreferenceManager class. Given the resource ID of some preference XML, PreferenceManager will find all android:defaultValue attributes and then persist those default values to the SharedPreferences under their respective keys.
Listening to Preference Value Changes

Sometimes, you will have components that need to know when preference values are changed elsewhere in your app. For example, you may have a Service that is using information from SharedPreferences, and the Service may need to know when those values change.

One approach, used in all the sample apps, is simply to re-read the preference values as needed, rather than caching them in data members or something. After the first time SharedPreferences are accessed, the SharedPreferences themselves are held in heap space, and so accessing them can be fairly cheap. So, the sample apps’ launcher activities just re-read the preference values in onResume() and update the UI that way.

If, however, that is inappropriate, inconvenient, or otherwise not what you want to do, you can call registerOnSharedPreferenceChangeListener() on a SharedPreferences object, supplying an instance of an implementation of the OnSharedPreferenceChangeListener interface. That object will be called with onSharedPreferenceChanged() every time a preference value changes. You are given the key to the changed value, so you can implement a filter to only pay attention to keys that matter to you. When one of those keys is reported to have changed, you can ask the SharedPreferences for the new value.

Dynamic ListPreference Contents

Many times, the items that the user can choose from in your ListPreference or MultiSelectListPreference are fixed, allowing you to populate them from <string-array> resources. However, sometimes, the items (display names and corresponding values) are dynamic, based upon information held elsewhere: database, server, or something at a system level. For those, we need to be able to define the preference in XML, but configure its contents in Java code.

For example, the Introspection/SAWMonitor sample project is a monitor for new and upgraded apps that ask for the SYSTEM_ALERT_WINDOW permission. Such apps have the right to draw over top of other apps, for anything from Facebook “chatheads” to tapjacking attacks.

However, some apps may request this permission that you are perfectly fine with having it. By default, SAWMonitor will point out this permission on each subsequent update, which can get tiresome after a while. Hence, SAWMonitor
allows you to add apps to a “whitelist”; those apps will be ignored, even if they request SYSTEM_ALERT_WINDOW.

To that end, we have a settings.xml resource describing some preferences to collect from the user:

```xml
<?xml version="1.0" encoding="utf-8"?>
  <SwitchPreference
    android:key="enabled"
    android:title="@string/msg_enable"
    android:defaultValue="true"/>
  <MultiSelectListPreference
    android:key="whitelist"
    android:title="@string/msg_whitelist" />
</PreferenceScreen>
```

Here we have two preferences: a SwitchPreference for whether we should be monitoring for SYSTEM_ALERT_WINDOW at all, and a MultiSelectListPreference to allow the user to control the whitelist.

In onCreate() of our SettingsFragment, we load up those preferences into the UI via addPreferencesFromResource(), use findPreference() to retrieve both of the Preference objects, and use setOnPreferenceChangeListener() to be notified about changes to the enabled preference:

```java
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    addPreferencesFromResource(R.xml.settings);
    pm=getActivity().getPackageManager();

    enabled=(SwitchPreference)findPreference(MonitorApp.PREF_ENABLED);

    populateWhitelist((MultiSelectListPreference)findPreference("whitelist"));
}
```

The populateWhitelist() call is where we fill in the details for the MultiSelectListPreference. In our case, the possible values are the apps presently installed that have requested the SYSTEM_ALERT_WINDOW permission. So, we use PackageManager to find those, then use that information to populate the whitelist.
Most of the code is determining which applications have that permission. However, `MultiSelectListPreference` complicates matters, by having two separate setter methods for its contents:

```java
void populateWhitelist(MultiSelectListPreference whitelist) {
    List<ApplicationInfo> apps = pm.getInstalledApplications(0);

    Collections.sort(apps,
        new ApplicationInfo.DisplayNameComparator(pm));

    ArrayList<CharSequence> displayNames =
        new ArrayList<CharSequence>();
    ArrayList<String> packageNames = new ArrayList<String>();

    for (ApplicationInfo app : apps) {
        try {
            PackageInfo pkgInfo =
                pm.getPackageInfo(app.packageName,
                PackageManager.GET_PERMISSIONS);

            if (pkgInfo.requestedPermissions != null) {
                for (String perm : pkgInfo.requestedPermissions) {
                    if (SYSTEM_ALERT_WINDOW.equals(perm)) {
                        displayNames.add(app.loadLabel(pm));
                        packageNames.add(app.packageName);
                        break;
                    }
                }
            }
        } catch (PackageManager.NameNotFoundException e) {
            // should not happen, quietly ignore
        }
    }

    whitelist
        .setEntries(displayNames
            .toArray(new CharSequence[displayNames.size()]));
    whitelist
        .setEntryValues(packageNames
            .toArray(new String[packageNames.size()]));
}
```

(from Introspection/SAWMonitor/app/src/main/java/com/commonsware/android/sawmonitor/SettingsFragment.java)

Most of the code is determining which applications have that permission. However, `MultiSelectListPreference` complicates matters, by having two separate setter methods for its contents:
ADVANCED PREFERENCES

- `setEntries()` sets the display names, what the user will see in the multi-select dialog
- `setEntryValues()` sets the corresponding values, what will be stored in the SharedPreferences based upon the user’s input

These each take arrays of CharSequence implementations, like String. Hence, we need two parallel arrays of values, rather than a single ArrayList of Pair objects or something.

With that in mind, `populateWhitelist()`:

- Gets the list of installed applications from the PackageManager (pm is a field initialized in `onCreate()`)
- Sorts those by display name, so our results will wind up in alphabetical order
- Creates an ArrayList for the display names and a separate one for the package names, which will serve as our entry values
- Iterates over the applications, gets the permissions requested by each app, and if any of those is `SYSTEM_ALERT_WINDOW`, add the display name (`loadLabel()`) and the package name to their respective lists
- Converts each of those ArrayList objects into a corresponding Java array, and passes them to their appropriate setters
The resulting `SettingsFragment` has the two preferences:

![SAWMonitor SettingsFragment](image)

*Figure 596: SAWMonitor SettingsFragment*
ADVANCED PREFERENCES

Tapping on the “Whitelist” entry brings up the MultiSelectListPreference:

![SAWMonitor Whitelist MultiSelectListPreference](image)

If you run the app on your device or emulator, you will wind up with different possible entries in the MultiSelectListPreference, as the mix of apps requesting `SYSTEM_ALERT_WINDOW` will be different for different devices and users.

Dealing with External Changes to Preferences

What happens if you have a `PreferenceFragment` in the foreground, and the preference changes “behind the scenes” by some other component of your app?

For preferences with dialogs — `ListPreference`, `EditTextPreference`, etc. — the pattern seems to be “transaction by dialog”. Whatever the preference value is at the time the dialog appears is what the user sees, and that does not change (and cannot readily be changed) if the preference changes while that dialog is on the screen.

However, for inline preferences — `CheckBoxPreference`, `SwitchPreference`, etc. — while the UI will not automatically update based on the external change, you can handle that yourself.

For example, SAWMonitor offers an optional notification shade tile using a
**Advanced Preferences**

**TileService on Android 7.0+ devices.** The tile allows the user to enable and disable the monitoring, just as the user can from the SwitchPreference. So... what happens if the SettingsFragment is on the screen, the user slides open the notification shade, and taps the tile? By default, the SettingsFragment would be oblivious to this, with the result of the SwitchPreference being out of sync.

But, we can fix this.

In SettingsFragment, in `onStart()`, we register for preference changes, plus call a `syncEnabledStates()` method. We unregister from preference changes in `onStop()`:

```
@override
public void onStart() {
    super.onStart();

    prefs = PreferenceManager.getDefaultSharedPreferences(getActivity());
    prefs.registerOnSharedPreferenceChangeListener(this);
    syncEnabledStates();
}

@override
public void onStop() {
    super.onStop();

    prefs.unregisterOnSharedPreferenceChangeListener(this);
}
```

(from Introspection/SAWMonitor/app/src/main/java/com/commonsware/android/sawmonitor/SettingsFragment.java)

The `onSharedPreferenceChanged()` method on our SettingsFragment will be called when any of our preferences changes. If the enabled preference changes, we call `syncEnabledStates()`:

```
@override
public void onSharedPreferenceChanged(SharedPreferences prefs,
                                          String s) {
    if (MonitorApp.PREF_ENABLED.equals(s)) {
        syncEnabledStates();
    }
}
```

(from Introspection/SAWMonitor/app/src/main/java/com/commonsware/android/sawmonitor/SettingsFragment.java)

`syncEnabledStates()` simply updates the checked state of `enabled` based upon the now-current value in `SharedPreferences`: 
Hence, this also handles the case where our SettingsFragment was displayed, the user navigated elsewhere, one of our preferences changes, and then the user returns to our running SettingsFragment. Normally, the SettingsFragment might miss that preference change, but with this implementation, the SettingsFragment will be kept in sync with the actual preference value.

Preferences in Device Settings App

On Android 7.0+, you can have the Settings app show a “gear” icon on your activity that collects preferences. When the user taps that gear, the Settings app will launch your designated activity:

![Figure 598: Settings Activity Gear Icon](image)

To offer this, you need to add an `<intent-filter>` for your desired activity, with an `<action>` of `android.intent.action.APPLICATION_PREFERENCES`:
However, by default, there is a cost to this: *any app* can start your settings activity, whenever another app wants to. Your settings activity is exported once you add the `<intent-filter>`, and it needs to be exported for the Settings app to be able to start the activity.

However, it is fairly likely that this activity was not exported before you added this `<intent-filter>`. And while you may not mind it if the Settings app starts this activity, or if your own application code starts this activity, you may not want arbitrary other apps to start this activity. A general rule of thumb in modern development is to keep your “attack surface” low. Having an activity be exported for little value is an unnecessary increase in your app’s attack surface.

There is no officially-documented solution for this, though perhaps they will add one someday.

There are two candidate approaches. An unexpected one works: you can mark the activity as being not exported, via `android:exported="false"`. For some reason, the Settings app can still start up that activity, perhaps due to some system-level privilege. However, other apps will be unable to start the activity. This would result in an `<activity>` element like this:

```xml
<activity
    android:name="EditPreferences"
    android:label="@string/app_name">
    <intent-filter>
        <action android:name="android.intent.action.APPLICATION_PREFERENCES" />
        <category android:name="android.intent.category.DEFAULT" />
    </intent-filter>
</activity>
```

Another approach that should work is to use `android:permission` to limit what other apps can start your activity, choosing a permission that the Settings app is sure to have but that most other apps will lack. `WRITE_SECURE_SETTINGS` is one candidate:
ADVANCED PREFERENCES

<activity
    android:name="EditPreferences"
    android:label="@string/app_name"
    android:permission="android.permission.WRITE_SECURE_SETTINGS">
    <intent-filter>
        <action android:name="android.intent.action.APPLICATION_PREFERENCES" />
        <category android:name="android.intent.category.DEFAULT" />
    </intent-filter>
</activity>

Now, the only other apps that can start your activity must hold the WRITE_SECURE_SETTINGS permission, which ordinary Android SDK apps cannot hold.

Custom Preference Storage

SharedPreferences are stored in an app’s portion of internal storage as an XML file. This is fine in many cases. However, it is a problem for apps that need to ensure that persisted data is encrypted. While you can create a wrapper around SharedPreferences that encrypts the keys and values, that will not work well with things like the preference screen UI system. Basically, anything that does not know about the wrapper would try working with the actual SharedPreferences data and be broken by the encryption.

This has always been disappointing, considering that SharedPreferences is an interface, and so setting up some sort of decorator approach should have been fairly easy to add.

In Android 8.0+, Google does not do that.

However, they do add in another mechanism: PreferenceDataStore.

You can create a PreferenceDataStore and associate it with a PreferenceManager via setPreferenceDataStore(). Then, all SharedPreferences loaded from that PreferenceManager will not use the normal XML-based persistence. Instead, the PreferenceDataStore will be used instead. That interface has getter and setter methods for all of the types supported by SharedPreferences, and it is the responsibility of some instance of PreferenceDataStore to handle the persistence as you see fit.

This solution is goofy, but it works, after a fashion, as is illustrated in the Prefs/DataStore sample project.
In that project, we have a SillyDataStore implementation of the PreferenceDataStore interface. It just stuffs all the data into a HashMap:

```java
package com.commonsware.android.preffrag;

import android.preference.PreferenceDataStore;
import java.util.HashMap;
import java.util.Map;
import java.util.Set;

class SillyDataStore implements PreferenceDataStore {
    static private final SillyDataStore INSTANCE = new SillyDataStore();
    private Map<String, Object> cache = new HashMap<>();

    static SillyDataStore get() {
        return INSTANCE;
    }

    private SillyDataStore() {
        // just here to prevent accidental creation from outside
    }

    @Override
    public void putString(String key, String value) {
        cache.put(key, value);
    }

    @Override
    public void putStringSet(String key, Set<String> values) {
        cache.put(key, values);
    }

    @Override
    public void putInt(String key, int value) {
        cache.put(key, value);
    }

    @Override
    public void putLong(String key, long value) {
        cache.put(key, value);
    }

    @Override
    public void putFloat(String key, float value) {
        cache.put(key, value);
    }
}```
public void putBoolean(String key, boolean value) {
    cache.put(key, value);
}

public String getString(String key, String defValue) {
    return ((String)cache.getOrDefault(key, defValue));
}

public Set<String> getStringSet(String key, Set<String> defValues) {
    return ((Set<String>)cache.getOrDefault(key, defValues));
}

public int getInt(String key, int defValue) {
    return ((Integer)cache.getOrDefault(key, defValue));
}

public long getLong(String key, long defValue) {
    return ((Long)cache.getOrDefault(key, defValue));
}

public float getFloat(String key, float defValue) {
    return ((Float)cache.getOrDefault(key, defValue));
}

public boolean getBoolean(String key, boolean defValue) {
    return ((Boolean)cache.getOrDefault(key, defValue));
}

This implementation is truly silly, as it does no type checking and no persistence. It should be considered the bare minimum implementation of a PreferenceDataStore, though one that might be useful, instead of rolling a mock, in
unit testing.

(note: the @SuppressWarnings("Since15") annotations are because this code uses the getOrDefault() method on HashMap, which was added in Java 8 and is new to Android 8.0)

There is a singleton instance of SillyDataStore. That way we can ensure that the same instance is used wherever we want it.

We apply that singleton in the PreferenceFragment subclass:

```java
public static class Prefs extends PreferenceFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getPreferenceManager().getPreferenceDataStore()==null) {
            getPreferenceManager().setPreferenceDataStore(SillyDataStore.get());
        }

        addPreferencesFromResource(R.xml.preferences);
    }
}
```

(from Prefs/DataStore/app/src/main/java/com/commonsware/android/preffrag/EditPreferences.java)

Here, we check to see if there is a PreferenceDataStore associated with the PreferenceManager and, if not, we attach the SillyDataStore singleton. This causes the SharedPreferences used by this PreferenceFragment to use the SillyDataStore for storage, instead of the default XML-based persistence.

This works... somewhat. There are some problems.

First, a PreferenceManager is not a system service. Of note, each instance of our PreferenceFragment gets its own fresh PreferenceManager. This is why we need to check for, and set, the PreferenceDataStore on the PreferenceManager for the PreferenceFragment each time.

Second, we have no way of associating a PreferenceDataStore with the default SharedPreferences obtained from PreferenceManager.getDefaultSharedPreferences(). That will always use the standard XML backing store. The initial activity contents are in the form of a PreferenceContentsFragment that reads from the default SharedPreferences in
onResume(). Normally, that would cause changes that we make via our PreferenceFragment to show up when the PreferenceContentsFragment is resumed. In this specific sample, that does not happen, as the PreferenceContentsFragment is using the default XML data store, and our data is really in the SillyDataStore.

This illustrates the fatal flaw of this system: you can never really use the SharedPreferences. You cannot create PreferenceManager instances yourself, as it has no public constructors. All of the code that gives you SharedPreferences objects back other than through a PreferenceManager has no way of associating a PreferenceDataStore with the SharedPreferences.

Instead of using SharedPreferences... you have to read and write from your PreferenceDataStore itself. This, in turn, loses everything that you normally associate with SharedPreferences, such as atomicity of updates and preference-change listeners.

Worse, since PreferenceDataStore has no API telling you when to persist changes, you would have to do that yourself... somehow.

These can be overcome, with a sufficiently-robust PreferenceDataStore implementation and lots of documentation. However, for casual use, other than perhaps for test mocks, PreferenceDataStore is not a well-engineered solution and probably should be avoided.
Android ships with a number of dialog classes for specific circumstances, like DatePickerDialog and ProgressDialog. Similarly, Android comes with a smattering of Preference classes for your PreferenceActivity, to accept text or selections from lists and so on.

However, there is plenty of room for improvement in both areas. As such, you may find the need to create your own custom dialog or preference class. This chapter will show you how that is done.

We start off by looking at creating a custom AlertDialog, not by using AlertDialog.Builder, but via a custom subclass. Then, we show how to create your own dialog-style Preference, where tapping on the preference pops up a dialog to allow the user to customize the preference value.

**Prerequisites**

Understanding this chapter requires that you have read the chapter on dialogs, along with the chapter on the preference system. Also, the samples here use the custom ColorMixer View described in another chapter.

**Your Dialog, Chocolate-Covered**

For your own application, the simplest way to create a custom AlertDialog is to use AlertDialog.Builder, as described in a previous chapter. You do not need to create any special subclass — just call methods on the Builder, then show() the resulting dialog.
CUSTOM DIALOGS AND PREFERENCES

However, if you want to create a reusable AlertDialog, this may become problematic. For example, where would this code to create the custom AlertDialog reside?

So, in some cases, you may wish to extend AlertDialog and supply the dialog’s contents that way, which is how TimePickerDialog and others are implemented. Unfortunately, this technique is not well documented. This section will illustrate how to create such an AlertDialog subclass, as determined by looking at how the core Android team did it for their own dialogs.

The sample code is ColorMixerDialog, a dialog wrapping around the ColorMixer widget shown in a previous chapter. The implementation of ColorMixerDialog can be found in the CWAC-ColorMixer GitHub repository, as it is part of the CommonsWare Android Components.

Using this dialog works much like using DatePickerDialog or TimePickerDialog. You create an instance of ColorMixerDialog, supplying the initial color to show and a listener object to be notified of color changes. Then, call show() on the dialog. If the user makes a change and accepts the dialog, your listener will be informed.

Figure 599: The ColorMixerDialog
Basic AlertDialog Setup

The ColorMixerDialog class is not especially long, since all of the actual color mixing is handled by the ColorMixer widget:

```java
package com.commonsware.cwac.colormixer;

import android.app.AlertDialog;
import android.content.Context;
import android.content.DialogInterface;
import android.os.Bundle;

public class ColorMixerDialog extends AlertDialog
  implements DialogInterface.OnClickListener {
  static final String COLOR = "c";

  private ColorMixer mixer = null;
  private int initialColor;
  private ColorMixer.OnColorChangedListener onSet = null;

  public ColorMixerDialog(Context ctxt, int initialColor,
                           ColorMixer.OnColorChangedListener onSet) {
    super(ctxt);
    this.initialColor = initialColor;
    this.onSet = onSet;
    mixer = new ColorMixer(ctxt);
    mixer.setColor(initialColor);
    setView(mixer);
    setButton(ctxt.getText(R.string.cwac_colormixer_set),
              this);
    setButton2(ctxt.getText(R.string.cwac_colormixer_cancel),
               (DialogInterface.OnClickListener)null);
  }
  
  @Override
  public void onClick(DialogInterface dialog, int which) {
    if (initialColor != mixer.getColor()) {
      onSet.onColorChange(mixer.getColor());
    }
  }
  
  @Override
  public Bundle onSaveInstanceState() {
    Bundle state = super.onSaveInstanceState();
```
We extend the AlertDialog class and implement a constructor of our own design. In this case, we take in three parameters:

1. A Context (typically an Activity), needed for the superclass
2. The initial color to use for the dialog, such as if the user is editing a color they chose before
3. A ColorMixer.OnColorChangedListener object, just like ColorMixer uses, to notify the dialog creator when the color is changed

We then create a ColorMixer and call setView() to make that be the main content of the dialog. We also call setButton() and setButton2() to specify a “Set” and “Cancel” button for the dialog. The latter just dismisses the dialog, so we need no event handler. The former we route back to the ColorMixerDialog itself, which implements the DialogInterface.OnClickListener interface.

Handling Color Changes

When the user clicks the “Set” button, we want to notify the application about the color change...if the color actually changed. This is akin to DatePickerDialog and TimePickerDialog only notifying you of date or times if the user clicks Set and actually changed the values.

The ColorMixerDialog tracks the initial color via the initialColor data member. In the onClick() method — required by DialogInterface.OnClickListener — we see if the mixer has a different color than the initialColor, and if so, we call the supplied ColorMixer.OnColorChangedListener callback object:
if (initialColor != mixer.getColor()) {
    onSet.onColorChange(mixer.getColor());
}

State Management

Dialogs use onSaveInstanceState() and onRestoreInstanceState(), just like activities do. That way, if the screen is rotated, or if the hosting activity is being evicted from RAM when it is not in the foreground, the dialog can save its state, then get it back later as needed.

The biggest difference with onSaveInstanceState() for a dialog is that the Bundle of state data is not passed into the method. Rather, you get the Bundle by chaining to the superclass, then adding your data to the Bundle it returned, before returning it yourself:

```java
@override
public Bundle onSaveInstanceState() {
    Bundle state = super.onSaveInstanceState();
    state.putInt(COLOR, mixer.getColor());
    return state;
}
```

The onRestoreInstanceState() pattern is much closer to the implementation you would find in an Activity, where the Bundle with the state data to restore is passed in as a parameter:

```java
@override
public void onRestoreInstanceState(Bundle state) {
    super.onRestoreInstanceState(state);
    mixer.setColor(state.getInt(COLOR));
}
```

Preferring Your Own Preferences, Preferably

The Android Settings application, built using the Preference system, has lots of custom Preference classes. You too can create your own Preference classes, to collect things like dates, numbers, or colors. Once again, though, the process of creating such classes is not well documented. This section reviews one recipe for
CUSTOM DIALOGS AND PREFERENCES

making a Preference — specifically, a subclass of DialogPreference – based on the implementation of other Preference classes in Android.

The result is ColorPreference, a Preference that uses the ColorMixer widget. As with the ColorMixerDialog from the previous section, the ColorPreference is from the CommonsWare Android Components, and its source code can be found in the CWAC-ColorMixer GitHub repository.

One might think that ColorPreference, as a subclass of DialogPreference, might use ColorMixerDialog. However, that is not the way it works, as you will see.

The Constructor

A Preference is much like a custom View, in that there are a variety of constructors, some taking an AttributeSet (for the preference properties), and some taking a default style. In the case of ColorPreference, we need to get the string resources to use for the names of the buttons in the dialog box, providing them to DialogPreference via setPositiveButtonText() and setNegativeButtonText().

Here, we just implement the standard two-parameter constructor, since that is the one that is used when this preference is inflated from a preference XML file:

```java
public ColorPreference(Context ctxt, AttributeSet attrs) {
    super(ctxt, attrs);
    setPositiveButtonText(ctxt.getText(R.string.cwac_colormixer_set));
    setNegativeButtonText(ctxt.getText(R.string.cwac_colormixer_cancel));
}
```

Creating the View

The DialogPreference class handles the pop-up dialog that appears when the preference is clicked upon by the user. Subclasses get to provide the View that goes inside the dialog. This is handled a bit reminiscent of a CursorAdapter, in that there are two separate methods to be overridden:

- `onCreateDialogView()` works like `newView()` of CursorAdapter, returning a View that should go in the dialog
- `onBindDialogView()` works like `bindView()` of CursorAdapter, where the custom Preference is supposed to configure the View for the current preference value
In the case of ColorPreference, we use a ColorMixer for the View:

```java
@Override
protected View onCreateDialogView() {
    mixer = new ColorMixer(getContext());
    return mixer;
}
```

Then, in onBindDialogView(), we set the mixer's color to be lastColor, a private data member:

```java
@Override
protected void onBindDialogView(View v) {
    super.onBindDialogView(v);
    mixer.setColor(lastColor);
}
```

We will see later in this section where lastColor comes from – for the moment, take it on faith that it holds the user's chosen color, or a default value.

**Dealing with Preference Values**

Of course, the whole point behind a Preference is to allow the user to set some value that the application will then use later on. Dealing with values is a bit tricky with DialogPreference, but not too bad.

**Getting the Default Value**

The preference XML format has an android:defaultValue attribute, which holds the default value to be used by the preference. Of course, the actual data type of the value will differ widely — an EditTextPreference might expect a String, while ColorPreference needs a color value.

Hence, you need to implement onGetDefaultValue(). This is passed a TypedArray — similar to how a custom View uses a TypedArray for getting at its custom attributes in an XML layout file. It is also passed an index number into the array representing android:defaultValue. The custom Preference needs to return an Object representing its interpretation of the default value.

In the case of ColorPreference, we simply get an integer out of the TypedArray,
representing the color value, with an overall default value of 0xFFA4C639 (a.k.a., Android green):

```java
@Deprecated
protected Object onGetDefaultValue(TypedArray a, int index) {
    return a.getInt(index, 0xFFA4C639);
}
```

### Setting the Initial Value

When the user clicks on the preference, the DialogPreference supplies the last-known preference value to its subclass, or the default value if this preference has not been set by the user to date.

The way this works is that the custom Preference needs to override onSetInitialValue(). This is passed in a boolean flag (restoreValue) indicating whether or not the user set the value of the preference before. It is also passed the Object returned by onGetDefaultValue(). Typically, a custom Preference will look at the flag and choose to either use the default value or load the already-set preference value.

To get the existing value, Preference defines a set of type-specific getter methods — getPersistedInt(), getPersistedString(), etc. So, ColorPreference uses getPersistedInt() to get the saved color value:

```java
@Override
protected void onSetInitialValue(boolean restoreValue, Object defaultValue) {
    lastColor = (restoreValue ? getPersistedInt(lastColor) : (Integer)defaultValue);
}
```

Here, onSetInitialValue() stores that value in lastColor — which then winds up being used by onBindDialogView() to tell the ColorMixer what color to show.

### Closing the Dialog

When the user closes the dialog, it is time to persist the chosen color from the ColorMixer. This is handled by the onDialogClosed() callback method on your custom Preference:

```java
@Override
protected void onDialogClosed(boolean positiveResult) {
    super.onDialogClosed(positiveResult);
}
```
The passed-in boolean indicates if the user accepted or dismissed the dialog, so you can elect to skip saving anything if the user dismissed the dialog. The other DialogPreference implementations also call callChangeListener(), which is somewhat ill-documented. Assuming both the flag and callChangeListener() are true, the Preference should save its value to the persistent store via persistInt(), persistString(), or kin.

Using the Preference

Given all of that, using the custom Preference class in an application is almost anti-climactic. You simply add it to your preference XML, with a fully-qualified class name:

```xml
<PreferenceScreen
    xmlns:android="http://schemas.android.com/apk/res/android">
    <com.commonsware.cwac.colormixer.ColorPreference
        android:key="favoriteColor"
        android:defaultValue="0xFFA4C639"
        android:title="Your Favorite Color"
        android:summary="Blue.  No yel-- Auuuuuuugh!" />
</PreferenceScreen>
```

At this point, it behaves no differently than does any other Preference type. Since ColorPreference stores the value as an integer, your code would use getInt() on the SharedPreferences to retrieve the value when needed.
The user sees an ordinary preference entry in the PreferenceActivity:

*Figure 600: A PreferenceActivity, showing the ColorPreference*
CUSTOM DIALOGS AND PREFERENCES

When tapped, it brings up the mixer:

![The ColorMixer in a custom DialogPreference](image)

*Figure 601: The ColorMixer in a custom DialogPreference*

Choosing a color and clicking “Set” persists the color value as a preference.
Progress Indicators

Sometimes, we make the user wait. And wait. And wait some more.

Often, in these cases, it is useful to let the user know that something they requested is something that we are diligently working on. To do this, we can use some form of progress indicator. We saw basic use of a ProgressBar in the tutorials earlier in this book — now is the time to take a much closer look at ProgressBar and other means of displaying progress.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having read the chapters on dialogs, custom drawables, and animators is also a good idea.

Progress Bars

The classic way to tell the user that we are doing something for them is to use a ProgressBar widget, much as we briefly displayed one in the EmPubLite sample app in the tutorials.

However, a ProgressBar is much more than a simple spinning image. We can use it to display either indeterminate progress (“we will be done... sometime”) or specific progress (“we are 34% complete”). We can use it either as a circle or as a classic horizontal bar, the latter typically used for specific progress. And, for specific progress, we can actually show two tiers of progress, known as “primary” and “secondary” (e.g., primary for the progress in copying a directory’s worth of files, secondary for the progress on a specific file).
PROGRESS INDICATORS
In this section, we will take a look at these different ways of using ProgressBar.

Circular vs. Horizontal
As the name suggests, a ProgressBar denotes progress. As the name does not
suggest, a ProgressBar is not a bar, by default — it is a circle. Hence, the following
element from an XML layout resource:
<ProgressBar
android:id="@+id/progressCI"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:layout_gravity="center_horizontal"
android:layout_marginBottom="20dp"
android:layout_marginTop="20dp"/>
/>
(from Progress/BarSampler/app/src/main/res/layout/activity_main.xml)

1928


PROGRESS INDICATORS

gives us:

*Figure 602: Android 5.1 ProgressBar, Default Style*

*Figure 603: Android 4.0 ProgressBar, Default Style*

However, referencing `style="?android:attr/progressBarStyleHorizontal"` in the element:

```
<ProgressBar
    android:id="@+id/progressHI"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginBottom="20dp"
    android:indeterminate="true"/>
```

(from Progress/BarSampler/app/src/main/res/layout/activity_main.xml)
PROGRESS INDICATORS

gives us a horizontal bar:

Figure 604: Android 5.1 ProgressBar, Horizontal Style

Figure 605: Android 4.0 ProgressBar, Horizontal Style

Note that the look-and-feel of these widgets have changed over the years. On Android 1.x and 2.x, they will look like this:

Figure 606: Android 2.3.3 ProgressBar, Both Styles

Specific vs. Indeterminate

Typically, you use the circular ProgressBar style for indeterminate progress, where the circle simply spins in place to let the user know that work is proceeding and the device (or activity) has not frozen. The horizontal ProgressBar style is used to illustrate specific amounts of progress, from 0 to a value you choose.

However, while those patterns are typical, the choice of whether to use indeterminate or some specific amount of progress is independent of the style of the widget.
The `android:indeterminate` attribute controls whether the `ProgressBar` will render an indeterminate look or a specific look. For the latter, calls to `setMax()` (or the `android:max` attribute) will set the upper end of the progress range (the default is 100), and `setProgress()` or `incrementProgressBy()` will set how much progress along that range is illustrated.

**Primary vs. Secondary**

For specific progress, you actually have two independent amounts of progress. `setProgress()`, `incrementProgressBy()`, and `android:progress` control the primary progress, while `setSecondaryProgress()`, `incrementSecondaryProgressBy()`, and `android:secondaryProgress` control the secondary progress. Here, “primary progress” refers to the progress along an entire piece of work (e.g., copying a folder’s worth of files), while “secondary progress” refers the progress along a discrete chunk of the overall work (e.g., copying an individual file).
A ProgressBar will render these with different colors, though primary trumps secondary, and so the secondary progress will only be visible when its value exceeds that of the primary progress:

**Figure 610: Android 4.0 ProgressBar, Horizontal Style, Primary-Only and Primary-Plus-Secondary**

**Figure 611: Android 2.3.3 ProgressBar, Horizontal Style, Primary-Only and Primary-Plus-Secondary**

### ProgressBar and Threads

Normally, you cannot update the UI of a widget from a background thread. 

ProgressBar is an exception. You can safely call `setProgress()` and `incrementProgressBy()` from a background thread to update the primary progress, and you can safely call `setSecondaryProgress()` and `incrementSecondaryProgressBy()` from a background thread to update the secondary progress.

To see this in action, take a look at the [Progress/BarSampler](https://example.com) sample project.

This project has a single activity (`MainActivity`), whose layout (`activity_main.xml`) contains four ProgressBar widgets, two indeterminate and two for specific progress:

```xml
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"> 

    <ProgressBar android:id="@+id/progressCI"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_horizontal"
        android:layout_marginBottom="20dp"/>
```
The activity gets access to the latter two ProgressBar widgets and sets up a ScheduledThreadPoolExecutor to get control every second in a background thread, which calls our run() method. The run() method will increment both ProgressBar widgets primary progress by 2 each time, and the secondary progress by 10 (dropping back to the starting point when the secondary progress reaches the maximum of 100). When the primary progress gets to 100, we cancel our scheduled work in the ScheduledThreadPoolExecutor:

```java
package com.commonsware.android.progress;

import android.app.Activity;
import android.os.Bundle;
import android.widget.ProgressBar;
import java.util.concurrent.ScheduledThreadPoolExecutor;
import java.util.concurrent.TimeUnit;

public class MainActivity extends Activity implements Runnable {
  ...
The net effect is that you see the progress march across the screen, with the
Tailoring Progress Bars

The stock ProgressBar look and feel is decent, if perhaps not spectacular. Often times, the stock look is sufficient for your needs. If you wish to have greater control over the look of your ProgressBar, the following sections will demonstrate some possibilities.

Changing the Progress Colors

The ProgressBar uses different colors for primary and secondary specific progress. By default, those colors are defined by the theme you are using, and the stock themes have firmware-defined colors (e.g., yellows for Android 1.x and 2.x, blues for Android 3.x and higher).

However, you can change the colors by using a LayerListDrawable and associating it with a ProgressBar by means of the android:progressDrawable attribute.

The ProgressBar background image needs to be a LayerListDrawable with three specific layers:

- android:id="@android:id/background" for the background color of the bar
- android:id="@android:id/progress" for the primary progress
- android:id="@android:id/secondaryProgress" for the secondary progress

Whether those layers are defined as ShapeDrawable structures, or as nine-patch PNG files is up to you, but they will need the ability to stretch to fit however big your bar winds up being.

To see what this means, let's take a look at the Progress/Styled sample project. This is a near-clone of the Progress/BarSampler project from earlier, using custom backgrounds for the bars. Here, we will look at the horizontal ProgressBar widgets — in the next section, we will look at how to change the background of a circular indefinite ProgressBar.

For the first horizontal ProgressBar (progressHS), for Android 4.x, we will use a custom style created by the Android Holo Colors Generator, a Web site set up to help us create custom versions of the holographic widget theme.
When you visit this site in Google Chrome (note: other browsers are not supported at this time), you can fill in a name for your theme (e.g., “AppTheme”), the color scheme to use for the theme, and the foundation theme to use (light or dark):

![Android Holo Colors Generator, Basic Info](image)

*Figure 612: Android Holo Colors Generator, Basic Info*
You can then toggle on and off which widgets you intend to use, so the generator will create custom styles for them:

![Figure 613: Android Holo Colors Generator, Widget Selection](image)

Then, the generator will create a ZIP file that you can download that contains the generated resources for your custom styles.

The Progress/Styled project contains the files generated by the generator, replacing the original style resources. Note that the generator does not create a .DarkActionBar version of the style resource, so the values-v14 resource directory in the project has one hand-crafted based upon a regular generated style resource.

On Android 5.0+, we will use a theme with the same name, but where we are using tints in the theme to affect the colors of the progress indicators.

Our manifest points to our AppTheme as being how we wish to style widgets in this application:

```xml
```
That theme, defined in apptheme_themes.xml, points to style resources for horizontal ProgressBar widgets:

The ProgressBarAppTheme style resource is defined in a separate apptheme_styles.xml resource:
Here, we say that we want the android:progressDrawable property to be a progress_horizontal_holo_light drawable resource. We also set the android:indeterminateDrawable property — used for indeterminate bars — to a progress_indeterminate_horizontal_holo_light drawable resource.

Those are defined as XML-based drawables, in the res/drawable/ directory in the project. The progress_horizontal_holo_light resource is defined as:

```
<?xml version="1.0" encoding="utf-8"?>

limitations under the License.
-->

<layer-list xmlns:android="http://schemas.android.com/apk/res/android">
  <item android:id="@android:id/background"
        android:drawable="@drawable/progress_bg_holo_light" />
  <item android:id="@android:id/secondaryProgress">
    <scale android:scaleWidth="100%"
           android:drawable="@drawable/progress_secondary_holo" />
  </item>
  <item android:id="@android:id/progress">
    <scale android:scaleWidth="100%"
           android:drawable="@drawable/progress_primary_holo" />
  </item>
</layer-list>
```
The generator creates our LayerListDrawable resource with our three layers, each pointing to a nine-patch PNG file (with different versions for different densities) that contains our desired custom color. The progress and secondaryProgress layers use ScaleDrawable definitions to ensure that the images are measured against the complete width of the background layer, which in turn will be sized according to the size of the ProgressBar itself.

We will take a look at the progress_indeterminate_horizontal_holo_light drawable resource in the next section.

Note that you could skip the custom theme and style if you wished, and simply add the android:progressDrawable attribute to the ProgressBar widget definition in its layout XML resource.

Regardless, the result is that our progress bars have the desired purple color scheme:

![Figure 614: Custom ProgressBar Style, Primary and Secondary](image)

Also, you can have your LayerListDrawable use ShapeDrawable layers, to avoid creating nine-patch PNG files, if you prefer, using a resource like this:

```xml
<?xml version="1.0" encoding="utf-8"?>
  <item android:id="@android:id/background">
    <shape>
      <stroke android:width="1dip" android:color="#FF333333" />
      <gradient
        android:startColor="#FF9C9E9C"
        android:centerColor="#FF5A5D5A"
        android:centerY="0.71"
        android:endColor="#FF6B716B"
        android:angle="270"
      />
    </shape>
  </item>
  <item android:id="@android:id/secondaryProgress">
    <clip>
    </clip>
  </item>
</layer-list>
```
On Android 5.0+, we have it much easier, as ProgressBar automatically adopts the accent tint. So we go with a much simpler theme definition:

```xml
<resources>
  <style name="AppTheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
</resources>
```

This references colors from a separate colors.xml resource:

```xml
<?xml version="1.0" encoding="utf-8"?>
<resources>
```

1941
The result are yellow-tinted progress bars:

![Material Progress Bar Style, Primary and Secondary](image)

**Figure 615: Material ProgressBar Style, Primary and Secondary**

### Changing the Indeterminate Animation

Similarly, for indefinite progress “bars”, changing the progress drawable will let you change the way they look. However, in this case, the drawable also needs to implement the animation itself. You can accomplish this either by using an [AnimationDrawable](https://developer.android.com/reference/android/widget/AnimationDrawable) or by using some other type of drawable wrapped in an animation, such as a [ShapeDrawable wrapped in a <rotate> animation](https://developer.android.com/reference/android/animation/Rotation.Animation). For example, the Android 4.x custom theme created by the Android Holo Colors Generator assigns the following drawable resource to `android:indeterminateDrawable` in the theme:

```xml
<?xml version="1.0" encoding="utf-8"?>
<animation-list
```

Hence, every horizontal indeterminate ProgressBar will use that AnimationDrawable. The individual images in the animation are PNG files, with different versions for different densities.

Circular ProgressBar widgets also need a custom progress drawable, though obviously the image will need to be circular, not a bar. You can certainly use an AnimationDrawable for this, or you can use a ShapeDrawable, such as the res/drawable/progress_circular.xml resource shown below:

```xml
<rotate xmlns:android="http://schemas.android.com/apk/res/android"
    android:fromDegrees="0"
    android:pivotX="50%"
    android:pivotY="50%"
    android:toDegrees="360">
    <shape
        android:innerRadiusRatio="3"
        android:shape="ring"
        android:thicknessRatio="8"
        android:useLevel="false">
        <gradient
            android:centerColor="#4c737373"
            android:centerY="0.50"
            android:endColor="#ff9933CC"
            android:startColor="#4c737373"
            android:type="sweep"
            android:useLevel="false"/>
    </shape>
</rotate>
```

Here, we have a ring ShapeDrawable, with a certain thickness and radius, filled with
a gradient. Half of the fill is actually a solid color (#4c737373), as the start and center colors are the same. The other half is a sweep gradient from the starting color to the same purple shade that is used by the other bar styles. This ring is then wrapped in a rotate animation. This yields a simple gradient-filled ring, that rotates smoothly to indicate progress:

![Custom ProgressBar Styles, Including Circular Indefinite](image)

*Figure 616: Custom ProgressBar Styles, Including Circular Indefinite*

Note that the Android Holo Colors Generator does not generate circular indefinite ProgressBar resources as of the time of this writing.
Once again, Android 5.0+ can leverage Theme.Material and get rid of all the extra clutter. Just having an accent color defined will have your indefinite progress bars adopt that same color:

![Material ProgressBar Styles, Including Circular Indefinite](image)

**Figure 617: Material ProgressBar Styles, Including Circular Indefinite**

### Progress Dialogs

One use of a ProgressBar is to have it wrapped in a ProgressDialog. Like all dialogs, ProgressDialog is modal, preventing the user from interacting with an underlying activity while the dialog is displayed. From a UI design standpoint, a ProgressDialog is an easy way to temporarily show progress without having to find a spot for a ProgressBar widget somewhere in the UI. Also, since usually there are things in the activity that are dependent upon the work being done in the background, having the dialog in place prevents anyone from trying to use things that are not yet ready.

However, modal dialogs are not a great design approach, as they aggressively limit the user’s options. ProgressDialog is perhaps the worst in this regard, as the user can do nothing except wait. While part of your app may not yet be ready, other parts surely are, such as reading the documentation, or adjusting settings, or clicking on
your ad banners. Hence, using *anything* else other than ProgressDialog, while perhaps a bit more work, will be an improvement in the usability of your app.

That being said, let us see how to set up a ProgressDialog. The Progress/Dialog sample project is a near-clone of the Dialogs/DialogFragment sample project from the chapter on dialogs. The only difference is the onCreateDialog() method of our DialogFragment, where we directly create a ProgressDialog instead of using an AlertDialog.Builder to create an AlertDialog as before:

```java
@Override
public Dialog onCreateDialog(Bundle savedInstanceState) {
    ProgressDialog dlg=new ProgressDialog(getActivity());

    dlg.setMessage(getActivity().getString(R.string.dlg_title));
    dlg.setIndeterminate(true);
    dlg.setProgressStyle(ProgressDialog.STYLE_SPINNER);

    return(dlg);
}
```

We create the ProgressDialog via its constructor, set the message explaining what we are waiting for via setMessage(), indicate that the ProgressBar should be an indeterminate one via setIndeterminate(), and indicate that we want a circular “spinner” ProgressBar rather than a horizontal one by calling setProgressStyle(ProgressDialog.STYLE_SPINNER). There are a variety of other things you could configure on the ProgressDialog if desired, and ProgressDialog inherits from AlertDialog, so some things you could configure on an AlertDialog will also be available on the ProgressDialog.
The result is a dialog that you may have seen from other apps in Android:

![ProgressDialog](image)

### Title Bar and Action Bar Progress Indicators

Another place to let users know that you are doing something on their behalf is to put a progress indicator in the title bar or action bar of your activity. This avoids your having to put an indeterminate `ProgressBar` somewhere in your activity's UI. It is also very simple to set up, as we can see in the `Progress/TitleBar` sample project.

```java
package com.commonsware.android.titleprog;

import android.app.Activity;
import android.os.Bundle;
import android.view.Window;

public class MainActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    getWindow().requestFeature(Window.FEATURE_INDETERMINATE_PROGRESS);
    super.onCreate(savedInstanceState);
  }
}
```
Progress Indicators

```java
setContentView(R.layout.activity_main);
setProgressBarIndeterminateVisibility(true);
}
```

(from Progress/TitleBar/app/src/main/java/com/commonsware/android/titleprog/MainActivity.java)

Up front, as the first thing that you do in your `onCreate()` call, you need to call:

```java
getWindow().requestFeature(Window.FEATURE_INDETERMINATE_PROGRESS);
```

This tells Android to reserve space in your title bar or action bar for an indeterminate progress indicator, though the indicator does not appear at this point.

Later on, when you want the indicator to actually appear, call `setProgressBarIndeterminateVisibility(true)` on your activity, and later call `setProgressBarIndeterminateVisibility(false)` to make the indicator go away.

This particular application has `android:targetSdkVersion` set to 11 or higher, but it is not using an action bar backport. Hence, when you run it on an older Android environment, you get a classic title bar with the progress indicator on the right:

![Progress Indicator in Title Bar](image)

*Figure 619: Progress Indicator in Title Bar*
When you have an action bar, you get the same basic effect, albeit with a larger indicator to match the larger bar:

![Progress Indicator in Action Bar](image)

*Figure 620: Progress Indicator in Action Bar*

Note that this approach is not supported by Theme.Material or the appcompat-v7 action bar backport, which makes it far less commonly used today.

**Direct Progress Indication**

Sometimes, the best way to let the user know about updates is to simply update the data in place. Rather than have some separate indicator, let the core UI itself convey the work being done.

We saw this in the chapter on threads, where we populated a ListView in “real time” as we loaded in data into its adapter. Other variations on this theme include:

- Updating a page count TextView to show the number of downloaded pages, while the user is reading earlier pages, perhaps with some sort of style (e.g., italics) or color coding (e.g., red) to indicate data that is being loaded.
- Simply disabling the buttons, action bar items, and other ways that the user
could navigate to a point in your app where you need the data that is being loaded in the background. The key here is to make sure that users understand why those items are disabled, and sometimes that is not obvious. Hence, while this step may be necessary, it is often tied in with progress indicators in the title bar or action bar or other means of indicating to the user the reason they cannot perform certain operations.
More Fun with Pagers

In earlier chapters, we saw basic uses of ViewPager. However, there are other ways to apply ViewPager and integrate it into the rest of your application, some of which we will examine in this chapter.

Prerequisites

This chapter assumes that you have read the core chapters, particularly the one showing how to use ViewPager.

Hosting ViewPager in a Fragment

If you have a ViewPager use fragments for pages and also be itself in a fragment, you are using nested fragments: one fragment holds another fragment. This was not originally possible with fragments, but that capability was added to the library implementation of fragments in 2014 or so.

However, using nested fragments requires a minor modification to the way we set up a PagerAdapter, as is illustrated in the ViewPager/Nested sample project. This is the same project as ViewPager/Indicator, with the twist that the pages are fragments and the ViewPager is inside a fragment.

Our activity now implements the standard add-the-fragment-if-it-does-not-exist pattern that we have seen previously:

```java
package com.commonsware.android.pagernested;
import android.os.Bundle;
import android.support.v4.app.FragmentActivity;
```
More Fun with Pagers

```java
public class ViewPagerIndicatorActivity extends FragmentActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
            getSupportFragmentManager().beginTransaction().add(android.R.id.content, new PagerFragment()).commit();
        }
    }
}
```

This loads a PagerFragment, which contains most of the logic from our original activity:

```java
package com.commonsware.android.pagernested;

import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class PagerFragment extends Fragment {
    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup container, Bundle savedInstanceState) {
        View result = inflater.inflate(R.layout.pager, container, false);
        ViewPager pager = (ViewPager)result.findViewById(R.id.pager);
        pager.setAdapter(buildAdapter());
        return(result);
    }

    private PagerAdapter buildAdapter() {
        return(new SampleAdapter(getActivity(), getChildFragmentManager()));
    }
}
```

The biggest difference is that our call to the constructor of SampleAdapter no longer uses getSupportFragmentManager(). Instead, it uses getChildFragmentManager().
This allows SampleAdapter to use fragments hosted by PagerFragment, rather than ones hosted by the activity as a whole.

No other code changes are required, and from the user's standpoint, there is no visible difference.

## Pages and the Action Bar

Fragments that are pages inside a ViewPager can participate in the action bar, supplying items to appear as toolbar buttons, in the overflow menu, etc. This is not significantly different than how any fragment participates in the action bar:

- Call setHasOptionsMenu() early in the fragment lifecycle (e.g., onCreateView()) to state that the fragment wishes to contribute to the action bar contents
- Override onCreateOptionsMenu() and onOptionsItemSelected(), much as you would with an activity

ViewPager and FragmentManager will manage the contents of the action bar, based upon the currently-visible page. That page's contributions will appear in the action bar, then will be removed when the user switches to some other page.

To see this in action, take a look at the ViewPager/ActionBar sample project. This is the same as the ViewPager/Indicator project from before, except:

- In onCreateView(), for even-numbered page positions (0, 2, etc.), we call setHasOptionsMenu(true):

```java
@Override
public View onCreateView(LayoutInflater inflater, 
    ViewGroup container, 
    Bundle savedInstanceState) {
    View result = inflater.inflate(R.layout.editor, container, false);
    EditText editor = (EditText)result.findViewById(R.id.editor);

    position = getArguments().getInt(KEY_POSITION, -1);
    editor.setHint(getTitle(getActivity(), position));

    if (position % 2 == 0) {
        setHasOptionsMenu(true);
    }
```
return(result);
}

In onCreateOptionsMenu(), we inflate a res/menu/actions.xml menu resource:

```java
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
  inflater.inflate(R.menu.actions, menu);

  super.onCreateOptionsMenu(menu, inflater);
}
```

Normally, we would also implement onOptionsItemSelected(), to find out when the action bar item was tapped, though this is skipped in this sample.

The result is that when we have an even-numbered page position — equating to an odd-numbered title and hint — we have items in the action bar:

Figure 621: A ViewPager, PagerTabStrip, and Action Bar Item on Android 4.1
MORE FUN WITH PAGERS

...but as soon as we swipe to an odd-numbered page position — equating to an even-numbered title and hint — our action bar item is removed, as that fragment did not call `setHasOptionsMenu(true)`:

![Figure 622: A ViewPager and PagerTabStrip, Sans Action Bar Item on Android 4.1](image)

**ViewPagers and Scrollable Contents**

There are other things in Android that can be scrolled horizontally, besides a `ViewPager`:

- `HorizontalScrollView`
- `WebView`, for content that is wider than the width of the screen
- the deprecated `Gallery` widget
- maps from many mapping engines, such as Google Maps
- various third-party widgets

The challenge then comes in terms of dealing with horizontal swipe events. The ideal situation is for you to be able to swipe horizontally on the material inside the page, until you hit some edge (e.g., end of the `HorizontalScrollView`), then have swipe events move you to the adjacent page.

You can assist `ViewPager` in handling this scenario by subclassing it and overriding the `canScroll()` method. This will be called on a horizontal swipe, and it is up to
you to indicate if the contents can be scrolled (returning true) or not (returning false). If the built-in logic is insufficient, tailoring canScroll() to your particular needs can help.

We will see an example of this elsewhere in the book, when we put some maps into a ViewPager.

**Showing More Pages**

In some cases, when the ViewPager is on a larger screen, we simply want larger pages — a digital book reader, for example, would simply have a larger page in a bigger font for easier reading.

Sometimes, though, we might not be able to take advantage of the full space offered by the large screen, particularly when our ViewPager takes up the whole screen. In cases like this, it might be useful to allow ViewPager, in some cases, to show more than one page at a time. Each “page” is then designed to be roughly phone-sized, and we choose whether to show one, two, or perhaps more pages at a time based upon the available screen space.

Mechanically, allowing ViewPager to show more than one page is fairly easy, involving overriding one more method in our PagerAdapter: getPageWidth(). To see this in action, take a look at the ViewPager/MultiView1 sample project.

Each page in this sample is simply a TextView widget, using the activity’s style’s “large appearance”, centered inside a LinearLayout:

```xml
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:gravity="center"
  android:orientation="vertical">
  <TextView
    android:id="@+id/text"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:textAppearance="?android:attr/textAppearanceLarge"/>
</LinearLayout>
```

(from ViewPager/MultiView1/app/src/main/res/layout/page.xml)
The activity, in `onCreate()`, gets our ViewPager from the `res/layout/activity_main.xml` resource, and sets its adapter to be a SampleAdapter:

```java
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    pager = findViewById(R.id.pager);
    pager.setAdapter(new SampleAdapter());
    pager.setOffscreenPageLimit(6);
}
```

In this case, SampleAdapter is not a FragmentPagerAdapter, nor a FragmentStatePagerAdapter. Instead, it is its own implementation of the PagerAdapter interface:

```java
/*
 * Inspired by
 * https://gist.github.com/8cbe094bb7a783e37ad1
 */
private class SampleAdapter extends PagerAdapter {
    @Override
    public Object instantiateItem(ViewGroup container, int position) {
        View page = getLayoutInflater().inflate(R.layout.page, container, false);
        TextView tv = page.findViewById(R.id.text);
        int blue = position * 25;

        final String msg = String.format(getString(R.string.item), position + 1);

        tv.setText(msg);
        tv.setOnClickListener(new OnClickListener() {
            @Override
            public void onClick(View v) {
                Toast.makeText(MainActivity.this, msg, Toast.LENGTH_LONG)
                    .show();
            }
        });

        page.setBackgroundColor(Color.argb(255, 0, 0, blue));
        container.addView(page);

        return page;
    }
}
```

---

**MORE FUN WITH PAGERS**

1957
To create your own PagerAdapter, the big methods that you need to implement are:

- **instantiateItem()**, where you create the page itself and add it to the supplied container. In this case, we inflate the page, set the text of the TextView based on the supplied position, set the background color of the page itself to be a different shade of blue based on the position, set up a click listener to show a Toast when the TextView is tapped, and use that for our page. We return some object that identifies this page; in this case, we return the inflated View itself. A fragment-based PagerAdapter would probably return the fragment.
- **destroyItem()**, where we need to clean up a page that is being removed from the pager, where the page is identified by the Object that we had previously returned from instantiateItem(). In our case, we just remove it from the supplied container.
- **isViewFromObject()**, where we confirm whether some specific page in the pager (represented by a View) is indeed tied to a specific Object returned from instantiateItem(). In our case, since we return the View from instantiateItem(), we merely need to confirm that the two objects are indeed one and the same.
• `getCount()`, as with the built-in `PagerAdapter` implementations, to return how many total pages there are.

In our case, we also override `getPageWidth()`. This indicates, for a given position, how much horizontal space in the `ViewPager` should be given to this particular page. In principle, each page could have its own unique size. The return value is a `float`, from 0.0 to 1.0, indicating what fraction of the pager's width goes to this page. In our case, we return 0.5, to have each page take up half the pager.

The result is that we have two pages visible at a time:

![Figure 623: Two Pages in a ViewPager on Android 4.0.3](image)

It is probably also a good idea to call `setOffscreenPageLimit()` on the `ViewPager`, as we did in `onCreate()`. By default (and at minimum), `ViewPager` will cache three pages: the one presently visible, and one on either side. However, if you are showing more than one at a time, you should bump the limit to be 3 times the number of simultaneous pages. For a page width of 0.5 — meaning two pages at a time — you would want to call `setOffscreenPageLimit(6)`, to make sure that you had enough pages cached for both the current visible contents and one full swipe to either side.

`ViewPager` even handles “partial swipes” — a careful swipe can slide the right-hand
page into the left-hand position and slide in a new right-hand page. And ViewPager stops when you run out of pages, so the last page will always be on the right, no matter how many pages at a time and how many total pages you happen to have.

The biggest downside to this approach is that it will not work well with the current crop of indicators. PagerTitleStrip and PagerTabStrip assume that there is a single selected page. While the indicator will adjust properly, the visual representation shows that the left-hand page is the one selected (e.g., the tab with the highlight), even though two or more pages are visible. You can probably overcome this with a custom indicator (e.g., highlight the selected tab and the one to its right).

Also note that this approach collides a bit with setPageMargin() on ViewPager. setPageMargin() indicates an amount of whitespace that should go in a gutter between pages. In principle, this would work great with showing multiple simultaneous pages in a ViewPager. However, ViewPager does not take the gutter into account when interpreting the getPageWidth() value. For example, suppose getPageWidth() returns 0.5f and we setPageMargin(20). On a 480-pixel-wide ViewPager, we will actually use 500 pixels: 240 for the left page, 240 for the right page, and 20 for the gutter. As a result, 20 pixels of our right-hand page are off the edge of the pager. Ideally, ViewPager would subtract out the page margin before applying the page width. One workaround is for you to derive the right getPageWidth() value based upon the ViewPager size and gutter yourself, rather than hard-coding a value. Or, build in your gutter into your page contents (e.g., using android:layout_marginLeft and android:layout_marginRight) and skip setPageMargin() entirely.

**Columns or Pages**

Another pattern — using pages for smaller screens and having the “pages” side-by-side in columns for larger screens — will be explored later in the book.

**The Grid Pattern**

Yet another approach for taking advantage of larger screen sizes is to always show a full-size master and a full-size detail — perhaps using different activities — but to use a grid rather than a list for the master. This works well when the data being shown in the grid can be represented as “cards”, often dominated by some photo or other image.
The basic approach is to use fewer grid columns (e.g., 1 or 2) on smaller screen sizes and more grid columns (e.g., 3 or 4) on larger screen sizes. This way, the application flow is identical across screen sizes, yet the screen usage on larger screens is more effective. This is particularly true if you use one of the “staggered” grid widgets available from third parties, like Etsy’s AndroidStaggeredGrid or Maurycy Wojtowicz’s StaggeredGridView:

![StaggeredGridView Demo](image)

*Figure 624: StaggeredGridView Demo (image courtesy of Maurycy Wojtowicz)*

### Columns for Large, Pages for Small

In some cases, you can take better advantage of larger screens by using ViewPager more judiciously. In a previous chapter, we explored having ViewPager itself display more than one page at a time. A variation on that same theme is to only use a ViewPager on screen sizes where you lack sufficient room for everything, and to put those same pages on the screen at the same time when you have room for all of them.

For example, a Twitter client for Android could use the columns-or-pages support for displaying various streams of tweets: your timeline, your @ mentions, hashtags you follow, etc. Each stream is represented by a typical ListView, with one row per
More Fun with Pagers

tweet. On a phone, since screen space is at a premium, those ListView widgets are set up in a ViewPager, with one list per page. Users can swipe between the lists, or use tabs to navigate the available lists. However, tablets offer more room, so the app could show three ListView widgets side-by-side in landscape mode, so you can take in three sets of content without further interaction with the screen.

The ViewPager/Columns1 sample project will demonstrate how you can accomplish the same basic approach in your own app... with some limitations.

The Layouts

Our main activity layout — cunningly named main — has a ViewPager-based definition in res/layout/main.xml:

```xml
<?xml version="1.0" encoding="utf-8"?>
android:id="@+id/pager"
android:layout_width="match_parent"
android:layout_height="match_parent">
  <android.support.v4.view.PagerTabStrip
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
      android:layout_gravity="top"/>
</android.support.v4.view.ViewPager>
```

(from ViewPager/Columns1/app/src/main/res/layout/main.xml)

However, in res/layout-large/, for 5-inch devices on up, we have a horizontal LinearLayout with three FrameLayout containers, each representing an equal-sized slot for one of our "pages":

```xml
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
android:layout_width="match_parent"
android:layout_height="match_parent"
android:baselineAligned="false"
android:orientation="horizontal">
  <FrameLayout
      android:id="@+id/editor1"
      android:layout_width="0dp"
      android:layout_height="match_parent"
      android:layout_weight="1"/>
</LinearLayout>
```
MORE FUN WITH PAGERS

Android will automatically inflate the proper layout when we call setContentView(R.layout.main).

**The Activity**

However, while Android handles the inflation for us, we obviously need to populate the contents a bit differently. In this sample, though, we are relying upon the fact that screen size will not change on the fly. Hence, an instance of our application will either show a ViewPager or show the horizontal LinearLayout, and not have to switch between those at runtime.

Our SampleAdapter, therefore, can remain unchanged, except for reducing the page count to 3:

```java
package com.commonsware.android.pagercolumns;

import android.content.Context;
import android.support.v4.app.Fragment;
import android.support.v4.app.FragmentManager;
import android.support.v4.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
    Context ctxt=null;

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }
}
Our MainActivity will still use the SampleAdapter, and if we have a ViewPager, it will use it the same way as before. However, if we do not have a ViewPager, we must be showing three panes of content side by side, in which case we just execute a FragmentTransaction to populate the three FrameLayout containers with the three items created by the SampleAdapter:

```java
package com.commonsware.android.pagercolumns;

import android.os.Bundle;
import android.support.v4.app.FragmentActivity;
import android.support.v4.app.FragmentPagerAdapter;
import android.support.v4.view.ViewPager;

public class MainActivity extends FragmentActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        ViewPager pager=findViewById(R.id.pager);

        if (pager==null) {
            if (getSupportFragmentManager().findFragmentById(R.id.editor1)==null) {
                FragmentPagerAdapter adapter=buildAdapter();

                getSupportFragmentManager().beginTransaction()
                    .add(R.id.editor1, adapter.getItem(0))
                    .add(R.id.editor2, ...
```
adapter.getItem(1))
    .add(R.id.editor3,
        adapter.getItem(2)).commit();

}  
}  
else {  
pager.setAdapter(buildAdapter());
}  
}
private FragmentPagerAdapter buildAdapter() {
    return new SampleAdapter(this, getSupportFragmentManager());
}

(From ViewPager/Columns/app/src/main/java/com/commonsware/android/pagercolumns/MainActivity.java)

Of course, we skip the FragmentTransaction if the fragments already exist, such as due to a screen rotation configuration change.

The Results

On a phone, the ViewPager-based layout looks pretty much as it did before:

Figure 625: A ViewPager. Again.
However, on a tablet, we get our three editors side-by-side:

![Figure 626: Same App, Large-Screen Layout with Side-By-Side Editors](image)

**The Limitations**

The simplified large-screen layout does not contain any indicators above the three editors. This could be added by simple changes to the `res/layout-large/main.xml` layout resource, if desired.

The bigger limitation is that this only works if you want the same look in all configurations except screen size, and if the screen size never changes. However, it is eminently possible that you will want to have a different mix than that, such as using the three-column approach only on large-screen *landscape* layouts, using `ViewPager` everywhere else. In that case, our approach breaks down, as we will have different fragments inside the pager and outside the pager, meaning that we will lose our data on a configuration change. Addressing this issue is covered in the next two sections.
Focus Management and Accessibility

As developers, we are very used to creating apps that are designed to be navigated by touch, with users tapping on widgets and related windows to supply input.

However, not all Android devices have touchscreens, and not all Android users use touchscreens.

Internationalization (i18n) and localization (L10n) give you opportunities to expand your user base to audiences beyond your initial set, based on language. Similarly, you can expand your user base by offering support for non-touchscreen input and output. Long-term, the largest user base of these features may be those with televisions augmented by Android, whether via Android TV, OUYA consoles, or whatever. Short-term, the largest user base of these features may be those for whom touchscreens are rarely a great option, such as the blind. Supporting those with unusual requirements for input and output is called accessibility (a11y), and represents a powerful way for you to help your app distinguish itself from competitors.

In this chapter, we will first examine how to better handle focus management, and then segue into examining what else, beyond supporting keyboard-based input, can be done in the area of accessibility.

Prerequisites

Understanding this chapter requires that you have read the core chapters and are familiar with the concept of widgets having focus for user input.
Prepping for Testing

To test focus management, you will need an environment that supports “arrow key” navigation. Here, “arrow key” also includes things like D-pads or trackballs – basically, anything that navigates by key events instead of by touch events.

Examples include:

- The Android emulator, with the `Dpad support` hardware property set to `yes`
- Phones that have actual D-pads, trackballs, arrow keys, or the like
- Television-based Android environments, such as Android TV or the OUYA console
- Devices that have dedicated keyboard accessories, such as the keyboard “slice” available for the ASUS Transformer series of tablets
- A standard Android device accessed via a Bluetooth keyboard, gamepad, or similar sort of pointing device

Hence, even if the emulator will be insufficient for your needs, you should be able to set up a hardware test environment relatively inexpensively. Most modern Android devices support Bluetooth keyboards, and such keyboards frequently can be obtained at low relative cost.

For accessibility beyond merely focus control, you will certainly want to enable TalkBack, via the Accessibility area of the Settings app. This will cause Android to verbally announce what is on the screen, by means of its text-to-speech engine.

On Android 4.0 and higher devices, enabling Talkback will also optionally enable “Explore by Touch”. This allows users to tap on items (e.g., icons in a GridView) to have them read aloud via TalkBack, with a double-tap to actually perform what ordinarily would require a single-tap without “Explore by Touch”.

Controlling the Focus

Android tries its best to have intelligent focus management “out of the box”, without developer involvement. Many times, what it offers is sufficient for your needs. Other times, though, the decisions Android makes are inappropriate:

- Trying to navigate in a certain direction (e.g., right) moves focus to a widget that is not logically what should have the focus
- Focus has other side effects, like showing the soft keyboard on an EditText
widget, that is not desirable

Hence, if you feel that you need to take more control over how focus management is handled, you have many means of doing so, covered in this section.

**Establishing Focus**

In order for a widget to get the focus, it has to be focusable.

You might think that the above sentence was just a chance for the author to be witty. It was... a bit. But there are actually two types of “focusable” when it comes to Android apps:

- Is it focusable when somebody is using a pointing device or the keyboard?
- Is it focusable in touch mode?

There are three major patterns for the default state of a widget:

1. Some are initially focusable in both cases (e.g., EditText)
2. Some are focusable in non-touch mode but are not focusable in touch mode (e.g., Button)
3. Some are not focusable in either mode (e.g., TextView)

So, when a Button is not focusable in touch mode, that means that while the button will take the focus when the user navigates to it (e.g., via keys), the button will *not* take the focus when the user simply taps on it.

You can control the focus semantics of a given widget in four ways:

- You can use `android:focusable` and `android:focusableInTouchMode` in a layout
- You can use `setFocusable()` and `setFocusableInTouchMode()` in Java

We will see examples of these shortly.

**Requesting (or Abandoning) Focus**

By default, the focus will be granted to the first focusable widget in the activity, starting from the upper left. Often times, this is a fine solution.

If you want to have some other widget get the focus (assuming that the widget is
FOCUS MANAGEMENT AND ACCESSIBILITY

focusable, per the section above), you have two choices:

1. Call `requestFocus()` on the widget in question
2. You can give the widget's layout element a child element, named `[requestFocus /]`, to stipulate that this widget should be the one to get the focus

Note that this is a child element, not an attribute, as you might ordinarily expect.

For example, let's look at the Focus/Sampler sample project, which we will use to illustrate various focus-related topics.

Our main activity, creatively named MainActivity, loads a layout named `request_focus.xml`, and demonstrates the `[requestFocus /]` element:

```xml
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <Button
        android:id="@+id/button1"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/a_button"/>

    <EditText
        android:id="@+id/editText1"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/first_field"
        android:hint="@string/str_1st_field"
        android:inputType="text"/>

    <EditText
        android:id="@+id/editText2"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/second_field"
        android:hint="@string/str_2nd_field"
        android:inputType="text"/>

    <requestFocus/>
</LinearLayout>
```

1970
FOCUS MANAGEMENT AND ACCESSIBILITY

Here, we have three widgets in a horizontal LinearLayout: a Button, and two EditText widgets. The second EditText widget has the [requestFocus /] child element, and so it gets the focus when we display our launcher activity:

![Figure 627: Focus Sampler, Showing Requested Focus](image)

If we had skipped the [requestFocus /] element, the focus would have wound up on the first EditText... assuming that we are working in touch mode. If the activity had been launched via the pointing device or keyboard, then the Button would have the focus, because the Button is focusable in non-touch mode by default.

Calling requestFocus() from Java code gets a bit trickier. There are a few flavors of the requestFocus() method on View, of which two will be the most popular:

- An ordinary zero-argument requestFocus()
- A one-argument requestFocus(), with the argument being the direction in which the focus should theoretically be coming from
FOCUS MANAGEMENT AND ACCESSIBILITY

You might look at the description of the second flavor and decide that the zero-argument requestFocus() looks a lot easier. And, sometimes it will work. However, sometimes it will not, as is the case with our second activity, RequestFocusActivity.

In this activity, our layout (focusable_button) is a bit different:

```xml
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <EditText
        android:id="@+id/editText1"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/first_field"
        android:hint="@string/str_1st_field"
        android:inputType="text"/>
    <EditText
        android:id="@+id/editText2"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:contentDescription="@string/second_field"
        android:hint="@string/str_2nd_field"
        android:inputType="text"/>
    <Button
        android:id="@+id/button1"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:focusableInTouchMode="true"
        android:text="@string/a_button"/>
</LinearLayout>
```

Here, we put the Button last instead of first. We have no [requestFocus /] element anywhere, which would put the default focus on the first EditText widget. And, our Button has android:focusableInTouchMode="true", so it will be focusable regardless of whether we are in touch mode or not.

In onCreate() of our activity, we use the one-parameter version of requestFocus()
to give the Button the focus:

```java
@override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.focusable_button);
    initActionBar();

    button=findViewById(R.id.button1);
    button.requestFocus(View.FOCUS_RIGHT);
    button.setOnClickListener(this);
}
```

(from Focus/Sampler/app/src/main/java/com/commonsware/android/focus/RequestFocusActivity.java)

If there were only the one EditText before the Button, the zero-argument `requestFocus()` works. However, with a widget between the default focus and our Button, the zero-argument `requestFocus()` does not work, but using `requestFocus(View.FOCUS_RIGHT)` does. This tells Android that we want the focus, and it should be as if the user is moving to the right from where the focus currently lies.

All of our activities inherit from a `BaseActivity` that manages our action bar, with an overflow menu to get to the samples and the app icon to get to the original activity.
FOCUS MANAGEMENT AND ACCESSIBILITY

So, if you run the app and choose “Request Focus” from the overflow menu, you will see:

![Focus Sampler, Showing Manually-Requested Focus](image)

*Figure 628: Focus Sampler, Showing Manually-Requested Focus*

We also wire up the Button to the activity for click events, and in `onClickListener()`, we call `clearFocus()` to abandon the focus:

```java
@Override
public void onClick(View v) {
    button.clearFocus();
}
```

(from `Focus/Sampler/app/src/main/java/com/commonsware/android/focus/RequestFocusActivity.java`)
What clearFocus() will do is return to the original default focus for this activity, in our case the first EditText:

![Focus Sampler, After Clearing the Focus](image)

**Figure 629: Focus Sampler, After Clearing the Focus**

### Focus Ordering

Beyond manually placing the focus on a widget (or manually clearing that focus), you can also override the focus order that Android determines automatically. While Android's decisions usually are OK, they may not be optimal.

A widget can use `android:nextFocus...` attributes in the layout file to indicate the widget that should get control on a focus change in the direction indicated by the `...` part. So, `android:nextFocusDown`, applied to Widget A, indicates which widget should receive the focus if, when the focus is on Widget A, the user “moves down” (e.g., presses a DOWN key, presses the down direction on a D-pad). The same logic holds true for the other three directions (`android:nextFocusLeft`, `android:nextFocusRight`, and `android:nextFocusUp`).

For example, the `res/layout/table.xml` resource in the FocusSampler project is based on the TableLayout sample from early in this book, with a bit more focus control:
In the original TableLayout sample, by default, pressing either RIGHT or DOWN while the EditText has the focus will move the focus to the “Cancel” button. This certainly works. However, it does mean that there is no single-key means of moving from the EditText to the “OK” button, and it would be nice to offer that, so those using the pointing device or keyboard can quickly move to either button.

This is a matter of overriding the default focus-change behavior of the EditText widget. In our case, we use android:nextFocusRight="@+id/ok" to indicate that the “OK” button should get the focus if the user presses RIGHT from the EditText. This gives RIGHT and DOWN different behavior, to reach both buttons.

(from Focus/Sampler/app/src/main/res/layout/table.xml)
Scrolling and Focusing Do Not Mix

Let’s suppose that you have a UI design with a fixed bar of widgets at the top (e.g., action bar), a ListView dominating the activity, and a panel of widgets at the bottom (e.g., a Toolbar). This is a common UI pattern on iOS, though it is relatively uncommon on Android nowadays. You used to see it with the so-called “split action bar”, which is now officially deprecated as a pattern:

![Figure 630: Split Action Bar](image)

However, this UI pattern does not work well for those using pointing devices or keyboards for navigation. In order to get to the bottom panel of widgets, they will have to scroll through the entire list first, because scrolling trumps focus changes. So while this is easy to navigate via a touchscreen, it is a major problem to navigate for those not using a touchscreen.

Similarly, if the user has scrolled down the list, and now wishes to get to the action bar at the top, the user would have to scroll all the way to the top of the list first.

Workarounds include:

- Overriding focus control such that left and right navigation from the list
FOCUS MANAGEMENT AND ACCESSIBILITY

moves you to the action bar or bottom Toolbar (e.g., left moves you to the action bar, right moves you to the Toolbar)

• In a television setup, having the "action bar" be vertical down the left, and the tools be vertical down the right, so you automatically get the left/right navigation to move between these “zones”
• Eliminating the Toolbar entirely, moving those items instead to the action bar, or perhaps an action mode (a.k.a., contextual action bar) if the items are only relevant if the user checks one or more items in the list
• Offer a hotkey, separate from navigation, that repositions the focus (e.g., Ctrl-A to jump to the action bar), if you believe that users will read your documentation to discover this key combination

Accessibility and Focus

People suffering from impaired vision, including the blind, have had to rely heavily on proper keyboard navigation for their use of Android apps, at least prior to Android 4.0 and “Explore by Touch”. These users need focus to be sensible, so that they can find their way through your app, with TalkBack supplying prompts for what has the focus. Having widgets that are unreachable in practice will eliminate features from your app for this audience, simply because they cannot get to them.

“Explore by Touch” provides accessibility assistance without reliance upon proper focus. However:

• “Explore by Touch” is new to Android 4.0, and a few visually-impaired users will be using older devices
• “Explore by Touch” is less reliable than keyboard-based navigation, insofar as users have to remember specific screen locations (and get to them without seeing those locations), rather than simply memorizing certain key combinations
• “Explore by Touch”, by requiring additional taps (e.g., double-tap to tap a Button), may cause some challenges when the UI itself requires additional taps (e.g., a double-tap on a widget to perform an action — is this now a triple-tap in “Explore by Touch” mode?)
• “Explore by Touch” is mostly for the visually impaired, and does not help others that might benefit from key-based navigation (e.g., people with limited motor control)

So, even though “Explore by Touch” will help people use apps that cannot be navigated purely through key events, the better you can support keyboards, the
Accessibility Beyond Focus

While getting focus management correct goes a long way towards making your application easier to use, it is not the only thing to consider for making your application truly accessible by all possible users. This section covers a number of other things that you should consider as part of your accessibility initiatives.

Content Descriptions

For TalkBack to work, it needs to have something useful to read aloud to the user. By default, for most widgets, all it can say is the type of widget that has the focus (e.g., “a checkbox”). That does not help the TalkBack-reliant user very much.

Please consider adding `android:contentDescription` attributes to most of your widgets, pointing to a string resource that briefly describes the widget (e.g., “the Enabled checkbox”). This will be used in place of the basic type of widget by TalkBack.

Classes that inherit from `TextView` will use the text caption of the widget by default, so your `Button` widgets may not need `android:contentDescription` if their captions will make sense to TalkBack users.

However, with an `EditText`, since the text will be what the user types in, the text is not indicative of the widget itself. Android will first use your `android:hint` value, if available, falling back to `android:contentDescription` if `android:hint` is not supplied.

Also, bear in mind that if the widget changes purpose, you need to change your `android:contentDescription` to match. For example, suppose you have a media player app with an ImageButton that you toggle between “play” and “pause” modes by changing its image. When you change the image, you also need to change the `android:contentDescription` as well, lest sighted users think the button will now “pause” while blind users think that the button will now “play”.

Labels

Sometimes, we have `TextView` widgets that serve as on-screen labels for some adjacent other widget, such as an `EditText`. In those cases, you can associate the two
by using `android:labelFor` on the `TextView`, supplying the ID of the widget for which the `TextView` is a label. This will help accessibility tools properly announce the widgets, as otherwise those tools do not know that these widgets are related.

**Custom Widgets and Accessibility Events**

The engine behind TalkBack is an accessibility service. Android ships with some, like TalkBack, and third parties can create other such services.

Stock Android widgets generate relevant accessibility events to feed data into these accessibility services. That is how `android:contentDescription` gets used, for example — on a focus change, stock Android widgets will announce the widget that just received the focus.

If you are creating custom widgets, you may need to raise your own accessibility events. This is particularly true for custom widgets that draw to the `Canvas` and process raw touch events (rather than custom widgets that merely aggregate existing widgets).

The Android developer documentation provides instructions for when and how to supply these sorts of events.

**Announcing Events**

Sometimes, your app will change something about its visual state in ways that do not get picked up very well by any traditional accessibility events. For example, you might use `GestureDetector` to handle some defined library of gestures and change state in your app. Those state changes may have visual impacts, but `GestureDetector` will not know what those are and therefore cannot supply any sort of accessibility event about them.

To help with this, API Level 16 added `announceForAccessibility()` as a method on `View`. Just pass it a string and that will be sent out as an “announcement” style of `AccessibilityEvent`. Your code leveraging `GestureDetector`, for example, could use this to explain the results of having applied the gesture.

**Font Selection and Size**

For users with limited vision, being able to change the font size is a big benefit. Android 4.0 finally allows this, via the Settings app, so users can choose between
small, normal, large, and huge font sizes. Any place where text is rendered and is measured in sp will adapt.

The key, of course, is the sp part.

sp is perhaps the most confusing of the available dimension units in Android. px is obvious, and dp (or dip) is understandable once you recognize the impacts of screen density. Similarly, in, mm, and pt are fairly simple, at least once you remember that pt is 1/72nd of an inch.

If the user has the font scale set to “normal”, sp equates to dp, so a dimension of 30sp and 30dp will be the same size. However, values in dp do not change based on font scale; values in sp will increase or decrease in physical size based upon the user’s changes to the font scale.

We can see how this works in the Accessibility/FontScale sample project.

In our layout (res/layout/activity_main.xml), we have six pieces of text: two each (regular and bold) measured at 30px, 30dp, and 30sp:

```xml
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/LinearLayout1"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">
    <TextView
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginTop="10dp"
        android:text="@string/normal_30px"
        android:textSize="30px"
        tools:context=".MainActivity"/>
    <TextView
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="@string/bold_30px"
        android:textSize="30px"
        android:textStyle="bold"
        tools:context=".MainActivity"/>

    <TextView
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="@string/normal_30dp"
        android:textSize="30dp"
        tools:context=".MainActivity"/>
    <TextView
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="@string/bold_30dp"
        android:textSize="30dp"
        android:textStyle="bold"
        tools:context=".MainActivity"/>

    <TextView
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="@string/normal_30sp"
        android:textSize="30sp"
        android:textStyle="bold"
        tools:context=".MainActivity"/>
    <TextView
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="@string/bold_30sp"
        android:textSize="30sp"
        android:textStyle="bold"
        tools:context=".MainActivity"/>

</LinearLayout>
```
You will be able to see the differences between 30px and 30dp on any Android OS release, simply by running the app on devices with different densities. To see the changes between 30dp and 30sp, you will need to run the app on an Android 4.0+ device or emulator and change the font scale from the Settings app (typically in the Display section).
Here is what the text looks like with a normal font scale:

![Font Scale](image)

30px Normal
30px Bold
30dp Normal
**30dp Bold**
30sp Normal
**30sp Bold**

*Figure 631: Fonts at Normal Scale*

As you can see, 30dp and 30sp are equivalent.
If we raise the font scale to “large”, the 30sp text grows to match:

![Font Scale](image)

**Figure 632: Fonts at Large Scale**
Moving to “huge” scale increases the 30sp text size further:

*Figure 633: Fonts at Huge Scale*
In the other direction, some users may elect to drop their font size to “small”, with a corresponding impact on the 30sp text:

![Figure 634: Fonts at Small Scale](image)

As a developer, your initial reaction may be to run away from sp, because you do not control it. However, just as Web developers should deal with changing font scale in Web browsers, Android developers should deal with changing font scale in Android apps. Remember: the user is changing the font scale because the user feels that the revised scale is easier for them to use. Blocking such changes in your app, by avoiding sp, will not be met with love and adoration from your user base.

Also, bear in mind that changes to the font scale represent a configuration change. If your app is in memory at the time the user goes into Settings and changes the scale, if the user returns to your app, each activity that comes to the foreground will undergo the configuration change, just as if the user had rotated the screen or put the device into a car dock or something.

**Widget Size**

Users with ordinary sight already have trouble with tiny widgets, as they are difficult to tap upon.
Users trying to use the Explore by Touch facility added in Android 4.1 have it worse, as they cannot even see (or see well) the tiny target you are expecting them to tap upon. They need to be able to reliably find your widget based on its relative position on the screen, and their ability to do so will be tied, in part, on widget size.

The Android design guidelines recommend 7-10mm per side minimum sizes for tappable widgets. In particular, they recommend 48dp per side, which results in a size of about 9mm per side.

You also need to consider how closely packed your widgets are. The closer the tap targets lie, the more likely it is that all users — whether using Explore by Touch or not — will accidentally tap on the wrong thing. Google recommends 8dp or more of margin between widgets. Also note that the key is margins, as while increasing padding might visually separate the widgets, the padding is included as part of the widget from the standpoint of touch events. While padding may help users with ordinary sight, margins provide similar help while also being of better benefit to those using Explore by Touch.

**Gestures and Taps**

If you employ gestures, be careful when employing the same gesture in different spots for different roles, particularly within the same activity.

For example, you might use a horizontal swipe to the right to switch pages in a ViewPager in some places and remove items from a ListView in others. While there may be visual cues to help explain this to users with ordinary sight, it may be far less obvious what is going on for TalkBack users. This is even more true if you are somehow combining these things (e.g., the ListView in question is in a page of the ViewPager).

Also, be a bit careful as you “go outside the box” for tap events. You might decide that a double-tap, or a two-finger tap, has special meaning on some widgets. Make sure that this still works when users use Explore by Touch, considering that the first tap will be “consumed” by Explore by Touch to announce the widget being tapped upon.

**Enhanced Keyboard Support**

All else being equal, users seeking accessibility assistance will tend to use keyboards when available. For users with limited (or no) sight, tactile keyboards are simply easier to use than touchscreens. For users with limited motor control, external
devices that interface as keyboards may allow them to use devices that otherwise they could not.

Of course, plenty of users will use keyboards outside of accessibility as well. For example, devices like the ASUS Transformer series form perfectly good “netbook”-style devices when paired with their keyboards.

Hence, consider adding hotkey support, to assist in the navigation of your app. Some hotkeys may be automatically handled (e.g., Ctrl-C for copy in an EditText). However, in other cases you may wish to add those yourself (e.g., Ctrl-C for “copy” with respect to a checklist and its selected rows, in addition to a “copy” action mode item).

API Level 11 adds KeyEvent support for methods like isCtrlPressed() to detect meta keys used in combination with regular keys.

Audio and Haptics

Of course, another way to make your app more accessible is to provide alternative modes of input and output, beyond the visual.

Audio is popular in this regard:

- Using tones or clicks to reinforce input choices
- Integrating your own text-to-speech to augment TalkBack
- Integrating speech recognition for simple commands

However, bear in mind that deaf users will be unable to hear your audio. You are better served using both auditory and visual output, not just one or the other.

In some cases, haptics can be helpful for input feedback, by using the Vibrator system service to power the vibration motor. While most users will be able to feel vibrations, the limitation here is whether the device is capable of vibrating:

- Some tablets lack a vibration motor
- Television-based Android environment may or may not have some sort of vibration output (e.g., remote controls probably will not, but game controllers might)
- Devices not held in one’s hand, such as those in a dock, will make haptics less noticeable
So, audio and vibration can help augment visual input and output, though they should not be considered complete replacements except in rare occurrences.

Color and Color Blindness

Approximately 8% of men (and 0.5% of women) in the world are colorblind, meaning that they cannot distinguish certain close colors:

...It’s not that colorblind people (in most cases) are incapable or perceiving “green,” instead they merely distinguish fewer shades of green than you do. So where you see three similar shades of green, a colorblind user might only see one shade of green.

(from “Tips for Designing for Colorblind Users”)

Hence, relying solely on colors to distinguish different items, particularly when required for user input, is not a wise move.

Make sure that there is something more to distinguish two pieces of your UI than purely a shift in color, such as:

- Labels or icons
- Textures (e.g., solid vs. striped)
- Borders (e.g., drop shadow)

Accessibility Beyond Impairment

Accessibility is often tied to impaired users: ones with limited (or no) sight, ones with limited (or no) hearing, ones with limited motor control, etc.

In reality, accessibility is for situations where users may have limitations. For example, a user who might not normally think of himself as “impaired” has limited sight, hearing, and motor control when those facilities are already in use, such as while driving.

Hence, offering features that help with accessibility can benefit all your users, not just ones you think of as “impaired”. For example:

- Offer a UI mode with an eye towards use in low-visibility situations that can either be manually invoked (e.g., via a preference) or automatically invoked
Focus Management and Accessibility

(e.g., via a car dock)
- Offer voice input (commands) and output (text-to-speech) — iOS’s Siri is not just for the blind, after all
- Offer hotkeys, not only to help those requiring a keyboard as their primary mode of input (e.g., blind users minimizing touchscreen use), but to help those who opt into using it for input (e.g., using a keyboard with an Android tablet in lieu of a traditional notebook or netbook)
While well-written GUI frameworks are better organized than [XKCD's take on home organization](https://xkcd.com/235/), there are always a handful of tidbits that do, indeed, get categorized as “miscellaneous”.

**Prerequisites**

Understanding this chapter requires that you have read the core chapters of this book. Having an appreciation for XKCD is welcome, but optional.

**Full-Screen and Lights-Out Modes**

Full-screen mode, in Android parlance, means removing any system-supplied “bars” from the screen: title bar, action bar, status bar, system bar, navigation bar, etc. You might use this for games, video players, digital book readers, or other places where the time spent in an activity is great enough to warrant removing some of the normal accouterments to free up space for whatever the activity itself is doing.

Lights-out mode, in Android parlance, is where you take the system bar or navigation bar and dim the widgets inside of them, such that the bar is still usable, but is less visually distracting. This is a new concept added in Android 3.0 and has no direct analogue in Android 1.x or 2.x.

**Android 1.x/2.x**

To have an activity be in full-screen mode, you have two choices:

1. Having the activity use a theme of `Theme.NoTitleBarFullscreen` (or some
custom theme that inherits from Theme.NoTitleBar.Fullscreen

2. Execute the following statements in `onCreate()` of your activity before calling `setContentView()`:

```java
requestWindowFeature(Window.FEATURE_NO_TITLE);
getWindow().setFlags(WindowManager.LayoutParams.FLAG_FULLSCREEN,
    WindowManager.LayoutParams.FLAG_FULLSCREEN);
```

The first statement removes the title bar or action bar. The second statement indicates that you want the activity to run in full-screen mode, hiding the status bar.

**Android 4.0+**

Things got significantly more messy once we started adding in the system bar (and, later, the navigation bar as the replacement for the system bar). Since these bars provide the user access to HOME, BACK, etc., it is usually important for them to be available. Android’s behavior, therefore, varies in how you ask for something to happen and what then happens, based upon whether the device is a phone or a tablet.

The [Activities/FullScreen](#) sample project tries to enumerate some of the possibilities. On an Android 4.0 device, we have three `RadioButton`s:

```xml
<RelativeLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <RadioGroup
        android:id="@+id/screenStyle"
        android:layout_width="match_parent"
        android:layout_height="wrap_content">
        <RadioButton
            android:id="@+id/normal"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:checked="true"
            android:text="@string/display_normal"/>
        <RadioButton
            android:id="@+id/lowProfile"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"/>
    </RadioGroup>
</RelativeLayout>
```
Figure 635: Sample UI, As Initially Launched on Android 4.0

...while on Android 4.1 or higher, we have another two possibilities:

```xml
<RelativeLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentBottom="true"
    android:text="@string/something_at_the_bottom"/>
</RelativeLayout>
```
<RadioGroup
    android:id="@+id/screenStyle"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">
    <RadioButton
        android:id="@+id/normal"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:checked="true"
        android:text="@string/display_normal"/>
    <RadioButton
        android:id="@+id/lowProfile"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/display_low_profile"/>
    <RadioButton
        android:id="@+id/hideNav"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/display_hide_navigation"/>
    <RadioButton
        android:id="@+id/hideStatusBar"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/hide_status_bar"/>
    <RadioButton
        android:id="@+id/fullScreen"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/display_full_screen"/>
</RadioGroup>

<Button
    android:id="@+id/button"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentBottom="true"
    android:text="@string/something_at_the_bottom"/>
Figure 636: Sample UI, As Initially Launched on a Nexus 4/Android 4.2

(from Activities/FullScreen/app/src/main/res/layout-v16/main.xml)

1995
Controlling the full-screen and lights-out modes is managed via a call to `setSystemUiVisibility()`, a method on `View`. You pass in a value made up of an OR'd (|) set of flags indicating what you want the visibility to be, with the default being normal operation. Hence, in the screenshot above, you see a Nexus 4 in normal mode. Here is the same UI on a Nexus 10 in normal mode:

![Sample UI, As Initially Launched on a Nexus 10/Android 4.2](image)

*Figure 637: Sample UI, As Initially Launched on a Nexus 10/Android 4.2*
Lights-out, or low-profile mode, is achieved by calling `setSystemUiVisibility()` with the `View.SYSTEM_UI_FLAG_LOW_PROFILE` flag. This will dim the navigation or system bar, so the bar is there and the buttons are still active, but that they are less visually intrusive:
MISCELLANEOUS UI TRICKS

Figure 639: Sample UI, Lights-Out Mode, Nexus 10/Android 4.2
You can temporarily hide the navigation bar (or system bar) by passing `View.SYSTEM_UI_FLAG_HIDE_NAVIGATION` to `setSystemUiVisibility()`. The bar will disappear, until the user touches the UI, in which case the bar reappears:

*Figure 640: Sample UI, Hidden-Navigation Mode, Nexus 4/Android 4.2*
Figure 641: Sample UI, Hidden-Navigation Mode, Nexus 10/Android 4.2
Similarly, you can hide the status bar by passing View.SYSTEM_UI_FLAG_FULLSCREEN to setSystemUiVisibility(). However, despite this flag’s name, it does not affect the navigation or system bar:

Figure 642: Sample UI, “Full-Screen” Mode, Nexus 4/Android 4.2
### MISCELLANEOUS UI TRICKS

**Figure 643: Sample UI, “Full-Screen” Mode, Nexus 10/Android 4.2**

<table>

---

2002
Hence, to hide both the status bar and the navigation or system bar, you need to pass both flags (View.SYSTEM_UI_FLAG_FULLSCREEN | View.SYSTEM_UI_FLAG_HIDE_NAVIGATION):

![Sample UI, True Full-Screen Mode, Nexus 4/Android 4.2](image)

*Figure 644: Sample UI, True Full-Screen Mode, Nexus 4/Android 4.2*
Note that showing and hiding the ActionBar is also possible, via calls to `show()` and `hide()`, respectively.

### Offering a Delayed Timeout

Android makes it easy for activities to keep the screen on while the activity is in the foreground, by means of `android:keepScreenOn` and `setKeepScreenOn()`.

However, these are very blunt instruments, and too many developers simply ask to keep the screen on constantly, even when that is not needed and can cause excessive battery drain. That is because it is very easy to *always* keeps the screen on.

Say, for example, you are playing a game. Keeping the screen on while the game is being played is probably a good thing, particularly if the game does not require constant interaction with the screen. However, if you press the in-game pause button, the game might keep the screen on while the game is paused. This might lead you to press pause, put down your tablet (expecting it to fall asleep in a normal period of time), and then have the tablet keep going and going and going... until the battery runs dead.
Whether you use `setKeepScreenOn()` or directly use a `WakeLock`, it is useful to think of three tiers of user interaction.

The first tier is when your app is doing its "one big thing": playing the game, playing the video, displaying the digital book, etc. If you expect that there will be periods of time when the user is actively engaged with your app, but is not interacting with the screen, keep the screen on.

The second tier is when your app is delivering something to the user that probably would get used without interaction in the short term, but not indefinitely. For example, a game might reasonably expect that 15 seconds could be too short to have the screen time out, but if the user has not done anything in 5-10 minutes, most likely they are not in front of the game. Similarly, a digital book reader should not try to keep the screen on for an hour without user interaction.

The third tier is when your app is doing anything other than the main content, where normal device behavior should resume. A video player might keep the screen on while the video is playing, but if the video ends, normal behavior should resume. After all, if the person who had been watching the video fell asleep, they will not be in position to press a power button.

The first and third tiers are fairly easy from a programming standpoint. Just acquire() and release() the `WakeLock`, or toggle `setKeepScreenOn()` between true and false.

The second tier — where you are willing to have a screen timeout, just not too quickly — requires you to add a bit more smarts to your app. A simple, low-overhead way of addressing this is to have a `postDelayed()` loop, to get a Runnable control every 5-10 seconds. Each time the user interacts with your app, update a `lastInteraction` timestamp. The Runnable compares `lastInteraction` with the current time, and if it exceeds some threshold, release the `WakeLock` or call `setKeepScreenOn(false)`. When the user interacts again, though, you will need to re-acquire the `WakeLock` or call `setKeepScreenOn(true)`. Basically, you have your own inactivity timing mechanism to control when you are inhibiting normal inactivity behavior or not.

To see the second tier in action, take a look at the MiscUI/DelayedTimeout sample project.

The UI is a simple button. We want to keep the screen awake while the user is using the button, but let it fall asleep after a period of inactivity that we control. To
accomplish this, we will use a `postDelayed()` loop, to get control every 15 seconds to see if there has been user activity:

```
package com.commonsware.android.timeout;

import android.app.Activity;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;

public class MainActivity extends Activity implements Runnable {
    private static int TIMEOUT_POLL_PERIOD=15000; // 15 seconds
    private static int TIMEOUT_PERIOD=300000; // 5 minutes
    private View content=null;
    private long lastActivity=SystemClock.uptimeMillis();

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        content=findViewById(R.id.content);
        content.setKeepScreenOn(true);
        run();
    }

    @Override
    public void onDestroy() {
        content.removeCallbacks(this);

        super.onDestroy();
    }

    @Override
    public void run() {
        if ((SystemClock.uptimeMillis() - lastActivity) > TIMEOUT_PERIOD) {
            content.setKeepScreenOn(false);
        }

        content.postDelayed(this, TIMEOUT_POLL_PERIOD);
    }

    public void onClick(View v) {
        lastActivity=SystemClock.uptimeMillis();
    }
}
```

(from MiscUI/DelayedTimeout/app/src/main/java/com/commonsware/android/timeout/MainActivity.java)
In `onCreate()`, we call `setKeepScreenOn(true)` to keep the screen on, regardless of what the user’s default timeout is. Then, we call the `run()` method from our `Runnable` interface (implemented on the activity itself). `run()` sees if 5 minutes has elapsed since the last bit of user activity (initially set to be the time the activity launches). If 5 minutes has elapsed, we revert to normal screen-timeout behavior with `setKeepScreenOn(false)`. We also schedule ourselves, as a `Runnable`, to get control again in 15 seconds, to see if 5 minutes has elapsed since the last-seen activity. Our button’s `onClick()` method simply updates the last-seen timestamp, and `onDestroy()` cleans up our `postDelayed()` loop by calling `removeCallbacks()` to stop invoking our `Runnable`.

The net is that the device’s screen will remain on for 5 minutes since the last time the user taps the button, even if the user’s default screen timeout is set to shorter than 5 minutes. Yet, at the same time, we do not keep the screen on forever, causing unnecessary battery drain.

Note that to test this, you will probably need to unplug your USB cable after installing the app on the device (since many developers have it set up to keep the screen on while plugged in). Also, you will need to set your device’s screen timeout to be under 5 minutes, if it is not set that way already.

This is a primitive implementation, missing lots of stuff that you would want in production code (e.g., it never calls `setKeepScreenOn(true)` if we flipped it to `false` but then tap the button). And the complexity of determining if the user interacted with the screen will be tied to the complexity of your UI.

That being said, by having a more intelligent use of `WakeLock` and `setKeepScreenOn()`, you can deliver value to the user while not accidentally causing excessive battery drain. Users do not always remember to press the power button, so you need to make sure that just because the user made a mistake, that you do not make it worse.
Earlier in the book, we covered the concept of an event bus as a way of communicating between portions of our app, focusing on one event bus implementation: greenrobot’s EventBus. Later, in the chapter on broadcast Intent objects, we briefly covered LocalBroadcastManager.

However, those are not the only event buses available for Android, and others may fit your needs better. In this chapter, we will explore these and other event bus implementations, to compare and contrast.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly the chapters on basic event bus usage, broadcast Intents, AlarmManager and the scheduled service pattern, and Notifications.

A Brief Note About the Sample Apps

The sample apps in this chapter are generally designed to run forever.

It is unlikely that you really want them to run forever, though. Hence, please uninstall each sample after experimenting with it, particularly if you are testing on hardware, such as your personal phone. Your battery will appreciate it.

Standard Intents as Event Bus

You can think of the standard Intent and <intent-filter> system as a three-channel event bus:
EVENT BUS ALTERNATIVES

- One channel is used for starting activities
- One channel is used for starting or binding to services
- One channel is used for more ad-hoc “broadcast” events

The component starting an activity does not need to communicate directly with code for that activity — in fact, often times this is impossible, as they are separate apps running in separate processes. Instead, the component starting an activity sends an event indicating the particular operation to be performed (e.g., view this URL), and Android and the user determine which of candidate consumers is the one to process that event.

However, broadcast Intent objects are a closer analogue to a real “event bus”, in that an event produced by somebody can be consumed by zero, one, or several subscribed consumers, based upon the filtering provided by <intent-filter> elements in the manifest or IntentFilter objects for use with registerReceiver().

In theory, you could use broadcast Intent objects as the backbone for a fairly flexible event bus within your app. In practice, this is not usually a good idea:

- Each broadcast involves inter-process communication (IPC), even if the event producer and consumer(s) are in the same process. This adds overhead.
- Because broadcasts are intrinsically IPC, you have to take security into account, to ensure only authorized producers can publish events that the consumers pick up.

However, if you specifically need a cross-process event bus, such as between a suite of related apps, using a broadcast Intent is a very likely choice.

LocalBroadcastManager as Event Bus

As was briefly noted earlier in the book, the Android Support package offers a LocalBroadcastManager. This is designed to offer an event bus with a feel very similar to classic broadcast Intent objects, but local to your process. Not only does this avoid IPC overhead, but it improves security, as other apps have no means of spying on your internal communications.

LocalBroadcastManager is supplied by both the support-v4 and support-v13 libraries. Generally speaking, if your minSdkVersion is less than 13, you probably should choose support-v4.
A Simple LocalBroadcastManager Sample

Let’s see LocalBroadcastManager in action via the Intents/Local sample project.

Here, our LocalActivity sends a command to a NoticeService from onCreate():

```java
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    notice=(TextView)findViewById(R.id.notice);
    startActivity(new Intent(this, NoticeService.class));
}
```

The NoticeService simply delays five seconds, then sends a local broadcast using LocalBroadcastManager:

```java
package com.commonsware.android.localcast;

import android.app.IntentService;
import android.content.Intent;
import android.os.SystemClock;
import android.support.v4.content.LocalBroadcastManager;

public class NoticeService extends IntentService {
    public static final String BROADCAST="com.commonsware.android.localcast.NoticeService.BROADCAST";
    private static Intent broadcast=new Intent(BROADCAST);

    public NoticeService() {
        super("NoticeService");
    }

    @Override
    protected void onHandleIntent(Intent intent) {
        SystemClock.sleep(5000);
        LocalBroadcastManager.getInstance(this).sendBroadcast(broadcast);
    }
}
```

Specifically, you get at your process’ singleton instance of LocalBroadcastManager by
calling getInstance() on the LocalBroadcastManager class.

Our LocalActivity registers for this local broadcast in onStart(), once again using getInstance() on LocalBroadcastManager:

```java
@override
public void onStart() {
    super.onStart();

    IntentFilter filter = new IntentFilter(NoticeService.BROADCAST);
    LocalBroadcastManager.getInstance(this).registerReceiver(onNotice, filter);
}
```

LocalActivity unregisters for this broadcast in onStop():

```java
@override
public void onStop() {
    super.onStop();

    LocalBroadcastManager.getInstance(this).unregisterReceiver(onNotice);
}
```

The BroadcastReceiver simply updates a TextView with the current date and time:

```java
private BroadcastReceiver onNotice = new BroadcastReceiver() {
    public void onReceive(Context ctxt, Intent i) {
        notice.setText(new Date().toString());
    }
};
```

If you start up this activity, you will see a “(waiting...)” bit of placeholder text for about five seconds, before having that be replaced by the current date and time.

The BroadcastReceiver, the IntentFilter, and the Intent being broadcast are the same as we would use with full broadcasts. It is merely how we are using them — via LocalBroadcastManager — that dictates they are local to our process versus the standard device-wide broadcasts.
A More Elaborate Sample

That sample is not terribly realistic, but it is simple.

A somewhat more realistic sample is the one using AlarmManager and JobIntentService from elsewhere in the book. However, that app is also fairly unrealistic, at least in terms of its output, as LogCat is not very useful to users. A more typical approach for a background service like this is to notify a foreground Activity, if there is one, about work that was accomplished, and otherwise display a Notification. We described that pattern in the chapter on Notifications.

In the EventBus/LocalBroadcastManager sample project, we blend:

- Having a service wake up every so often to do some work
- Arranging to let the user know of background accomplishments via an Activity or a Notification
- Using LocalBroadcastManager to keep the communications in-process

The Activity

The EventDemoActivity that is our app's entry point is a bit similar to the one used in the AlarmManager demo, in that it calls scheduleAlarms() on PollReceiver to set up the AlarmManager schedule:

```java
package com.commonsware.android.eventbus.lbm;
import android.support.v4.app.FragmentActivity;
import android.os.Bundle;
public class EventDemoActivity extends FragmentActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
            getSupportFragmentManager().beginTransaction().add(android.R.id.content, new EventLogFragment()).commit();
            PollReceiver.scheduleAlarms(this);
        }
    }
}
```

However, we also put an EventLogFragment on the screen, if it is not already there,
via a FragmentTransaction. This is where we will display events coming from the service, while our activity is in the foreground. We will examine EventLogFragment and how it participates in the event bus shortly.

The PollReceiver

PollReceiver is largely unchanged from its AlarmManager demo original edition. This BroadcastReceiver will be used both for getting control at boot time (to reschedule the alarms, wiped on the reboot) and for sending the work to the ScheduledService for processing:

```java
package com.commonsware.android.eventbus.lbm;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class PollReceiver extends BroadcastReceiver {
    private static final int PERIOD=60000; // 1 minute
    private static final int INITIAL_DELAY=5000; // 5 seconds

    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (i.getAction() == null) {
            ScheduledService.enqueueWork(ctxt);
        } else {
            scheduleAlarms(ctxt);
        }
    }

    static void scheduleAlarms(Context ctxt) {
        AlarmManager mgr=(AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
        Intent i=new Intent(ctxt, PollReceiver.class);
        PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

        mgr.setRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
                         SystemClock.elapsedRealtime() + INITIAL_DELAY,
                         PERIOD, pi);
    }
}
```
ScheduledService and Sending Events

Before, our ScheduledService just dumped a message to LogCat. This was crude but effective for what that demo required. Now, we want our service to let the UI layer know about some work that was accomplished, or to raise a Notification.

In this case, the “work” is generating a random number.

```java
package com.commonsware.android.eventbus.lbm;

import android.app.Notification;
import android.app.NotificationChannel;
import android.app.NotificationManager;
import android.app.PendingIntent;
import android.content.Context;
import android.content.Intent;
import android.os.Build;
import android.support.v4.app.JobIntentService;
import android.support.v4.app.NotificationCompat;
import android.support.v4.content.LocalBroadcastManager;
import java.util.Calendar;
import java.util.Random;

public class ScheduledService extends JobIntentService {
    private static int NOTIFY_ID = 1337;
    private static final int UNIQUE_JOB_ID = 1337;
    private static final String CHANNEL_WHATEVER = "channel_whatever";
    private Random rng = new Random();

    static void enqueueWork(Context ctxt) {
        enqueueWork(ctxt, this, UNIQUE_JOB_ID,
                    new Intent(ctxt, ScheduledService.class));
    }

    @Override
    public void onHandleWork(Intent i) {
        Intent event = new Intent(EventLogFragment.ACTION_EVENT);
        long now = Calendar.getInstance().getTimeInMillis();
        int random = rng.nextInt();

        event.putExtra(EventLogFragment.EXTRA_RANDOM, random);
        event.putExtra(EventLogFragment.EXTRA_TIME, now);

        if (!LocalBroadcastManager.getInstance(this).sendBroadcast(event)) {
            NotificationManager mgr =
                    (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

            if (Build.VERSION.SDK_INT > Build.VERSION_CODES.O &&
                    mgr.getNotificationChannel(CHANNEL_WHATEVER) == null) {
                mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
                        "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
            }
            NotificationCompat.Builder b = new NotificationCompat.Builder(this, CHANNEL_WHATEVER);
        }
    }
}
```
LocalBroadcastManager, as we have seen, uses the same Intent and IntentFilter and BroadcastReceiver structures as are used with regular broadcasts, just via a singleton message bus (LocalBroadcastManager.getInstance()) instead of the framework's IPC engine. Hence, we need an Intent that represents the message, so we create one, using an action string published by the EventLogFragment. We also attach two extras to this Intent, using keys published by EventLogFragment: the random number, plus the time of this event.

We then call sendBroadcast() on the singleton LocalBroadcastManager. This returns a boolean value, true indicating that one or more locally-registered receivers were delivered the Intent, false otherwise. Hence, if sendBroadcast() returns true, we can assume that somebody in the UI layer picked up our message and is now responsible for displaying these results to the user.

Conversely, if sendBroadcast() returns false, we must assume that the UI layer did not receive the message, and so the service should inform the user directly, in this case via a Notification, showing the random number as the text in the notification drawer.

**EventLogFragment and Receiving Events**

EventLogFragment, therefore, is responsible for:

- Registering (and unregistering) to receive the broadcasts to be sent locally by the service
- Doing something with those events to inform the user about the all-important random numbers

In this case, we use a retained ListFragment with a ListView set into transcript mode, meaning that entries are added at the bottom, and older entries scroll off the

        super.onCreate(savedInstanceState);

        setRetainInstance(true);
    }

    @Override
    public void onViewCreated(@NonNull View view, @Nullable Bundle savedInstanceState) {
        super.onViewCreated(view, savedInstanceState);

        getListView().setTranscriptMode(ListView.TRANSkkerM_MODE_NORMAL);

        if (adapter == null) {
            adapter = new EventLogAdapter();
        }
    }
}
```java
setListAdapter(adapter);

@Override
public void onStart() {
    super.onStart();

    IntentFilter filter = new IntentFilter(ACTION_EVENT);
    LocalBroadcastManager.getInstance(getActivity())
        .registerReceiver(onEvent, filter);
}

@Override
public void onStop() {
    LocalBroadcastManager.getInstance(getActivity())
        .unregisterReceiver(onEvent);
    super.onStop();
}

class EventLogAdapter extends ArrayAdapter<Intent> {
    DateFormat fmt = new SimpleDateFormat("HH:mm:ss", Locale.US);

    public EventLogAdapter() {
        super(getActivity(), android.R.layout.simple_list_item_1,
            new ArrayList<Intent>();
    }

    @SuppressLint("DefaultLocale")
    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        TextView row =
            (TextView) super.getView(position, convertView, parent);
        Intent event = getItem(position);
        Date date = new Date(event.getLongExtra(EXTRA_TIME, 0));

        row.setText(String.format("%s = %x", fmt.format(date),
                event.getIntExtra(EXTRA_RANDOM, -1)));

        return row;
    }
}

private BroadcastReceiver onEvent = new BroadcastReceiver() {
    @Override
```
The `ListAdapter` for the `ListView` is an `EventLogAdapter`, an `ArrayAdapter` for `Intent` objects, where in `getView()` we populate the list rows with the time and random value.

In `onStart()` and `onStop()`, we register for (and unregister from) the desired broadcast, pointing to an `onEvent BroadcastReceiver` that adds the incoming `Intent` to the `EventLogAdapter`. That, in turn, updates the `ListView`.

The result is that while the activity is in the foreground, the events will be displayed to the user directly:

![Local Broadcast Event Demo](image)

*Figure 646: LocalBroadcastManager as Event Bus, Demo Activity*
Whereas if events are processed while the activity is not in the foreground, a Notification will be shown with the last results:

![LocalBroadcastManager as Event Bus, Demo Notification](image)

**Figure 647: LocalBroadcastManager as Event Bus, Demo Notification**

### Reference, Not Value

When you send a “real” broadcast Intent, your Intent is converted into a byte array (courtesy of the [Parcelable interface](#)) and transmitted to other processes. This occurs even if the recipient of the Intent is within your own process — that is what makes LocalBroadcastManager faster, as it avoids the inter-process communication.

However, since LocalBroadcastManager does not need to send your Intent between processes, that means it does not turn your Intent into a byte array. Instead, it just passes the Intent along to any registered BroadcastReceiver with a matching IntentFilter. In effect, while “real” broadcasts are pass-by-value, local broadcasts are pass-by-reference.

This can have subtle side effects.

For example, there are a few ways that you can put a collection into an Intent extra, such as putStringArrayListExtra(). This takes an ArrayList as a parameter. With
a real broadcast, once you send the broadcast, it does not matter what happens to the original ArrayList — the rest of the system is working off of a copy. With a local broadcast, though, the Intent holds onto the ArrayList you supplied via the setter. If you change that ArrayList elsewhere (e.g., clear it for reuse), the recipient of the Intent will see those changes.

Similarly, if you put a Parcelable object in an extra, the Intent holds onto the actual object while it is being broadcast locally, whereas a real broadcast would have resulted in a copy. If you change the object while the broadcast is in progress, the recipient of the broadcast will see those changes.

This can be a feature, not a bug, when used properly. But, regardless, it is a non-trivial difference, one that you will need to keep in mind.

Limitations of Local

While LocalBroadcastManager is certainly useful, it has some serious limitations.

The biggest is that it is purely local. While traditional broadcasts can either be internal (via setPackage()) or device-wide, LocalBroadcastManager only handles the local case. Hence, anything that might involve other processes, such as a PendingIntent, will not use LocalBroadcastManager. For example, you cannot register a receiver through LocalBroadcastManager, then use a getBroadcast() PendingIntent to try to reach that BroadcastReceiver. The PendingIntent will use the regular broadcast Intent mechanism, which the local-only receiver will not respond to.

Similarly, since a manifest-registered BroadcastReceiver is spawned via the operating system upon receipt of a matching true broadcast, you cannot use such receivers with LocalBroadcastManager. Only a BroadcastReceiver registered via registerReceiver() on the LocalBroadcastManager will use the LocalBroadcastManager.

Also, LocalBroadcastManager does not offer ordered or sticky broadcasts.

greenrobot’s EventBus 3.x

LocalBroadcastManager has two major advantages:

1. It is part of the Android Support package, and therefore it is part of the
officially-supported corner of the Android ecosystem

2. It works like traditional broadcasts, which will make it easier for some developers to “wrap their heads around” it

However, that same dependency on the Intent and IntentFilter structure adds bulk and limits flexibility. Hence, it is not surprising that there are alternative event buses to LocalBroadcastManager.

Java, outside of Android, has had a few event bus implementations. One of the more popular ones in recent years has been the event bus that is part of Google's Guava family of libraries. However, while a Java event bus perhaps can be used on Android, it may not be optimal for Android. Hence, a few projects have started with Guava’s event bus implementation and have extended it to be a bit more Android-aware, or perhaps even Android-centric.

greenrobot’s EventBus is one such event bus.

NOTE: For the purposes of this chapter, “greenrobot’s EventBus” refers to the library, and “EventBus” refers to the EventBus Java class in that library.

Basic Usage and Sample App

With LocalBroadcastManager, you work with a singleton instance, calling methods like registerReceiver() and sendBroadcast() upon it to subscribe to and raise events, respectively.

With greenrobot’s EventBus, you work with an EventBus instance, calling methods like register() and post() upon it to subscribe to and raise events, respectively. Usually, we use the singleton instance of EventBus that we get by calling getDefault() on the EventBus class, but you are welcome to have different EventBus objects, representing distinct communications channels, if you wish.

Hence, at the core, greenrobot’s EventBus behaves much like LocalBroadcastManager. What differs is in the nature of the events and the subscribers.

With LocalBroadcastManager, events are Intent objects. With greenrobot’s EventBus, an event can be whatever data type you like. Hence, you can create your own …Event classes, holding whatever bits of data, in whatever data types suit you — you are not restricted to things that can go in an Intent extra. However, as has been noted on occasion, “with great power comes great responsibility”, and so you
**Event Bus Alternatives**

will need to ensure that you use this carefully and do not wind up creating some sort of memory leak as a result. For example, do not pass something from an Activity to a Service via a custom event, where the Service will hold onto that information for a long time, if that “something” holds a reference back to the Activity.

With LocalBroadcastManager, subscribers are BroadcastReceivers, who use an IntentFilter to identify which events they are interested in. With greenrobot’s EventBus, subscribers are any class you want. A special @Subscribe annotation is used to both indicate what sorts of events the subscriber is interested in (based on the parameter to the annotated method) and what method should be invoked when a matching event is raised (the annotated method itself). Hence, not only do you use custom event classes to allow you to carry along custom data, but you use them as a filtering mechanism, much like you would use custom action strings with LocalBroadcastManager.

To see how this works, take a look at the EventBus/GreenRobot3 sample project, which is a clone of the EventBus/LocalBroadcastManager demo, but one where we substitute in greenrobot’s EventBus as a replacement for LocalBroadcastManager. Our activity and PollReceiver are unchanged: they did not directly interact with LocalBroadcastManager and do not need to interact with greenrobot’s EventBus. The changes are isolated in our ScheduledService and EventLogFragment.

**ScheduledService and Sending Events**

We will need an EventBus instance, one that serves the same basic role as does the singleton LocalBroadcastManager retrieved by getInstance(). As noted above, you can call getDefault() on EventBus to get a singleton EventBus instance, and this suffices in most cases.

When it comes time for us to send a message, we can call post() on the EventBus, supplying whatever sort of event object that we want:

```java
EventBus.getDefault().post(randomEvent);
```

Here, we are posting an instance of a RandomEvent:

```java
package com.commonsware.android.eventbus.greenrobot;

import java.util.Calendar;
import java.util.Date;
```
EVENT BUS ALTERNATIVES

```java
public class RandomEvent {
    Date when = Calendar.getInstance().getTime();
    int value;

    RandomEvent(int value) {
        this.value = value;
    }
}
```

**EventLogFragment and Receiving Events**

Over in our EventLogFragment, rather than register and unregister a BroadcastReceiver in onStart() and onStop(), we register and unregister the fragment itself with the EventBus:

```java
@Override
public void onStart() {
    super.onStart();
    EventBus.getDefault().register(this);
}

@Override
public void onStop() {
    EventBus.getDefault().unregister(this);
    super.onStop();
}
```

Now, we can use the @Subscribe annotation to arrange to receive any event we want that is delivered via this EventBus, based on event class. Since we want to receive RandomEvent messages, we merely need to have a public void method, taking a RandomEvent parameter, marked with the @Subscribe annotation, such as onRandomEvent():
**Event Bus Alternatives**

Note that the method name can be anything we want, as it is the annotation, not the method name, that identifies this as being an event handling method.

Since Java annotations can take key-value pairs for configuration, EventBus 3.x uses that to configure the behavior of @Subscribe. Here, we use @Subscribe(threadMode = ThreadMode.MAIN), to indicate that we want this event to be delivered to this method on the main application thread.

In this method, we can do what we need to with our RandomEvent. In our case, EventLogAdapter has been modified to be an ArrayAdapter of RandomEvent, as opposed to being an ArrayAdapter of Intent as in the earlier sample. What we want to do is append the new RandomEvent to the end of the adapter.

**Handling the “Nobody’s Home” Scenario**

What is missing, though, is the logic we used in LocalBroadcastManager to determine if somebody received our message, where we raised a Notification if that is not the case.

The solution for this with greenrobot’s EventBus is to call hasSubscriberForEvent(), with the Java Class object of the event that we would like to post(). If this returns true, we have a current subscriber; otherwise, we do not.

So, the full onHandleWork() implementation uses hasSubscriberForEvent() and either uses post() to raise the event or displays a Notification itself:

```java
@Override
public void onHandleWork(Intent i) {
    RandomEvent randomEvent = new RandomEvent(rng.nextInt());

    if (EventBus.getDefault().hasSubscriberForEvent(randomEvent.getClass())) {
        EventBus.getDefault().post(randomEvent);
    } else {
        NotificationManager mgr = (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

        if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.O &&
            mgr.getNotificationChannel(CHANNEL_WHATEVER) == null) {
            mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
                "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
        }

        NotificationCompat.Builder b = new NotificationCompat.Builder(this, CHANNEL_WHATEVER);
        Intent ui = new Intent(this, EventDemoActivity.class);
```
There is a race condition, though. Since our hasSubscriberForEvent() call is happening on a background thread, it is possible that between the hasSubscriberForEvent() call and the post() call that the subscriber unsubscribes. This is an unlikely occurrence here, but it is worth keeping in mind.

**Other Notable Capabilities**

In addition to the threading features, greenrobot’s EventBus has a few other noteworthy bells and whistles:

- Other thread modes are available, including ThreadMode.POSTING (events are delivered on the same thread they are posted from) and ThreadMode.BACKGROUND (events are delivered on a background thread, with EventBus using its own thread if the event was posted from the main application thread).
- postSticky() and registerSticky() allow you to have sticky events, much like sticky broadcasts with the classic broadcast Intent system.
- Ordered event processing as an option, akin to ordered broadcasts. You accomplish this by assigning a priority to the event handling method (e.g., @Subscribe(priority = 1)). If a higher-priority handler wants to consume the event, it can call cancelEventDelivery() on the EventBus, passing in the event object.

**Hey, What About Otto?**

For a few years, a third major event bus implementation was popular: Square’s Otto. Like greenrobot’s EventBus, Otto was based off of Guava’s EventBus class and was tuned towards Android app development. It shared some characteristics with greenrobot’s EventBus, owing to the shared heritage. On the whole, greenrobot’s EventBus was a bit more complex to use but offered greater flexibility.
EVENT BUS ALTERNATIVES

Square has since discontinued work on Otto, so unless you have existing legacy code that uses Otto, you should use some other event bus implementation.
One of the most confusing aspects of Android to deal with is the concept of tasks. Fortunately, the automatic management of tasks is almost enough to get by, without you having to do much customization. However, some developers will need to tailor how their app interacts with the task system. Understanding what is possible and how to do it is not easy. It is made even more complicated by changes to Android, from both engineering and design perspectives, over the years.

This chapter will attempt to untie the knot of knowledge surrounding Android’s task system, explaining why things are the way they are. However, there will be a few places where the knot turns a bit Gordian, and we will have to settle for more about “how” and less about “why” the task system works as it does.

**Prerequisites**

Understanding this chapter requires that you have read the core chapters of this book.

One sample app makes heavy use of the PackageManager system service and refers in a few places to the Launchalot sample app profiled in that chapter.

**First, Some Terminology**

It will be useful to establish some common definitions of terms that you will encounter, both in this chapter and in other materials that describe the task system.
So, what exactly is a “task”? The Android developer documentation describes it as:

A task is a collection of activities that users interact with when performing a certain job. The activities are arranged in a stack (the back stack), in the order in which each activity is opened.

In that sense, a task is reminiscent of a tab in a tabbed browser. As the user navigates, clicking links and submitting forms, the user advances into other Web pages. Those pages could be on the same site as they started or could be on different sites. The browser BACK button is supposed to reverse the navigation, allowing the user to return from whence they came.

**Back Stack**

The user perceives tasks mostly in the form of pressing the BACK button, using this to return to previous “screens” that they had been on previously.

Sometimes, BACK button processing is handled within a single activity, such as when you put a dynamic fragment onto the “back stack” via addToBackStack() on a FragmentTransaction. Or, the activity could override onBackPressed() and do special stuff in certain scenarios. Those are part of the user experience of pressing BACK. From the standpoint of the task system, though, internal consumption of the BACK button presses do not affect the task.

At the task level, the “back stack” refers to a chain of activities. This matches the behavior of Web sites, where while pressing the browser BACK button might trigger in-page behavior, usually it returns you to the previous page. Similarly, while pressing BACK on an Android device might trigger in-activity behavior, usually it triggers a call to finish() on the foreground activity and returns control to whatever had preceded it on the back stack.

**Recent Tasks**

In a tabbed Web browser, if we have several tabs open, we think of all of them as being “running”. Frequently, we do not really even think about the concept, any more than we might think about the state of tabs in an IDE other than the one that
we are working in right now. However, if you have ever had some browser tab all of a
sudden start playing audio, such as from a reloaded page pulling in an audio-
enabled ad banner, you are well aware that tabs are “running”, while you are also
“running” to try to figure out what tab is playing the audio so you can get rid of it.

However, that is the behavior on a desktop Web browser. A desktop Web browser is
not subject to heap size limitations the way Android apps are. And, historically,
mobile devices had less system RAM than did their desktop and notebook
counterparts, though that is rapidly changing.

In Android, therefore, developers are used to the notion that their processes may be
terminated, while in the background, to free up memory for other processes. This is
being done to allow for more apps to deliver more value in less system RAM.

However, from a multitasking standpoint, having apps just up and vanish is
awkward. Hence, Android has the notion of “recent tasks”. These are tasks, with
their corresponding back stacks, that the user has been in “recently”. How far back
“recently” goes depends a bit on the version of Android – there could be as few as
eight items. These “recent tasks” may or may not have a currently-running process
associated with them. However, if the user chooses to return to one of those recent
tasks, and there is no process for it, Android will seamlessly fork a fresh process, to
be able to not only start up those apps, but return the user to where they were, in
terms of UI contents (e.g., saved instance state Bundle) and in terms of back stack
contents (e.g., where the user goes if the user now presses BACK).

**Overview Screen**

In a tabbed Web browser, you can navigate between different tabs in some browser-
specific way. Some tabs may have the actual “tab” visible around the address bar.
Some tabs might only be reachable via some sort of scrolling operation, or via a
drop-down list, for people who have lots and lots of tabs open. Regardless, there is
some UI means to pick the tab that you want to be viewing in the main browser
area.

In Android, the “overview screen” is where the user can view the recent tasks and
choose to return to one of them. Many people, including this author, refer to this as
the “recent tasks list”, but apparently the official term is “overview screen”.

The way the overview screen has looked and worked has changed over the years.
Tasks

Android 1.x/2.x

In the early days of Android, long-pressing the HOME button would bring up the overview screen, with up to eight recent tasks:

And... that was pretty much it.

Android 3.x/4.x

The overall move to the holographic theme for Android brought with us a new icon, for a dedicated way to get to the overview screen:

Devices that offered a navigation bar at the bottom would have this button. Devices that chose to have off-screen affordances for BACK and HOME might have a similar button for the overview screen. For those that neither had a navigation bar nor a dedicated off-screen button for the overview screen, long-pressing HOME would bring up the overview screen.
The overview screen could have more apps (15 or so) before old tasks would be dropped:

![Figure 650: Overview Screen, from Android 4.3](image)

The overview screen also added more improvements:

- Thumbnails of the top activity in each task’s back stack, except for those activities that used `FLAG_SECURE` to block this, and except on some emulator images
- Swiping an entry off the list would remove that recent task

**Android 5.x**

Functionally, the Android 5.x overview screen functions much like its 4.x counterpart, with the ability to see previews of tasks and remove tasks from the screen.
However, there are some differences, starting with the navigation bar icon used to bring up the overview screen:

Figure 651: Overview Screen/Recent Tasks Navigation Bar Icon, from Android 5.0

Also, the previews are larger and stacked like cards, more so than being a classically vertically-scrolling list:

Figure 652: Overview Screen, from Android 5.0

More importantly:
Tasks

- The roster of recent tasks will be restored after a reboot, and
- If there is a limit on how many entries can appear in the list, the author has not run into it yet

Running Tasks

A running task is a task that has running process(es) associated with it. Recent tasks may or may not be running.

And Now, a Bit About Task Killers

In October 2008, the first Android device was publicly released (the T-Mobile G1, a.k.a., HTC Dream).

Around December of 2008, the first task killers appeared on the Android Market (now the Play Store).

While the techniques used in 2008 to kill tasks were removed in later releases, some amount of task management behavior still exists in Android. Having a task killer is useful for understanding how tasks (and their killers) behave on Android. In particular, it is useful to have a way to emulate an app's process being terminated due to low memory conditions... which is exactly what modern task killers do.

So, in this section, we will explore the concept of task killers, including how to implement one, before using this tool to help us explore the overall Android task system.

What Do Task Killers Do?

Despite the name, task killers do not kill tasks.

Rather, task killers terminate background processes. This does not impact the task, insofar as it will still be in the recent tasks roster and will still show up on the overview screen. However, the process for the app associated with the task will shut down.

Task killers can only request to terminate background processes. If your app is in the foreground (i.e., has the foreground activity), it cannot be terminated by a task killer.
To terminate background processes, task killers need to hold the KILL_BACKGROUND_PROCESSES permission, via a <uses-permission> element in their manifests. That enables them to be able to call the killBackgroundProcesses() method on ActivityManager. Supplied an application ID, killBackgroundProcesses() will terminate any background process(es) associated with that application. Normally, there will only be one such process, but if the app in question is using the android:process attribute in the manifest to have multiple processes, then all the app's processes will be terminated.

This termination is done using the same internal mechanism that is used by the “out-of-memory killer”, which is responsible for freeing up system RAM due to low memory conditions.

**Killing vs. Force-Stopping**

For ordinary users, there are a few options for terminating background processes. Using a task killer, or swiping the task off the overview screen on Android 4.0+, will terminate background processes. Both use killBackgroundProcesses() (or internal equivalents).

However, users can also go into the Settings app, find the app in the list of installed apps, and click a “Force Stop” button associated with that app. On the surface, this has a similar effect to the above techniques, as the background process is terminated. However, force-stopping the app also unschedules any AlarmManager or JobScheduler events for that app, plus moves the app back into the “stopped state”, blocking manifest-registered broadcast receivers. Hence, force-stopping an app has a much larger impact than does merely using a task killer.

A few devices have manufacturer-supplied task managers (a.k.a., task killers), where stopping an app from those apps actually does a force stop behind the scenes, rather than killBackgroundProcesses(). This is not a good idea, as force-stopping an app has the aforementioned side effects. Fortunately, third-party task killers cannot force-stop apps, barring any security flaws in Android that might make this possible.

**Why Use One?**

Nowadays, normally, users do not need task killers. Occasionally one can be useful, to stop a background process for a poorly-written app (e.g., one that powers on GPS but fails to let go of GPS when the app moves to the background). On most modern Android devices, swiping the app off the overview screen usually suffices, and so
task killers are not nearly as crucial as they were in Android 1.x/2.x, where there was no such built-in background process management solution.

For developers, the problem with swiping an app off the overview screen is that it not only terminates background processes, but it also removes the task entirely. This makes it difficult to see what the behavior is when apps' processes terminate for more conventional reasons (e.g., out-of-memory killer) and how tasks tie into that. While developers have the ability to stop processes through development tools (e.g., the process list in DDMS), that just terminates the process, and it may do so slightly differently than does the out-of-memory killer. Hence, having a task killer around can be useful for experimentation purposes.

And, since getting a task killer on an emulator can be challenging (since emulators do not have access to the Play Store), having the source code for a simple task killer is useful for developers. So, let's look at how to implement a task killer.

### A Canary for the Task’s Coal Mine

In order to see some of the effects of fussing with our tasks, we need an app where we can see when our saved instance state comes and goes. To that end, we have the `Tasks/TaskCanary` sample application. It consists of a single activity, with a UI that is merely a full-screen EditText. In addition to the automatic saving of the EditText contents in the saved instance state Bundle, we also keep track of the time we first worked with that Bundle, in a data member named `creationTime`, backed by a `STATE_CREATION_TIME` entry in the Bundle itself:

```java
class MainActivity extends Activity {
    private static final String STATE_CREATION_TIME = "creationTime";
    private long creationTime = -1L;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
    }
}
```

```java
package com.commonsware.android.task.canary;
import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.provider.Settings;
import android.util.Log;
import android.view.Menu;
import android.view.MenuItem;
```

```java
    public class MainActivity extends Activity {
        private static final String STATE_CREATION_TIME = "creationTime";
        private long creationTime = -1L;

        @Override
        public void onCreate(Bundle state) {
            super.onCreate(state);
        }
    }
```
Tasks

```java
setContentView(R.layout.activity_main);

@Override
protected void onRestoreInstanceState(Bundle savedInstanceState) {
    super.onRestoreInstanceState(savedInstanceState);
    dumpBundleToLog("restore", savedInstanceState);
    creationTime = savedInstanceState.getLong("STATE_CREATION_TIME", -1L);
}

@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);
    outState.putLong("STATE_CREATION_TIME", getCreationTime());
    dumpBundleToLog("save", outState);
}

@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
    return super.onCreateOptionsMenu(menu);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.settings) {
        startActivity(new Intent(Settings.ACTION_DATE_SETTINGS));
    } else if (item.getItemId() == R.id.other) {
        startActivity(new Intent(this, OtherActivity.class));
    }
    return super.onOptionsItemSelected(item);
}

private long getCreationTime() {
    if (creationTime == -1L) {
        creationTime = System.currentTimeMillis();
    }
    return creationTime;
}

// inspired by http://stackoverflow.com/a/14948713/115145
```
Each time we save and restore the instance state, we dump the Bundle to Logcat, so we can see what is in that Bundle. We wind up with lines like:

D/MainActivity: (save) android:viewHierarchyState: Bundle[...]
D/MainActivity: (save) creationTime: 1427032894794
D/MainActivity: (restore) android:viewHierarchyState: Bundle[...]
D/MainActivity: (restore) creationTime: 1427032894794

(where the ... is a bit long to reproduce in the book and is not essential for the sample)

This way, both in the UI and in the logs, we can confirm that our state is being saved and restored as expected... or perhaps not as expected, in some cases.

You will notice that we have a pair of action bar items. One will bring up a screen from the Settings app, which we will use to see how this affects our task. The other one will bring up another activity from our app, which we will use to explore how to start a clean task.

The Default User Experience

With all that behind us, let’s start talking about tasks, focusing first on what behavior the developer gets “out of the box”, with no task-specific logic in the app. In other words, what is the default user experience for an ordinary Android app?

NOTE: if you wish to reproduce the results described here, you will want to have the Task Canary installed on your device or emulator.
Starting from the Home Screen

Assume that we are “starting from scratch”. For example, the user has installed your app (or bought a device with your app pre-installed) but has never run your app before. Or, perhaps the overview screen is cleared of all tasks.

If the user taps your home screen launcher icon, not only is a process forked to run your app, but a new task is created, and your app’s task will appear in the overview screen.

(see! that wasn't so hard!)

To reproduce this behavior:

- Clear the overview screen of all tasks, by swiping them off the screen. Note that this may take some time on an Android 5.x device that is really being used (versus just being some test device), as there may be a lot of tasks to clear.
- Run your app, from the home screen or IDE.

Resuming from the Overview Screen

Eventually, the user wanders away from your app. Then, later on, the user returns to your app, by finding the task associated with your app in the overview screen and tapping upon it.

In the end, you wind up in the same state as before: you have a process for your app, and your task is still in the overview screen. How we get there depends a bit on what happened with your process, in between when you had been in the foreground and when the user taps on your task in the overview screen.

If your app’s process was still running, nothing much happens of note, other than you return to the foreground. From a state standpoint, your app would be called with onSaveInstanceState() when the user left your app, but you will not be called with onRestoreInstanceState(), because your activity was not destroyed yet. Note that this assumes that you did not undergo a configuration change (e.g., user originally was in your app in portrait, then returned to you from the overview screen while the device was in landscape). In the case of a configuration change, your activity would be destroyed and recreated by default, and you would be called with onRestoreInstanceState(), but that would be due to the configuration change more so than the use of the task and the overview screen.
To reproduce the above behavior, given that your device was in the state after the “Starting from the Home Screen” section above:

• Press HOME to move your app to the background, and notice the “(saved)” entries being reported to Logcat.
• Quickly press RECENTS (or, if you have no such option, long-press HOME) to bring up the overview, and tap on your task there.

However, it is entirely possible that while your task is around that your process is terminated to free up memory for other processes. If the user returns to your app via the overview screen, a fresh process will be forked for your app. This would trigger a call to `onRestoreInstanceState()`, because your old activity no longer exists, because its process no longer exists.

Note that if you leave a task for an extended period of time — say, 30 minutes or so — the task may be “cleared” when you return to it. This means that you are taken back to whatever the “root” activity of the task is, where by “root” we mean the original activity put into the task.

**Starting Another App**

Some apps only start up other activities within the same app. However, many apps start up activities from other apps, either directly via `startActivity()` or indirectly (e.g., clicking on links in a `WebView`). For example, the Task Canary app has an item in the action bar overflow that, when clicked, brings up the Settings screen for adjusting date and time settings.

You might think that when the user taps on this overflow item, and Task Canary calls `startActivity()`, that a new task is created. After all, the Settings app is a completely separate app from the Task Canary app.

However, try this:

• Clear the overview screen
• Launch Task Canary
• Choose the Settings action bar overflow item to bring up the date-and-time Settings screen
• Press HOME to bring up the home screen
• Press RECENTS or otherwise bring up the overview screen

You will see one entry in the overview screen, for Task Canary, rather than two.
Furthermore, particularly on Android 5.x devices, you will see the Settings screen as the top-most activity within the Task Canary task:
However, suppose that instead of using ACTION_DATE_SETTINGS for the Intent, we used ACTION_APN_SETTINGS instead, to allow the user to view mobile access point names and such. You might think, given the above flow, that we would wind up with just one task, as we did with ACTION_DATE_SETTINGS. In reality, you will see two tasks, instead of just one:

![Figure 654: Two Tasks on Android 5.1](image)

This is where things start to get a bit confusing.

**Explaining the Default Behavior**

With the user experience as background, let’s now dive into what is really going on with these operations.

**When Tasks are Created**

A task is not created just because an activity is started. Otherwise, even individual apps would have lots of tasks, one per activity.

A task is not created just because a task from a different app is started. Otherwise, the two Settings scenarios above would have both resulted in a new task.

Instead, tasks are created when somebody asks for a task to be created. That “somebody” could be the author of the app calling `startActivity()` or the author of
the activity being started.

There are three major approaches for indicating that a new task should be started: flags on the Intent used with `startActivity()`, task affinity values, and launch modes. We will get into launch modes later in this chapter, as the normally-used launch modes have no impact on tasks. Instead, we will focus on the other two approaches here.

**Task-Management Intent Flags**

If you want to start an activity, and ensure that the activity starts in a new task, add `Intent.FLAG_ACTIVITY_NEW_TASK` to the flags on the Intent being used with `startActivity()`:

```java
startActivity(new Intent(SOME_ACTION_STRING)
    .addFlags(Intent.FLAG_ACTIVITY_NEW_TASK))
```

What will happen, when you call `startActivity()` with `FLAG_ACTIVITY_NEW_TASK`, is that Android will see if there is a task that already has this activity in it. If there is, that task will be brought to the foreground, and the user will see whatever is on the top of that task's stack. Otherwise, if there is no task with this activity in it, Android will create a new task and associate a new instance of the activity with this task.

This is what home screen launchers do. When you tap on a home screen launcher icon, if there is a task that has a copy of your home screen activity in it, that task is brought back to the foreground. Otherwise, a new task is started.

If you also add `Intent.FLAG_ACTIVITY_MULTIPLE_TASK`, then Android skips the search for existing tasks and unconditionally launches the activity into a new task. This is generally not a good idea, as the user can wind up with many copies of this activity, not know which one is which, and perhaps have difficulty getting back to the right one.

**Task Affinities**

By default, if Android needs to create a new task as a result of `FLAG_ACTIVITY_NEW_TASK`, it just creates a task. And, if there is no such flag on the Intent, Android will put the activity into the task of whoever called `startActivity()`.

If, however, the activity has an `android:taskAffinity` attribute in its `<activity>`
Tasks

Element in the manifest, then Android will specifically start this activity in a certain task, identified by the string value of the attribute. Other activities with the same task affinity will also go into this task.

The reason why the two Settings screens behave differently is that the ACTION_APN_SETTINGS activity has a certain task affinity value, while ACTION_DATE_SETTINGS does not. The task affinity of the ACTION_APN_SETTINGS activity is shared by many, though not all, activities within the Settings app. Those activities, when started, will always go into the task identified by the affinity. Hence, when we start ACTION_DATE_SETTINGS, it goes in our task (because that activity has no affinity and we did not include FLAG_ACTIVITY_NEW_TASK), but when we start the ACTION_APN_SETTINGS activity, it goes into a Settings-specific task.

Note that you can also have the android:taskAffinity value defined on the <application> element, to provide a default task affinity for all activities. The overall default is "", or no affinity.

When Tasks are Removed

On Android 3.0 and higher, the user can get rid of a task by swiping the task off of the overview screen.

Otherwise, prior to Android 5.0, a task would automatically go away after some amount of user activity, as there were only so many “slots” available for tasks.

On Android 5.0+, though, it is unclear if there is an upper bound to how many tasks can exist. Beyond that, tasks survive a reboot, as information about those tasks is persisted. We will get more into the ramifications of this, and how you can take advantage of it, later in this chapter.

When Tasks (and Processes) are Resumed

A task will be resumed and brought back to the foreground in several situations, including:

- the user manually requests it via the overview screen, by clicking on one of the recent tasks
- if FLAG_ACTIVITY_NEW_TASK is added (without FLAG_ACTIVITY_MULTIPLE_TASK) to the Intent used to start an activity, and there is a task containing the activity in question
- if the taskAffinity for the activity being started ties it to another task
• if the launch mode for the activity being started ties it to another task

However, just because the task exists does not mean that the process(es) exist for the activities in the task. As needed, Android will fork fresh processes, to be able to load in the app’s code and start the necessary activities. Android will deliver to the newly-created activities the same Intent that was used to create the original incarnation of the activity (via getIntent()) and the saved instance state Bundle.

What Happens to Services

In theory, services are immune to task behavior. Tasks can come and go, and services are usually oblivious to this.

A service should be called with onTaskStopped() if a task associated with one or more of the app’s activities is removed. The service might use that as a signal that it too should shut itself down.

There appears to be a quasi-documented android:stopWithTask attribute on the <service> element in the manifest. The default is false, but if you override it to be true on your <service>, then onTaskStopped() will not be called, and Android will simply destroy your service when the task is removed.

However, as of Android 4.4, there are many reports that services may be destroyed when a task is removed, even without android:stopWithTask="true", though on a slight delay. Developers concerned about this should keep an eye on this issue and this issue, both for various hacky workarounds and for any signs that this is being permanently addressed.

What’s Up with onDestroy()?

If the user swipes away the task using the overview screen, onDestroy() will be called on all outstanding activities. If a “task killer” terminates your background process, your onDestroy() methods will not be called when your process is terminated by those apps.

So, removing a task is a graceful exit, and Android calls onDestroy(), but an explicit termination of your process by another is a not-so-graceful exit, and Android skips onDestroy().

As a result, as previously advised in this book and elsewhere, you cannot count on your onDestroy() methods being called, and you need to take this into account in

2046
Basic Scenarios for Changing the Behavior

In many cases, the default behavior of tasks is just fine. However, there are many scenarios in which we may want to override the default behavior, routing activities to specific tasks, to have a better flow for the user.

Reusing an Activity

By default, each time you call startActivity(), a new instance of the activity is created. Depending upon the user flow, that may not be a bad approach. For example, it may be that the only logical path out of the started activity will be to press BACK and destroy it.

However, there will be plenty of cases where we will not want to keep creating new activity instances. For example, if you elect to have several activities reachable via a nav drawer, you do not want to create fresh instances of activities that the user has already visited via that drawer. Otherwise, they will keep piling up, continuing to consume heap space. Instead, it would be better to try to reuse an existing activity instance, if one is available, creating a fresh one only if needed.

The most flexible approach for accomplishing this involves using a flag on the Intent used to start the activity: Intent.FLAG_ACTIVITY_REORDER_TO_FRONT. This tells Android to bring an existing activity matching our Intent to the foreground, if one already exists in our task. If there is no such activity, then go ahead and create a new instance.

The Tasks/RoundRobin sample application demonstrates this. It consists of two activities (FirstActivity and SecondActivity), each of whose UI consists of one really big button. Clicking the button should start the other activity, so clicking the button in FirstActivity should start an instance of SecondActivity. But, we want to reuse activity instances where available, and confirm that indeed we are reusing those instances.

FirstActivity accomplishes that by adding FLAG_ACTIVITY_REORDER_TO_FRONT to the Intent used to start SecondActivity when the button is clicked:

```java
package com.commonsware.android.tasks.roundrobin;

import android.app.Activity;
```
import android.content.Intent;
import android.os.Bundle;
import android.util.Log;
import android.view.View;

public class FirstActivity extends Activity implements View.OnClickListener {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.first);
        findViewById(R.id.button).setOnClickListener(this);
        Log.d(getClass().getSimpleName(),
             String.format("onCreate for %x", hashCode()));
    }
    @Override
    protected void onResume() {
        super.onResume();
        Log.d(getClass().getSimpleName(),
             String.format("onResume for %x", hashCode()));
    }
    @Override
    protected void onDestroy() {
        super.onDestroy();
        Log.d(getClass().getSimpleName(),
             String.format("onDestroy for %x", hashCode()));
    }
    @Override
    public void onClick(View view) {
        startActivity(new Intent(this, SecondActivity.class)
                       .addFlags(Intent.FLAG_ACTIVITY_REORDER_TO_FRONT));
    }
}

(from Tasks/RoundRobin/app/src/main/java/com/commonsware/android/tasks/roundrobin/FirstActivity.java)

SecondActivity has a nearly identical implementation, just routing back to FirstActivity.

If you run the app, the user’s perspective is that clicking the button “ping-pons” the user between the two activities. Looking at Logcat, you will see new instances
created the first time the user visits an activity, courtesy of the Log.d() call in onCreate(). But, if the user returns to an existing instance via the button click, you will see that onCreate() is not called, and that the hashCode() reported in onResume() matches the hashCode() of the previously-created instance of this activity:

D/FirstActivity: onCreate for b31b9430
D/FirstActivity: onResume for b31b9430
D/SecondActivity: onCreate for b31eb8a8
D/SecondActivity: onResume for b31eb8a8
D/FirstActivity: onResume for b31b9430
D/SecondActivity: onResume for b31eb8a8

Note that launch modes offer another way to control this behavior, having the activity being started indicate that its instance should always be reused. However, this is a specialty case, one that most apps will not require.

Forcing a Clean Task

Let’s suppose that you have an app that requires in-app authentication, via some form of login screen. For example, your app’s data is held in SQLCipher for Android, and so you need the user to supply a passphrase for the database.

In the beginning, when your app is launched from the home screen, your LAUNCHER activity appears. If that is your login screen, all is good. You collect the passphrase, create your singleton instance of the SQLCipher-enabled SQLiteOpenHelper, and you can access the database.

Eventually, the user presses HOME, and time passes. Android terminates your process to free up system RAM. The user then tries returning to your existing task, such as via the overview screen. Android creates a fresh process for you and takes you to the activity on the top of that task’s back stack. But at this point, your singleton SQLiteOpenHelper is gone, and you need to collect a passphrase again.

You might think that this is purely a UI issue. Rather than collecting the passphrase in an activity, you collect it in a fragment, one that your LAUNCHER activity uses directly, and one that other activities can use via a DialogFragment. This way, you can arrange for every activity to be able to complete the re-initialization of your process and give you access to the encrypted database again.

Another approach would be to say that you want to wipe out this task and start over, routing the user back to the LAUNCHER activity for authentication.
There are two main approaches for implementing this: setting Intent flags or using android:clearTaskOnLaunch in the manifest.

**Starting a Cleared Task Yourself**

One way to do that is to have each activity check to see if a new task is needed (e.g., “is the SQLiteOpenHelper singleton null?”). When that situation is detected, you call startActivity() for your LAUNCHER activity, with two flags: FLAG_ACTIVITY_NEW_TASK and FLAG_ACTIVITY_CLEAR_TASK.

For example, the Tasks/Tasksalot sample application is a straight-up clone of Launchalot with only one change of substance: using FLAG_ACTIVITY_CLEAR_TASK instead of FLAG_ACTIVITY_RESET_TASK_IF_NEEDED:

```java
@Override
protected void onListItemClick(ListView l, View v,
                                 int position, long id) {
  ResolveInfo launchable=adapter.getItem(position);
  ActivityInfo activity=launchable.activityInfo;
  ComponentName name=new ComponentName(activity.applicationInfo.packageName,
                                         activity.name);
  Intent i=new Intent(Intent.ACTION_MAIN);
  i.addCategory(Intent.CATEGORY_LAUNCHER);
  i.setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
              Intent.FLAG_ACTIVITY_CLEAR_TASK);
  i.setComponent(name);
  startActivity(i);
}
```

(from Tasks/Tasksalot/app/src/main/java/com/commonsware/android/tasksalot/MainActivity.java)

To see this in action:

- Run the TaskCanary sample app and use the overflow to bring up OtherActivity
- Press HOME
- Run Tasksalot
- Click on the “Task Canary” entry in Tasksalot

At this point, you will see the TaskCanary sample app return to the screen. From the logs in Logcat, you will see it is the same task ID as before. Yet, you are seeing the FirstActivity. OtherActivity was removed from the task as part of
FLAG_ACTIVITY_CLEAR_TASK processing.

This differs from what you see in a home screen, with FLAG_ACTIVITY_RESET_TASK_IF_NEEDED. If you run the same test, but rather than use Tasksalot, you tap on the “Task Canary” icon in the home screen launcher, the task will return to the foreground, but you will be taken to OtherActivity. FLAG_ACTIVITY_CLEAR_TASK always clears the task and makes the activity that you are starting up be the root of the newly-cleared task.

**Always Starting a Cleared Task**

Perhaps you always want to start with a cleared task, whenever the user returns to the task after having left it previously. In other words, you always want to start back at whatever your task’s root activity is, which is typically your launcher activity.

To do this, simply have android:clearTaskOnLaunch="true" on that launcher activity. Then, for any task where that activity is the root, when the user returns to the task, any other activities in the task are reparented (if applicable) or dropped.

Note, though, that this does not mean that you get a new process. Hence, any singletons you had before may or may not still be there.

So, in the authentication scenario described above, using android:clearTaskOnLaunch="true" would take the user back to your initial activity, where you can perform the authentication. However, if you detect that the SQLiteOpenHelper still exists, and therefore you do not need the user to log in again, you could switch over to showing your initial content (e.g., run a FragmentTransaction).

This is far simpler than having the detect-the-null-singleton-on-each-activity approach. However, the downside is that the user loses context. If they were six activities deep into your app, and they get interrupted by a phone call, when they come back to your app, they are back at the beginning.

**Launching an App Into a New Task**

A home screen launcher app, when it invokes the user’s selected activity, will use code something like this from the Launchalot sample:

```java
@Override
protected void onListItemClick(ListView l, View v,
```
Tasks

```java
int position, long id) {
    ResolveInfo launchable=adapter.getItem(position);
    ActivityInfo activity=launchable.activityInfo;
    ComponentName name=new ComponentName(activity.applicationInfo.packageName,
            activity.name);
    Intent i=new Intent(Intent.ACTION_MAIN);
    i.addCategory(Intent.CATEGORY_LAUNCHER);
    i.setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
            Intent.FLAG_ACTIVITY_RESET_TASK_IF_NEEDED);
    i.setComponent(name);
    startActivity(i);
}
```

(from Introspection/Launchalot/app/src/main/java/com/commonsware/android/launchalot/Launchalot.java)

Here, we:

- Create a ComponentName identifying the specific activity in the specific app to be started (in this case, based on the ResolveInfo that the user chose)
- Create an Intent for the MAIN action and the LAUNCHER category
- Set the FLAG_ACTIVITY_NEW_TASK and the
  FLAG_ACTIVITY_RESET_TASK_IF_NEEDED flags in the Intent
- Attach the ComponentName to the Intent, to convert it from an implicit Intent into an explicit Intent
- Start the activity using the Intent

FLAG_ACTIVITY_NEW_TASK indicates that we want the activity being started to be the root of a new task. If there is no outstanding task for this app, a new task will be created, a new activity instance will be created, and that activity will be the root of the task. Here, “root” means that if the user presses BACK and destroys the activity, the task itself is removed and the user returns to the home screen.

However, despite its name, FLAG_ACTIVITY_NEW_TASK does not necessarily create a new task. If there is an existing task for this app containing this activity, that task is brought back to the foreground and is left intact. The activity we request is not created, let alone brought to the foreground.

That is where FLAG_ACTIVITY_RESET_TASK_IF_NEEDED comes in. It ensures that the task that is brought to the foreground is showing the requested activity. This may involve reparenting activities as well.

Another possibility, instead of FLAG_ACTIVITY_RESET_TASK_IF_NEEDED, is
FLAG_ACTIVITY_MULTIPLE_TASK. This always starts a fresh task, with a fresh instance of the requested activity in the root of that task. However, this now may mean that the user has multiple tasks for the same app, which may be confusing in some circumstances. However, this also lies at the core of Android 5.0’s documents-as-tasks support and therefore may become more familiar to users over time.

The Invisible Activity

Several sample apps in this book use an “invisible activity”, one with the theme set to Theme.Translucent.NoTitleBar. These are useful in cases where something outside your app needs an activity, but you do not really have a UI that you want to display. In the case of the book samples, having a LAUNCHER activity makes it much easier for readers like you to simply run the samples from the IDE.

However, those sample apps usually do not have any other activities. The invisible activity is just there to kick-start something else, such as AlarmManager events.

However, if you have a mix of invisible and regular activities in an app, your invisible activities still wind up potentially having a visible impact.

For example, suppose that we have an ordinary Android app, with regular activities. However, we want a home screen shortcut icon to allow the user to start something in the background, such as playing music. While an app widget would allow us to control what happens when the user taps on an icon in that app widget, a home screen shortcut icon always launches an activity. So, we make the start-the-music activity invisible via Theme.Translucent.NoTitleBar.

If the user taps on that shortcut, and none of our other activities are part of a task, things proceed as expected: the music starts and the user sees nothing (other than perhaps a Toast that we show to let the user know that we are responding to their request).

But, if one or more of our activities are in some task, launching the invisible activity brings the task back to the foreground. While our invisible activity is still invisible, the user now sees whatever other activity of ours they had last been in. It is possible that this is a feature, and not a bug, for some apps. But, in other cases, we might want the invisible activity to not have this effect.

The solution: task affinity.

Your ordinary activities can use the default task affinity, or have other task affinities
as needs dictate. Your invisible activity, though, would have an android:taskAffinity value that is distinct from all others, to force it into its own task. That way, when the user taps on the shortcut, the invisible activity routes to its own task. That task will not yet exist, so the invisible activity causes the task to be created. When the invisible activity calls finish() to destroy itself after kicking off the background work, the task is now empty and is removed. Since this was a new task, no existing UI would be brought back to the foreground, and since the task is removed in the end, we are “reset” for the next time the user taps on the shortcut.

Reparenting Tasks

One of the more unusual features of Android's task system is the ability for activities to be “reparented”, or moved from one task to another. On the surface, this feels a bit odd, as if a Web page on one browser tab might magically show up in a separate browser tab, just via navigation. And, in truth, it is a specialized use case, but one that could conceivably apply to your app.

Suppose that you were writing an SMS client. You have an activity that is your message composer, where the user can type in a text message to send to somebody. You export that activity, with Intent actions like ACTION_SEND and ACTION_SENDTO. A third-party app, using one of those Intent actions, starts up your message composer activity. In the absence of a taskAffinity to stipulate otherwise, by default, your message composer activity will be in the task of the third-party app.

Now, suppose that the user fails to actually send a message, such as by pressing HOME from the third-party app’s task. Some time later, the user taps on your app’s home screen launcher icon. At this point, there are two possibilities as to what happens:

1. You may decide that you want to have the already-running message composer activity appear, to remind the user that they were in the middle of composing a text message and failed to either send it or explicitly BACK out of the activity.
2. You may decide that you do not care, and you are willing to ignore that outstanding message composer activity instance.

The default is option #2. If, instead, you want to offer option #1, that is where task reparenting comes into play.

On your <activity> (or on <application> to set an app-wide default), you can have android:allowTaskReparenting="true". This indicates to Android that the message
composing activity, that is on some other app's task, can move to your app's task when that task is created.

The trigger for this “reparenting” is the task affinity. If you do not specify a task affinity for an activity, the default affinity is for a task rooted in one of your app’s activities, typically the launcher activity. In some circumstances, when a task for your app is created, Android will search through other tasks to see if there is any activity, in another task, that has an affinity for your task and allows reparenting. If there is a match, that activity is brought into your task.

The “some circumstances” mentioned in the preceding paragraph is something using two Intent flags when calling startActivity():

- `FLAG_ACTIVITY_NEW_TASK`, to create a new task if one is needed, and
- `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED`, to clear out the task if it already has contents and reparent any activities in other tasks to this one if appropriate

As it turns out, home screen launchers are supposed to use this pair of flags when they respond to the user tapping on a home screen launcher icon.

The `Tasks/ReparentDemo` sample Android Studio project contains a pair of applications as modules that demonstrate this effect, based on David Wasser’s [epic Stack Overflow answer](https://stackoverflow.com/questions/25700749/android-task-affinity-reparenting).

One module, `app/`, contains an application with two activities, where the second activity (`ReparentableActivity`) has `android:allowTaskReparenting="true"`:

```
<manifest
    xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonsware.android.tasks.reparent">

<application
    android:allowBackup="true"
    android:label="@string/app_name"
    android:icon="@drawable/ic_launcher">
    <activity
        android:name=".MainActivity">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>
            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
    <activity
        android:name=".ReparentableActivity"
        android:allowTaskReparenting="true">
The two activities just display static messages, indicating which of those two activities you are seeing in the foreground. They also log process and task IDs to Logcat. MainActivity does that in onCreate():

```java
package com.commonsware.android.tasks.reparent;

import android.app.Activity;
import android.os.Bundle;
import android.util.Log;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        Log.d(getApplicationInfo().loadLabel(getPackageManager()).toString(),
            String.format("Process ID %d, Task ID %d", android.os.Process.myPid(), getTaskId()));
    }
}
```

ReparentableActivity logs the same information in onResume():

```java
package com.commonsware.android.tasks.reparent;

import android.app.Activity;
import android.os.Bundle;
import android.util.Log;

public class ReparentableActivity extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.reparent);
    }
}
```
The other module, app2/, contains an application with one activity, whose UI consists of one really big button. Clicking that button triggers a launch() method that calls startActivity() on an Intent identifying the ReparentableActivity from the first app:

```
package com.commonsware.android.tasks.reparent.app2;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.util.Log;
import android.view.View;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);
        Log.d(getApplicationInfo().loadLabel(getPackageManager()).toString(),
              String.format("Process ID %d, Task ID %d", android.os.Process.myPid(), getTaskId()));
    }

    public void launch(View v) {
        startActivity(new Intent("com.commonsware.android.tasks.reparent.WHEEEEE"));
    }
}
```

To see this behavior in action, install both apps. If you run them straight from your IDE, you will want to clear out all relevant tasks, either by swiping them off the recent-tasks list (or by rebooting the device or emulator, if it runs Android 4.4 or lower).

Then, start up the “Reparent Demo Aux” app (from the app2/ module). Click the
button, and you will see the ReparentableActivity appear. If you press HOME, bring up the recent-tasks list, and go back to this task, you will see the same ReparentableActivity. The task, however, is for “Reparent Demo Aux”.

Now, press HOME, then start up the “Reparent Demo” app (from the app/ module). Rather than seeing the MainActivity from that app, you see the ReparentableActivity instance from before. The logs will illustrate that your process ID has not changed, but that the task ID for this activity has changed, from the task ID used by the app2/ app to the task ID created for app/. The activity has been reparented.

The use of FLAG_ACTIVITY_RESET_TASK_IF_NEEDED may sound a lot like FLAG_ACTIVITY_CLEAR_TASK. The “if needed” part comes into play in two cases:

- If a new task is being created, the “reset” work is really the reparenting described above
- If an existing task is being brought back to the foreground, then get rid of resettable activities

Here, by “resettable activities”, we mean:

- Activities launched with the FLAG_ACTIVITY_CLEAR_WHEN_TASK_RESET flag
- Any activities that are higher on the back stack than other explicitly resettable activities

So, if our back stack consists of activities A-B-C-D, and C was started with FLAG_ACTIVITY_CLEAR_WHEN_TASK_RESET, and we start up one of these activities (say, A) with FLAG_ACTIVITY_RESET_TASK_IF_NEEDED, and this existing task is coming back to the foreground, C and D will be cleared from the task. The user ordinarily would be taken to activity D, but instead will be taken to activity B, because C is explicitly resettable and D is higher on the back stack.

**The Self-Destructing Activity**

Sometimes, you only want an activity around while it is in the foreground and the user can see it. Once the user leaves the app, you no longer want that activity to exist. For example, a bank app showing bank account details might want this behavior, so that highly-sensitive information like this does not hang around. Or, you might want this for certain activities that are memory-intensive, so they release their heap space and reduce the odds of an OutOfMemoryError.
You could attempt to manage this yourself, via timely calls to finish(), but catching all the cases when finish() is needed could get troublesome.

Instead, Android has a pair of options to have no-history activities: activities that automatically finish when the user leaves them:

- An activity can decide for itself that it should be removed upon a task switch via the android:noHistory attribute on the <activity> in the manifest
- You can decide ad-hoc to have activities exhibit this behavior by adding Intent.FLAG_ACTIVITY_NO_HISTORY on the Intent used to start those activities

You can see these in action in the Tasks/NoHistory sample application. This is a near-clone of a simple two-activity app that we saw back when we first learned about how to have multiple activities.

There are only two real differences in this version of the sample app.

First, the launcher activity (MainActivity) has android:noHistory="true" on its <activity> element:

```xml
<activity
    android:name=".MainActivity"
    android:label="@string/app_name"
    android:noHistory="true">
    <intent-filter>
        <action android:name="android.intent.action.MAIN"/>
        <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
</activity>
```

(from Tasks/NoHistory/app/src/main/AndroidManifest.xml)

Second, when that activity goes to start OtherActivity, it adds FLAG_ACTIVITY_NO_HISTORY to the Intent used with startActivity():

```java
public void showOther(View v) {
    Intent other = new Intent(this, OtherActivity.class);
    other.putExtra(OtherActivity.EXTRA_MESSAGE, getString(R.string.other));
    other.addFlags(Intent.FLAG_ACTIVITY_NO_HISTORY);
}
```
Both of these inherit from the original sample's LifecycleLoggingActivity, which just logs messages to Logcat on the major lifecycle methods. If you run the app, click the big button to go from MainActivity to OtherActivity, then switch to some other app (via the overview screen, via the home screen launcher, etc.), you will see that both activities are destroyed, even though we do not press BACK, call finish(), or do anything else ourselves to destroy them.

This has a key side-effect: you cannot combine no-history with startActivityForResult() especially well. If the activity that calls startActivityForResult() has no-history enabled (via the manifest attribute or the Intent flag), it will simply not be called with onActivityResult().

A related attribute is android:finishOnTaskLaunch. If set to true, and if the user leaves the task and returns to it, the activity is destroyed. Whereas android:noHistory removes the activity when the user leaves the activity, android:finishOnTaskLaunch only removes the activity when the user leaves the task and returns to it.

The Hidden Task

Perhaps you have a use case where you want your entire task to be hidden from the overview screen.

To do that, you can indicate that the activity that is the root of the task (e.g., your launcher activity) is to be “excluded from recents”. To do that, you can:

- Add android:excludeFromRecents="true" to the appropriate <activity> element in your manifest, or
- Add Intent.FLAG_ACTIVITY_EXCLUDE_FROM_RECENTS to the Intent used to start up the activity and its task

Note that this only matters if the activity in question is the task root (i.e., the one that started the task). Having this setting on other activities higher in the back stack will have no effect on the visibility of the task.

Also, please note that this does not eliminate the task itself. It merely hides it from the overview screen. So, for example, suppose you were to:

```java
startActivity(other);
}
```
Tasks

- Add `android:excludeFromRecents="true"` to `MainActivity` in the TaskCanary sample
- Run the sample app
- Press HOME and note the task ID that shows up in Logcat
- Press RECENTS and note that the task does not show up there
- Return to the home screen, find TaskCanary in the launcher, and tap on the launcher icon
- Press HOME again and note the task ID that shows up in Logcat

You will see that those task IDs are the same. So, the task is there, and we can return to that task, but the task is merely suppressed from the listing shown in the overview screen.

Dealing with the Persistent Tasks

As noted previously in this chapter, on Android 5.0+, tasks live forever, insofar as they survive a reboot. That, coupled with a seemingly-infinite roster of recent tasks — compared with rather finite lists in earlier versions of Android — means that your app usually will be brought back from an existing task on Android 5.0+.

However, there are a few key differences.

The State of Your State

For normal process termination, in between device reboots, the Bundle that we get in `onSaveInstanceState()` is held onto in RAM by some core OS process. Of course, on a reboot, that process is terminated along with everything else. And a Bundle can hold onto objects that, while perhaps Parcelable, are not designed to be persisted.

The default behavior is that when your task is brought back to the foreground after a reboot, only the task’s root activity is created, and that is the only activity in the task. This effectively mimics the behavior of pre-Android 5.0 versions of Android.

However, if you want to, you can control a bit more how your task behaves on a reboot.

Your `<activity>` element in the manifest can have a largely-undocumented `android:persistableMode` attribute. If you set this to `persistAcrossReboots` on the activity that serves as the root of your task (e.g., your launcher activity), then you will be able to override three additional methods on your `Activity`:
Right now, you may think that the author of this book is drunk, as we covered those methods already, far earlier in the book.

However, what API Level 21 adds, for `persistAcrossReboots` activities, are flavors of those methods that take two parameters: a `Bundle` (as normal) and a `PersistableBundle`. Values that you store in the latter parameter will be delivered to you when your activity is re-created as part of your task coming back to the foreground, even after a reboot.

Note that all of the above requires that you set your `compileSdkVersion` to 21 or higher.

`PersistableBundle` allows you to save `int`, `long`, `double`, and `String` values, along with arrays of each. On Android 5.1+, you can also save `boolean` and arrays of `boolean` values. Notably, you cannot put a `Parcelable` (or, strangely, a `Serializable`) in a `PersistableBundle`.

If your activity has `persistAcrossReboots` set — as does `MainActivity` in the `Tasks/PersistentCanary` sample application — you will be called both with the single-parameter and dual-parameter versions of those methods, in that order. Unless your app has a `minSdkVersion` of 21 or higher, you will probably wind up overriding both versions of each method, where you put stuff in the `Bundle` in the single-parameter method and you put stuff in the `PersistableBundle` in the dual-parameter method. Since versions of Android prior to 5.0 do not know about `PersistableBundle` or methods that take one, only the single-parameter versions of those methods will be called on those devices. If your `minSdkVersion` is 21 or higher, though, you could just override the dual-parameter versions of the methods and work with both `Bundle` and `PersistableBundle` as needed.

**Where You Return To**

Normally, if your task is in the overview screen, and the user returns to it, the user will be taken to whatever activity was at the top of the back stack.

However, if the device reboots, and the user returns to your task, what happens depends on that semi-documented `persistableMode` value:
• If the value for the root activity of the task is `persistNever`, the task is not persisted across reboots
• If the value for the root activity of the task is `persistRootOnly`, the task will be persisted, but only for that root activity; other activities higher on the back stack are discarded
• If the value for the root activity of the task is `persistAcrossReboots`, then not only is the task persisted for the root activity, but other activities on the back stack are also persisted if they too have `persistAcrossReboots` (and were not launched with the `FLAG_CLEAR_TASK_WHEN_RESET` flag)

So, in the case of `PersistentCanary`, even if you use the overflow to bring up the date-and-time Settings screen, since that activity has the default `persistRootOnly` value for `persistableMode`, only the `MainActivity` will be in the task after a reboot.

**Documents As Tasks**

Tasks used to be relatively app-centric. By and large, each app had its own task, and just one task.

Android 5.0 extended the task system to support the notion of “documents” as tasks. Now, an app may be in several tasks, with different tasks focused on different “documents” or other specific contexts.

The vision is that this would be used by:

• Web browsers, where different browser tabs would be represented as separate tasks
• Editors, where different editing sessions on different content could be represented as separate tasks
• And so on

The benefit to the user is a standard way to switch between these different contexts, by means of the overview screen. The risk is that the overview screen becomes unwieldy, choked with too many entries to sift through.

**When You Should Do This**

An app should open a new “document” based on some specific explicit “open” operation by the user. So, for example:
If the user asks to open a new “tab” in a browser, that could start a new document

If the user asks to open a new file into an editor, that *might* start a new document, if you feel that the user understands that there are N other documents out there already opened in this editor

If the user launches one of your activities from outside of the home screen, such as by clicking on a link in a Web browser, that might start a new document, to keep that work separate from any past work that might be part of other active tasks

Conversely, an app should not open a new document based on pure navigation operations:

- Swiping to a new page in a `ViewPager` should not open a new document
- Choosing an item in a nav drawer should not open a new document
- Tapping on an action bar item on its own should not open a new document, though it might lead the user down a path to open a new document

### Adding a Document

You have a few options for launching an activity as a new document, indicating that it should have a separate entry on the Android 5.0+ overview screen.

**android:documentLaunchMode**

If you always want this activity to form the basis of a new document, add `android:documentLaunchMode="always"` to the `<activity>` element of your manifest, and you are done. Every time you start up an instance, you will get a new document.

This can be seen in the [Tasks/Docs](https://github.com/androiddeveloper/tvcookbook/tree/master/2064) sample application, which has an `EditorActivity` with the aforementioned attribute:

```xml
<activity
    android:name=".EditorActivity"
    android:documentLaunchMode="always"
    android:maxRecents="3"
    android:autoRemoveFromRecents="true"/>
```

(from [Tasks/Docs/app/src/main/AndroidManifest.xml](https://github.com/androiddeveloper/tvcookbook/tree/master/2064))

(we will cover those other new attributes shortly)
There are four possible values for android:documentLaunchMode:

- always, as noted, always starts a new document
- intoExisting, which looks for an existing document, where the root activity is the same class and the Intent is for the same Uri, and brings it back to the foreground, or starts a new document if a match cannot be found
- never prevents this activity from ever being launched as a new document
- none, which is the default, indicates that the activity will only be launched as a new document if Intent flags indicate that it should, as will be explained shortly

Since intoExisting depends upon Uri matches, you only want to use intoExisting if you are passing Uri values into the activity when starting it. Otherwise, use always.

**FLAG_ACTIVITY_NEW_DOCUMENT**

To conditionally launch an activity as a new document, have its android:documentLaunchMode set to none (or missing, since that is the default), and add Intent.FLAG_ACTIVITY_NEW_DOCUMENT to the Intent that is used to start up the activity that would represent a new document. This will have the behavior akin to intoExisting for android:documentLaunchMode, meaning that Android will search for a matching document and bring it back to the foreground if the match is available.

To replicate always functionality, add both Intent.FLAG_ACTIVITY_NEW_DOCUMENT and Intent.FLAG_ACTIVITY_MULTIPLE_TASK to the Intent.

**Capping the Number of Documents**

By default, you can launch as many documents as you want. However, unless you get rid of the document (as will be described below), or the user gets rid of the document (by swiping it off the overview screen), your roster of documents can keep piling up. Users may get frustrated if their overview screen is flooded by entries for your app.

You can employ an automatic least-recently-used (LRU) algorithm here by adding android:maxRecents to the <activity> that is the root of the task for the document. This indicates the maximum number of entries there should be in the overview screen for that activity, where Android will remove older tasks to make way for new
ones if needed.

So, in the Docs sample, `android:maxRecents="3"` limits the number of `EditorActivity` tasks to 3; if the user tries opening more than this, older ones are quietly removed.

Note that the default value for `android:maxRecents` is 16. Also, there is a cap, ranging from 25 to 50, depending on device RAM — you will be unable to set it higher than this.

### Removing and Retaining Documents

Android’s default behavior is that the document will exist forever, or until the user swipes it off the overview screen.

It is rather unlikely that this is really the behavior that you or your users will want. Hence, you are going to want to take some steps to ensure that your documents will go away from the overview screen when they are no longer needed.

The simplest solution is to add `android:autoRemoveFromRecents="true"`. This indicates that once the root activity is finished (e.g., the user presses BACK), the document is removed. By default, pressing BACK does not remove the document, so you need to opt into this behavior.

However, that approach assumes that it is fairly easy for the user to get back to the task’s root activity and press BACK. If you have a complex navigation of activities within the “document”, it may not be easy for the user to trigger document removal this way.

You can also forcibly get rid of the document by calling `finishAndRemoveTask()` yourself on an activity in the task. For example, in a tabbed Web browser, if you have a “close tab” UI element (e.g., action bar item), that could call `finishAndRemoveTask()` to get rid of the “document”.

### Other Task-Related Activity Properties

There are other attributes that you can place on your `<activity>` element in the manifest that have impacts on how that activity participates with the task system.
Occasionally, particular techniques become much too popular in Android development, courtesy of some blog posts or other resources touting them as “quick hacks” to address certain issues. The `android:launchMode` attribute is one of those. Most Android apps should have no need to change `launchMode` off of its default value of `standard`, or occasionally `singleTop`. Yet, because the Android task system is rather confusing, some developers latch onto other launch modes and use them in places where there are better, more fine-grained solutions.

That being said, let’s explore the launch modes, with the help from the fine people at Novoda. The Novoda developers released an app on the Play Store, and an accompanying GitHub repo that helps to illustrate the launch modes.

That app has four activities, one for each of the four launch modes:

- `standard`
- `singleTop`
- `singleTask`
- `singleInstance`

The launcher activity is the `standard` activity. Each activity has four buttons, to start up that activity via `startActivity()`, by default with no particular `Intent` flags (though there’s a legacy options menu that allows you to play with those as well). The color-coded UI for each activity also shows a unique identifier of the activity, the task ID of the task that the activity is in, the lifecycle methods that were invoked on that instance, and a set of stacked bars designed to illustrate what should be on the back stack for that task (using some techniques of dubious reliability, but the sort of thing that should be OK for a demo app like this).
So, when we launch the app, we get a green UI for a standard activity:

![Figure 655: Novoda Demo App, As Initially Launched](image)

**singleTop**

Using singleTop for the `launchMode` has one effect: controlling whether a new instance of the activity is created. Normally, calling `startActivity()` will create a new instance of the activity, unless `Intent` flags dictate otherwise. With singleTop, if the activity being started is already at the top of its stack, that existing instance is simply called with `onNewIntent()`. Otherwise, singleTop behaves as does standard.
So, if we tap the button to launch a `singleTop` method in the Novoda demo app, from our earlier state, we get a blue `singleTop` activity:

*Figure 656: Novoda Demo App, After Starting singleTop Activity*
Tasks

That worked just like standard. But, if we tap the same button again, we do not get a new instance of the activity. However, the transcript of lifecycle methods shows that `onNewIntent()` was called:

![Figure 657: Novoda Demo App, After Starting singleTop Activity Again](image)

Note that you can get a similar result by including `Intent.FLAG_ACTIVITY_SINGLE_TOP` on a `startActivity()` call. Using `launchMode` says you always want single-top behavior; using `FLAG_ACTIVITY_SINGLE_TOP` says that this time you want single-top behavior.

Pressing BACK returns you to the original green standard activity, with the blue singleTop activity having been destroyed.

**singleTask**

A `launchMode` of `singleTask` says that this activity must always be the root activity of a task.

If the task does not have that activity, a new task is created. So, if we tap the button to launch the singleTask activity in the Novoda demo app, we get a new task (ID 978, compared to the previous 977), with an instance of the yellow singleTask
activity as its root:

![Diagram of singleTask activity]

*Figure 658: Novoda Demo App, After Starting singleTask Activity*

However, if the activity in question is already there as the root of the task, all other activities on the back stack are cleared, and we are taken to the `singleTask` activity again.
So, in the Novoda demo app, if after we start the `singleTask` activity, we tap the button to launch a standard activity or two:

*Figure 659: Novoda Demo App, Two standard Activities After singleTask Activity*
...then tap the button to launch the singleTask activity, we get largely the same screen as before, just with a few more lifecycle methods logged:

It is the same task and the same instance, but with the other activities removed.

**singleInstance**

singleInstance works much like singleTask, except that the task will only ever hold this one activity. No other activities will be placed into the task.
So, tapping the button to start a singleInstance activity in the Novoda demo app brings up the red singleInstance UI:

![Image](image1)

*Figure 661: Novoda Demo App, After Starting singleInstance Activity*

Tapping the same button again just triggers onNewIntent() and other lifecycle methods on the same activity in the same task. If, however, you try tapping on the button for the standard activity, your activity will go to another task. Depending on when and how you try the Novoda demo app, this could be a prior task associated with our app (e.g., one you used for earlier standard tests), or it could be a new task (if you do not have any other ones). This is based on the taskAffinity of the activity being started.

In general, singleTask and singleInstance are for unusual use cases, and ordinary Android apps should have little reason to use them. Google specifically urges you *not to use them*:

...standard is the default mode and is appropriate for most types of activities. SingleTop is also a common and useful launch mode for many types of activities. The other modes — singleTask and singleInstance — are not appropriate for most applications, since they result in an interaction model that is likely to be unfamiliar to users and is very different from most
other applications.

**alwaysRetainTaskState**

As noted earlier in the chapter, tasks may be cleared by Android if the user has not been in the task for some time (e.g., 30+ minutes). In these cases, the user is taken back to the root activity.

If, however, the root activity has `android:alwaysRetainTaskState="true"` in its manifest entry, then Android will not apply this timeout rule. So long as the task exists, its entire state will be retained and used when the user returns to the task. This is useful for tasks where there is a lot of state that the user might regret losing.

**Other Task-Related Activity Methods**

There are a handful of other task-related methods and such floating around the `Activity` class:

**finishAffinity()**

This calls `finish()` not only on the current activity, but on all activities immediately behind it on the back stack for this task that have the same `taskAffinity` as does the current activity. Much of the time, the activities on the stack will all share an affinity, and therefore this will frequently finish all activities in the task. If the task has a mixed set of affinities (e.g., a mix of explicitly-named affinities and other activities using the default affinity), this method would only wipe out those behind the current with a specific match.

This method is not commonly used.

**finishAndRemoveTask()**

This calls `finish()` on all activities in the task and removes the task outright.

For example, a “logout” operation might call `finishAndRemoveTask()` to flush the current task, then call `startActivity()` to launch the login activity. That login activity will wind up in a fresh task (since the current one will be removed), and the old activity instances will go away, so the user cannot somehow stumble into them when they are not yet logged in.
**Tasks**

**getTaskId()**

Returns a unique integer that identifies the task the activity resides in.

This method is not commonly used.

**isTaskRoot()**

`isTaskRoot()` is a method on `Activity`. It will return `true` if this activity instance is at the root of a task, meaning that pressing BACK should remove the task and return the user to the home screen.

**moveTaskToBack()**

This method moves the current task to the background. What comes to the foreground is undocumented but generally seems to be the task for the home screen. Some apps use this to offer a “minimize” or “go to background” option within the app, though this is superfluous, as the task will move to the background naturally as the user navigates their device.

**setTaskDescription()**

For Android 5.0+, `setTaskDescription()` allows you to associate an `ActivityManager.TaskDescription` instance with your task. Here you can provide values that help drive what the task looks like on the overview screen. Specifically, you can provide the icon, title, and background color to use for the title bar over your thumbnail on the overview screen.
The Assist API ("Now On Tap")

Android 6.0 introduced the concept of the device “assistant”. The assistant can be triggered by a long-press of the HOME button or via a spoken phrase (if the user has always-on keyphrase detection) enabled. An assistant is a special app that has access to the content of the foreground activity and other visible windows, much like an accessibility service does.

For the vast majority of users of Google Play ecosystem devices running Android 6.0 or higher, the “assistant” is known as Now On Tap. On some devices, such as the Google Pixel series, this assistant is known simply as the “Google Assistant”. This is marketed as an extension of the Google Now UI, where Now On Tap/Google Assistant will take the data from the foreground activity and use that to find other relevant things for the user to do based upon that data.

(for the purposes of this chapter, this Google-supplied assistant will be referred to as “Now On Tap”, to distinguish Google’s assistant from assistants that others might write using these APIs)

For example, suppose the user receives a text message, suggesting dinner at a particular restaurant. The restaurant is merely named — no URL — and so the text messaging client would just display the name of the restaurant as part of the message. If the user invokes Now On Tap, Google will take the contents of this message (and anything else on the screen), and presumably send it to Google’s servers, sending back things like details about the restaurant (e.g., URL to Web site, Google’s scanned reviews of the restaurant, link to Google Maps for driving directions). Google’s search engine technology would scan the data from the app, recognize that the restaurant name appears to be something significant, and give Now On Tap details of what to offer the user.

As with many things from Google, Now On Tap is very compelling and very much a
privacy problem. Now On Tap is automatically installed and enabled on Android 6.0 devices — users have to go through some work to disable it. Users and app developers have limited ability to control Now On Tap, in terms of what data it collects and what it does with that data. On the other hand, certain apps (for which there are no privacy considerations) might wish to provide more data to Now On Tap, beyond what is visible in widgets, to help provide more context for Now On Tap to help users.

In this chapter, we will explore the Assist API, in terms of:

• what data gets collected
• how apps can add to that data
• how apps can block sensitive information from the assistant
• how to write your own assistant, as a Now On Tap replacement

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

What Data Gets Disclosed

Quite a bit of data is made available to Now On Tap or other assistants through the Assist API alone, as will be explored in this section.

Assistants are welcome to use other APIs as well, subject to standard Android permissions and such. So, for example, an app might not show the device’s location, and therefore an assistant could not get the location from the Assist API, but the assistant could use LocationManager or the Play Services location API to find out the device’s location.

There is also a risk of pre-installed assistants using undocumented means of getting at data beyond what the normal Android SDK would allow.

All that being said, assistants will get a lot of information about the currently-visible UI, just from what the Assist API provides.

Screenshot

Assistants can get a screenshot of the current screen contents — minus the status
THE ASSIST API (“NOW ON TAP”)

bar — when the user activated the assistant (e.g., long-pressed HOME). Developers can block this for select activities or other windows. Hence, an assistant cannot assume that it will get a screenshot, though frequently it will.

Presumably, the “vision” here is to use computer vision and other image recognition techniques on the screenshot to find things of interest. For example, the user might bring up Now On Tap for some activity that is showing a photo of a monument. The activity might not be showing any other details about the monument, such as its name. However, Google’s servers might well recognize what monument it is and therefore give the user links to Wikipedia pages about the monument, a map of where the monument is located, etc.

View Structure

By far the largest dump of data that the assistant gets comes in the form of the view structure. This is represented by a tree of AssistStructure.ViewNode objects, one per widget or container within a window. These provide similar information as to what one gets from the accessibility APIs. For most assistants, the key data is the text or content description in the widget. In the case of text, this is available as a CharSequence and so may contain additional information (e.g., hyperlinks represented in URLSpan objects) beyond the words visible to the user.

Developers can restrict what widgets and containers are disclosed, but that is something developers have to do explicitly. In other words, making data available to assistants is something a developer has to opt out of, not opt into.

Other Data

In addition to the view structure and a largely-undocumented Bundle, the other piece of data supplied to the assistant is the AssistContent. Here is where an app can provide some additional context about the foreground activity.

Specifically, the app can provide:

- an Intent that represents the activity, replacing the Intent that was used to start the activity, if there is a better one for long-term use (e.g., the activity was started via a Notification action and you want to route the user through a different Intent for other scenarios)
- a Uri that points to some Web page of relevance for this activity
- a string of “structured data”, designed to be populated by a snippet of JSON using the schema.org specification, to provide details of the book, song,
video, or whatever happens to be in the activity at the moment
  • another undocumented Bundle
  • an undocumented ClipData

Assistants can use this directly (e.g., offer a link to the Uri supplied in this content) or indirectly (e.g., using the schema.org JSON to find places where the user can purchase related content).

**Adding to the Data**

You may wish to provide some additional information to Now On Tap or other assistants, such as the Intent or JSON described above. Or, you may just generally want to ensure that your app provides the maximum amount of information to these assistants, without necessarily trying to invent new data to provide.

There are a few options for accomplishing this.

**Accessibility**

The big one is to ensure that your app provides text or content descriptions for everything visible. This will not only help these assistants, but this will make your app far more accessible to those using TalkBack or other accessibility services.

Mostly, this is a matter of ensuring that your ImageView widgets and other non-textual widgets have a content description, whether set via android:contentDescription attributes or by setContentDescription() in Java. TextView and its subclasses automatically use their text as the content description; EditText will use the hint if there is no text in the field at the moment.

More advice regarding accessibility can be found in [the chapter on accessibility and focus management](#).

**Assist-Specific Data**

Beyond that, you can contribute to the AssistContent (where the Intent, Uri, and JSON live) and other assist-related information for a given invocation of the assistant by the user.

You have a few options of where to place this logic: in one spot globally, on a per-activity basis, and, for custom views, on a per-view basis.
Globally

You can call registerOnProvideAssistDataListener() on the global Application object (retrieved by calling getApplicationContext() on some other Context, like your Activity). This takes an OnProvideAssistDataListener implementation, which in turn provides an onProvideAssistData() implementation, that will be called when the assistant is requested. You are passed the Activity of yours that is in the foreground, along with a Bundle that you can fill in.

However, the documentation only says that the Bundle will go into the EXTRA_ASSIST_CONTEXT extra on the Intent that invokes the assistant. What that Bundle is supposed to contain is undocumented.

Per-Activity

Your primary hooks for customizing the assist data come in the form of two callbacks on your Activity subclasses: onProvideAssistData() and onProvideAssistContent().

onProvideAssistData() is given the same Bundle that is given to the OnProvideAssistDataListener on a global basis. However, it is unclear what goes in that Bundle, and the contents of that Bundle do not appear to make it to the assistant, at least through the documented Assist API.

onProvideAssistContent(), though, is more relevant.

The Assist/MoAssist sample project is another version of the ViewPager-of-editors sample seen elsewhere in the book. The clone overrides onProvideAssistData() and onProvideAssistContent():

```java
@override
public void onProvideAssistData(Bundle data) {
    super.onProvideAssistData(data);
    data.putInt("random-value", new SecureRandom().nextInt());
}

@TargetApi(23)
@Override
public void onProvideAssistContent(AssistContent outContent) {
    super.onProvideAssistContent(outContent);
}
The onProvideAssistData() simply puts a random number into the Bundle. That random number does not appear anywhere in the data collected by an assistant.

onProvideAssistContent() fills in two items in the AssistContent:

- a Web URL of relevance to the activity, in this case the home page of the book’s publisher
- a bit of JSON, following the published schema.org Book structure, with metadata about this book

This information is supplied to assistants and can be used by them to do something useful, such as offer links for the user to click on to visit the sites.

**Per-View**

If you are implementing your own custom views, particularly those that render their own text using low-level Canvas APIs, you may wish to override onProvideStructure() and/or onProvideVirtualStructure(). These will be called on your widgets to provide the AssistStructure.ViewNode details to be passed to the assistant.

However, in all likelihood, you would want to instead work with the accessibility APIs to publish data to be used by accessibility services, such as the text that you are rendering. If you do that, the default implementations of onProvideStructure() and onProvideVirtualStructure() should suffice.
Removing from the Data

While some developers may embrace Now On Tap, others may specifically want to prevent Now On Tap or other assistants from “spying” on application data. You have a few options for controlling what is provided to assistants; however, all require work and some have side effects. For example, there is nothing in the manifest that you can specify to make your activities opt out of providing assist data.

FLAG_SECURE

The standard approach for making private activities really private is to use `FLAG_SECURE`:

```java
public class FlagSecureTestActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        getWindow().setFlags(LayoutParams.FLAG_SECURE,
                              LayoutParams.FLAG_SECURE);

        setContentView(R.layout.main);
    }
}
```

Call `setFlags()` before `setContentView()`, in this case setting `FLAG_SECURE`.

The classic effect of `FLAG_SECURE` is to block screenshots, both user-initiated ones and system-initiated ones (e.g., the screenshots used in the overview/recent-tasks screen on Android 4.0+).

If the user triggers an assistant for a secure activity, the assistant will not get the full view structure (i.e., no widgets and no text) and will not get a screenshot.

Password Fields

An `EditText` that is set up as a password field will have its text blocked from the view structure. The widget will be listed, but its text will be `null`.

Presumably, this relies on the `EditText` using a `PasswordTransformationMethod`, as that is Android’s typical approach for determining whether or not an `EditText` is deemed to be secure. If you have implemented your own `TransformationMethod`
(e.g., with a different approach for shrouding the user input), either have it extend PasswordTransformationMethod or use other approaches to prevent this field’s contents from being published to assistants.

NoAssistFrameLayout

The apparently-official way to block a widget or container from participating in the assist API is to create a subclass of it and override dispatchProvideStructure(). The stock implementation of this triggers the calls to onProvideStructure() and onProvideVirtualStructure(). Plus, for a ViewGroup, it will iterate over the children and call dispatchProvideStructure() on each of them.

If you are creating your own custom view, and you want it eliminated from the view structure, just override dispatchProvideStructure() and have it do nothing.

Or, you can create a container that is there solely to block the assist data collection. The Assist/NoAssist sample project does this, in the form of a NoAssistFrameLayout:

```java
package com.commonsware.android.assist.no;

import android.annotation.TargetApi;
import android.content.Context;
import android.os.Build;
import android.util.AttributeSet;
import android.view.ViewStructure;
import android.widget.FrameLayout;

public class NoAssistFrameLayout extends FrameLayout {
    public NoAssistFrameLayout(Context context) {
        super(context);
    }

    public NoAssistFrameLayout(Context context,
        AttributeSet attrs) {
        super(context, attrs);
    }

    public NoAssistFrameLayout(Context context,
        AttributeSet attrs,
        int defStyleAttr) {
        super(context, attrs, defStyleAttr);
    }

    public NoAssistFrameLayout(Context context,
        AttributeSet attrs,
        int defStyleAttr,
        int defStyleRes) {
        super(context, attrs, defStyleAttr, defStyleRes);
    }
}
```
**THE ASSIST API (“NOW ON TAP”)**

```java
@TargetApi(Build.VERSION_CODES.LOLLIPOP)
public NoAssistFrameLayout(Context context,
        AttributeSet attrs,
        int defStyleAttr,
        int defStyleRes) {
    super(context, attrs, defStyleAttr, defStyleRes);
}

@Override
public void dispatchProvideStructure(ViewStructure structure) {
    // no, thanks
}
```

(from Assist/NoAssist/app/src/main/java/com/commonsware/android/assist/no/NoAssistFrameLayout.java)

EditorFragment — responsible for showing a large multi-line EditText for the user to type into — will conditionally use a NoAssistFrameLayout, specifically on the third tab (a ViewPager position of 2):

```java
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup container,
        Bundle savedInstanceState) {
    int position=getArguments().getInt(KEY_POSITION, -1);
    View result;
    if (position==2) {
        ViewGroup doctorNo=new NoAssistFrameLayout(getActivity());
        inflater.inflate(R.layout.editor, doctorNo);
        result=doctorNo;
    } else {
        result=inflater.inflate(R.layout.editor, container, false);
    }

    EditText editor=result.findViewById(R.id.editor);
    editor.setHint(getTitle(getActivity(), position));

    if (position==1) {
        editor.setTransformationMethod(PasswordTransformationMethod.getInstance());
    }

    return(result);
```

2085
If we are on the third tab, we create a NoAssistFrameLayout and inflate our EditText into it. Otherwise, we inflate the layout normally.

Note that this sample also applies a PasswordTransformationMethod for the second page of the ViewPager (a position of 1), to illustrate the null text that will be recorded as a result.

**Blocking Assist as a User**

It is possible that your reaction to all of this is that you want to opt out of Now On Tap as a user. Or, perhaps you want to provide some instructions to your users on how to opt out of Now On Tap.

Go to Settings > Apps. There should be an option for advanced app configuration actions (on Nexus-series devices, this is a gear icon in the action bar). Tap that, then choose “Default Apps” to bring up categories of default apps for various actions:

![Android 6.0 Default Apps Screen in Settings](image)

*Figure 662: Android 6.0 Default Apps Screen in Settings*
In there, tap on “Assist & voice input”. By default, you should see “Google App” as the chosen option, which means that Now On Tap is active:

Figure 663: Android 6.0 Assist & Voice Input Screen in Settings
Tapping on that entry will bring up a list of available options, including “None”:

![Android 6.0 Assist & Voice Input Options in Settings](image)

**Figure 664: Android 6.0 Assist & Voice Input Options in Settings**

---

**Implementing Your Own Assistant**

While Now On Tap is pre-installed and pre-activated, and while users can disable Now On Tap, another option for users is to activate some other assistant. Any app that implements the proper pieces of the Assist API will appear in the roster of available assistants for the user to choose from, as described in the previous section. The `Assist/AssistLogger` sample project represents one such app.

Primarily, this app is for diagnostic purposes, showing you exactly what your activity is “leaking” to assistants. It was essential in figuring out how the APIs shown in earlier examples in this chapter worked, for instance. However, it also serves as a demonstration of the minimum requirements to implement an assistant in general.

Creating an assistant is technically part of a larger bit of work on handling voice interactions in Android. However, if all you want is an assistant, you can ignore the voice-related bits.
THE ASSIST API (“NOW ON TAP”)

A Stub VoiceInteractionService
Some of what is needed to set up an assistant is some boilerplate.
For example, the entry point for assistants and voice interactions is a custom
subclass of VoiceInteractionService. If you only are concerned with implementing
an assistant, your VoiceInteractionService can be empty:
package com.commonsware.android.assist.logger;
import android.service.voice.VoiceInteractionService
android.service.voice.VoiceInteractionService;
public class AssistLoggerService extends VoiceInteractionService {
}
(from Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerService.java)

However, it needs to exist, and in particular it needs to have its <service> entry in
your manifest:
<service
android:name=".AssistLoggerService"
android:permission="android.permission.BIND_VOICE_INTERACTION">
>
<meta-data
android:name="android.voice_interaction"
android:resource="@xml/assist_service"/>
/>
<intent-filter>
<action android:name="android.service.voice.VoiceInteractionService"/>
/>
</intent-filter>
</service>
(from Assist/AssistLogger/app/src/main/AndroidManifest.xml)

The keys to the manifest entry are:
• It needs to have the android:permission attribute, limiting it clients that
hold the BIND_VOICE_INTERACTION permission, which should limit clients to
those that are part of the device firmware
• It needs to have the <intent-filter> advertising that it supports the
android.service.voice.VoiceInteractionService action string
• It needs an android.voice_interaction <meta-data> element, pointing to
an XML resource that further configures the voice interaction/assistant
implementation

2089


The sample project has that metadata in res/xml/assist_service.xml:

```xml
<voice-interaction-service
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:recognitionService="com.commonsware.android.assist.logger.AssistLoggerService"
    android:sessionService="com.commonsware.android.assist.logger.AssistLoggerSessionService"
    android:supportsAssist="true"/>

<!--
    android:settingsActivity="com.android.test.voiceinteraction.SettingsActivity"
-->
```

(from Assist/AssistLogger/app/src/main/res/xml/assist_service.xml)

There are three attributes required on the `<voice-interaction-service>` root element to enable an assistant:

- android:recognitionService points back to your VoiceInteractionService subclass
- android:sessionService points to a subclass of VoiceInteractionSessionService (we will examine the project’s implementation shortly)
- android:supportsAssist should be true

If you want, you can also have an android:settingsActivity attribute, shown in this XML as a commented-out snippet at the end of the file. This can point to an activity in your app. If you have this, a gear icon will appear on the “Assist & voice input” Settings screen that, when tapped, will bring up this activity, to configure the behavior of your assistant. The sample app skips this.

### A Trivial VoiceInteractionSessionService

The service pointed to by android:sessionService in the metadata needs to be a subclass of VoiceInteractionSessionService. The only method that you need to override is `onNewSession()`, where you can return an instance of a VoiceInteractionSession:

```java
package com.commonsware.android.assist.logger;

import android.os.Bundle;
import android.service.voice.VoiceInteractionSession;
import android.service.voice.VoiceInteractionSessionService;

public class AssistLoggerSessionService extends VoiceInteractionSessionService {
  @Override
  public void onNewSession(VoiceInteractionSession session) {
    // do something
    // override this
  }
}
```
Here, we return an instance of `AssistLoggerSession`, which is where all of our real business logic resides for our assistant.

Note that this service also should use `android:permission` to limit clients to those that hold the `android.permission.BIND_VOICE_INTERACTION` permission:

```
<service
    android:name=".AssistLoggerSessionService"
    android:permission="android.permission.BIND_VOICE_INTERACTION"/>
```

### The VoiceInteractionSession

`VoiceInteractionSession` has a *lot* of methods that you can override, both for voice interactions and for assistant invocations. The sample app overrides the minimum required for an assistant, as its mission simply is to log all of the data received by our assistant to files on external storage, for diagnostic purposes.

**NOTE:** Running this sample app on hardware that is actually used with private data is stupid beyond words. Any app can then read the files on external storage and see what information is published by whatever apps are in the foreground at the times when you invoke the assistant. Please use this only on test environments.

### Basic Setup

Akin to components, a `VoiceInteractionSession` has an `onCreate()` method, called as part of setting up the session. In there, `AssistLoggerSession` sets up an output directory for logging the results, assuming that external storage is available:

```java
@Override
public void onCreate() {
    super.onCreate();

    if (Environment.MEDIA_MOUNTED
        .equals(Environment.getExternalStorageState())) {
```
THE ASSIST API (“NOW ON TAP”)

```java
String logDirName =
    "assistlogger_" +
    new SimpleDateFormat("yyyyMMdd\'-'HHmmss'").format(new Date());

logDir =
    new File(getContext().getExternalCacheDir(), logDirName);
logDir.mkdirs();
```

(from Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerSession.java)

**onHandleScreenshot()**

If the user invokes your assistant, you will be called with `onHandleScreenshot()`. Usually, you will be passed a `Bitmap` that contains the screenshot. However, if the foreground activity is using `FLAG_SECURE`, the `Bitmap` that is passed to you will be `null`, so make sure you check it before doing anything with it.

The `AssistLoggerSession` forks a `ScreenshotThread` to save this screenshot in the background:

```java
@Override
public void onHandleScreenshot(Bitmap screenshot) {
    super.onHandleScreenshot(screenshot);

    if (screenshot != null) {
        new ScreenshotThread(getContext(), logDir, screenshot).start();
    }
}
```

(from Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerSession.java)

`ScreenshotThread`, in turn, just uses `compress()` on `Bitmap` to write the image out as a PNG to the directory that we are using for logging:

```java
private static class ScreenshotThread extends Thread {
    private final File logDir;
    private final Bitmap screenshot;
    private final Context ctxt;

    ScreenshotThread(Context ctxt, File logDir, Bitmap screenshot) {
        this.ctxt = ctxt.getApplicationContext();
        this.logDir = logDir;
        this.screenshot = screenshot;
    }
```

2092
@Override
public void run() {
    if (logDir!=null) {
        try {
            File f=new File(logDir, "screenshot.png");
            FileOutputStream fos=new FileOutputStream(f);

            screenshot.compress(Bitmap.CompressFormat.PNG, 100, fos);
            fos.flush();
            fos.getFD().sync();
            fos.close();

            MediaScannerConnection.scanFile(ctxt, new String[] {f.getAbsolutePath()},
                                            new String[] {"image/png"}, null);

            Log.d(getClass().getSimpleName(),
                  "screenshot written to: "+f.getAbsolutePath());
        } catch (IOException e) {
            Log.e(getClass().getSimpleName(),
                  "Exception writing out screenshot", e);
        }
    } else {
        Log.d(getClass().getSimpleName(),
              String.format("onHandleScreenshot: %dx%d", 
                           screenshot.getWidth(), screenshot.getHeight()));
    }
}
}

(from Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerSession.java)

onHandleAssist()
onHandleAssist() is your other main assistant callback. Here is where you get:

• a Bundle of undocumented stuff
• the AssistStructure outlining the contents of the windows, including the view hierarchy
• the AssistContent with the Intent, Web Uri, JSON, and so on

AssistLoggerSession kicks off an AssistDumpThread to record this data in the
THE ASSIST API (“NOW ON TAP”)

background:

```java
@Accessory
public void onHandleAssist(Bundle data,
   AssistStructure structure,
   AssistContent content) {
   super.onHandleAssist(data, structure, content);

   new AssistDumpThread(getContext(), logDir, data, structure,
   content).start();
}
```

(from Assist/AssistLogger/app/src/main/java/com/commonsware/android/assist/logger/AssistLoggerSession.java)

AssistDumpThread itself is a `long` class that generates a JSON file containing the information found in the parameters to onHandleAssist():

```java
package com.commonsware.android.assist.logger;

import android.app.assist.AssistContent;
import android.app.assist.AssistStructure;
import android.content.Context;
import android.content.Intent;
import android.media.MediaScannerConnection;
import android.os.Bundle;
import android.util.Log;
import org.json.JSONArray;
import org.json.JSONException;
import org.json.JSONObject;
import java.io.File;
import java.io.FileOutputStream;
import java.io.OutputStreamWriter;
import java.io.PrintWriter;
import java.util.Set;

class AssistDumpThread extends Thread {
private final File logDir;
private final Bundle data;
private final AssistStructure structure;
private final AssistContent content;
private final Context ctxt;

AssistDumpThread(Context ctxt, File logDir, Bundle data,
   AssistStructure structure,
   AssistContent content) {
   thisctxt=ctxt.getApplicationContext();
   this.logDir=logDir;
}
```
THE ASSIST API ("NOW ON TAP")

```java
this.data=data;
this.structure=structure;
this.content=content;
}

@Override
public void run() {
    if (logDir!=null) {
        JSONObject json=new JSONObject();
        try {
            json.put("data", dumpBundle(data, new JSONObject()));
        } catch (JSONException e) {
            Log.e(getClass().getSimpleName(),
                    "Exception saving data", e);
        }

        try {
            json.put("content", dumpContent(new JSONObject()));
        } catch (JSONException e) {
            Log.e(getClass().getSimpleName(),
                    "Exception saving content", e);
        }

        try {
            json.put("structure", dumpStructure(new JSONObject()));
        } catch (JSONException e) {
            Log.e(getClass().getSimpleName(),
                    "Exception saving structure", e);
        }

        File f=new File(logDir, "assist.json");

        try {
            FileOutputStream fos=new FileOutputStream(f);
            OutputStreamWriter osw=new OutputStreamWriter(fos);
            PrintWriter pw=new PrintWriter(osw);

            pw.print(json.toString(2));
            pw.flush();
            fos.getFD().sync();
            fos.close();

            MediaScannerConnection.scanFile(ctxt,
```

2095
new String[] {f.getAbsolutePath()},
new String[] {"application/json"}, null;

Log.d(getClass().getSimpleName(),
"assist data written to: "+f.getAbsolutePath());
}
catch (Exception e) {
Log.e(getClass().getSimpleName(),
"Exception writing out assist data", e);
}
else {
Log.d(getClass().getSimpleName(), "onHandleAssist");
}
}

return (json);
Making a Real Assistant

AssistLogger is a faithful implementation of an assistant, but it does not really assist the user, except in seeing what sorts of information Google gets via Now On Tap.

If you wanted to make an actual assistant that is a true replacement for Now On Tap, you would also need to implement methods like:

- **onCreateContentView()**, where you can inflate a layout or otherwise assemble the basic UI to be shown to the user when your assistant is invoked
- **onShow()**, where you can populate that UI with the details for this particular assist request
- **onHide()**, called when your UI is no longer visible to the user

...and so on.

Determining the Active Assistant

If you elect to create your own assistant, you might be interested in knowing...
whether or not your app has been chosen as the user’s assistant. Unfortunately, there is no documented and supported means of doing this.

So, here is the undocumented and unsupported approach that works on Android 6.0.

**WARNING**: this code may not work on all Android 6.0 devices, let alone on future versions of Android, as it relies a bit on internal implementation that could be changed by device manufacturers or custom ROM authors. Please use this very carefully and do not be shocked if it stops working.

`Settings.Secure` holds the details of the currently-chosen assistant. However, the key under which those details are stored is a hidden entry in `Settings.Secure`, and so it does not show up in the Android SDK. The key is "voice_interaction_service". The value is the `ComponentName` of the assistant, serialized (or “flattened”) into a `String`. So, to get the `ComponentName` of the assistant, you can use:

```java
String assistant = Settings.Secure.getString(getContentResolver(), "voice_interaction_service");

boolean areWeGood = false;

if (assistant != null) {
    ComponentName cn = ComponentName.unflattenFromString(assistant);
}
```

cn will then hold the `ComponentName`.

**Leading the User to Make an Assistant Change**

If you implement your own assistant, and at the moment you are not the user's chosen assistant, you might have the need to lead the user over to the spot in the Settings app where they can change this. Once again, this is not explicitly documented.

However, for Android 6.0, `Settings.ACTION_VOICE_INPUT_SETTINGS` contains the action string that opens up the screen where the user can choose their assistant implementation. So, you could call:

```java
startActivity(new Intent(Settings.ACTION_VOICE_INPUT_SETTINGS));
```
THE ASSIST API ("NOW ON TAP")

to lead the user to that screen, plus use a Toast or something to remind the user to tap on the “Assist app” entry to choose the assistant.

However:

• Since Settings.ACTION_VOICE_INPUT_SETTINGS is not guaranteed to be on all devices, please wrap the startActivity() call in an ActivityNotFoundException try/catch block and deal with the missing action accordingly
• There is no guarantee that Settings.ACTION_VOICE_INPUT_SETTINGS will lead the user to the correct screen on all Android 6.0+ devices, as the Settings app might be altered by the device manufacturer or custom ROM author
The Autofill API

Many Web browsers, such as Chrome, offer “autofill”. The browser remembers things that you have typed into certain fields, like addresses, and offers to fill those back in when you go to fill in the same form again… or even a different form with similar fields.

Android 8.0 adds autofill capability to Android via the Autofill Framework. Values that users enter into your forms will be remembered and offered again when the user returns to your form, or to other forms that they encounter in other apps on the device. This all happens without any changes to your code... in theory. In practice, you may need some changes to your code.

However, Android itself does not store the form data, nor offer it as suggestions for autofilling in a form. Android is merely serving as a conduit between your app and a third-party autofill service. It is the service that is responsible for determining what could be autofilled in your form and saving prior entries. As with the Assist API, the user can choose an autofill service, and none ship by default with the O Developer Preview. In all likelihood, a Google-branded autofill implementation will be part of the production rollout of Android 8.0, but the user could choose other autofill apps... or perhaps none at all, for privacy reasons.

In this chapter, we will explore the AutoFill API, in terms of:

- what data gets collected
- how apps can block sensitive information from autofill
- how apps can better integrate with autofill

NOTE: O Developer Preview 2 renamed many of the Autofill Framework classes and methods to make the f in Autofill lowercase. So, for example, AutoFillService became AutofillService. Materials written based on O Developer Preview 1 (blog
posts, Stack Overflow answers, etc.) will have a capital F instead.

**Prerequisites**

Understanding this chapter requires that you have read the core chapters of this book.

There are commonalities between autofill and the Assist API, and so this chapter will refer back to that one from time to time.

**The Pieces of the Puzzle**

Android 8.0 provides a framework for apps with a UI to participate in autofill, by denoting roles that some of those widgets have (e.g., “this is the field for the username”). However, Android itself does not save any user input for later use with autofill, nor does Android itself decide what values are candidates for autofill. Instead, Android delegates that work to a separate autofill service. This works akin to how accessibility services and input method editors work:

- Android provides the conduit for apps and pluggable service implementations to communicate
- Android provides a UI in Settings for the user to choose which service implementation(s) to use for a particular role
- App developers provide the actual service implementations
Hence, with autofill, there are three pieces: the app with the UI, Android itself, and the autofill service:

![Figure 665: Pieces of Autofill](image)

Here, `onFillRequest()` and `onSuccess()` are part of the API for autofill service implementations.

**The User Experience**

Before we get into the implementation, let's see how this looks from the standpoint of the user.

**NOTE:** These screenshots and explanations are from the O Developer Preview 4. It is possible that this flow will change by the time Android O ships in final form, or even in future developer previews.
While Completing a Form

If an autofill service is activated, and the user visits a screen with a form to be filled in, the user may get a drop-down list from the form, indicating possible “datasets” to use to complete the form:

![Figure 666: Autofill Datasets for User to Choose From](image)

The actual presentation here (“dataset-2”) comes from the autofill service. It is actually a RemoteViews, not just some text, and so different autofill services will use different formats here.
After Completing a Form

After the user has completed a form, with data not represented in one of those datasets, once the activity containing the form is destroyed, the user gets a “bottom sheet” panel asking if the data should be saved for later autofill use:

![Figure 667: Autofill Save Prompt](image)

This works akin to the pop-up dialog a desktop Web browser might use to ask if certain data should be saved (e.g., authentication credentials) for future visits to that page.

What Data Gets Disclosed

The Assist API discloses quite a bit of data to the user’s chosen assistant app.

The autofill API discloses a bit less. Mostly, it is the view hierarchy, in the form of a ViewStructure.

An autofill service gets information about what is in the UI at two points:

1. When it is time to determine if there is anything that could be autofilled-in
2. When it is time to save data for future autofill requests

Here is what an autofill service might see from a small form with username, password, and cc fields (the latter for a credit card number), along with related labels and a “save” button, when it is time to determine if there is anything that could be autofilled-in:

Roughly speaking, you get all the same information that an accessibility service might. Most of this information is likely to be useless to an autofill service, but a few elements, such as idEntry (the widget ID) and text (the contents of a TextView or things inheriting from TextView) will be of importance.

**Blocking Autofill as a User**

The O Developer Preview 3 ships with an “Autofill with Google” autofill service, pre-installed and pre-enabled. Presumably, many devices that ship with Android 8.0 will ship with an autofill service pre-installed, whether that is one from Google, from the device manufacturer, or from another party.
THE AUTOFILL API

If you, as a user, do not trust the autofill service, you can disable it or switch to a different one via the Settings app. Specifically, Settings > System > Languages & input > Advanced has an “Autofill service” preference:

Figure 668: Advanced “Languages & input” in Settings, Showing “Autofill service”
Tapping the gear icon next to the configured autofill service (if there is one) will allow you to configure the service. Tapping the rest of the list row brings up a dialog for you to choose an autofill service from the available candidates, or “None” to opt out of autofill entirely:

![Figure 669: “Autofill service” Selection in Settings](image)

**Supporting Autofill with Standard Widgets**

The documentation suggests that apps do not need to be modified to work with the Autofill Framework. That is incorrect, at least in general. Layouts do need some modification to work with autofill services, to help those autofill services identify the roles of those widgets and how those roles tie into saved data that could be autofilled-in.

The thing to bear in mind about autofill is that we have three parties to the content negotiation:

- Your app
- The Android Autofill Framework
- The autofill service implementation
This requires some common ground, as otherwise the autofill service will not know what is and is not to be considered candidates for autofill.

Identifying Roles via Hints

The primary thing that you need to do is to identify the roles of various widgets in your form. After all, a field containing a user ID might be called userid, userId, uid, username, user_name, login, or anything else. An autofill service needs to know that your EditText with an android:id of @+id/snicklefritz represents a user ID, for example.

To do this, use android:autofillHints in a layout resource, or setAutofillHints() from Java. These indicate, for the particular View you are configuring what role or role(s) the View holds within the world of autofill.

Autofill hint values are strings. Typically, a given widget only needs one hint, and so you can set the hints to that particular string. If, for whatever reason, a widget qualifies for more than one hint, use a comma-delimited list as the value for android:autofillHints, or pass multiple strings to setAutofillHints() via varargs.

The roster of possible hints, by name and Java View constant, are:
<table>
<thead>
<tr>
<th>Value</th>
<th>View Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>creditCardExpirationDate</td>
<td>AUTOFILL_HINT_CREDIT_CARDExpiration_DATE</td>
</tr>
<tr>
<td>creditCardExpirationDay</td>
<td>AUTOFILL_HINT_CREDIT_CARDExpiration_DAY</td>
</tr>
<tr>
<td>creditCardExpirationMonth</td>
<td>AUTOFILL_HINT_CREDIT_CARDExpiration_MONTH</td>
</tr>
<tr>
<td>creditCardExpirationYear</td>
<td>AUTOFILL_HINT_CREDIT_CARDExpiration_YEAR</td>
</tr>
<tr>
<td>creditCardNumber</td>
<td>AUTOFILL_HINT_CREDIT_CARD_NUMBER</td>
</tr>
<tr>
<td>creditCardSecurityCode</td>
<td>AUTOFILL_HINT_CREDIT_CARD_SECURITY_CODE</td>
</tr>
<tr>
<td>emailAddress</td>
<td>AUTOFILL_HINT_EMAIL_ADDRESS</td>
</tr>
<tr>
<td>name</td>
<td>AUTOFILL_HINT_NAME</td>
</tr>
<tr>
<td>password</td>
<td>AUTOFILL_HINT_PASSWORD</td>
</tr>
<tr>
<td>phone</td>
<td>AUTOFILL_HINT_PHONE</td>
</tr>
<tr>
<td>postalAddress</td>
<td>AUTOFILL_HINT_POSTAL_ADDRESS</td>
</tr>
<tr>
<td>postalCode</td>
<td>AUTOFILL_HINT_POSTAL_CODE</td>
</tr>
<tr>
<td>username</td>
<td>AUTOFILL_HINT_USERNAME</td>
</tr>
</tbody>
</table>

Here, name is for a real name (e.g., “Mark Murphy”), whereas username is for something more like a login value (e.g., “commons guy”).

Since these are strings, and since the Android Autofill Framework (probably) does not care about the specific values, it is theoretically possible for autofill services to document additional hints that they honor (e.g., birthDate).

**Indicating Importance**

Independent from the hint system is android:importantForAutofill and the corresponding setImportantForAutofill() method. These indicate whether you, as the developer of the UI, think that certain widgets should or should not be considered for autofill purposes. For example, you might have a form that a user
The Autofill API

might fill out repeatedly and might want autofill capability, but some fields do not fit specific roles governed by the hint system, and so the autofill service might ignore them by default.

The default importance is auto, meaning that the autofill service will make its own guess, probably based on whether there is an autofill hint or not. This maps to IMPORTANT_FOR_AUTOFILL_AUTO in setImportantForAutofill().

There are four alternatives:

<table>
<thead>
<tr>
<th>XML Attribute Value</th>
<th>Java Constant</th>
<th>Role</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>IMPORTANT_FOR_AUTOFILL_NO</td>
<td>widget should be ignored from an autofill standpoint</td>
</tr>
<tr>
<td>noExcludeDescendants</td>
<td>IMPORTANT_FOR_AUTOFILL_NO_EXCLUDE_DESCENDANTS</td>
<td>widget and all its children should be ignored</td>
</tr>
<tr>
<td>yes</td>
<td>IMPORTANT_FOR_AUTOFILL_YES</td>
<td>widget should always be considered for autofill</td>
</tr>
<tr>
<td>yesExcludeDescendants</td>
<td>IMPORTANT_FOR_AUTOFILL_YES_EXCLUDE_DESCENDANTS</td>
<td>widget and all its children should be considered</td>
</tr>
</tbody>
</table>

For example:

- To block autofill from seeing the value of a sensitive widget, use
The Autofill API

android:importantForAutofill="no" or
setImportantForAutofill(View.IMPORTANT_FOR_AUTOFILL_NO) on the
affected View
• To block autofill for an entire activity, use this in onCreate() of the activity:

getWindow()
  .getDecorView()
  .setImportantForAutofill(View.IMPORTANT_FOR_AUTOFILL_NO_EXCLUDE_DESCENDANTS);

Supporting Autofill with Custom Widgets

Other than having identifiable roles via hints, standard widgets are handled
automatically via the Autofill Framework. However, the framework has no idea how
to handle custom views of your own design, particularly those that use low-level
drawing APIs like Canvas to render their contents.

The O Developer Preview documentation has some instructions, for developers of
custom views to follow, if and where those views should be participating in autofill.

Dealing with Dynamic Changes

Sometimes, the form content changes significantly on the fly as the user is
interacting with it. For example, you might dynamically add some widgets based on
user input (e.g., tapping a “+” icon to add a row to a table). Hence, there may be
cases when you need to tell the Autofill Framework more explicitly when it should
do (or re-do) its work.

There is an AutofillManager system service that is your gateway to the Autofill
Framework. You can obtain an instance from
getSystemService(AutofillManager.class) called on a convenient Context, such
as your activity.

Then:

• If you need to tell the Autofill Framework to discard any existing autofill
  logic applied to the current form (e.g., the user did something to reset the
  form contents), call cancel() on the AutofillManager
• If you want to ask the Autofill Framework specifically to re-apply the autofill
  logic for the current form, call requestAutofill() on the AutofillManager
• If you want to do something differently depending upon whether or not
autofill is enabled, call isEnabled() on the AutofillManager

- If you want the Autofill Framework to complete its processing of the current form contents, without waiting for the activity to be destroyed, call commit() on the AutofillManager

So, for example, if you want to bail out of your activity right away if autofill is enabled — for example, you are concerned that you cannot adequately defend the privacy of your users — you could have the following code snippet in onCreate() of the activity:

```java
if (getSystemService(android.view.autofill.AutofillManager.class).isEnabled()) {
    Toast.makeText(this, "Ick!", Toast.LENGTH_LONG).show();
    finish();
}
```

(where you would replace the Toast with something else to explain the situation to the user)

Or, if you wanted to ensure that the contents of your form were not submitted to the autofill service — again, with privacy in mind — you can cancel() the autofill operation in onBackPressed(), or perhaps in other lifecycle methods:

```java
@Override
public void onBackPressed() {
    getSystemService(android.view.autofill.AutofillManager.class).cancel();
    super.onBackPressed();
}
```

**Security Requirements of Autofill Services**

Of course, a poorly written autofill provider can leak sensitive data.

That quote is from a comment on a security issue regarding a security flaw in Android 8.0’s autofill implementation. While those links may not work for you, as the issue is still locked as of February 2019, it contains a long chain of comments about this flaw and how Google expects the Android ecosystem to deal with the flaw.

**First, the Flaw**

Autofill will fill in widgets that the user cannot see, because:
The widget is marked as invisible (android:visibility="invisible")
• The widget has no size (width and height of 0dp) or is impossibly tiny (width and height of 1dp)
• The widget has negative margins that cause it to display off-screen
• The widget is behind some other opaque widget (on the Z axis), and so the widget cannot be seen

There may be other similar scenarios. For example some discussion on the issue suggests that autofill will supply data for a widget that does not exist at all in the view hierarchy, but rather is faked by the activity as part of how it populates the ViewStructure of information that goes to the autofill service.

Given this flaw, a malicious activity could obtain data that the user does not realize will go to that activity. For example, the activity might have a field for the user to confirm their postal code and have hidden widgets that collect other data, such as the rest of the address, credit card details, usernames/passphrases, etc.

This flaw can be demonstrated using Google's own sample autofill service, though in the future that sample should be updated to show a more secure implementation.

A copy of the flawed autofill service sample, along with a client demonstrating how malicious activities can obtain data covertly from the autofill service, can be found in this GitHub repo. Instructions for reproducing the problem can be found there as well.

Google’s Response

Google's engineers on the security issue admit that the flaw exists and that it would be difficult, if not impossible, to defend against malicious activities.

As such, Google is taking the approach of dumping this issue on the laps of the developers of autofill services. That is the context for the quote at the top; Google believes that well-crafted autofill services will resolve this issue. In the issue, Google has stated that their own autofill service implementation that ships pre-installed and pre-enabled on Android 8.0 will be well-crafted.

There are two problems:

1. At present, there is little documentation or sample code on what a well-crafted autofill service looks and works like, so many other developers looking to implement autofill services are left in the dark
2. Their advice will not resolve the problem completely, though it will reduce the scope

What Secure Autofill Services Need To Do

Unfortunately, the documentation for writing autofill services is limited and does not address very well the issue of how to write a secure autofill service. Instead, Google “work<s> closely with most major autofill providers”, focusing on that instead of documentation, sample code, and public test suites. This approach is difficult to defend, given that there may be entire markets for which Google’s efforts have no impact (e.g., China, if none of the “major autofill providers” distribute their apps there).

So, what is it that Google is expecting autofill service developers to do?

Partition the Dataset

The one bit of advice that Google has published publicly (as of the time this was written) was to partition the dataset. This involves two steps:

1. Cluster the possible requested autofill hints into partitions (e.g., address/phone versus credit card versus username/password)
2. Only hand back the data for one partition at a time, based on what widget has the focus at the time the autofill request is made of the service

So, for example, suppose the form has fields for address, phone number, and the typical batch of credit card details (number, name, expiration date, etc.) A poorly-crafted autofill service provides autofill data for all of that when Android asks for it… despite the fact that this is what the API would appear to expect the autofill service to do. Instead, you need to:

• Identify which widget has the focus
• Determine which partition (address/phone or credit card) that widget belongs to
• Only supply autofill data for that partition on this request

Later on, if the user puts the focus on a field that is eligible for autofill but for which you did not provide the data previously, you will get a second chance at the same form, where you repeat the process, only supplying autofill data for the partition associated with the now-focused partition.
See the “Data Partitioning” section in the AutofillService JavaDocs for complete details.

**Only Give Data Back to the App That Supplied It**

Another bit of advice: only give data back to the app that supplied it, for anything that you or the user might consider to be sensitive.

On the Web, some autofill works across all domains. Data that you fill into a form on one Web site can be captured by the browser and offered up as candidate responses on other sites, including ones that you have never visited before. If the user fills in an email address for Site A, that email address is available to supply via autofill to Site B.

The equivalent behavior with Android's autofill would be for the autofill service to have a single pool of data that could be autofilled-in for any app. If the user fills in an email address for App A, that email address is available to supply via autofill to App B.

Google feels that this is fine, so long as the data is not something that the user would consider to be sensitive. In particular, they recommend that usernames and passwords be locked to an individual app and not pooled, which makes perfect sense. For such sensitive content, an autofill service must only provide data back to the specific app that supplied it, via a combination of the applicationId ("package") of the app and the public signing key of that app:

An autofill provider must verify the **package+signature** to prevent phishing - this guarantees that even if a sideloaded app uses another app’s package name and mimics its UI cannot get access to sensitive data associated with it.

At the present time, this “only give data back to the app that supplied it” requirement is undocumented, outside of the aforementioned security issue. According to the developers, it will be documented sometime in the future.

**Hint to the User What Data Is Being Autofilled In**

The autofill service API has support for the service to require authentication before actually providing the autofill data. In a nutshell, the service creates a PendingIntent pointing to the authentication activity associated with the autofill
service and includes that PendingIntent in its response to an autofill request. If the user elects to proceed, the PendingIntent is used to display the authentication activity. If the user successfully authenticates, the user is returned to the activity they had been on previously, but now the secured autofill data should now be available for use.

For anything that is deemed sensitive, Google not only recommends that autofill services use this authentication flow, but that the authentication activity display details of exactly what data will be released. This way, for whatever autofill request triggered the authentication, the user will be informed about all fields that would be filled in... including those that the user cannot see.

This requirement is also undocumented at this time.

**What Google’s Advice Does Not Solve**

There are gaps in Google's advice.

First, there is no real enforcement that any autofill service follow the advice. This might be checked manually for the Play Store:

However, we’ll have a manual procedure in place to verify such compliance for apps that want to be listed as an Autofill service option in the “Add Autofill Service” Play Store page that is launched from Settings.

How well this works, and whether any other app distribution channel will implement similar checks, remains to be seen. Similarly, whether any security firms or other independent parties offer some sort of compliance check remains to be seen.

Second, the “only give data back to the app that supplied it” rule will fail for apps for whom the form and the data come from outside the app... such as for Web browsers. There, the app is the *browser*, not the Web site. The autofill service has no obvious means of distinguishing one site from another, or even that there is a concept of “site” that needs to be taken into account.

Third, what the *user* considers to be sensitive data, what *Google* considers to be sensitive data, and what *autofill service developers* consider to be sensitive may differ. For example, the user might be rather concerned about their address being made available. But if the autofill service developers do not consider that to be sensitive data, Google’s recommendations may be ignored. In particular, if you implement the
partitioning, but do not limit data sharing between apps, a malicious activity can still steal data within a single partition, such as obtaining all the credit card details when just asking visibly for the expiration year.

Fourth, the hint-when-authenticating approach helps, but a malicious activity can defeat simple implementations, by requesting multiple partitions and setting the focus such that an innocuous partition is requested first. For example, the malicious activity’s form might have visible fields for email address and postal code, followed by invisible fields for the rest of the address. Putting the email address field first and giving it the focus will cause any authentication to happen for the email partition. If the authentication activity only hints to the user about fields that will be autofilled in from that one partition, the user will only be told about the visible email address field. Authentication should not be required when the user advances to the postal code field, as the user just authenticated, and so the user might not receive the hint about the hidden address fields after the postal code field.
The Data Binding Framework

To quote Rudyard Kipling:

East is East and West is West, and never the twain shall meet

In many programming environments, including classical Android development, one could paraphrase Kipling as “models are models and views are views, and never the twain shall meet, except by means of some controller or presenter or something”. The result is a fair amount of code that populates views with model-supplied data and updates those models as the user alters the data in the views (e.g., types something in an EditText widget).

Data binding, in general, refers to frameworks or libraries designed to help simplify some of this data migration, where the definitions of the models and views can be used to automatically “bind” them without as much custom controller- or presenter-style logic.

Interest in data binding spiked in 2015, when Google released the first beta editions of data binding support via Android Studio, the Android Gradle Plugin, and a new data-binding support library.

This chapter explores Google’s data binding support and how to use it to simplify your Android app development.

Prerequisites

This chapter requires that you have read the core chapters of this book. In particular, the sample apps are based off of samples from the chapter on Internet access. Also, some samples use RecyclerView.
The What, Now?

In this book, we have examined a few variations of a sample app that retrieved the latest android questions from Stack Overflow and displayed them in a ListView. Our QuestionsFragment would populate a ListView or RecyclerView with the questions. For example, here is a getView() implementation that uses Picasso to populate a question:

```java
@Override
public View getView(int position, View convertView, ViewGroup parent) {
    View row = super.getView(position, convertView, parent);
    Item item = getItem(position);
    ImageView icon = row.findViewById(R.id.icon);

    Picasso.with(getActivity()).load(item.owner.profileImage)
        .fit().centerCrop()
        .placeholder(R.drawable.owner_placeholder)
        .error(R.drawable.owner_error).into(icon);

    TextView title = row.findViewById(R.id.title);
    title.setText(Html.fromHtml(getItem(position).title));

    return row;
}
```

Some parts of this are clearly distinct for this application, notably using Picasso to download the question asker's avatar and using Html.fromHtml() to handle HTML-style entities in the title.

However, the general process used here is fairly rote:

- Get the widget out of the row
- Stuff the data into the widget for the row
- Do the above for each widget needing to be updated as part of binding data to the row (a.k.a., “lather, rinse, repeat”)

Data binding, as a general technique, aims to reduce that rote coding by declaratively telling a framework how to pull data from model objects (e.g., instances of Item) and pour that data into widgets (e.g., ImageView and TextView).
The Basic Steps

With that in mind, let's examine what it takes to convert this sample over to using Google's data binding system.

The code samples shown in this section come from the DataBinding/Basic sample project.

Setting Up the Toolchain

Data binding only really works well with up-to-date versions of Android Studio (1.3 or higher) and the Android Gradle Plugin (1.5.0 or higher recommended).

The data binding system consists of two pieces: another plugin for Gradle, and a library that gets bundled with our app. However, we do not need to set those up manually. Instead, we simply tell the Android Gradle Plugin that we want data binding, and it adds the requisite plugin and library for us.

All we need is a small `dataBinding` closure, where we set the `enabled` property to `true`:

```groovy
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit2:converter-gson:2.3.0'
    implementation 'com.android.support:support-fragment:27.1.1'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'
    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
        versionCode 1
        versionName "1.0"
    }
    dataBinding {
        enabled = true
    }
}
```
Once you do this, future times that you open this project in Android Studio may result in you getting a “Source folders generated at incorrect location” message:

![Image](from DataBinding/Basic/app/build.gradle)

This is due to a bug that, in the fullness of time, may get fixed. However, the messages appear to be benign, and they should not cause any problems with your app.

**Augmenting the Layout… and the Model**

The real fun begins with the layout for our ListView row. The original edition of this layout resource was a typical LinearLayout with an ImageView and TextView:

```xml
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">

    <ImageView
        android:id="@+id/icon"
        android:layout_width="@dimen/icon"
        android:layout_height="@dimen/icon"
        android:layout_gravity="center_vertical"
        android:contentDescription="@string/icon"
        android:padding="8dip"/>

    <TextView
        android:id="@+id/title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="20sp"
        android:layout_gravity="left|center_vertical"/>

</LinearLayout>
```

(from [HTTP/Picasso/app/src/main/res/layout/row.xml](http://HTTP/Picasso/app/src/main/res/layout/row.xml))
We need to make some changes to that in order to leverage data binding:

```xml
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android">
  <data>
    <variable
      name="item"
      type="com.commonsware.android.databind.basic.Item"/>
  </data>

  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">
    <ImageView
      android:id="@+id/icon"
      android:layout_width="@dimen/icon"
      android:layout_height="@dimen/icon"
      android:layout_gravity="center_vertical"
      android:contentDescription="@string/icon"
      android:padding="8dip"/>

    <TextView
      android:id="@+id/title"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:layout_gravity="left|center_vertical"
      android:text="@{item.title}"
      android:textSize="20sp"/>
  </LinearLayout>
</layout>
```

(from DataBinding/Basic/app/src/main/res/layout/row.xml)

First, the entire resource file gets wrapped in a `<layout>` element, on which we can place the `android` namespace declaration.

That `<layout>` element then has two children. The second child is our `LinearLayout`, representing the root `View` or `ViewGroup` for the resource. The first child is a `<data>` element, and that is where we configure how data binding should proceed when this layout resource gets used. Specifically, the `<variable>` element indicates that we want to bind data from an `Item` object into widgets defined in this
Then, if you look at the TextView, you will see that it now has an android:text attribute that the original layout resource lacked. More importantly, the value for android:text is unusual: @{item.title}. The @{} syntax indicates that rather than interpreting the value as a plain string, or even a reference to a string resource, that the value is really an expression, in a data binding expression language, that should be computed at runtime to get the value to assign to the text of the TextView.

In this case, the expression is item.value. item is the name given to the Item object in the <variable> element. Any place where we want to pull data from that Item object, we can use dot notation to reference things on the item expression language variable.

item.value means “get the value from the item”. At runtime, the data binding library will attempt to get this value either from a public getter method (getValue()) or a public field (value) on the Item class. The original project had a value field, but it was not public, so the revised project marks the Item fields as public, so we can use them in data binding:

```java
package com.commonsware.android.databind.basic;

public class Item {
    public String title;
    public Owner owner;
    public String link;

    @Override
    public String toString() {
        return(title);
    }
}
```

As we will see in this chapter, the expression language used here is much more complex than simply referencing JavaBean-style properties on objects, but for now, this will suffice.

### Applying the Binding

The layout configures one side of the binding: pulling data into widgets. We still need to do some work to configure the other side of the binding: supplying the
source of that data. In the case of this example, we need to provide the Item object for this layout resource.

That is handled via some modifications to the getView() method of the ItemsAdapter from its original version:

```java
@Override
public View getView(int position, View convertView, ViewGroup parent) {
    RowBinding rowBinding = DataBindingUtil.getBinding(convertView);

    if (rowBinding == null) {
        rowBinding = RowBinding.inflate(getActivity().getLayoutInflater(),
                parent, false);
    }

    Item item = getItem(position);
    ImageView icon = rowBinding.icon;

    rowBinding.setItem(item);

    Picasso.with(getActivity()).load(item.owner.profileImage)
            .fit().centerCrop()
            .placeholder(R.drawable.owner_placeholder)
            .error(R.drawable.owner_error).into(icon);

    return rowBinding.getRoot();
}
```

(from DataBinding/Basic/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java)

There are four changes here: we create the binding, provide the model (Item) to the binding, retrieve other widgets from the binding, and retrieve the root view of the layout.

## Creating the Binding

When we use <layout> in a layout resource and set up the layout side of the data binding system, the build system code-generates a Java class associated with that layout file. The class name is derived from the layout name, where names_like_this get converted into NamesLikeThis and have Binding appended. So, since our layout resource was row.xml, we get RowBinding. This is code-generated into a databinding Java sub-package of the package name from the manifest. Hence, the fully-qualified import statement for this class is:
import com.commonsware.android.databind.basic.databinding.RowBinding;

This is a subclass of ViewDataBinding, supplied by the databinding library that is added to your project by enabling data binding in your build.gradle file.

Creating an instance of the binding also inflates the associated layout. Your binding class has a number of factory methods for inflating the layout and creating the binding. These mirror other methods that you have used elsewhere:

• setContentView(), taking an Activity and the layout resource ID as parameters, inflates the layout, passes the result to setContentView() on the Activity, and creates the binding
• inflate(), with a variety of parameter list options, just inflates the layout using a LayoutInflater, and creates the binding

Here, we use the three-parameter flavor of inflate(), which takes a LayoutInflater (obtained from the hosting activity), the parent container, and false. This mirrors the inflate() one would use on LayoutInflater itself, except that it also gives us our binding.

Of course, this is a ListView, and so we have to deal with the possibility that rows get recycled. The DataBindingUtil class has a getBinding() method that returns the binding for a given root view from the inflated layout — in this case, our convertView. So, we try to get the existing binding first, then fall back to inflating a new one if and only if that is necessary. Since getBinding() properly handles null values for convertView, we do not need to check for null ourselves explicitly.

Pouring the Model into the Binding

The generated binding class will have setters for each <variable> in our <data> element in the layout. Setter names are generated from the variable names using standard JavaBean conventions, so our item variable becomes setItem(). When we call setItem(), the data binding system will use that Item object to populate our TextView, applying the binding expression from our android:text attribute.

Retrieving Widgets from the Binding

However, we did not do anything related to data binding for the ImageView widget in the layout (though we will, later in this chapter). Hence, we still need to manage that manually, getting Picasso to fetch the avatar asynchronously and put it in the ImageView.
However, that implies that we have the ImageView. Normally, we would call findViewById() on the inflated layout's root View to obtain that.

However, our binding class has code-generated public fields on it for each widget in the layout resource that has an android:id value (at least for @id/... and @+id/... values). Our ImageView has an android:id value of @+id/icon, and so the RowBinding class has an icon field that holds our ImageView. We can simply reference it, rather than doing the findViewById() lookup ourselves.

**Getting the Actual View**

Since getView() is supposed to return the inflated layout's root view, we need some way to get that from the binding. Fortunately, ViewDataBinding has a getRoot() method that our generated class inherits, so we can just call that to get the value to return from getView().

**Results**

Visually, this app is the same as before (though this version uses Theme.Material on compatible devices). Functionally, the app is the same as before. And, from a code complexity standpoint, the app is probably worse than before, as we went through a lot of work just to avoid calling findViewById() a couple of times and setText() once.

Hence, while the data binding system is nice, it really only adds value to larger projects, particularly those with complex layouts. By the end of this chapter, you should have a better sense for when data binding is useful and when it is overkill.

**The Extended Layout Resource**

As we saw in the preceding example, much of the knowledge that we impart into our app to power the data binding comes in the form of an extended layout resource syntax. The last child of the root <layout> element is what our layout resources used to hold: the View or ViewGroup at the root of the view hierarchy of this layout. Other children of <layout> configure the data binding behavior (and perhaps other features in the future).

With that in mind, let's explore a bit more about what you can do with elements in the <layout>. 
Imports and Statics

The preceding example lost one feature with respect to the sample app that served as its starting point: handling HTML in titles. While Stack Overflow does not serve HTML tags in question titles, it does serve HTML entities in question titles. A question title of “Foo & Bar” would come to us in the JSON as “Foo &amp; Bar”. The examples in the chapter on Internet access handle that via Html.fromHtml(). However, we do not have that in our data binding.

One way to address this is to add a getter-style method to Item that returns the title after passing through Html.fromHtml(). For example, we could have a getTitleWithEntitiesFixed() or getTitleAfterHavingRunItThroughHtmlFromHtml(). We would then refer to that method in our android:text expression (e.g., @{item.interpretedTitle}).

However, this blurs the line dividing the responsibilities of model objects and the UI layer. The model itself does not care that the title has HTML entities in it, and some ways of using that model data (e.g., displaying in a WebView) might specifically need those HTML entities. The fact that we need to convert those HTML entities is a UI responsibility, because the UI chose to use a TextView, which does not handle those entities automatically.

A fairly easy way to get our Html.fromHtml() logic back in would be to apply it in the layout resource itself. It would be cool if we could have our expression be @{Html.fromHtml(item.title)}, for example.

The good news is: that is eminently possible.

However, if you just used that syntax without other changes, the data binding framework would complain that it does not know what Html is. In effect, we need to teach the layout resource where to import Html from.

To do that, we need to add [import type="android.text.Html"/] into the <data> element of our layout resource. Now, the generated code will contain that import statement and our references to Html will resolve.

You can see that in the DataBinding/Static sample project. This is a clone of DataBinding/Basic with the two changes (expression and <import> applied), giving us the following layout resource:

```xml
<?xml version="1.0" encoding="utf-8"?>
```
If you run this version of the app, and it so happens that there is a Stack Overflow question with an HTML entity in its title among the recent questions, you will see that entity show up properly in the ListView. On the other hand, if you run the previous sample, the HTML entity will show up in HTML source form (e.g., & instead of &).

The rules for imports here are reminiscent of those of regular Java:

- Do not have conflicting imports (e.g., android.view.Menu and
com.myrestaurant.Menu

• Do not try to import classes that are automatically imported (e.g., java.lang.String)

Variables

As we saw in the preceding samples, you can have <variable> elements representing objects that can be referenced by binding expressions.

The type attribute for the <variable> element can be:

• a fully-qualified class name, as seen in the item variable from the examples
• the name of a class that you added via an <import> element
• the name of any class automatically imported into all Java classes (e.g., Integer)

So, for example, instead of:

```xml
<data>
  <variable
    name="item"
    type="com.commonsware.android.databind.basic.Item"/>
</data>
```

we could have:

```xml
<data>
  <import type="com.commonsware.android.databind.basic.Item"/>

  <variable
    name="item"
    type="Item"/>
</data>
```

If you have different versions of the same layout in different resource sets for different configurations (e.g., res/layout/ and res/layout-land/), your <layout> element needs to be compatible between them. This particularly holds true with respect to variables. If you define a variable foo as a String in one version of the resource, you cannot define foo to be a Restaurant in another version of the resource. There is one binding class created for each layout resource, spanning all of the different versions of that resource, and that class cannot have two separate, conflicting definitions for the same variable.
The Binding Expression Language

To a basic approximation, the binding expression language that you can use in layout resources works just like its Java counterpart. If you can include it in a Java expression, you can include it in a binding expression. This not only covers your typical mathematical, logical, and string concatenation operations, but also:

- Casts
- Using parentheses for grouping (e.g., \texttt{@{((Location)(restaurant.location)).latitude}})
- Calling methods, both on objects in the expression and static methods on imported classes
- Accessing fields by name, both on objects and on static classes that you have imported
- Accessing array contents using square-bracket notation, including using other variables as the index (e.g., \texttt{@{movie.actor<index>.fullName}})
- Using the ternary operator for inline if-style branching (e.g., \texttt{@{movie.isNew ? View.VISIBLE : View.GONE}})

Stuff You Won’t Find in Java

The expression language contains a few conveniences that go beyond what you will see in standard Java.

One of these has already been mentioned: JavaBean-style accessor usage. So, \texttt{foo.bar} will try to find a field named \texttt{bar} on the \texttt{foo} object. If that is not found, \texttt{foo.bar} will try to find a \texttt{getBar()} method on the \texttt{foo} object. This allows the model object to decide whether or not to expose the data via a field or getter method; the binding expression works with either.

If you have a variable that is a \texttt{Map}, you can use square-bracket notation to access the map by key, instead of having to call \texttt{get()}. If you try accessing a field or calling a method on \texttt{null}, you normally would get a \texttt{NullPointerException}. The expression evaluator tries to mitigate that:

- If the field or method is designed to return some primitive, the result of accessing the field or calling the method on \texttt{null} returns whatever the default primitive value is (e.g., \texttt{int} and \texttt{long} values are 0)
- Otherwise, if the field or method returns some object, the result of accessing
Another way of working with null values is the `??"null coalescing operator"`. In the expression `foo ?? bar`, the result is:

- `foo`, if `foo` is not null
- `bar`, if `foo` is null

This is useful when you want to replace some optional value with a default when the optional value is null. For example, you might use `sub.expirationDate ?? @string/not_yet_subscribed` to either show the expiration date of some subscription, or pull in the value of a string resource to use if there is no expiration date.

That example demonstrates yet another feature of the expression language: references to resources. In general, you reference them just as you would without the data binding system. So, these are equivalent:

- `android:text="@string/foo"
- `android:text="@{@string/foo}"`

Of course, the power comes in when using those resources in actual expressions, such as using a boolean resource with the ternary operator (e.g., `@{@boolean/i_can_haz_foo ? foo : bar}`).

Note that a few resource types use different names in the binding expressions, as the expression evaluator needs to know the data type. So, for example, you normally reference array resources as simply `@array/name`. In binding expressions, you replace `@array` with a different symbol to indicate the type, such as `@stringArray` or `@intArray`.

**Caveats**

Of course, if all of this were simple, it wouldn’t be Android...

**Handling String Literals**

Numeric literals and null can be used in expressions easily enough. String literals get interesting, as the standard Java "quotation system runs afoul of the default XML "quotation system for attribute values. Your options are:
THE DATA BINDING FRAMEWORK

- Use single quotes for the XML attribute, so you can use double quotes for the string literal (e.g., android:text='@{foo[“bar”]}'}
- Use backticks for the string delimiter instead of double quotes
- Use HTML-style &quot; entities for the string delimiter (e.g., android:text="@{foo[&quot;bar&quot;]}")

Of the three, the latter one is your worst choice, in terms of readability.

Watch Out For Mis-Interpreted Integers

Suppose that you want to have the android:text attribute of a TextView hold a numeric value, pulled from a variable. You might try using something like android:text="@{question.score}", where score is an int.

When you try it, you will crash at runtime, with an error indicating that there is no resource with the ID of some hex value, where that hex value happens to be your score.

That is because android:text supports strings or string resources. The integer value for score will be interpreted as a reference to a string resource, not converted into a string itself.

You then might try android:text="@{question.score.toString()}". That fails to compile, if score is an int, as Java primitives do not support methods, let alone toString().

The right solution is to use static methods on Integer to convert the int into a string: android:text="@{Integer.toString(question.score)}"

Other Caveats

Because this stuff appears in plain XML, you will need to escape any [ or ] signs used in the expressions as &lt; and &gt;, respectively, which is aggravating.

You cannot use the new operator to create objects. However, you are welcome to call methods that happen to create new objects. So, in a pinch, create yourself a factory method somewhere to create the object that you were trying to instantiate via new. All things considered, though, the more object instantiation you do in layout binding, the slower that binding can become, particularly for oft-inflated layouts like rows in a rapidly-scrolling list.
You do not have access to this or super, as these would be with reference to the generated binding class itself.

**Observables and Updating the Binding**

Variables, and the fields or method results that you access on them, can populate View properties, as we have seen so far in this chapter. This is interesting, but it may not “move the needle” for you in terms of adopting data binding. While there may be some minor code maintenance benefit, it hardly seems worth it.

Where data binding really shines, though, is when the variables, and the fields or method results that you access on them, are observable objects (i.e., ones implementing android.databinding.Observable). Then, not only do the expressions update your View properties when the layout resources are inflated, **but also when the data changes**. If you have observable models, simply updating those model objects automatically propagates those changes to any live View objects looking at those models.

For example, suppose that you are writing a to-do sort of checklist. The user can tap a CheckBox widget to indicate that the particular task is completed, and at that point you want to change the rendering of the task overall in its RecyclerView row in addition to updating the model object representing the task. Since the CheckBox is part of that same row, bound to the model for the row, handling both the UI updates and the model updates in the same OnClickListener may be easy. However, what happens if you do not want to update the rendering until the model change has been saved to the database or the network? Now, some arbitrary number of milliseconds after OnClickListener returns, you need to update some row of the RecyclerView... if there happens to be a row pointing at this model object. After all, the user might have scrolled, or even left this RecyclerView entirely, in which case the original row should not be changed.

The obvious tradeoff is defining your model objects to use Observable. The less-obvious tradeoff is in reorganizing your code to have *durable model objects*, where operations like Web service calls update those model objects in place, rather than replace those model objects with brand-new instances. The latter approach breaks data binding in general, but it is a much bigger problem when trying to update your UI from those models.
Observable Primitives

The entire model object itself does not have to be Observable. Whatever your binding expressions use, in terms of data, has to be Observable. That could be individual fields, if you are willing to publish those fields as Observable objects, such as by having them be `public final`.

An easy way to make a field be Observable, if the field is a primitive value (e.g., `int`), is to replace the field with the equivalent Observable... class (e.g., `ObservableInt`):

```java
public final ObservableInt score = new ObservableInt();
```

Your code can use `get()` and `set()` methods on the Observable... primitive wrappers to get and set the primitive value itself. Calling `set()` also notifies all registered observers that the data has changed, and the data binding system uses that to find out that it needs to update your UI.

While this may sound a bit clunky, Java developers have used this pattern in other places. A common example are the Atomic... classes (e.g., `AtomicInteger`), that make modifying a primitive be guaranteed to be atomic, when that value might be get and set on multiple parallel threads.

ObservableField

For non-primitive values, but where the entire value changes in unison, you can use the generic `ObservableField` approach. In particular, a `String` is not a primitive, yet it is immutable, so changing the value means replacing the old `String` object with a new `String` object. `ObservableField` lets you set up observable strings:

```java
public final ObservableField<String> title = new ObservableField<String>();
```

This only works when you are replacing the entire object with a new object. So, for example, wrapping a `Location` in an `ObservableField` only works if you change the location by replacing the `Location`, instead of calling `setLatitude()` and `setLongitude()` on the existing `Location`. Replacing the `Location` outright triggers `ObservableField` to tell observers about the change. In contrast, `ObservableField` has no way to know that you called a method on the wrapped object that changes its state in a way that observers need to know about.
ObservableArrayList and ObservableArrayMap

The data binding system ships with two Observable classes that are collections.

One, ObservableArrayList, is fairly straightforward: it lets you add and remove members of the list, and it informs observers about those changes. Once again, it has no means of knowing if you change the state of a given list member, only if you change the state of the list itself.

The other is ObservableArrayMap. Android added the ArrayMap class in API Level 19. Functionally, ArrayMap works like a HashMap, as a collection of values accessed via keys, albeit with some additional APIs for working with the contents by numerical index, as you see with ArrayList. The implementation, though, trades off CPU time for memory efficiency. ObservableArrayMap adds Observable characteristics, such that changes to the contents of the ArrayMap are reported to observers.

Custom Observables

You can create your own class implementing the Observable interface. Most likely, you would do that by extending BaseObservable.

On the one hand, this does not have to be too complicated. For example, here is the implementation of ObservableBoolean from the data binding support library:

```java
package android.databinding;
import android.os.Parcel;
import android.os.Parcelable;
import java.io.Serializable;
/**
 * An observable class that holds a primitive boolean.
 *<p>
 * Observable field classes may be used instead of creating an Observable object:
 *<p>
 * <code>public class MyDataObject {
 *    public final ObservableBoolean isAdult = new ObservableBoolean();
 */
```
Fields of this type should be declared final because bindings only detect changes in the field's value, not of the field itself.

This class is parcelable and serializable but callbacks are ignored when the object is parcelled / serialized. Unless you add custom callbacks, this will not be an issue because data binding framework always re-registers callbacks when the view is bound.

```java
public class ObservableBoolean extends BaseObservable implements Parcelable, Serializable {
    static final long serialVersionUID = 1L;
    private boolean mValue;

    /**
     * Creates an ObservableBoolean with the given initial value.
     *
     * @param value the initial value for the ObservableBoolean
     */
    public ObservableBoolean(boolean value) {
        mValue = value;
    }

    /**
     * Creates an ObservableBoolean with the initial value of <code>false</code>.
     */
    public ObservableBoolean() {
    }

    /**
     * @return the stored value.
     */
    public boolean get() {
        return mValue;
    }

    /**
     * Set the stored value.
     */
    public void set(boolean value) {
        if (value != mValue) {
            mValue = value;
            notifyChange();
        }
    }

    @Override
    public int describeContents() {
        return 0;
    }

    @Override
    public void writeToParcel(Parcel dest, int flags) {
        dest.writeInt(mValue ? 1 : 0);
    }

    public static final Parcelable.Creator<ObservableBoolean> CREATOR =
            new Parcelable.Creator<ObservableBoolean>() {
                @Override
                public ObservableBoolean createFromParcel(Parcel source) {
                    return new ObservableBoolean(source.readInt() == 1);
                }

                @Override
                public ObservableBoolean[] newArray(int size) {
                    return new ObservableBoolean[size];
                }
            };
}
```
A lot of that code is dealing with making `ObservableBoolean` be `Parcelable`. The key, from the standpoint of `BaseObservable`, is the call to `notifyChange()` in the `set()` method. This tells `BaseObservable` to tell all observers that stuff inside this `Observable` changed, and if they are tied to this `Observable`, they should go do something. Usually, “do something” will be to re-evaluate a binding expression and update a property of a `View`, such as updating the text of a `TextView` where a binding expression was used in the `android:text` attribute.

However, creating more complex custom observables is not especially well documented, and so we will explore that more later in this chapter.

**An Observable Example**

With all that behind us, let's look at another rendition of the Stack Overflow sample.

There are lots of values that are published for questions via the Stack Exchange API, beyond the ones used so far. One is the score, representing the net of upvotes and downvotes on the question. Of the question properties that we had been using before, only the title has a chance of changing in real time, and that does not happen very often. On the other hand, scores are far more likely to change on the fly.

So, the `DataBinding/Scored` sample project starts from the `DataBinding/Static` project and adds in support for the score property. It also makes the title and score observable and adds a refresh action bar item. Tapping that item will update the data for the questions loaded in the app; any changes to titles or scores will be reflected directly, without additional code, by updating the models.

Of course, this sample app was not written with data binding in mind. While the previous two samples added on bits of data binding without significantly changing the app, this time we will have to take a chainsaw to our code to get what we want.

**The Limitations of Earlier Examples**

The specific problem we have to work around is the nature of our data model.

The previous versions of this sample would request the model objects via Retrofit and then slap them into an adapter to show in the `ListView`. From that point onward, the models were static — no code existed to add new questions, modify existing questions, etc.

However, Retrofit is designed to create new model objects on every call to a Web
service interface. So, if we call once to get the latest questions, and then make another call to get updated versions of those questions, we wind up with two separate collections of model objects.

If we were not trying to use data binding, we could take a “caveman” approach: just replace the contents of the adapter with the new model collection. This would work, albeit with some impacts on the user experience (e.g., perhaps scrolling the list back to the top).

However, with data binding, we are effectively tying our original data model objects to our views more tightly. This means that when we get a new set of model objects from Retrofit, we cannot use them directly. Instead, we have to use them as a source of data, to be poured into our original model objects. Through the Observable mechanism, we can update the original models and not worry about the ListView rows, as data binding will take care of that for us. But this does mean that we need to have one “magic” set of model objects that represent the bound data, distinct from any model objects representing updates to that data.

**Questions vs. Items**

We could address the above problem by giving Item the ability to update its state from another Item. Our original query to get the most recent questions would create a collection of Item objects that would be our “durable” model, the one that we bind our UI to. Later updates that create new Item objects would be used solely to update the original durable Item objects’ contents, not replace those objects.

But now we run into another problem: the Observable requirements of the data binding system may run counter to requirements imposed elsewhere.

In the case of this sample, Item is being populated by Gson, after Retrofit receives the JSON response from the server. Gson does not know anything about ObservableField, ObservableInt, or any such things. There are two main approaches for dealing with this problem:

1. Use Gson’s system of type adapters to try to teach Gson how to take JSON properties and update corresponding ObservableField, ObservableInt, etc. fields in the model. Most likely, this is the right direction for long-term use, though it is conceivable that something about Gson has irreconcilable differences with something about observable elements.
2. Have separate “model” objects. One represents the result of the Web service call (and gets populated by Gson), while the other represents the durable
model (and has observable properties).

This revised edition of the sample takes the second approach. There is a new model class, Question, which models a Stack Overflow question. Our data binding will be applied to Question. Item is still there, but it represents the response from the Stack Exchange Web service call.

**Keeping Score (and the ID)**

Beyond dealing with the duality of Question and Item, we have two more JSON properties from the Web service response that we need to track. One is the score, as mentioned earlier. The other is the question_id, a unique ID for the question. We need this in order to be able to update an existing Question with data from a new Item, when we retrieve updates for our models.

The easy part is getting the new data from Retrofit and Gson. We just need to add two more fields to Item, for the score and question ID:

```java
package com.commonsware.android.databind.basic;

import com.google.gson.annotations.SerializedName;

public class Item {
    String title;
    Owner owner;
    String link;
    int score;
    @SerializedName("question_id") String id;
}
```

(from DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/Item.java)

In the case of the question ID, the JSON property is question_id. In Java, we will use id instead, using Gson's @SerializedName annotation to teach Gson to fill question_id properties into the id field.

We now also have a Question class that will be our observable, durable data model:

```java
package com.commonsware.android.databind.basic;

import android.databinding.ObservableField;
import android.databinding.ObservableInt;

public class Question {
```

2156
It holds the same five values as does Item, except that title and score are now Observable, via ObservableField and ObservableInt, respectively. The owner, link, and id values should be immutable, and we are not binding on them anyway, so keeping them as ordinary fields is fine.

Question has a constructor and an updateFromItem() method that both copy data from a Item into the Question. updateFromItem() handles the two Observable fields, and we will use this when we eventually fetch updates to the question. The constructor calls updateFromItem() plus populates the three final non-observable fields.

QuestionsFragment now has a more apropos name, as we will have it show the list of Question objects. Among other things, this requires changes to QuestionsAdapter, to work off of Question objects instead of Item objects:

class QuestionsAdapter extends ArrayAdapter<Question> {
    QuestionsAdapter(List<Question> items) {
        super(getActivity(), R.layout.row, R.id.title, items);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        RowBinding rowBinding =
            DataBindingUtil.getBinding(convertView);
        }
    }
}
if (rowBinding==null) {
    rowBinding =
    RowBinding.inflate(getActivity().getLayoutInflater(),
    parent, false);
}

Question question=getItem(position);
ImageView icon=rowBinding.icon;

rowBinding.setQuestion(question);

Picasso.with(getActivity()).load(question.owner.profileImage)
    .fit().centerCrop()
    .placeholder(R.drawable.owner_placeholder)
    .error(R.drawable.owner_error).into(icon);

return(rowBinding.getRoot());
}

(from DataBinding/Scored/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java)

Similarly, the <variable> in row.xml needs to be a Question now:

```xml
<layout xmlns:android="http://schemas.android.com/apk/res/android">
    <data>
        <import type="android.text.Html"/>
        <variable
            name="question"
            type="com.commonsware.android.databind.basic.Question"/>
    </data>
    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal">
        <ImageView
            android:id="@+id/icon"
            android:layout_width="@dimen/icon"
            android:layout_height="@dimen/icon"
            android:layout_gravity="center_vertical"
            android:contentDescription="@string/icon"/>
    </LinearLayout>
</layout>
```
The Data Binding Framework

You will note that the binding expression for the score TextView is @{Integer.toString(question.score)}. That is because the score field on Question is an int, and by default, the data binding system will think that is a reference to a string resource. We have to convert the score into a String to get the results that we want. We will see this more later in this chapter.

Refreshing the Data

Of course, having a QuestionsAdapter that adapts Question object only works if we have Question objects.

QuestionsFragment now holds onto two collections of Question objects: an ArrayList in the order that we get them from the Web service API, and a HashMap to find a Question object given its ID:

```java
private ArrayList<Question> questions = new ArrayList<Question>();
private HashMap<String, Question> questionMap =
```
Our call to the questions() method on our StackOverflowInterface still returns a collection of Item objects. In onCreateView(), where we call questions(), we arrange to use those Item objects to create the corresponding group of Question objects:

```java
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup container, Bundle savedInstanceState) {
    View result = super.onCreateView(inflater, container, savedInstanceState);

    so.questions("android").enqueue(new Callback<SOQuestions>() {
        @Override
        public void onResponse(Call<SOQuestions> call, Response<SOQuestions> response) {
            for (Item item : response.body().items) {
                Question question = new Question(item);
                questions.add(question);
                questionMap.put(question.id, question);
            }
            setListAdapter(new QuestionsAdapter(questions));
        }
    });
    return result;
}
```
That is sufficient to get our app to run again, showing the scores along with the question titles and asker avatars:

![Figure 671: Stack Overflow Questions with Scores](image)

However, we wanted to allow the user to refresh the data for these questions, so we can see a score being updated in real time via the data binding system. That requires a different call to the Stack Exchange API. It is still `/2.1/questions`, but now we have an additional path segment, one that takes a semi-colon-delimited list of question IDs. So, we add a new `@GET` method to `StackOverflowInterface` for this:

```java
package com.commonsware.android.databind.basic;

import retrofit2.Call;
import retrofit2.http.GET;
import retrofit2.http.Path;
import retrofit2.http.Query;

public interface StackOverflowInterface {
  @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
  Call<SOQuestions> questions(@Query("tagged") String tags);

  @GET("/2.1/questions/{ids}?site=stackoverflow")
  Call<SOQuestions> update(@Path("ids") String tags);
}
```
Note the use of @Path("ids") on the first parameter, corresponding to the {ids} placeholder in the path expressed in the @GET annotation. @Path("ids") says “the following parameter can be injected as a path segment into the URL”, and {ids} indicates specifically where that parameter’s value should go. Note, though, that it is a String, not a String array or ArrayList of strings. That is because we do not have a way to teach Retrofit how to concatenate a collection of strings into a single path segment.

In addition, this sample now has a menu resource directory, with an actions.xml resource in it, defining a single “refresh” menu item. The QuestionsFragment opts into participating in the action bar and, in onCreateOptionsMenu(), applies the actions menu resource. In onOptionsItemSelected(), if the user chose our refresh menu item, we call a private updateQuestions() method. This method needs to use the new update() method on StackOverflowInterface to update our collection of questions:

```java
private void updateQuestions() {
    ArrayList<String> idList = new ArrayList<String>();

    for (Question question : questions) {
        idList.add(question.id);
    }

    String ids =TextUtils.join(";", idList);

    SOQuestionsHolder.enqueue(new Callback<SOQuestions>() {
        @Override
        public void onResponse(Call<SOQuestions> call, Response<SOQuestions> response) {
            for (Item item : response.body().items) {
                Question question = questionMap.get(item.id);

                if (question != null) {
                    question.updateFromItem(item);
                }
            }
        }

        @Override
        public void onFailure(Call<SOQuestions> call, Throwable t) {
            onError(t);
        }
    });
}
We collect all of the question IDs, then use `TextUtils.join()` to give us a single string with all the question IDs concatenated with semicolons. That, in turn, is passed to `update()`. For each returned Item, we find the corresponding Question in the HashMap and update it with the new data from the Item.

What we do not do is touch our UI.

However, if you run the app, choose a good question out of the list of questions, upvote the question, and refresh the list, you will see the new score appear immediately after the refresh. The data binding system handled that for us, without additional manual intervention on our part.

**Two-Way Binding**

So far, the focus has been on getting data from models into views. That is the most common scenario, as usually a subset of views accept user input, and plenty of user interfaces are read-only.

Plus, the original version of the data binding system only handled populating views from models.

But, in 2016, the data binding system was updated with “two-way binding”, where views can populate models, in addition to having models populate views. While this feature is presently undocumented, we have some limited information on how to make it work.

The change to the layout resources is very simple: use `@=` instead of `@`:

```xml
android:checked="@={question.expanded}".
```

This configures the attribute (the checked state of a CompoundButton) with the initial value of the expanded property on a question variable. It also updates the property if the user checks or unchecks the CompoundButton.

To make this work, you cannot use a simple public field for the property. It needs to either have a setter method (e.g., `setExpanded()`) or be a public Observable field.

For example, the `DataBinding/TwoWay` sample project is a clone of the DataBinding/
The Data Binding Framework

Scored sample project from earlier in this chapter. However, now the Question will track some local state, information not obtained from the Stack Exchange API. Specifically, it will track a boolean value named expanded:

```java
package com.commonsware.android.databind.basic;

import android.databinding.ObservableBoolean;
import android.databinding.ObservableField;
import android.databinding.ObservableInt;

public class Question {
    public final ObservableField<String> title = new ObservableField<>();
    public final Owner owner;
    public final String link;
    public final ObservableInt score = new ObservableInt();
    public final String id;
    public ObservableBoolean expanded = new ObservableBoolean(true);

    Question(Item item) {
        updateFromItem(item);
        owner = item.owner;
        link = item.link;
        id = item.id;
    }

    void updateFromItem(Item item) {
        title.set(item.title);
        score.set(item.score);
    }
}
```

(from DataBinding/TwoWay/app/src/main/java/com/commonsware/android/databind/basic/Question.java)

Our row layout resource now has a Switch widget, bound to the expanded property using the @= syntax shown above:

```xml
<?xml version="1.0" encoding="utf-8"?>
<layout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">
    <import type="android.text.Html" />
    <variable
        name="question"
        type="com.commonsware.android.databind.basic.Question" />
</layout>
```
THE DATA BINDING FRAMEWORK

```
<variable
    name="controller"
    type="com.commonsware.android.databind.basic.QuestionController" />
</data>

    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    cardview:cardCornerRadius="4dp">
    <LinearLayout
        android:id="@+id/row_content"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:background="?android:attr/selectableItemBackground"
        android:gravity="center_vertical"
        android:onClick="@{()->controller.showQuestion(question)}"
        android:onTouch="@{(v,event)->controller.onTouch(v,event)}"
        android:orientation="horizontal">
        <Switch
            android:id="@+id/expanded"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:checked="@={question.expanded}"
        />
        <ImageView
            android:id="@+id/icon"
            android:layout_width="@dimen/icon"
            android:layout_height="@dimen/icon"
            android:layout_gravity="center_vertical"
            android:contentDescription="@string/icon"
            android:padding="8dip"
            app:error="@{@drawable/owner_error}"
            app:imageUrl="@{question.owner.profileImage}"
            app:placeholder="@{@drawable/owner_placeholder}" />
        <TextView
            android:id="@+id/title"
            android:layout_width="0dp"
            android:layout_height="wrap_content"
            android:layout_gravity="left|center_vertical"
            android:layout_weight="1"
            android:text="@{Html.fromHtml(question.title)}"
            android:textSize="20sp" />
        <TextView
            android:id="@+id/score"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_gravity="center_vertical"
            android:layout_marginLeft="8dp"
            android:layout_marginRight="8dp"
            android:text="@{Integer.toString(question.score)}"
            android:textSize="40sp"
            android:textStyle="bold" />
    </LinearLayout>
</android.support.v7.widget.CardView>
```
If you run the sample project, all of the switches will be checked at the outset, as we are defaulting expanded to true. If you uncheck some of them, and scroll around, you will see that the checked/unchecked state is handled properly, even though rows are being recycled along the way. And we did not have to add any Java code, other than the new property — in particular, neither our ViewHolder nor our Adapter need to worry about the Switch.

Other Features of Note

There are a number of other “bells and whistles” that you can utilize in the data binding system.

Obtaining Views via the Binding Class

The sample apps have been retrieving the ImageView widget for the row from the RowBinding. Any View in the layout file that has an android:id value will have a corresponding field in the ...Binding generated class. So, for cases like the Picasso scenario, where we cannot use data binding to populate the ImageView and have to resort to classic bind-it-in-the-adapter logic, we do not have to do the findViewById() call ourselves. Instead, we just access the field in the binding class.

Manipulating Variables in the Binding

We have seen using a setter method to bind an object to a layout via the generated binding class. In the sample apps, we have been calling setItem() or setQuestion() to provide the model object to use in binding expressions. If needed, though, there is also a corresponding getter method (getItem(), getQuestion()) to retrieve the last-set value.

Views, Setters, and Binding

We have seen the use of android:text with a binding expression, to set the text for a TextView.

What really is going on is:

- The binding system evaluates the expression. This not only gives us the value
to be bound, but also determines the data type of that value (e.g., String, int).

- The data binding system looks for a setter named set...(), where the ... part is based on the name of the attribute (minus any namespace), where the data type matches the data type of the expression result. So, in the case where the binding expression generates a String for an android:text attribute, the data binding system will look for setText(String) on the widget, in our case a TextView. If the binding expression were to return an int, instead, the data binding system would look for setText(int). In the case of TextView, that exists, and it is expecting the int to be a string resource. That is why, in the Scored sample app, we needed to convert the int to a String.

Of course, this is just the simple scenario.

**Synthetic Properties**

The data binding system maps attribute names to setters. But, what happens if you use an attribute name that does not actually exist?

Like the honey badger, the data binding system don’t care.

All the data binding system is doing is using the attribute name to try to find an associated setter method. The fact that the attribute name is not actually part of the LayoutInflater-supported XML structure is irrelevant.

This means that you can use *any* attribute that maps to a setter method.

For example, ViewPager has no XML attributes of its own, beyond those it inherits from View or ViewGroup. But, you are welcome to use attributes like app:currentItem or app:pageMargin in your data binding-enhanced layout resources (where app points to a custom namespace of yours). LayoutInflater will parse them, but ViewPager will ignore them. However, the data binding system will happily let you bind values to them, triggering calls to setCurrentItem() and setPageMargin(), respectively.

Hence, do not feel that you are limited to only those attributes that are officially supported by LayoutInflater and the widgets. If the data binding system can find a setter, you can use it.

However, there is one key limitation with these synthetic properties: the value has to
be a binding expression. That is true even if you are not really evaluating much of an expression.

For example, this will not work:

```xml
<ImageView
    android:id="@+id/icon"
    android:layout_width="@dimen/icon"
    android:layout_height="@dimen/icon"
    android:layout_gravity="center_vertical"
    android:contentDescription="@string/icon"
    android:padding="8dip"
    app:error="@drawable/owner_error"
    app:imageUrl="@{question.owner.profileImage}"
    app:placeholder="@drawable/owner_placeholder" />
```

Here, we have three synthetic properties, `app:error`, `app:imageUrl`, and `app:placeholder`. Only `app:imageUrl` is using a binding expression, and its use of one makes sense, as we are pulling in data from a variable (`question`). The other two refer to drawables. Ideally, this would work. In practice, it does not work, as the binding system ignores the properties, and then Android complains that the attribute is not recognized.

This, however, works:

```xml
<ImageView
    android:id="@+id/icon"
    android:layout_width="@dimen/icon"
    android:layout_height="@dimen/icon"
    android:layout_gravity="center_vertical"
    android:contentDescription="@string/icon"
    android:padding="8dip"
    app:error="@{@drawable/owner_error}"
    app:imageUrl="@{question.owner.profileImage}"
    app:placeholder="@{@drawable/owner_placeholder}" />
```

Now, `app:error` and `app:placeholder` use binding expressions... that happen to just return a drawable resource reference. This works, if one of two things are true:

1. There are setter methods for those properties (e.g., `setError()`) on `ImageView`, which in this case, there isn't, or
2. We use other techniques to tell the data binding system that those attributes get routed elsewhere, as will be seen in the next two sections.
Using Different Methods

Of course, finding a setter may be a challenge. Frequently, the attribute name and the setter name follow the described convention (android:foo maps to setFoo()). Every now and then, though, the attribute name and setter name differ.

For example, View has an android:fadeScrollbars attribute, used to determine whether or not the scrollbars for a scrollable widget should automatically fade out after a stable period when the widget is not scrolling. However, the associated setter method is not setFadeScrollbars(), but instead setScrollbarFadingEnabled(). By default, in theory, the data binding system will not find the appropriate setter for android:fadeScrollbars.

In practice, the documentation suggests that Google has already fixed up all of the standard attributes from Android framework classes. However, there may still be gaps, particularly in Android Support-supplied classes, let alone third-party widgets.

To overcome the mis-matched attribute/setter pair, you can teach the data binding system how to find the setter for the attribute. To do this, you are supposed to be able to define a class-level @BindingMethods annotation, containing one or more @BindingMethod annotations, which in turn map an attribute on a type to a setter method name:

```java
@BindingMethods({
   @BindingMethod(type = "android.view.View",
      attribute = "android:fadeScrollbars",
      method = "setScrollbarFadingEnabled"),
})
```

BindingAdapters, and the Picasso Scenario

Sometimes, even that is insufficient. Perhaps the setter method takes additional parameters, even though in your case they could be simply hard-coded or pulled from elsewhere in the widget. Perhaps the “setter method” is not really setting a property, but arranging to do some work related to the property.

For example, so far, we have not been able to use data binding with the ImageView. While the URL to the image is related to the android:src attribute, android:src does not take a URL, and we want to use Picasso to retrieve the image asynchronously anyway. Hence, we have been stuck with configuring the ImageView “the old-fashioned way” in getView(), by retrieving the ImageView and then telling
The Data Binding Framework

Picasso how to populate it.

However, the data binding system can handle this too, by defining a custom @BindingAdapter.

Let’s take a look at the DataBinding/Picasso sample project. This starts with the Scored sample from before, but now uses the data binding system to update the ImageView.

The ImageView XML from a little bit ago appears in our revised row.xml layout resource:

```xml
<?xml version="1.0" encoding="utf-8"?>
<layout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">
    <data>
        <import type="android.text.Html"/>
        <variable
            name="question"
            type="com.commonsware.android.databind.basic.Question"/>
    </data>
    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal">
        <ImageView
            android:id="@+id/icon"
            android:layout_width="@dimen/icon"
            android:layout_height="@dimen/icon"
            android:layout_gravity="center_vertical"
            android:contentDescription="@string/icon"
            android:padding="8dp"
            app:error="@{@drawable/owner_error}"
            app:imageUrl="@{question.owner.profileImage}"
            app:placeholder="@{@drawable/owner_placeholder}"/>
        <TextView
            android:id="@+id/title"
            android:layout_width="0dp"
            android:layout_height="wrap_content"/>
    </LinearLayout>
</layout>
```
Here, we have three synthetic properties: attributes that are not really part of ImageView, but that we are using with the help of the data binding system.

To make that work, the data binding system has to know what to do with those three values. ImageView lacks setters for those, and so in the absence of anything else, the data binding system will trigger a compilation error, complaining that it does not know what to do with the values we have in the layout.

To make this work, we need a static method somewhere, with the @BindingAdapter annotation. In this case, we have it defined on QuestionsFragment:

```java
@BindingAdapter({"app:imageUrl", "app:placeholder", "app:error"})
public static void bindImageView(ImageView iv,
        String url,
        Drawable placeholder,
        Drawable error) {
    Picasso.with(iv.getContext())
        .load(url)
        .fit()
        .centerCrop()
        .placeholder(placeholder)
        .error(error)
        .into(iv);
}
```
The method name does not matter, so call it whatever will help remind you of its role. It needs to return void, and take as parameters:

- the View type that the synthetic properties will appear on (in this case, ImageView)
- the values of those properties, in the order that they appear in the list of strings in the @BindingAdapter annotation

In our case, app:placeholder and app:errorMessage are resolving to Drawable resources, while app:imageUrl is resolving to a String.

This declaration teaches the data binding framework to call this method any time it finds a View of the designated type (ImageView) with the list of synthetic properties, instead of trying to find setter methods for those properties. Since the <ImageView> element in our layout file meets those criteria, the bindImageView() method will be called.

In that method, it is our job to do whatever it is that we need to do to consume those synthetic property values and apply their results to the supplied View. In this case, we have the snippet of Picasso code formerly found in the getView() method. However, before, the values of the drawables (placeholder and error) were hard-coded in Java. Now, they are in the layout XML file, which is a bit more flexible, particularly if we are using different layout resources for different configurations.

This means we can junk the last of the manual binding code from getView(), leaving behind only the connection from our ArrayAdapter to the RowBinding:

```java
class QuestionsAdapter extends ArrayAdapter<Question> {
    QuestionsAdapter(List<Question> items) {
        super(getActivity(), R.layout.row, R.id.title, items);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        RowBinding rowBinding;
        DataBindingUtil.getBinding(convertView);

        if (rowBinding == null) {
            rowBinding =
            RowBinding.inflate(getActivity().getLayoutInflater(),
            parent, false);
        }
```
Note, though, that to make this sample work, we needed to make one other change. `app:imageUrl` refers to the `profileImage` field on the `Owner` class. Formerly, that was package-private, which means that the data binding generated code could not access it. Instead, we had to make it public:

```java
package com.commonsware.android.databind/basic;

import com.google.gson.annotations.SerializedName;

public class Owner {
  public @SerializedName("profile_image") String profileImage;
}
```

As an additional feature, a binding adapter can receive not only the new values for the properties, but the old ones as well (i.e., what had been used for a previous binding). To make that work, you double up all of the parameters, other than the View itself. First come the parameters that will be the old values, then come the parameters that will be the new values. If we wanted to use that in the sample shown in this section, we would have needed seven total parameters:

```java
@BindingAdapter({"app:imageUrl", "app:placeholder", "app:error"})
public static void bindImageView(ImageView iv,
  String oldUrl,
  Drawable oldPlaceholder,
  Drawable oldError,
  String newUrl,
  Drawable newPlaceholder,
  Drawable newError) {
  // do good stuff here
}
```

For another example, the chapter on advanced keyboard and mouse support demonstrates a BindingAdapter to add a focusMode option to layouts, for a more flexible alternative to the `[requestFocus/]` XML element for controlling the widget
that gets the focus.

**Two-Way Binding and InverseBindingAdapter**

Two-way binding works well in cases where the way you store the data in the models lines up well with the getters and setters of the associated widget. In the two-way binding example presented earlier, a boolean field in the model works well with the checked property of a CompoundButton like a Switch, as CompoundButton has an `isChecked()` method returning a boolean and a `setChecked()` accepting a boolean.

A BindingAdapter allows you to create other mappings between data types and properties, but only for the classic model->view binding. To accomplish the same thing in the reverse direction, you wind up creating an InverseBindingAdapter. As the name suggests, this serves the same basic role as a BindingAdapter, but in the inverse direction, taking data from the widget and preparing it for the model using custom code. Here, the “preparing it for the model” means converting it into a suitable data type for a setter, Observable field, etc. for your model.

This is fairly unusual.

The example used in some places is “what if I want to tie a float to an EditText?”. The InverseBindingAdapter would look something like this:

```java
@InverseBindingAdapter(attribute = "android:text")
public static float getFloat(EditText et) {
    try {
        return Float.parseFloat(et.getText().toString());
    } catch (NumberFormatException e) {
        return 0.0f; // because, um, what else can we do?
    }
}
```

The problem is if the user types in something that is not a valid floating-point number, like snicklefritz. `parseFloat()` will fail with a `NumberFormatException`. You *should* let the user know that their data entry was invalid. However, two-way data binding does not support this, with a default value (e.g., `0.0f`) being handed to the model instead.

**Event Handling**

So far, we have focused on binding expressions returning data that populates
widgets, specifically by configuring how that widget looks.

But what about configuring how that widget *behaves*?

Whether this is a good idea is up for debate. On the one hand, it reduces the amount of boilerplate Java code necessary to wire up widgets. On the other hand, some might worry about a blurring of the lines separating views from things like controllers or presenters.

A 2016 update to the data binding system made it easier to set up these sorts of connections, though at the present time, this feature is undocumented.

**Thinking Back to android:onClick**

In the beginning, there was android:onClick, and it was good.

You could add the android:onClick attribute to a view in your layout resource XML, with a value of a method name in the activity that used the layout. That method needed to be public, return void, and take a View as a parameter — the same basic method signature as onClick() of an OnClickListener. When the user clicked the view, the method named in android:onClick would be called, without having to call setOnClickListener() in Java with an OnClickListener implementation.

Over time, android:onClick faded in utility, as other things, such as fragments, started being where we wanted the click events to go. android:onClick could only call a method on the hosting activity, not a method on an arbitrary other class. No other attributes were created for other event handlers (long-click, touch, etc.), suggesting that this was a one-off experiment that would fade into oblivion.

And it did fade... until 2016, when the data binding system brought back the concept.

**Tying Events to Methods Directly**

For most events that you will care about with views, you can use a data binding expression to identify a method, on one of your variables, that will be called when the event is raised. Because this ties back to your variables, the method can be on any object that you inject into the binding, not just the activity.

It does make the syntax a bit more verbose. Instead of android:onClick="doSomething", it becomes
android:onClick="@{controller::doSomething}"}, where controller is some object that you want to respond to the event (e.g., an MVC-style controller, an MVP-style presenter).

The methods referenced this way must have the same basic signature as the corresponding listener methods, just implemented on a custom class and with a custom name. So, for example, onLongClick() of an OnLongClickListener needs to return a boolean, indicating whether the event is consumed. If you use android:onLongClick to route that event to some custom method, that method must also return a boolean. Overall:

- The method must be public
- The method must take the same parameters as does the corresponding method on the regular listener class for this event
- The method must have the same return type as does the corresponding method on the regular listener class for this event

**Tying Events to Methods via Lambda Expressions**

Those restrictions on the methods tied in via data binding expressions can be a pain. In particular, you have no way of passing additional information from bound variables into the method, since those would not be part of the standard event handling method parameters.

However, the data binding system has another option for tying in event handlers: Java 8-style lambda expressions. So, you can have android:onClick="@{() -> controller::doSomething(thing)}", where thing is some variable in your layout resource, or a view (based on its android:id value), or the magic name context to provide a Context. It could also involve expressions using any of those as part of calculations (e.g., concatenating two strings).

You can also blend in parameters that are normally available to the event, such as android:onClick="@{(v) -> controller::doSomething(v, thing)}".

However, the argument list in the lambda function (the left-hand set of parentheses) either needs to be:

- empty, or
- have one entry for every parameter to the event handling method, even if you do not want all of those objects
The Data Binding Framework

For example, the onCheckedChanged() method on OnCheckedChangeListener for a CompoundButton takes two parameters: the View whose state changed, and a boolean indicating the new state. You cannot have android:onCheckedChanged="@{(state)->controller::heyNow(state, thing)}" or android:onCheckedChanged="@{(view)->controller::heyNow(view, thing)}".

Instead, if you want either of those, you need to declare both, then just ignore the one that you do not need, such as android:onCheckedChanged="@{(v, state)->controller::heyNow(state, thing)}".

Also, the method that you call still has to be public and still has to return the proper return type based on the event (e.g., void for onClick, boolean for onLongClick()).

With that in mind, the DataBinding/RecyclerView sample project demonstrates how this can work, along with how to use the data binding system to populate a RecyclerView instead of an AdapterView.

Converting to a RecyclerView/CardView UI

First, independent of data binding, we need to migrate the app over to use RecyclerView. Along the way, we can also add in support for CardView, to make the individual elements of the vertically-scrolling list look like cards, complete with rounded corners, drop shadows, and the like.

To that end, we add recyclerview-v7 and cardview-v7 to our roster of dependencies in build.gradle:

```groovy
dependencies {
    implementation 'org.greenrobot:eventbus:3.1.1'
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit2:converter-gson:2.3.0'
    implementation 'com.android.support:recyclerview-v7:27.1.1'
    implementation 'com.android.support:cardview-v7:27.1.1'
    implementation 'com.android.support:support-v4:27.1.1'
}
```

Our previous samples had used ListFragment. We do not have a RecyclerViewFragment given to us by the recyclerview-v7 library. But, we can have our own, copied from one of the RecyclerView sample projects:

```java
package com.commonsware.android.databind.basic;
```

2177
All this does is manage a RecyclerView on our behalf, including allowing us to manipulate the adapter and the layout manager.

The revised QuestionsFragment now inherits from that RecyclerViewFragment. We configure the RecyclerView in onViewCreated(), mostly just using the code from before, except that we also need to call setLayoutManager() to indicate how we want the items to be laid out — in this case, opting for a vertically-scrolling list:
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    setLayoutManager(new LinearLayoutManager(getActivity()));

    so.questions("android").enqueue(new Callback<SOQuestions>() {
        @Override
        public void onResponse(Call<SOQuestions> call, Response<SOQuestions> response) {
            for (Item item : response.body().items) {
                Question question = new Question(item);

                questions.add(question);
                questionMap.put(question.id, question);
            }

            setAdapter(new QuestionsAdapter(questions));
        }

        @Override
        public void onFailure(Call<SOQuestions> call, Throwable t) {
            onError(t);
        }
    });
}

(from DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java)

Our QuestionsAdapter also has to change, to be a RecyclerView.Adapter, instead of an ArrayAdapter:

class QuestionsAdapter
    extends RecyclerView.Adapter<QuestionController> {
    private final ArrayList<Question> questions;

    QuestionsAdapter(ArrayList<Question> questions) {
        this.questions = questions;
    }

    @Override
    public QuestionController onCreateViewHolder(ViewGroup parent, int viewType) {
        RowBinding rowBinding =
            RowBinding.inflate(getActivity().getLayoutInflater(),
            parent, false);

        return(new QuestionController(rowBinding));
    }

    @Override
We take in the roster of questions in the constructor and stash that for later use. `getItemCount()` and `getItem()` simply access that roster of questions. Data binding takes places in `onCreateViewHolder()`, where we create the `RowBinding` and use that to set up a `QuestionController`. `QuestionController` is a subclass of `RecyclerView.ViewHolder` and serves as the local controller for the row in our list — we will look at `QuestionController` in greater detail shortly. `onBindViewHolder()` simply tells the `QuestionController` to bind to the supplied `Question` model object.

`RecyclerView.ViewHolder` requires the root `View` for the row be supplied to its constructor. So, in the `QuestionController` constructor, we call `getRoot()` to get that `View` from the `RowBinding` and supply that, along with stashing the `RowBinding` in a field:

```java
private final RowBinding rowBinding;

public QuestionController(RowBinding rowBinding) {
    super(rowBinding.getRoot());

    this.rowBinding = rowBinding;
}
```

And, in `bindModel()`, we use the `RowBinding` to bind our `Question`, so the binding expressions will pull the title, score, and so forth into our views:
The Data Binding Framework

```java
void bindModel(Question question) {
    rowBinding.setQuestion(question);
    rowBinding.setController(this);
    rowBinding.executePendingBindings();
}
```

(from DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionController.java)

In a 2016 Google I/O presentation on data binding, Google engineers recommend that if you use RecyclerView, as part of onBindViewHolder() processing, that you call executePendingBindings() on the binding (e.g., RowBinding in the case of this example). This forces the data binding framework to get all of the bindings set up immediately, rather than waiting until the natural time to do it.

In our case, we just tuck that call into the bindModel() method of QuestionController, shown above.

You will notice that we also call a setController() method on the RowBinding. This is in support of our event handling binding work, as you will see next.

What About the Event Listeners?

QuestionController has two event-related methods. One is onTouch(), for handling the ripple effect on Android 5.0+:

```java
@Override
public boolean onTouch(View v, MotionEvent event) {
    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.LOLLIPOP) {
        v.findViewById(R.id.row_content)
            .getBackground()
            .setHotspot(event.getX(), event.getY());
    }
    return(false);
}
```

(from DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionController.java)

The other is showQuestion(), which, surprisingly enough, will be called when we want to show the actual question:

```java
public void showQuestion(Question question) {
    EventBus.getDefault().post(new QuestionClickedEvent(question));
}
```

(from DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionController.java)
THE DATA BINDING FRAMEWORK
(from DataBinding/RecyclerView/app/src/main/java/com/commonsware/android/databind/basic/QuestionController.java)

It contains the EventBus logic to tell somebody to go show some specified Question.
Those are tied into our app via the data binding framework:
<LinearLayout
android:id="@+id/row_content"
android:layout_width="match_parent"
android:layout_height="wrap_content"
android:background="?android:attr/selectableItemBackground"
android:onClick="@{()->controller.showQuestion(question)}"
android:onTouch="@{controller::onTouch}"
android:orientation="horizontal">
>
(from DataBinding/RecyclerView/app/src/main/res/layout/row.xml)

For android:onTouch, we use the method-reference approach, asking the data
binding framework to call onTouch() on our controller. For android:onClick, we
use the lambda expression approach, calling showQuestion() on our controller,
passing in the question variable, so we have our Question to go show.
And that’s it. No other changes are needed to tie in these events, either in the
QuestionController or in the QuestionsAdapter.

Type Converters
The result of a binding expression gets cast to the data type expected by the setter,
field, or binding adapter that the data binding system identified as being the one to
use.
Hopefully, this works.
However, it is possible that you will need to change your binding expression, such as
in the case cited earlier in this chapter, where android:text can accept an integer,
but you wanted that integer to be shown as text, not be a reference to a string
resource.
In other cases, there may not be a clear match. Google’s documentation cites the
case where your binding expression returns the ID of a color resource, but the setter
takes a Drawable, such as is the case with setBackground() on View.
One way of addressing this disparity is via a @BindingMethod. This teaches the data
2182


binding system to use a different method for the setter (e.g., setBackgroundColor()). However, this is always used for that particular widget class and attribute combination. In the particular case of the android:background attribute, there are a variety of possible setters:

- setBackground(Drawable)
- setBackgroundColor(int) (taking the actual color, not a color resource)
- setBackgroundDrawable(Drawable) (as setBackground(Drawable) is new to API Level 16)
- setBackgroundResource(int)

You may not be in position to use one of these for android:background exclusively.

Hence, another approach is to teach the data binding system how to convert data from one type to another, using a @BindingConversion-annotated static method:

```java
@BindingConversion
public static ColorDrawable colorToDrawable(int color) {
    return new ColorDrawable(color);
}
```

As with binding adapters, the name of the method does not matter. What matters is that it takes an int as input and returns a ColorDrawable. The data binding system will take this into account and use it if it has a case where the binding expression returned an int and it needs a ColorDrawable... or a Drawable.

Here, though, we start to run into problems with Google's insistence on using int values everywhere. This colorToDrawable() conversion method takes an int. That int could be a color. It could be a color resource ID, or a string resource ID, or a layout resource ID, or the score of a Stack Overflow question, or countless other things. The depicted @BindingConversion, therefore, may not be especially useful.

Another scenario for @BindingConversion is to be able to extract something from deep inside a model without exposing the whole model structure as public. For example, the DataBinding/Conversion sample project uses a @BindingConversion to allow an Owner to be turned into a String, by means of returning the profileImage value:

```java
@BindingConversion
public static String ownerToString(Owner owner) {
    return owner.profileImage;
}
```
THE DATA BINDING FRAMEWORK
(from DataBinding/Conversion/app/src/main/java/com/commonsware/android/databind/basic/QuestionsFragment.java)

Once again, the method name does not matter; what matters is that this conversion
knows how to handle taking an Owner and returning a String.
Now, the app:imageUrl attribute in the ImageView in the layout can refer to
question.owner instead of question.owner.profileImage:
<ImageView
android:id="@+id/icon"
android:layout_width="@dimen/icon"
android:layout_height="@dimen/icon"
android:layout_gravity="center_vertical"
android:contentDescription="@string/icon"
android:padding="8dip"
app:error="@{@drawable/owner_error}"
app:imageUrl="@{question.owner}"
app:placeholder="@{@drawable/owner_placeholder}"/>
/>
(from DataBinding/Conversion/app/src/main/res/layout/row.xml)

Chained Expressions
The original edition of the data binding system allowed you to create expressions
based on variables and static methods. An update to data binding in 2016 added in
“chained expressions”, where expressions can refer to attributes of other widgets in
the same layout resource. While this feature is presently undocumented, the basics
are straightforward enough: just refer to the widgets by ID.
For example, the DataBinding/Chained sample project is a clone of the
DataBinding/TwoWay sample project from earlier in the chapter. There, we added a
Switch widget tied to an expanded property on the Question model objects. The
reason for the name “expanded” was in preparation for the DataBinding/Chained
sample, where the visibility of the avatar icon and the score would be toggled based
on the Switch status.
The Switch has an android:id of expanded:
<Switch
android:id="@+id/expanded"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:checked="@={question.expanded}" />
(from DataBinding/Chained/app/src/main/res/layout/row.xml)

2184


THE DATA BINDING FRAMEWORK
The android:visibility of the icon ImageView now is set based on a data binding
expression, checking the checked state of the expanded widget, using a ternary
operator to convert that into appropriate View values:
<ImageView
android:id="@+id/icon"
android:layout_width="@dimen/icon"
android:layout_height="@dimen/icon"
android:layout_gravity="center_vertical"
android:contentDescription="@string/icon"
android:padding="8dip"
android:visibility="@{expanded.checked ? View.VISIBLE : View.GONE}"
app:error="@{@drawable/owner_error}"
app:imageUrl="@{question.owner.profileImage}"
app:placeholder="@{@drawable/owner_placeholder}" />
(from DataBinding/Chained/app/src/main/res/layout/row.xml)

Note that this requires us to import View, to be able to reference View.VISIBLE and
View.GONE:
<import type="android.view.View" />
(from DataBinding/Chained/app/src/main/res/layout/row.xml)

The score TextView could use the exact same expression as was used for the icon
ImageView. However, in this case, the visibility of score depends upon the
visibility of icon:
<TextView
android:id="@+id/score"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:layout_gravity="center_vertical"
android:layout_marginLeft="8dp"
android:layout_marginRight="8dp"
android:text="@{Integer.toString(question.score)}"
android:textSize="40sp"
android:textStyle="bold"
android:visibility="@{icon.visibility}" />
(from DataBinding/Chained/app/src/main/res/layout/row.xml)

This way, if the rules for how we derive the visibility change, all we need to do is
change icon, leaving score alone.

2185


Now, as the user toggles the Switch, the visibility of the icon and the score toggles with it.

**Custom Binding Class Names**

As noted earlier in this chapter, the binding class name for a layout resource is determined automatically by default. The layout filename is converted into a “Pascal case” rendition, then has Binding appended (e.g., `res/layout/foo_bar.xml` becomes `FooBarBinding`). This class goes in the .databinding sub-package under the base Java package for your app, as defined in the package attribute in your `<manifest>`.

However, this may result in awkward Java class names. Or, perhaps you want to have the classes be generated in some other Java package, for some reason. You can use the class attribute on the `<data>` element to control the actual Java class name used for the binding class.

This can come in one of three forms:

- `class="Foo"` will name the binding class `Foo` and will place it in the standard .databinding sub-package
- `class=".Foo"` will name the binding class `Foo`, but will place it in the base package for your app (as defined in the package attribute), instead of in the separate .databinding sub-package
- `class="this.is.fully.qualified.Foo"` will name the binding class `Foo` and place it in the designated Java package

**Extended Include Syntax**

Android has supported `<include>` as a tag in layout resources since Android 1.0. The tag takes a layout attribute, pointing to a layout resource. The contents of the pointed-to layout resource are inserted into the view hierarchy of the original resource. So, if we have:

```xml
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <include layout="@layout/foo"/>

    <!-- other widgets go here -->
</LinearLayout>
```

2186
... then whatever is in the foo layout resource will be added to the LinearLayout, ahead of any other widgets in that LinearLayout.

With the data binding system, you can pass variables from the outer layout to the included one, without having to somehow bind the variable yourself in the included layout from Java code:

```xml
<layout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:bind="http://schemas.android.com/apk/res-auto">
    <data>
        <variable name="foo" type="com.thingy.Foo"/>
    </data>

    <LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
                  android:orientation="vertical"
                  android:layout_width="match_parent"
                  android:layout_height="match_parent">
        <include layout="@layout/foo" bind:bar="@{foo}"/>
        <!-- other widgets go here -->
    </LinearLayout>
</layout>
```

Here, if the foo layout resource has a variable named bar, it will be populated by evaluating the @{foo} binding expression, so the foo resource can refer to bar in its own binding expressions.

**Custom Observables**

What you want may not fit any of these patterns. In that case, you are going to have to roll your own Observable implementation. The simplest way to do that is to extend BaseObservable, which handles all of the observer registration logic for you.

There are two types of changes for which you can notify observers:

- Changes to properties, which can be handled by the individual property observers described above, such as ObservableField
- Changes to other intrinsic aspects of the model itself, that cannot be captured in a simple Observable wrapper on some property
THE DATA BINDING FRAMEWORK

For example, you might have a `Person` class that has `birthDate` field, of type `Date`, representing the date on which the person was born. If you wanted to use that date in a binding expression, you could have `birthDate` be `public`, or have a `getBirthDate()` that returned it. If you wanted a binding expression to be updated when the birth date changed (e.g., correcting a typo), you could have `birthDate` be an `ObservableField` wrapped around a `Date`.

However, suppose what you really want to use in the binding expression is the person's age. It is easy enough for `Person` to calculate that, based on the current date and `birthDate`. However, this would be awkward to publish via an `ObservableField`, since there should not be an `age` field — age is a derived value, not a stored value. Instead, you could say that your `getAge()` method publishes a simple `int`, and you will handle notifying observers whenever the age changes, either due to a change in `birthDate`, or if the date changed and it is now the person's birthday.

Bindable Properties

On a `BaseObservable`, you can annotate getter-style methods with `@Bindable`. This tells the data binding framework that those methods represent values that can be bound. Because `BaseObservable` implements `Observable`, the data binding framework can call `addOnPropertyChangedCallback()` to register an `OnPropertyChangedCallback` to find out when `@Bindable` properties are changed.

To make that work, `BaseObservable` supplies a `notifyPropertyChanged()` method. You can call this from the setter method or other place where you are changing the value of the property, to let `BaseObservable` know that the property changed. This, in turn, will let all `OnPropertyChangedCallback` instances know about the change, which will trigger the data binding framework to re-evaluate any binding expressions tied to that property.

Unfortunately, this is broken in the 1.5.1 build of Android Studio and the 1.5.0 edition of the Android Gradle Plugin.

For example, here is a revised version of the Question model class that has it use `BaseObservable` and `notifyPropertyChanged()`:

```java
package com.commonsware.android.databind.basic;

import android.databinding.BaseObservable;
import android.databindingBindable;
import com.commonsware.android.databind.basic.BR;
```
public class Question extends BaseObservable {
    private String title;
    private final Owner owner;
    private final String link;
    private int score;
    private final String id;

    Question(Item item) {
        updateFromItem(item);
        owner=item.owner;
        link=item.link;
        id=item.id;
    }

    @Bindable
    public String getTitle() {
        return(title);
    }

    @Bindable
    public Owner getOwner() {
        return(owner);
    }

    @Bindable
    public String getLink() {
        return(link);
    }

    @Bindable
    public int getScore() {
        return(score);
    }

    @Bindable
    public String getId() {
        return(id);
    }

    void updateFromItem(Item item) {
        this.title=item.title;
        this.score=item.score;

        notifyPropertyChanged(BR.title);
        notifyPropertyChanged(BR.score);
    }
}
Here, BR is a generated class. According to the documentation:

The Bindable annotation generates an entry in the BR class file during compilation. The BR class file will be generated in the module package.

Unfortunately, while this is all true, Android Studio does not recognize any of the generated fields, and so while you can import BR, BR.title and BR.score — the int values identifying those properties — are not recognized and result in compile errors.

**Notifying About Intrinsic Changes**

If the BaseObservable itself is what is used in the binding expression, or if you want to use bindable properties and need to work around the BR issue mentioned above, BaseObservable also offers notifyChange(), indicating that all binding expressions tied to the BaseObservable instance should be re-evaluated.

The [DataBinding/Observable](#) sample project is another variation of the sample project that we have been analyzing in this chapter. This one has Question extend BaseObservable. However, unlike the code snippet above, where we tried using BR and notifyPropertyChanged(), here we just settle for notifyChange():

```java
package com.commonsware.android.databind.basic;

import android.databinding.BaseObservable;
import android.databindingBindable;
import android.databinding.ObservableInt;
import android.databinding.ObservableField;
import android.databinding.ObservableField;
import com.commonsware.android.databind.basic.BR;

public class Question extends BaseObservable {
  private String title;
  private final Owner owner;
  private final String link;
  private int score;
  private final String id;

  Question(Item item) {
    updateFromItem(item);
    owner=item.owner;
    link=item.link;
    id=item.id;
  }

  @Bindable
}
```
public String getTitle() {
    return title;
}

@Bindable
public Owner getOwner() {
    return owner;
}

@Bindable
public String getLink() {
    return link;
}

@Bindable
public int getScore() {
    return score;
}

@Bindable
public String getId() {
    return id;
}

void updateFromItem(Item item) {
    this.title = item.title;
    this.score = item.score;

    notifyChange();
}

Even though we are storing title as a simple String and score as a simple int, we can use them in binding expressions, because their getters are @Bindable and we are notifying BaseObservable when their values change.

**Thinking Outside the Box**

Data binding will usually be used for things like the text of a TextView, or the image shown in an ImageView. However, you are welcome to have other things vary based upon binding expressions. For example, perhaps you want a certain background color or color bar on a row in a list, based upon some category associated with the model objects. You could use data binding to set that color.
Lisa Wray pointed out another inventive use of data binding: custom fonts.

Historically, using a custom Typeface required Java code. That Java code might be fairly limited, if you only need to update one TextView. Or, that Java code might pull in a library like Calligraphy to be able to apply arbitrary fonts to arbitrary widgets from within layout files.

The data binding framework can handle that for you, if you create a custom BindingAdapter for some synthetic property (e.g., wray:font). In your layout, you would have wray:font attributes that name the typeface that you want on relevant widgets (e.g., TextView):

```xml
<TextView
    wray:font="@{`MgOpenCosmetica.ttf`}" 
    android:layout_width="wrap_content"
    android:layout_height="wrap_content" />
```

The BindingAdapter would retrieve the Typeface for that font name, then apply it to the associated widget:

```java
@BindingAdapter({"wray:font"})
public static void setFont(TextView tv, String font){
    String assetPath = "fonts/" + font;
    Typeface type = Typeface.createFromAsset(tv.getContext().getAssets(), assetPath);

    tv.setTypeface(type);
}
```

This particular implementation has performance issues, as it creates a new Typeface object on every binding, which is inefficient. Lisa has a complete sample app that demonstrates caching the Typeface objects to reduce the performance overhead.

It is likely that the Android community will come up with other interesting tricks for simplifying code using fancy data binding adapters, converters, and the like.
Desktop applications have long offered drag-and-drop, both within and between applications. Android has supported this for quite some time, but you could only drag and drop within a single activity. As a result, this was not especially popular.

However, starting in Android 7.0, you can drag and drop between applications, so long as their windows are visible in a multi-window environment. Not only does this make drag-and-drop more compelling in general, but in a freeform multi-window environment, users will expect Android apps to behave like their desktop counterparts. Hence, users will expect drag-and-drop capabilities where it makes sense.

In this chapter, we will explore Android's drag-and-drop facility, including how to perform it between separate applications.

**Prerequisites**

Understanding this chapter requires that you have read the core chapters of this book, as well as the chapter on the clipboard.

One example uses RecyclerView, so reviewing that chapter is a good idea. Similarly, one sample uses StreamProvider, so you may wish to read the section on it as well.

**The Scope of Drag and Drop**

Since the term “drag-and-drop” means different things to different people – including different developers used to different platforms — it will help if we understand exactly what Android’s definition of “drag-and-drop” is.
What Are We Dragging and Dropping?

In Android, the focus is on dragging and dropping content, meaning some information identified by a `Uri` and an associated MIME type. We are using the drag-and-drop process to select some piece of content and inform something else about that content. Specifically, the content that we are dragging and dropping is represented by a `ClipData` object, the same as we could use with the clipboard.

Technically, the `ClipData` does not have to represent content. The clipboard supports plain text `ClipData` items, and nothing is stopping you from using drag and drop for plain text as a result. When dragging and dropping between apps, this may cause some compatibility issues, though the drag-and-drop framework takes steps to help deal with this. Within an app, options like plain text allow you to “cheat” to an extent, allowing drag-and-drop to support anything you want, so long as you can identify the specific “anything you want” by a string ID or key.

From the user’s standpoint, the user is dragging some visual representation of this content. That can be whatever bitmap you want, and you will have a few options for specifying what this bitmap is. This bitmap is referred to as the “shadow”.

Where Are We Dragging From?

You will need to provide some UI that triggers a drag-and-drop operation, not only allowing the user to say “let's drag this somewhere” but also “here is what ‘this’ I want to drag”.

A typical trigger for this is a long-click. So, for example, a long-click on a list row might trigger a drag-and-drop of the content identified by that row.

Usually, the trigger is tied to some view, as drag-and-drop intrinsically is a visual operation. Technically, this is not required, if you can find some other approach that users will understand and appreciate.

Where Are We Dropping To?

You will need to identify possible drop targets, in the form of views. A view can be registered as a potential drop target, then stipulate whether it is a candidate for a specific drag-and-drop operation when that operation begins. For example, if you have two lists, and you want the user to drag items between the lists, both are potential drop targets. However, you might elect to say that the user cannot drag
from a list back into that same list, so if the content being dragged originated from
the list, that list is not a candidate for that specific drag-and-drop operation.

**The Pieces of Drag-and-Drop**

As noted above, what we are really dragging and dropping is a ClipData, which can
represent whatever we want, so long as the recipient of that ClipData knows how to
work with whatever the provider of that ClipData put in it.

However, there are a few other pieces to the drag-and-drop process.

**The Drag Shadow**

The drag shadow is the visual representation of what the user is dragging and
dropping. Programmatically, the shadow is defined as an instance of
View.DragShadowBuilder (which, despite the name, does not implement a builder-
style API).

You have two main choices for creating this shadow: use a View, or use a Canvas.

**...From a View**

You can create a View.DragShadowBuilder via the constructor that takes a View as a
parameter. This tells View.DragShadowBuilder that the drag shadow should be a
translucent copy of whatever the View is showing at the time we start the drag-and-
drop operation.

This is very easy to implement, and it works well if you have a View that makes for a
likely visual representation of what is being dragged and dropped.

On the other hand, it will not handle all scenarios. Suppose that you want to allow
the user to drag from a list. Furthermore, suppose that you want the user to be able
to multi-select items in the list and drag the entire selection. Now you no longer
have a single View that you can use as the basis for the drag shadow.

Also, keep the drag shadow relatively small. It needs to be big enough that the user
can see it despite a finger potentially being in the way. However, it also needs to be
small enough to make it clear where the user is dropping it. This is another reason
why the multi-select list scenario does not work well with creating a
View.DragShadowBuilder from a View — even if you chose the ListView or
Drag and Drop

RecyclerView as being the View from which to create the drag shadow, odds are that the list will be far too large.

...From a Canvas

For cases where using a View as the basis of your drag shadow will not work, you can create your own subclass of View.DragShadowBuilder and define the drag shadow however you want.

To do this, you will override two methods. One is onProvideShadowMetrics(), where you fill in a pair of Point objects. The first represents the size of the drag shadow in pixels. The other represents the point within the drag shadow where the touch point will be — in other words, where is the drag shadow with respect to where the finger is touching the screen.

The other method is onDragShadow(), where you are given an appropriately-sized Canvas and you can draw whatever you want into that Canvas to serve as the drag shadow. For example, you might draw a Bitmap in onDragShadow() using the dimensions of the Bitmap and its center point in onProvideShadowMetrics().

Technically, you can combine the two approaches. You create the View.DragShadowBuilder using a View but then override one or both of the aforementioned View.DragShadowBuilder methods to alter the default behavior a bit. For example, by default, the touch point will be the center of the View, but you might want the touch point to be offset towards one corner — you could handle this by overriding onProvideShadowMetrics(), chaining to the superclass, then updating the second Point object as you see fit.

The Drag Event Listener

To react to drag events in a drop target View, you can call setOnDragListener(), supplying an implementation of View.OnDragListener. This interface has a single method, onDrag(), that you will need to implement.

The sample apps in this chapter implement View.OnDragListener on the activity that has the drop targets. Typically, you will implement View.OnDragListener on whatever object in your UI handles events raised by the widgets (e.g., a controller or presenter).
The Drag Events

onDrag() of your View.OnDragListener is passed two objects: the View that you called setOnDragListener() on, and a DragEvent representing what is happening with respect to the drag-and-drop process.

The DragEvent contains an action int value, representing what the state change is in the drag-and-drop operation. Depending on the action, other aspects of the DragEvent may be available to you as well.

ACTION_DRAG_STARTED

When the user begins a drag-and-drop operation, and your window is visible (e.g., the user started the drag-and-drop within your own activity), you will receive a DragEvent whose action is ACTION_DRAG_STARTED.

Your primary job is to return true from onDrag() if you wish to be considered a drop target for this drag-and-drop operation. Prior to Android 7.0, you might always return true, since you are certain to be in control over both the drag and the drop. Starting with Android 7.0, you might conditionally return true, if the drag-and-drop operation looks like it might be one that you can handle. Unfortunately, your primary means of determining this is via getClipDescription() on the DragEvent, which gives you a ClipDescription describing the ClipData that is the content. This does not give you much to go on, as we will see in upcoming samples.

If you are a valid drop target, you might also consider adjusting the look and feel of this View to indicate to the user that this is a valid drop target. Android does not do anything on its own for this. You might tint the View, or add an outline, or something, to help clue the user in that dropping over your View might have a positive result.

If you return true, you will be notified about the progress of the drag-and-drop event through the other event actions listed below. If you return false, you are indicating that this drag-and-drop operation does not concern you, and you will not be given any further DragEvents for it.

ACTION_DRAG_ENTERED

You will receive a DragEvent with this action once it is possible for the user to drop in your View. This will come when the drag shadow enters the bounding box of the
If you are still interested in this drag-and-drop operation, you should:

- Return `true` from `onDrag()`, and
- Alter the widget’s appearance yet again, to reflect the fact that if the user lifts her finger, the content will be dropped into this widget.

If precise placement within the widget is important for the drag-and-drop operation (e.g., you wish to highlight some specific cell in a grid), you can call `getX()` and `getY()` on the `DragEvent` to try to determine where the drop point is. Unfortunately, it is not documented whether `getX()` and `getY()` are relative to your widget, the screen, or something else.

**ACTION_DRAG_LOCATION**

If you return `true` from the `ACTION_DRAG_ENTERED` `DragEvent`, you may receive additional `DragEvents` with `ACTION_DRAG_LOCATION` actions, indicating that the user has moved within the bounding box of your widget. If you are using `getX()` and `getY()` to deal with the highlighting, these values will have changed, and so you will want to update the highlighting to match.

**ACTION_DRAG_EXITED**

If you return `true` from the `ACTION_DRAG_ENTERED` `DragEvent`, you may receive a `DragEvent` for `ACTION_DRAG_EXITED`. This indicates that the user dragged the item outside of your widget without dropping it. Any state changes to your widget, such as a highlight, that you applied in `ACTION_DRAG_ENTERED` or `ACTION_DRAG_LOCATION` should be reverted. However, the drag-and-drop operation is still proceeding, so any highlight you use for that (e.g., in `ACTION_DRAG_STARTED`) should still be used.

**ACTION_DROP**

Of course, the fun action is `ACTION_DROP`, which means that the user dropped the content over this widget as the drop target. You can call `getClipData()` to get at the `ClipData` for this content, along with final `getX()` and `getY()` values.

If you return `true` in `onDrag()`, this indicates that you handled the drop request.

However, you may not be able to handle the drop request. For example, suppose you...
are looking to have a Uri pointing to a video be dropped into your app. All you can determine from the ClipDescription, in your ACTION_DRAG_STARTED processing, is that the ClipData has a Uri. So, you have to return true from onDrag() in your ACTION_DRAG_STARTED logic. But, then, in ACTION_DROP processing, when you get the real Uri, you find out that it has a different MIME type (e.g., text/html, instead of video/*). You will need to return false from onDrag() in your ACTION_DROP logic. Unfortunately, what happens from this point forward is undocumented.

**ACTION_DRAG_ENDED**

If you returned true from the ACTION_DRAG_STARTED DragEvent, you should receive a DragEvent when the drag-and-drop operation is over, with ACTION_DRAG_ENDED as the action. Any state change you made to your widget in ACTION_DRAG_STARTED should be reverted here. If it matters to you whether the user did a valid drop or not, call getResult() on the DragEvent to find out.

**Drag-and-Drop, within an Activity**

The classic drag-and-drop scenario, prior to Android 7.0, was to drag-and-drop between widgets in a single activity.

The DragDrop/Simple sample project demonstrates this scenario. It is based on the RecyclerView/VideoList sample app from the chapter on RecyclerView.

**The Landscape Layout**

On smaller screens, we just have the RecyclerView as before. However, on larger screens (e.g., 9” tablets in landscape), we put a VideoView and an ImageView alongside the RecyclerView:

```xml
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal">
    <android.support.v7.widget.RecyclerView
        android:id="@+id/video_list"
        xmlns:android="http://schemas.android.com/apk/res/android"
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="1" />
</LinearLayout>
```
The idea is that the user will be able to drag from the RecyclerView into the other two widgets, which will play the video or show a larger rendition of the thumbnail, respectively.

The VideoView and the ImageView are each wrapped in a FrameLayout. Mostly, that is to give us a place to render a border around the widgets, indicating that they are drop targets. We have a pair of <shape> drawables for this. One is a red dashed line indicating a potential drop target:
DRAG AND DROP

The other is a solid green line indicating a “live” drop target, used to indicate that dropping the content here should work:

```
<shape xmlns:android="http://schemas.android.com/apk/res/android"
       android:shape="rectangle">
  <stroke
    android:width="4dp"
    android:color="#2e7d32">
  </stroke>
</shape>
```

(from DragDrop/Simple/app/src/main/res/drawable-nodpi/drop.xml)

Registering as Drop Targets

This version of the sample app avoids the RecyclerViewActivity used in the RecyclerView/VideoList sample app. Instead, MainActivity manages all of its widgets directly, including the RecyclerView.

In `onCreate()`, after inflating the layout, we attempt to retrieve the VideoView and ImageView. If we find them, we call `setOnDragListener()`, supplying our MainActivity instance itself as the OnDragListener implementation:

```
player=findViewById(R.id.player);

if (player!=null) {
  player.setOnDragListener(this);
}

thumbnailLarge=findViewById(R.id.thumbnail_large);

if (thumbnailLarge!=null) {
```

2201
We will examine the `onDrag()` method that `OnDragListener` requires shortly.

### Starting to Drag

This app supports a long-click on a row in our `RecyclerView` to enter drag-and-drop mode, as we call `setOnLongClickListener()` on the row itself, in `RowController` (our `RecyclerView.ViewHolder` for our list rows):

```java
RowController(View row) {
    super(row);
    title=(TextView)row.findViewById(android.R.id.text1);
    thumbnail=(ImageView)row.findViewById(R.id.thumbnail);
    row.setOnClickListener(this);
    row.setOnLongClickListener(this);
}
```

In `onLongClick()`, we:

- Create a `ClipData` based on the `Uri` obtained from `MediaStore` for the video, plus its caption (pulled from the `title` `TextView`)
- Create a drag shadow, using `View.DragShadowBuilder`, with the `thumbnail` `ImageView` as the basis
- Call `startDrag()` on the row itself, accessed via the `itemView` field on the `ViewHolder` base class

```java
@override
public boolean onLongClick(View v) {
    ClipData clip=ClipData.newRawUri(title.getText(), videoUri);
    View.DragShadowBuilder shadow=new View.DragShadowBuilder(thumbnail);
    itemView.startDrag(clip, shadow, Boolean.TRUE, 0);
    return(true);
}
```
Besides the ClipData and View.DragShadowBuilder, startDrag() takes two other parameters:

- An arbitrary Object referred to as the “local state”, which can provide additional information between the drag source and the drop target, but only when both are in the same window (usually meaning the same activity)
- A set of flags (here unused, so set to 0)

For the local state, we are using Boolean.TRUE. That is a fairly arbitrary choice, but it is a good idea to pass a non-null value here, for reasons that we will get into later in this chapter.

Reacting to Drag Events

Our onDrag() method in MainActivity will handle all of the events related to our registered drop targets:

```java
@Override
public boolean onDrag(View v, DragEvent event) {
    boolean result=true;
    switch (event.getAction()) {
    case DragEvent.ACTION_DRAG_STARTED:
        if (event.getLocalState()==null) {
            result=false;
        } else {
            applyDropHint(v, R.drawable.droppable);
        }
        break;

    case DragEvent.ACTION_DRAG_ENTERED:
        applyDropHint(v, R.drawable.drop);
        break;

    case DragEvent.ACTION_DRAG_EXITED:
        applyDropHint(v, R.drawable.droppable);
        break;

    case DragEvent.ACTION_DRAG_ENDED:
        applyDropHint(v, -1);
        break;

    case DragEvent.ACTION_DROP:
        ClipData.Item clip=event.getClipData().getItemAt(0);
```
Uri videoUri=clip.getUri();

if (v==player) {
    player.setVideoURI(videoUri);
    player.start();
} else {
    Picasso.with(thumbnailLarge.getContext())
        .load(videoUri.toString())
        .fit().centerCrop()
        .placeholder(R.drawable.ic_media_video_poster)
        .into(thumbnailLarge);
}

break;

return(result);

(from DragDrop/Simple/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java)

For most of the actions, we apply (or remove) a drawable from the FrameLayout containers wrapping our VideoView and ImageView widgets, via an applyDropHint() utility method:

private void applyDropHint(View v, int drawableId) {
    View parent=(View)v.getParent();

    if (drawableId>-1) {
        parent.setBackgroundResource(drawableId);
    } else {
        parent.setBackgroundResource(null);
    }
}

(from DragDrop/Simple/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java)

Here, we use -1 as the “ID” of a resource meaning to remove any previous background.

In onDrag(), we ignore ACTION_DRAG_LOCATION events, as we are not using getX() and getY() and so do not care if those values change.

However, we do handle two actions a bit differently:
• ACTION_DRAG_STARTED examines the local state and rejects any DragEvent where that state is null, for reasons that we will get into later in this chapter
• ACTION_DROP retrieves the ClipData.Item for the ClipData we set as the drag content, retrieves the Uri of the video from the ClipData.Item, then either plays the video or shows the thumbnail, depending on which widget the user dropped the content into

The Result

If you run the sample app on a large-enough device with a roster of videos, you will get the list of videos on one side, and the empty VideoView and ImageView on the other side:

![Simple Drag-and-Drop Demo, As Initially Launched](image)

---

2205
Once the user long-taps on a list row, a shadow based on the thumbnail appears under the user's finger, and the two drop targets show their red dashed outlines:

![Simple Drag-and-Drop Demo, After Drag Started](image-url)
If the user drags the drop shadow over one of the drop targets, it gets the ACTION_DRAG_ENTERED event and changes its outline to the green solid line:
Finally, if the user drops the item in one of the drop targets, it receives the ACTION_DROP event and can actually use the content:

![Simple Drag-and-Drop Demo, After Drop](image)

Note that both widgets no longer show an outline, as they each received ACTION_DROP_ENDED, where they removed their outlines.

**The Android 9.0 Bug**

Simply put, the local state does not work on Android 9.0. `getLocalState()` always returns null. Reportedly, this is fixed for a future version of Android, but it is unlikely that this fix will ever make it to Android 9.0 devices.

As a result, you will need an alternative to the local state, at least for Android 9.0 devices.

**Drag-and-Drop, Between Apps**

Android 7.0’s multi-window capability ushers in a new era for drag-and-drop, where users drag-and-drop between apps. In theory, very little has to change to support
drag-and-drop between apps.

However, there are challenges, the biggest one being permissions. The app with the drop target needs permission to work with whatever content is represented in the drag-and-drop operation. If that content is simply some plain text or something else that can be stuffed into a ClipData, permissions are part of drag-and-drop processing, as only the drop target selected by the user gets the ACTION_DROP event and can access that ClipData.

However, if the ClipData contains one or more Uri values, the app with the drop target needs access to that underlying content, just as it needs it for the clipboard or any other situation where a Uri is passed between apps.

The DragDrop/Permissions sample project demonstrates dragging and dropping between apps. This project has two app modules: drag and drop. As you might imagine, drag contains an activity that allows the user to drag something (in this case, an image), while drop contains an activity that accepts an image Uri and displays it.

Because cross-app drag-and-drop requires Android 7.0, both modules are set up with 7.0-compatible build settings in build.gradle — we will see the drag/build.gradle file shortly.

The Drag App

The drag app has a very simple UI: a single ImageView, set to fill the available space:

```xml
<?xml version="1.0" encoding="utf-8"?>
<ImageView
    android:id="@+id/asset"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:scaleType="fitCenter" />
```

(from DragDrop/Permissions/drag/src/main/res/layout/main.xml)

The idea is that the user will long-click the ImageView to start the drag-and-drop operation. Hence, this is reminiscent of the DragDrop/Simple app, just with a single image, rather than one per row in a list.
The Custom Shadow

One problem with using the ImageView as the way to start the drag-and-drop operation comes with the drag shadow. In DragDrop/Simple, we used the image as the drag shadow. This worked well, because the image was a thumbnail, which usually is a good size for a drag shadow. In the drag app in DragDrop/Permissions, though, the ImageView is huge, far too large to use as the drag shadow. As a result, we cannot use the ImageView directly as before, but instead need to create a custom View.DragShadowBuilder subclass, named ThumbDragShadow:

```java
private class ThumbDragShadow extends View.DragShadowBuilder {
    @Override
    public void onProvideShadowMetrics(Point shadowSize, Point shadowTouchPoint) {
        shadowSize.set(iv.getWidth()/8, iv.getHeight()/8);
        shadowTouchPoint.set(shadowSize.x/2, shadowSize.y/2);
    }

    @Override
    public void onDrawShadow(Canvas canvas) {
        iv.draw(canvas);
    }
}
```

This is a nested class inside MainActivity, and so it has access to the fields of MainActivity, such as our ImageView, named iv.

In onProvideShadowMetrics(), we set the size of the shadow to be 1/8th of the size of the ImageView. This is a sloppy approach and may wind up with too small of an image on smaller-screen devices. However, it does keep the aspect ratio of the ImageView. In addition, we set the touch point to be in the middle of the image — based on some Google sample code, it appears that this is a reasonable algorithm.

In onDrawShadow(), we need to draw something on the supplied Canvas that represents the drag shadow. In this case, we ask the ImageView to draw itself into that Canvas. This results in a cropped image, as the ImageView is much larger than our Canvas, which is sized based on the Point values we populated in onProvideShadowMetrics(). A better implementation would work with a Bitmap and scale it so the entire image would be seen in the drag shadow; this approach is used here for simplicity.
The StreamProvider

The image itself is stored in assets/. The photo is of One World Trade Center (a.k.a., “Freedom Tower”) in New York City.

The reason for storing it in assets/ is that not only do we need the image, but we need to provide other apps with access to the image. In this app, we will handle that using StreamProvider, from the author's CWAC-Provider library, as described in one of the chapters on the ContentProvider component.

To that end, we include the cwac-provider artifact in our drag/build.gradle file:

```gradle
apply plugin: 'com.android.application'

dependencies {
    compile 'com.android.support:recyclerview-v7:25.3.1'
    compile 'com.squareup.picasso:picasso:2.5.2'
}

android {
    compileSdkVersion 24
    buildToolsVersion '26.0.2'

    defaultConfig {
        applicationId "com.commonsware.android.dragdrop.drag"
        minSdkVersion 24
        targetSdkVersion 24
    }

    aaptOptions {
        noCompress 'jpg'
    }
}

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    compile 'com.commonsware.cwac:provider:0.4.0'
}
```

(from DragDrop/Permissions/drag/build.gradle)
Also note that we take steps to ensure that the build tools do not try to compress the JPEG further, by excluding .jpg files from aapt compression via noCompress in aaptOptions.

The manifest contains a <provider> element for our StreamProvider:

```xml
<provider
    android:name="com.commonsware.cwac.provider.StreamProvider"
    android:authorities="${applicationId}.provider"
    android:exported="false"
    android:grantUriPermissions="true">
    <meta-data
        android:name="com.commonsware.cwac.provider.STREAM_PROVIDER_PATHS"
        android:resource="@xml/provider"/>
    <meta-data
        android:name="com.commonsware.cwac.provider.USE_LEGACY_CURSOR_WRAPPER"
        android:value="true"/>
</provider>
```

(from DragDrop/Permissions/drag/src/main/AndroidManifest.xml)

That sets up the authority string to be the application ID with .provider appended. It also points StreamProvider to some XML metadata in res/xml/provider.xml:

```xml
<?xml version="1.0" encoding="utf-8"?>
<paths>
    <asset name="assets" />
</paths>
```

(from DragDrop/Permissions/drag/src/main/res/xml/provider.xml)

Here, we say that we are willing to serve anything from assets/.

The Drag Request

In onCreate(), we use Picasso to load the image out of assets/ and display it. However, we also register a Callback to find out when that has been completed:

```java
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);
}
```
Drag and Drop

```java
iv=(ImageView)findViewById(R.id.asset);

Picasso.with(this)
    .load("file:///android_asset/FreedomTower-Morning.jpg")
    .fit().centerCrop()
    .into(iv, new Callback() {
        @Override
        public void onSuccess() {
            iv.setOnLongClickListener(MainActivity.this);
        }
        @Override
        public void onError() {
            // TODO
        }
    });
```

We only call `setOnLongClickListener()` once the image has been loaded successfully, as until then, the user would not know what she is dragging and dropping.

Then, in `onLongClick()`, we start the drag-and-drop operation:

```java
@override
public boolean onLongClick(View view) {
    Uri uri=PROVIDER
        .buildUpon()
        .appendEncodedPath(StreamProvider.getUriPrefix(AUTHORITY))
        .appendEncodedPath("assets/FreedomTower-Morning.jpg")
        .build();

    ClipData clip=ClipData.newRawUri(getString(R.string.msg_photo), uri);
    View.DragShadowBuilder shadow=new ThumbDragShadow();

    iv.startDragAndDrop(clip, shadow, Boolean.TRUE,
                        View.DRAG_FLAG_GLOBAL|View.DRAG_FLAG_GLOBAL_URI_READ|View.DRAG_FLAG_GLOBAL_PERSISTABLE_URI_PERMISSION);

    return(true);
}
```

First, we need a `Uri` pointing to our asset. We build such a `Uri` from:

(from DragDrop/Permissions/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java)
Drag and Drop

- A static PROVIDER Uri, which incorporates our authority string:

```java
private static final String AUTHORITY = BuildConfig.APPLICATION_ID + ".provider";
piece static final Uri PROVIDER = Uri.parse("content://" + AUTHORITY);
```

(from DragDrop/Permissions/drag/src/main/java/com/commonsware/android/dragdrop/MainActivity.java)

- The unique prefix used for this app by StreamProvider (via getUriPrefix())
- The path to our asset

We then build a ClipData from that Uri, plus a string pulled from a resource. Note that it is unclear where this string is used, though accessibility options is one likely candidate.

The drag shadow is an instance of the ThumbDragShadow shown above.

To start the drag-and-drop operation, we call startDragAndDrop(). This is simply a new name for the startDrag() method. startDrag() is marked as deprecated in Android 7.0, replaced with startDragAndDrop(). However, for older, in-app drag-and-drop, feel free to use startDrag(), as it is your only option for Android 6.0 and older devices.

This time, we pass in some flags:

- DRAG_FLAG_GLOBAL indicates that we want the drag-and-drop operation to work between apps. If we left the flags as 0, the drag-and-drop would be limited only to this app. In this respect, a drag is local by default, with cross-app drag-and-drop being something you have to explicitly opt into.
- DRAG_FLAG_GLOBAL_URI_READ indicates that we want the other app to be able to read the content identified by the Uri that we are putting into the ClipData. Without this, any app receiving the DragEvent would be unable to display the image. Note that there is an equivalent DRAG_FLAG_GLOBAL_URI_WRITE if you want to offer write access.
- DRAG_FLAG_GLOBAL_PERSISTABLE_URI_PERMISSION indicates that we want to grant the recipient app durable rights to the content identified by the Uri that we are putting into the ClipData. The term “persistable”, and the documentation for this flag, suggests that this access survives reboots. That may be excessive here. We will explore why we are using this flag when we look at the drop app.
The Drop App

The drop app is a version of the drop logic from DragDrop/Simple, reduced to just handling the drop in an ImageView. However, it does have a few wrinkles, both related to drag-and-drop (permissions) and related to general Android development (configuration change support).

The Layout

The revised layout is simply the ImageView, wrapped in the FrameLayout for the drop hint drawables:

```xml
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout
    android:id="@+id/thumbnail_frame"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:layout_margin="4dp"
    android:padding="4dp">
    <ImageView
        android:id="@+id/thumbnail_large"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:scaleType="centerInside" />
</FrameLayout>
```

(from DragDrop/Permissions/drop/src/main/res/layout/main.xml)

In onCreate() and onSaveInstanceState(), we load that layout, get the ImageView, and populate it (via the same showThumbnail() as before) if we have a thumbnailUri from our saved instance state Bundle:

```java
@override
public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);

    image=(ImageView)findViewById(R.id.thumbnail_large);
    image.setOnDragListener(this);

    if (state!=null) {
        imageUri=state.getParcelable(STATE_IMAGE_URI);
        if (imageUri!=null) {
            // Populate the ImageView with the thumbnailUri
        }
    }
```
The Drag Event

The `onDrag()` method is the same as before, except for two events: `ACTION_DRAG_STARTED` and `ACTION_DROP`.

We are expecting to get a Uri pointing to an image from the outside app via a drag-and-drop operation. Ideally, we would validate that in `ACTION_DRAG_STARTED`, returning false if the content is something else:

```java
@Override
public boolean onDrag(View v, DragEvent event) {
    boolean result=true;
    switch (event.getAction()) {
        case DragEvent.ACTION_DRAG_STARTED:
            if (event.getClipDescription() .hasMimeType(ClipDescription.MIMETYPE_TEXT_URI)) {
                applyDropHint(v, R.drawable.droppable);
            } else {
                result=false;
            }
            break;
        case DragEvent.ACTION_DRAG_ENTERED:
            applyDropHint(v, R.drawable.drop);
            break;
        case DragEvent.ACTION_DRAG_EXITED:
            applyDropHint(v, R.drawable.droppable);
```
Unfortunately, all we can do is determine that we are getting some Uri. The MIME type in our ClipDescription is not the MIME type of the content underlying our Uri, but rather will be ClipDescription.MIMETYPE_TEXT_URI_LIST. This is because a ClipData can have several items, each with Uri values. We have no way, given just the ClipDescription to determine if we actually have an image Uri. So, as long as we are getting a Uri value, we assume that the drop might be meaningful and return true.

For ACTION_DROP, we first call requestDragAndDropPermissions(), to grant our app the rights offered to us by whatever app initiated the drag-and-drop operation:

```java
  case DragEvent.ACTION_DROP:
    requestDragAndDropPermissions(event);

    ClipData.Item clip=event.getClipData().ItemAt(0);
    imageUri=clip.getUri();
    showThumbnail();
    break;
```

The requestDragAndDropPermissions() method returns a DragAndDropPermissions object. The JavaDocs for this class point out the lifetime of our permissions:
The life cycle of the permissions is bound to the activity used to call requestDragAndDropPermissions(). The permissions are revoked when this activity is destroyed, or when release() is called, whichever occurs first.

However, the user could destroy your activity at any point in time, via a configuration change. As a result, you have three main options here:

1. Make a local copy of the content as soon as you get the Uri, hopefully before your activity gets destroyed via a configuration change
2. Opt out of the automatic destroy-and-recreate cycle for configuration changes for any activity that has drop targets, via android:configChanges in the manifest, and deal with all the problems that technique raises
3. Ignore the issue and hope that the app that started the drag-and-drop operation included DRAG_FLAG_GLOBAL_PERSISTABLE_URI_PERMISSION in its startDragAndDrop() call

But, after the requestDragAndDropPermissions() call, we grab the first Uri out of the ClipData, store that in the imageUri field, and have showThumbnail() display that image via Picasso. A better approach would examine each possible Uri in the ClipItem for one that represents an image (showing that one), and returning false from onDrag() if no such Uri is found, so the drag-and-drop operation remains active.
The Results

If you run both apps, and have them both visible in a multi-window environment (e.g., split-screen mode on a phone or tablet), you will be able to drag and drop between them:

Figure 676: Cross-App Drag-And-Drop, Showing Both Activities As Initially Launched
Figure 677: Cross-App Drag-And-Drop, Showing Drag Shadow

Figure 678: Cross-App Drag-And-Drop, Showing Result of Drag-and-Drop
Detecting Cross-App Drag Events

In the DragDrop/Permissions sample, there is nothing in our onDrag() method, or anywhere else, that indicates that we want to allow drag events from third-party apps. That happens by default, and there is no way to stop it. Hence, any app implementing official drag-and-drop support has to support arbitrary apps passing in content. With luck, this too will get changed.

We were given this recipe for detecting cross-app drag-and-drop:

- Fill in a non-null value for the local state in the call to startDragAndDrop()
- Check in ACTION_DRAG_STARTED to see if the local state is null, in which case, the drag-and-drop must have started from some other app

However, this does not work well. The local state is local to a window, not an app or process. As a result, if your app is visible in more than one window — for example, you used FLAG_ACTIVITY_LAUNCH_ADJACENT to start up another activity in another window — then you will lose the local state even for in-app drag-and-drop across these windows.

In the Simple drag-and-drop sample from earlier, we check to see if the local state is null and reject the drag event if it is. There, we are not expecting to have activities in multiple windows, so all drag-and-drop work should be local. Conversely, we do not check the local state in the Permissions sample, where we specifically want cross-app drag-and-drop.

Intra-App Cross-Window Drag-and-Drop

Drag-and-drop not only works between apps with Android 7.0’s multi-window feature — it also works for two windows within the same app.

The DragDrop/SplitScreen sample project is a clone of the DragDrop/Permissions project. However, both the drag activity (MainActivity) and the drop activity (DropActivity) are in the same app module (app/).

Also, MainActivity now has an action bar with a “launch” item that, when tapped, will bring up the DropActivity in an adjacent window:
if (item.getItemId()==R.id.launch) {
    startActivity(new Intent(this, DropActivity.class)
            .setFlags(Intent.FLAG_ACTIVITY_LAUNCH_ADJACENT |
            Intent.FLAG_ACTIVITY_NEW_TASK |
            Intent.FLAG_ACTIVITY_MULTIPLE_TASK));

    return(true);
}

return(super.onOptionsItemSelected(item));
}

(from DragDrop/SplitScreen/app/src/main/java/com/commonsware/android/dragdrop/MainActivity.java)

Launching MainActivity, entering multi-window mode, and launching DropActivity gives you those two activities in separate windows, such as in split-screen mode:

![Split-Screen Drag Demo, With Both Activities Showing](image-url)

*Figure 679: Split-Screen Drag Demo, With Both Activities Showing*
And, as in the cross-app scenario, you can drag from one window into the other:

![Split-Screen Drag Demo, Part-Way Through a Drag](image1)

Figure 680: Split-Screen Drag Demo, Part-Way Through a Drag

![Split-Screen Drag Demo, After Drag-and-Drop](image2)

Figure 681: Split-Screen Drag Demo, After Drag-and-Drop

However, as was noted above, the local state data is lost in these cross-window drag-and-drop operations, making them indistinguishable from cross-app drag-and-drop operations.
Pondering Legacy Multi-Window

In principle, cross-app drag-and-drop could work with Samsung’s legacy multi-window support. However, calling startDrag() (the pre-Android 7.0 equivalent of startDragAndDrop()) will not grant permissions to the other app to use the content associated with any Uri. The only way to make this work would be if the content identified by the Uri was readable by all apps, which is not great from a security standpoint.

LG’s legacy multi-window support does not seem to support cross-app drag-and-drop.

Also, Chrome OS does not support cross-app drag-and-drop as of the August 2016 round of developer previews.

Dragging and Dropping Simple Stuff

This chapter focuses on drag-and-drop of content, represented by a Uri. That is not your only option, just as that is not your only option for putting stuff onto, or removing stuff from, the clipboard.

A ClipData object contains one or more ClipData.Item objects. These can be of three main forms:

- Text, in the form of a CharSequence, including support for any standard Android spans
- An Intent, usually designed for creating some sort of shortcut to be able to launch an activity identified by the Intent
- A Uri

Outside of specialized cases (e.g., home screens), if you are not using Uri, probably you are using text.

If you are implementing a drop target, and all you know how to do is handle text, you can call coerceToText() on a ClipData.Item object to get the best text representation of whatever it is. For Uri values pointing to text content, coerceToText() will read in the content and return it. For anything else, you get back toString() on the content, more or less.
Multi-Action Drag-and-Drop

The previous section brings up home screens as an example of drag-and-drop. On many Android home screen implementations, if you long-click on an icon in the launcher, you can drag-and-drop that icon into the home screen itself, thereby creating a shortcut. However, in addition to that, many home screens also offer special drop targets tied to specific actions, such as “Uninstall”. If the user drops the icon over the home screen area, a shortcut gets created; if the user drops the icon over a special drop target, the action for that target is performed.

You can do this too.

Mostly, it is a matter of arranging to show those special drop targets only during a drag-and-drop operation, then handling those drops specifically. However, due to the nature of Android’s view hierarchy and the drag-and-drop framework, you need to ensure that you show the special drop target’s view before you start the drag-and-drop operation. Otherwise, the special drop target’s view will never receive ACTION_DRAG_ENTERED or ACTION_DROP events.

We can see how this works in practice in the DragDrop/Action sample project. This is a clone of the DragDrop/Simple app from earlier in this chapter, except that we have added a special “Video Info” drop target.

The Layout

The -w800dp layout is mostly as it was in the original app, except that we have added an info TextView above the RecyclerView:

```xml
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal">

    <LinearLayout
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:orientation="vertical">

        <TextView
            android:id="@+id/info"
            android:text="Drag and Drop"
        />

    </LinearLayout>
</LinearLayout>
```
DRAG AND DROP

```xml
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:layout_gravity="center_horizontal"
android:layout_margin="8dp"
android:padding="8dp"
android:text="@string/label_video_info"
android:textAppearance="?android:textAppearanceLarge"
android:visibility="gone" />

<android.support.v7.widget.RecyclerView
android:id="@+id/video_list"
android:layout_width="match_parent"
android:layout_height="match_parent" />
</LinearLayout>

<LinearLayout
android:layout_width="0dp"
android:layout_height="match_parent"
android:layout_weight="1"
android:orientation="vertical">

<FrameLayout
android:id="@+id/video_frame"
android:layout_width="match_parent"
android:layout_height="0dp"
android:layout_marginBottom="4dp"
android:layout_weight="1"
android:padding="4dp">

<VideoView
android:id="@+id/player"
android:layout_width="match_parent"
android:layout_height="match_parent"
android:layout_gravity="center" />

</FrameLayout>

<FrameLayout
android:id="@+id/thumbnail_frame"
android:layout_width="match_parent"
android:layout_height="0dp"
android:layout_weight="1"
android:padding="4dp">

<ImageView
android:id="@+id/thumbnail_large"
android:layout_width="match_parent"
android:layout_height="match_parent"
android:scaleType="centerInside" />
```

2226
However, this TextView has a visibility of gone at the outset, so it will not show up for users.

**Showing and Hiding the Action**

onCreate() initializes an info field with the TextView, much as it initializes the fields for the VideoView and ImageView:

```java
player=findViewById(R.id.player);
if (player!=null) {
    player.setOnDragListener(this);
}
thumbnailLarge=findViewById(R.id.thumbnail_large);
if (thumbnailLarge!=null) {
    thumbnailLarge.setOnDragListener(this);
}
info=findViewById(R.id.info);
if (info!=null) {
    info.setOnDragListener(this);
}
```

However, since info is gone, the user cannot drag anything over it. We need to arrange to make it visible.

You might try making it visible in onDrag(), when we get the ACTION_DRAG_STARTED event. After all, this would seem to describe what we want: when the drag begins, show the special drop target as an option for the user. Unfortunately, this does not work: while the user can see the info TextView, that TextView does not get any further onDrag() events.

Instead, we are forced to arrange to make the info view visible before starting the drag-and-drop operation. As a side effect, that requirement means that we cannot
use this technique for cross-app drag-and-drop, since we have no idea when some other app starts the drag-and-drop operation.

In fact, it is even a bit awkward to handle in this app, as it is the RowController that initiates the drag-and-drop operation. The RowController knows nothing about the info view, nor should it. Instead, we need to have the RowController let the MainActivity know that a drag-and-drop operation is about to start, so the activity can show the view.

To that end, RowController defines an OnStartDragListener interface. It expects to get such a listener as a constructor parameter, storing it in a field for later use:

```java
class RowController extends RecyclerView.ViewHolder
    implements View.OnClickListener, View.OnLongClickListener {

    interface OnStartDragListener {
        void onStartDrag();
    }

    final private TextView title;
    final private ImageView thumbnail;
    private Uri videoUri = null;
    private String videoMimeType = null;
    final private OnStartDragListener listener;

    RowController(View row, OnStartDragListener listener) {
        super(row);

        this.listener = listener;
        title = (TextView)row.findViewById(android.R.id.text1);
        thumbnail = (ImageView)row.findViewById(R.id.thumbnail);

        row.setOnClickListener(this);
        row.setOnLongClickListener(this);
    }

    @Override
    public boolean onLongClick(View v) {
        if (listener != null) {
            listener.onStartDrag();
        }
    }
```
The RowController instances are created by the VideoAdapter. Fortunately, VideoAdapter is a nested class inside of MainActivity. So, we implement OnStartDragListener on MainActivity and pass the activity instance to the RowController constructor:

```java
@Override
public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
    return new RowController(getLayoutInflater().inflate(R.layout.row, parent, false), MainActivity.this);
}
```

All the onStartDrag() method does is make the info view visible:

```java
public void onStartDrag() {
    info.setVisibility(View.VISIBLE);
}
```

If we make it visible, clearly we need to hide it again at some future point. That would be when the drag-and-drop operation has completed, and it is safe for us to mark info as GONE in our handling of ACTION_DRAG_ENDED in onDrag():

```java
    public void onDrag() { 
        case DragEvent.ACTION_DRAG_ENDED: 
            applyDropHint(v, -1); 
            info.setVisibility(View.GONE); 
            break; 
    }
```

Handling Drag Events

We still want to show the drop hint backgrounds, but in this case, we apply them
directly to the TextView, rather than going with a wrapping FrameLayout. So, we adjust applyDropHint() to only work with the parent of the view if this is not the info view:

```java
private void applyDropHint(View v, int drawableId) {
    if (v != info) {
        v = (View) v.getParent();
    }

    if (drawableId > -1) {
        v.setBackgroundResource(drawableId);
    } else {
        v.setBackgroundResource(null);
    }
}
```

And, in ACTION_DROP processing, if the user dropped the content over the info view, we simply show a Toast with the text of the Uri:

```java
case DragEvent.ACTION_DROP:
    ClipData.Item clip = event.getClipData().getItemAt(0);
    Uri videoUri = clip.getUri();

    if (v == player) {
        player.setVideoURI(videoUri);
        player.start();
    } else if (v == info) {
        Toast.makeText(this, videoUri.toString(), Toast.LENGTH_SHORT) .show();
    } else {
        Picasso.with(thumbnailLarge.getContext())
            .load(videoUri.toString())
            .fit().centerCrop()
            .placeholder(R.drawable.ic_media_video_poster)
            .into(thumbnailLarge);
    }
```
The Result

Now, when you run the app on a sufficiently-wide screen, and you start a drag-and-drop operation, the “Video Info” TextView appears and serves as a drop target:

![Figure 682: Drag-And-Drop, Showing Special Drop Target](image)

Nested Drop Targets

You may have a need for nested drop targets, where you are listening for drag events both on some container and on some view inside of that container. For example, if you are using the drag-and-drop APIs to support reordering items in a LinearLayout or RecyclerView, there is a good chance that you will need to have listeners both on that container and on existing items in the container (e.g., to animate them out of the way to allow the user to drop in the newly-vacant spot).

Alas, this is an area that has some undocumented behavior changes in Android 7.0, as Dan Lew uncovered in August 2016.

The [DragDrop/Nougat](#) sample project illustrates the old and new behavior, plus some code to get Android 7.0 to behave more like the older versions of Android.
The behavior change is triggered by nested drop targets, which means we need a nested layout, such as this one:

```xml
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout
    android:id="@+id/outer_container"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@color/outer_normal"
    android:padding="48dp">

    <FrameLayout
        android:id="@+id/inner_container"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:background="@color/inner_normal"
        android:padding="48dp">

        <ImageView
            android:id="@+id/thumbnail_large"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:background="@color/image_normal"
            android:contentDescription="@string/icon"
            android:scaleType="centerInside" />
    </FrameLayout>
</FrameLayout>
```

(from DragDrop/Nougat/app/src/main/res/layout/bug.xml)
Here, we have a FrameLayout holding onto another FrameLayout, which holds onto an ImageView, each with a different background color:

![Garish Background Colors](image)

*Figure 683: Garish Background Colors*

Further, suppose that we are interested in drag events for all three of these, so we call `setOnDragListener()` for each of them. In the code, we set the background of a drop target to green when we get an `ACTION_DRAG_ENTERED` event for the target, and we revert to the original background in `ACTION_DRAG_EXITED`, `ACTION_DRAG_ENDED`, and `ACTION_DROP`.

**The Behavior Prior to Android 7.0**

On Android 6.0 and earlier, drag events are inclusive. In other words, if the user has dragged an item into the inner `FrameLayout`, this is *also* considered to be inside the outer `FrameLayout`. From an event standpoint, the outer `FrameLayout` only gets an `ACTION_DRAG_EXITED` event when the dragged item leaves its outer boundaries.
So, as the user drags an item into our nested drop targets, outer targets remain green, even as the item enters inner targets:

*Figure 684: Dragging Over Outer Drop Target on Android 6.0*
Figure 685: Dragging Over Inner Drop Target on Android 6.0

Figure 686: Dragging Over ImageView Drop Target on Android 6.0
Android 7.0 Behavior

However, on Android 7.0, drag events are exclusive. If the user drags an item into the inner FrameLayout, the item will exit the outer FrameLayout from a drag-and-drop perspective. So, as the user drags the item towards the inner-most drop target, the user exits the outer drop targets, and we restore the backgrounds along the way:

Figure 687: Dragging Over Outer Drop Target on Android 7.0
**Figure 688:** Dragging Over Inner Drop Target on Android 7.0

**Figure 689:** Dragging Over ImageView Drop Target on Android 7.0
Getting Inclusive on Android 7.0

Which approach is “correct” is somewhat immaterial, as we need consistency across Android OS versions.

The sample app offers one workaround for the discrepancy: a DropTarget class that provides inclusive behavior on Android 7.0. Basically, it serves as a composite OnDragListener, forwarding onDrag() calls to widgets as appropriate. This includes forwarding events to parents of widgets, if those parents are part of the DropTarget coverage:

```java
package com.commonsware.android.dragdrop;

import android.os.Build;
import android.view.DragEvent;
import android.view.View;
import android.view.ViewParent;
import java.util.ArrayList;

public class DropTarget implements View.OnDragListener {
    private ArrayList<View> views = new ArrayList<>();
    private View.OnClickListener listener;

    public DropTarget(View... views) {
        for (View v : views) {
            this.views.add(v);
            v.setOnDragListener(this);
        }
        return(this);
    }

    public void to(View.OnDragListener listener) {
        this.listener=listener;
    }

    @Override
    public boolean onDrag(View view, DragEvent dragEvent) {
        if (Build.VERSION.SDK_INT<Build.VERSION_CODES.N) {
            return(listener.onDrag(view, dragEvent));
        }
        boolean result=listener.onDrag(view, dragEvent);
        ViewParent parent=view.getParent();
        while (parent!=null && parent instanceof View) {
```
Drag and Drop

```java
View parentView = (View) parent;

if (views.contains(parentView)) {
    listener.onDrag(parentView, dragEvent);
}

parent = parentView.getParent();

return (result);
```

(from DragDrop/Nougat/app/src/main/java/com/commonsware/android/dragdrop/DropTarget.java)

For each of the views that DropTarget is set to monitor, the DropTarget sets itself up as the OnDragListener. In onDrag(), if we are on a pre-7.0 version of Android, DropTarget just forwards the event along normally. If, however, we are on Android 7.0 or higher, onDrag():

- Calls onDrag() for the listener attached to the DropTarget, using the View originally passed into onDrag(), and holding onto the result boolean
- Walks the chain of parents, calling onDrag() on the listener for each of those that are part of our monitored set of views
- Returns the value from the original (inner-most) onDrag() call on the listener

Then, instead of registering the activity as the OnDragListener like this:

```java
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    image = (ImageView) findViewById(R.id.thumbnail_large);
    image.setOnDragListener(this);
    findViewById(R.id.outer_container).setOnDragListener(this);
    findViewById(R.id.inner_container).setOnDragListener(this);
}
```

(from DragDrop/Nougat/app/src/main/java/com/commonsware/android/dragdrop/BugActivity.java)

we can use DropTarget:

```java
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);
```

2239
The result is more inclusive behavior. In the case of this sample app, it happens to be sufficient to allow Android 7.0 to behave as does Android 6.0 and earlier. More sophisticated drag-and-drop implementations may need a more sophisticated approach than DropTarget to achieve a similar workaround.

The State of the Bugs

Both bugs filed by Dan Lew have been marked as “FutureRelease”, with a comment on one indicating that the new exclusive behavior would be restricted to apps with a targetSdkVersion of 24 or higher. It is unclear exactly when this change will be released. And, since many apps will have a targetSdkVersion of 24 or higher to avoid warning messages in Android 7.0+ multi-window, the proposed fixes may not help much.

Pondering Standards

Framework-supplied drag-and-drop has not been all that popular to date. As a result, there are no common conventions for how to designate drop targets for the user. Similarly, as of mid-2016, there appears to be no recommendations for this in the Material Design guidelines from Google.

Eventually, the Android development community will start to coalesce around certain patterns, with or without Google’s assistance. Experiment now, but watch for conventions to emerge, then adopt those conventions, where they make sense for your app.

Pondering Accessibility

Drag-and-drop is not particularly accessible. Visually-impaired users may have
difficulty discerning where one can drag from and where one can drag to. Motor-impaired users may have difficulty doing the gesture to initiate drag-and-drop or in dragging the shadow to the desired location.

As a result, while drag-and-drop is a worthy feature, ensure that it is not the only option for performing some action. There should be some other way to do that action, and perhaps more than one other way to do that action, such as:

- Keyboard shortcuts
- Copy-and-paste, perhaps using action modes
- Direct manipulation (e.g., use drag-and-drop on overview screens with lists, plus offer an action bar item or other affordances on detail screens to perform the same action)
More and more Android users are starting to use external keyboards and mice with their devices. Sometimes, the device is designed for such use, such as the Jide Remix Mini or all-on-one units like the HP Slate 21. Some people use Android devices designed for use with a TV as quasi-desktops. And, starting in 2016, we have Android available on some Chrome OS devices, most of which rely on keyboard and mouse/trackpad input.

Over time, more and more Android users are going to be expecting Android apps to behave like desktop apps with respect to keyboards and mice. Some of this capability will be built into Android. Some of this capability will need to be handled by apps or libraries.

In this chapter, we will explore various techniques for making your Android app more friendly to keyboards and mice.

**Prerequisites**

Understanding this chapter requires that you have read the core chapters. Many of the examples use RecyclerView, so you may wish to review that chapter if you have not used RecyclerView very much. Also, some of the examples are based on drag-and-drop samples covered elsewhere in the book.

**Offering Keyboard Shortcuts**

One thing that users will expect from desktop-style apps is the ability to use keyboard shortcuts. Basic keyboard navigation comes “for free” for a lot of Android use cases, though in some situations you will need to add in your own keyboard.
KEYBOARD AND MOUSE INPUT

smarts, such as for navigating a RecyclerView. And some keyboard shortcuts will come automatically, such as Ctrl-C and Ctrl-V for copy and paste within an EditText.

Anything beyond that, though, you would have to provide yourself.

Action Bar Item Shortcuts

The simplest way to add keyboard shortcuts is to use android:alphabeticShortcut or android:numericShortcut on your <item> elements in a <menu> resource that you use to populate an action bar. Android will automatically support those in concert with the Ctrl key. So, for example, if you had:

```xml
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/play_video"
    android:alphabeticShortcut="p"
    android:icon="@drawable/ic_movie_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_video" />
  <item
    android:id="@+id/show_thumbnail"
    android:alphabeticShortcut="t"
    android:icon="@drawable/ic_insert_photo_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_thumbnail" />
</menu>
```

(from KBMouse/HotkeysN/app/src/main/res/menu/actions.xml)

then your onOptionsItemSelected() method would be called not only if the user taps on the action bar items on-screen, but also if the user pressed Ctrl-P or Ctrl-T on the keyboard.

As the names suggest, android:alphabeticShortcut takes a letter and android:numericShortcut takes a number. However, try to avoid overriding existing shortcuts with unrelated logic. For example, you might consider using android:alphabeticShortcut="v" for a “play video” action, but that would conflict with the Ctrl-V shortcut used for paste. You would be better off going with android:alphabeticShortcut="p" to avoid the conflict.

In Android 8.0+, in Java, we can call variations on setAlphabeticShortcut(),
setNumericShortcut(), and setShortcuts() that allow us to change the modifier keys from the default. There are equivalent android:alphabeticModifiers and android:numericModifiers attributes for <item> elements in a menu resource, to indicate the modifier keys to be used with alphabetic and numeric shortcuts.

**Arbitrary Hotkeys**

You may find that the action bar approach is insufficient:

- It may not make sense to have action bar items for the particular operations that you want to offer keyboard shortcuts for
- You may want to support key combinations other than Ctrl and a letter or number

You are welcome to make anything be a keyboard shortcut or “hotkey”, by overriding the appropriate KeyEvent methods in an Activity or View.

The KBMouse/Hotkeys sample project is a clone of the DragDrop/Simple sample app from [the chapter on supporting drag-and-drop](#). As with the original app, we show a list of available videos on the device, which the user can play or view a larger thumbnail from the video. However, in addition to drag-and-drop as a way of doing those things, this sample app also supports keyboard shortcuts:

- **Alt-Right** to play the video
- **Ctrl-Right** to view the large thumbnail

However, these keyboard shortcuts imply that the user has chosen a video to play. So, this sample app blends in the keyboard-enabled RecyclerView code from [the corresponding section in the RecyclerView chapter](#). So, as the user presses the Down and Up arrow keys, the chosen row is highlighted. That will be the video that we work with, if the user then goes and presses **Alt-Right** or **Ctrl-Right**.

This means that we need our play-the-video and show-the-large-thumbnail code to be accessible from multiple entry points, so we pull those out into dedicated playVideo() and showLargeThumbnail() methods that take the video Uri as input:

```java
private void playVideo(Uri videoUri) {
    player.setVideoURI(videoUri);
    player.start();
}
```
KEYBOARD AND MOUSE INPUT

```java
private void showLargeThumbnail(Uri videoUri) {
    Picasso.with(thumbnailLarge.getContext())
        .load(videoUri.toString())
        .fit().centerCrop()
        .placeholder(R.drawable.ic_media_video_poster)
        .into(thumbnailLarge);
}
```

We then use those from the `ACTION_DROP` processing, for when the user drops the video into either the VideoView (referenced in the player field) or the ImageView:

```java
case DragEvent.ACTION_DROP:
    ClipData.Item clip=event.getClipData().getItemAt(0);
    Uri videoUri=clip.getUri();

    if (v==player) {
        playVideo(videoUri);
    } else {
        showLargeThumbnail(videoUri);
    }
    break;
```

Handling the keyboard shortcuts is relatively straightforward, courtesy of the `onKeyDown()` callback that we override:

```java
@Override
public boolean onKeyDown(int keyCode, KeyEvent event) {
    if (keyCode==KeyEvent.KEYCODE_DPAD_RIGHT && event.getRepeatCount()==0) {
        int position=adapter.getCheckedPosition();

        if (position>=0) {
            Uri videoUri=adapter.getVideoUri(position);

            if (event.isAltPressed()) {
                playVideo(videoUri);
            } else if (event.isCtrlPressed()) {
                showLargeThumbnail(videoUri);
            }
        }
    }
    return false;
}
```
We are passed an int keycode (keyCode) and the full KeyEvent for whatever key that the user pressed. If the main key was Right (identified as KEYCODE_DPAD_RIGHT for historical reasons, and to support D-pad directional navigation options), we find out which row in the RecyclerView is checked, if any. If we have a checked row, we find out what the Uri is of the video, then call isAltPressed() and isCtrlPressed() on the KeyEvent to find out which modifier key was pressed in conjunction with Right, if any. If we have a match, we call the associated playVideo() or showLargeThumbnail() method.

onKeyDown() tends to model user expectations, in that the user expects the event to occur when the key is pressed. However, if the user continues holding down the key, we will get a stream of onKeyDown() calls. That is why we also check getRepeatCount(), to ignore the repeated keypresses, so we only try playing the video or showing the large thumbnail once if the user holds down Alt-Right or Ctrl-Right.

**Android 7.0 Keyboard Shortcuts Helper**

The next challenge is letting the user know what keyboard shortcuts are available. Historically, our primary option would be to hope that the user reads the app’s documentation.

(you can stop laughing now)

Android 7.0 recognizes this and provides a system-wide keyboard shortcuts helper. The user can invoke this using one keyboard shortcut that (hopefully) the user will remember: Meta-/ . On a Windows-centric keyboard, the Meta key is the one with the Windows logo on it.

On pre-N devices, you could offer your own keyboard shortcut mapped to Alt- and pop up your own keyboard shortcut dialog. Since / is neither a letter or a number, and since having a keyboard shortcut action bar item might not make
Keyboard and Mouse Input

In the KBMouse/HotkeysN sample project, we will see how to:

- Add our own information to the keyboard shortcuts helper
- Show our own keyboard shortcuts helper on pre-N devices
- Use action bar item alphabetic shortcuts

Mostly, the project is a clone of the hotkey sample shown above, with the build.gradle file updated to build for Android 7.0:

```groovy
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.android.support:support-fragment:27.1.1'
    implementation 'com.android.support:recyclerview-v7:27.1.1'
    implementation 'com.squareup.picasso:picasso:2.5.2'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        applicationId "com.commonsware.android.kbmouse.hotkeys.n"
        minSdkVersion 23
        targetSdkVersion 27
    }
}
```

(from KBMouse/HotkeysN/app/build.gradle)

We have a menu resource now for our action bar, which happens to be the one shown towards the start of this chapter:

```xml
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:id="@+id/play_video"
        android:alphabeticShortcut="p"
        android:icon="@drawable/ic_movie_white_24dp"
        android:showAsAction="always"
        android:title="@string/menu_video" />
    <item android:id="@+id/show_thumbnail"
```
We inflate that menu resource in `onCreateOptionsMenu()` using the typical recipe:

```java
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
    return (super.onCreateOptionsMenu(menu));
}
```

In `onOptionsItemSelected()`, we need to confirm that the user has selected a row in the `RecyclerView` using the keyboard. If that is the case, we can play the video or show the thumbnail, depending upon which action bar item the user used. Otherwise, we show a `Toast` to point out the problem:

```java
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    int position = adapter.getCheckedPosition();

    if (item.getItemId()==R.id.play_video) {
        if (position>=0) {
            playVideo(adapter.getVideoUri(position));
        }
    } else {
        Toast.makeText(this, R.string.msg_choose, Toast.LENGTH_LONG).show();
    }

    return(true);
}
else if (item.getItemId()==R.id.show_thumbnail) {
    if (position>=0) {
        showLargeThumbnail(adapter.getVideoUri(position));
    }
} else {
    Toast.makeText(this, R.string.msg_choose,
    Toast.LENGTH_LONG).show();
}
```
Alternatively, you might elect to disable or hide those action bar items until the user selects a row with the keyboard.

We do not need to do anything special in our code to handle the alphabetic shortcuts — those are applied by Android automatically, routing to the same onOptionsItemSelected(). In other words, whether the user chooses the action bar item via a keyboard, mouse, or touchscreen, our same code runs.

The user will find out about those shortcuts through a keyboard shortcuts helper. On Android 7.0 and higher, the system will provide one for us. Note that this helper is implemented as a system-supplied dialog-themed activity. As such, our activity is paused (as we no longer get input) but not stopped (as the helper dialog is not full-screen).

We do not need to do anything special in our code to enable the keyboard shortcuts helper on Android 7.0. However, that helper only knows about our action bar item alphabetic shortcuts, plus system-wide shortcuts. It does not know anything about the Alt-Right and Ctrl-Right shortcuts that we are handling ourselves. However, we can override onProvideKeyboardShortcuts() in our activity to add information to this dialog about our custom shortcuts:
This is not especially well documented at this point. What seems to work is:

- Create a new List of KeyboardShortcutInfo objects
- Add one of those for each custom shortcut, via the KeyboardShortcutInfo constructor, where you provide a description, the primary key, and the modifier (e.g., META_ALT_ON) for the shortcut
- Wrap the List of KeyboardShortcutInfo objects in a KeyboardShortcutGroup, with your own caption for the group
- Add that KeyboardShortcutGroup to the passed-in List

This gives us:

![Android 7.0 Keyboard Shortcuts Helper, With Custom Info](image.png)

The alphabetic shortcuts from the menu appear in a group whose name matches our activity’s label. That is followed by our “Custom App Hotkeys” group. Ideally, these
two groups would be merged, since both lists are fairly short and both pertain to this app. While we might be able to retrieve the existing group from the supplied list of KeyboardShortcutGroup objects and modify it, since that is not documented, that is not safe.

This shortcut helper dialog is only available on Android 7.0. For consistency, it might be nice to offer a similar helper on older devices. To do that, we need to find out when the user presses Meta-/ on those older devices, which we handle in onKeyDown():

```java
@Override
public boolean onKeyDown(int keyCode, KeyEvent event) {
    if (event.getRepeatCount() == 0) {
        if (keyCode == KeyEvent.KEYCODE_DPAD_RIGHT) {
            int position = adapter.getCheckedPosition();
            if (position >= 0) {
                Uri videoUri = adapter.getVideoUri(position);
                if (event.isAltPressed()) {
                    playVideo(videoUri);
                }
                else if (event.isCtrlPressed()) {
                    showLargeThumbnail(videoUri);
                }
                return (true);
            }
        }
    } else if (keyCode == KeyEvent.KEYCODE_SLASH &&
               event.isMetaPressed() &&
               Build.VERSION.SDK_INT < Build.VERSION_CODES.N) {
        new ShortcutDialogFragment().show(getSupportFragmentManager(),
                                       "shortcuts");
        return (true);
    }
    return (super.onKeyDown(keyCode, event));
}
```

On those devices, we show a ShortcutDialogFragment, which just displays an AlertDialog with some simple text about our shortcuts:
Not every device will have a Meta key — the Pixel C’s keyboard dock, for example, lacks this key. However, we have no good way of determining if a given hardware keyboard has a Meta key. Our options would be:

- To offer keyboard shortcuts help using a different key combination, even if that is non-standard with respect to Android 7.0
- Ignore the problem, not offering keyboard shortcuts help on such devices, until such time as there is an official solution

**Custom Copy-and-Paste**

Since the alphabetic shortcuts for action bar items are triggered via the Ctrl key, one can have action bar items for Ctrl-C and Ctrl-V, offering custom copy and paste shortcuts for your activity. This is particularly important for accessibility, when your app is reliant upon something else to get content from one point to another. For example, custom copy and paste options could be used as alternatives to drag and drop, including Android 7.0’s cross-app drag-and-drop.
The KBMouse/CopyPaste sample project is a clone of the cross-app drag-and-drop sample, with two app modules: drag/ and drop/. This time, though, we are also going to allow the photo to be copied to the clipboard in drag/ and pasted from the clipboard in drop/, as a more accessible alternative. As a side benefit, this will work even on single-window environments, whereas cross-app drag-and-drop assumes that both apps are visible at the same time.

The drag/ app has a menu resource that contains our copy item, with android:alphabeticShortcut set to c:

```xml
<?xml version="1.0" encoding="utf-8"?>
<menu
    xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/copy"
        android:alphabeticShortcut="c"
        android:icon="@drawable/ic_content_copy_white_24dp"
        android:showAsAction="ifRoom"
        android:title="@android:string/copy"/>
</menu>
```

We load that resource in onCreateOptionsMenu() as normal. In onOptionsItemSelected(), we implement the copy by getting the ClipboardManager system service and calling setPrimaryClip() to populate the clipboard:

```java
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.copy) {
        getSystemService(ClipboardManager.class)
            .setPrimaryClip(buildClip());
        Toast
            .makeText(this, R.string.msg_copy, Toast.LENGTH_SHORT)
            .show();

        return(true);
    }
    return(super.onOptionsItemSelected(item));
}
```

Note that we use the API Level 23+ edition of getSystemService(), the one that takes the Java class object for the system service as a parameter (instead of a service
name) and returns to us the system service already in the proper data type.

What we put on the clipboard is the result of `buildClip()`, which creates a `ClipData` around a `Uri` to the photo that we are publishing from this app:

```java
private ClipData buildClip() {
    Uri uri = PROVIDER
        .buildUpon()
        .appendEncodedPath(StreamProvider.getUriPrefix(AUTHORITY))
        .appendEncodedPath("assets/FreedomTower-Morning.jpg")
        .build();

    return ClipData.newRawUri(getString(R.string.msg_photo), uri);
}
```

We happen to be using `StreamProvider` to serve the photo straight from assets, and so we are building up a `Uri` pointing to that asset.

The drop/ app also has a menu resource, this one set up for a paste action tied to `Ctrl-V`:

```xml
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/paste"
        android:alphabeticShortcut="v"
        android:icon="@drawable/ic_content_paste_white_24dp"
        android:showAsAction="ifRoom"
        android:title="@android:string/paste" />
</menu>
```

And here, `onOptionsItemSelected()` handles the paste request by getting the `Uri` off the clipboard and using that, in much the same way that we use the `Uri` dropped on our UI:

```java
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.paste) {
        boolean handled=false;

        ClipData clip=
            getSystemService(ClipboardManager.class)
```
.getPrimaryClip();

if (clip!=null) {
    ClipData.Item clipItem=clip.getItemAt(0);

    if (clipItem!=null) {
        imageUri=clipItem.getUri();

        if (imageUri!=null) {
            showThumbnail();
            handled=true;
        }
    }
}

if (!handled) {
    Toast.makeText(this, "Could not paste an image!", Toast.LENGTH_LONG)
        .show();
}

return(handled);
}

return(super.onOptionsItemSelected(item));

(from KBMouse/CopyPaste/drop/src/main/java/com/commonsware/android/dragdrop/MainActivity.java)

Note that we do not do any MIME type checking to see if the Uri points to an image that we can use. We are relying on Picasso to show an error image if it is unable to use the Uri, as part of the showThumbnail() processing:

private void showThumbnail() {
    Picasso.with(this)
        .load(imageUri)
        .fit().centerCrop()
        .placeholder(R.drawable.ic_photo_size_select_actual_black_24dp)
        .error(R.drawable.ic_error_black_24dp)
        .into(image);
}

(from KBMouse/CopyPaste/drop/src/main/java/com/commonsware/android/dragdrop/MainActivity.java)

A more sophisticated app might check to see if the MIME type associated with the Uri made sense, using either ContentResolver or DocumentFile. That way, we could offer a custom error message if the user attempted to copy something else.
However, we do have crude logic to handle:

- an empty clipboard
- aClipData with no items
- aClipData without a Uri (e.g., plain text copied to the clipboard)

**Physical Keyboards and Focusing**

In [an article complaining about Android's tablet support](https://arstechnica.com/gadgets/2014/01/ars-technica-android-tablets-hands-on/), Ars Technica's Ron Amodeo pointed out an interesting problem for devices with physical keyboards: setting the focus properly when an activity starts up. This can be addressed in a number of ways; this section shows how you can use a [custom BindingAdapter and the data binding framework](https://developer.android.com/guide/topics/data/data-binding) to help manage this problem.

**The Problem**

Suppose that you have a form that has a mix of widgets in it, including one or more EditText widgets. In particular, suppose that one of the EditText widgets is near the beginning of the activity's layout.

If you allow that widget to get the focus when the activity starts up, and the device does not have a physical keyboard, the input method editor (IME, a.k.a., “soft keyboard”) appears immediately. This can be annoying to users, as perhaps they do not want to type anything into that EditText. Depending on the orientation of the phone and other settings, either the IME ties up a bunch of screen space that could be used for other things, or the user cannot see anything other than the full-screen landscape IME.

To save the user having to keep dismissing the IME, you might elect to give some other widget the focus at the outset.

However, for devices with a physical keyboard, no IME will appear. And, for users who do want to start typing right away, having the focus lie elsewhere is aggravating.

It would be cool if Android offered a `android:requestFocus` attribute that took a few possible values:

- true, meaning this widget always got the focus (replacing the `[requestFocus/]` child element used for this today)
- false, the default
• ifHardKeyboard, meaning this widget should get the focus for devices with a physical keyboard
• ifNoHardKeyboard, meaning this widget should get the focus for devices without a physical keyboard

Layouts might then use android:requestFocus on two widgets, one with ifHardKeyboard and one with ifNoHardKeyboard, to designate which widget should get the focus in either case.

Alas, this attribute does not exist. However, with a bit of work, and the assistance of the data binding framework, we can implement something fairly close to it, as is demonstrated in the DataBinding/Focus sample project.

A requestFocus BindingAdapter

To invent new View attributes, like the proposed requestFocus attribute, we need a BindingAdapter. The @BindingAdapter annotation can be applied to a static method that takes a View (or some subclass, if it only applies to certain view types) and a parameter indicating what sort of attribute value it expects. Then, it is up to the method to actually update the View as needed.

So, the RequestFocusActivity that demonstrates this feature has a bindRequestFocus() @BindingAdapter method:

```java
@BindingAdapter("app:requestFocus")
public static void bindRequestFocus(View v, String focusMode) {
    Configuration cfg = v.getResources().getConfiguration();
    boolean hasNoKeyboard =
        cfg.keyboard == Configuration.KEYBOARD_NOKEYS;
    boolean keyboardHidden =
        cfg.hardKeyboardHidden == Configuration.HARDKEYBOARDHIDDEN_YES;
    boolean result = false;
    if (TRUE.equals(focusMode)) {
        result = true;
    } else if (IF_HARD_KEYBOARD.equals(focusMode)) {
        if (!hasNoKeyboard && !keyboardHidden) {
            result = true;
        }
    } else if (IF_NO_HARD_KEYBOARD.equals(focusMode)) {
        if (hasNoKeyboard || keyboardHidden) {
            result = true;
            if (hasNoKeyboard) v.setFocusableInTouchMode(true);
        }
    } else {
        throw new IllegalArgumentException("Unexpected focusMode value: "+focusMode);
    }
}
```
Unfortunately, there is no obvious way to constrain a BindingAdapter to some custom enumerated roster of values. So, we have bindRequestFocus() accept a String, and we throw an IllegalArgumentException if the attribute value is not true, if the attribute is not one of three recognized values:

```java
private static final String TRUE = "true";
private static final String IF_HARD_KEYBOARD = "ifHardKeyboard";
private static final String IF_NO_HARD_KEYBOARD = "ifNoHardKeyboard";
```

false is skipped as a potential value, but you could easily extend this to accept and ignore that value.

The key portion of this method is determining whether or not the user has access to a physical keyboard. This has two components:

1. Does the device have a physical keyboard?
2. Is the physical keyboard presently available?

The latter might be “no” for devices with a sliding keyboard, where the keyboard exists but is not presently exposed.

Using a Configuration object, we set up hasNoKeyboard and keyboardHidden boolean values for those two components. Then, we will call setFocusable(true) and requestFocus() on the View if:

- the attribute value is true, or
- the attribute value is ifHardKeyboard and the device has a physical keyboard and the keyboard is not hidden, or
- the attribute value is ifNoHardKeyboard and either the device lacks a physical keyboard or the physical keyboard is hidden

We also call setFocusableInTouchMode(true) if the device has no physical keyboard, to ensure that the widget in question can be focused in touch mode.
before we try setting its focus.

Using the BindingAdapter

The syntax for our attributes is a bit different than what we aimed for:

- We use the app prefix rather than android
- The value has to be a binding expression, otherwise the data binding framework ignores it, so we cannot just use a simple string, but instead have to wrap it in an expression (e.g., `@{"ifNoHardKeyboard"}`)

But, we can use `app:requestFocus` as needed, such as in this layout:

```xml
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto">
  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <Button
      android:id="@+id/button1"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/a_button"
      app:requestFocus='@{"ifNoHardKeyboard"}' />

    <EditText
      android:id="@+id/editText1"
      android:layout_width="0dp"
      android:layout_height="wrap_content"
      android:layout_weight="1"
      android:hint="@string/str_1st_field"
      android:inputType="text"
      app:requestFocus='@{"ifHardKeyboard"}' />

    <EditText
      android:id="@+id/editText2"
      android:layout_width="0dp"
      android:layout_height="wrap_content"
      android:layout_weight="1"
      android:hint="@string/str_2nd_field"
      android:inputType="text" />
  </LinearLayout>
</layout>
```
Here, if the device has an available physical keyboard, we put the focus on the first EditText widget, so that the user can start typing right away. But, if the device lacks an available physical keyboard, we put the focus on the Button, to avoid the IME appearing right away.

**Offering Mouse Context Menus**

One thing that users of mice and trackpads are used to having are context menus, typically displayed as the result of a right-mouse click. More specifically, they are used to a popup menu appearing adjacent to the mouse pointer when they click the right-mouse button.

Android has had its own context menu system since API Level 1. However, it does not look a lot like what desktop users are used to. We can create such a menu ourselves, but it takes a little work, due to bugs and limitations in Android.

Ideally, we would use `PopupMenu`. This does pretty much what the class name implies: displays a popup window containing a menu, driven by a menu resource. However, that popup window will appear to drop down from some anchor `View` that we specify, and there is no way in the public API to adjust its position to be closer to the mouse pointer. Hence, for larger widgets — such as rows in a `ListView` or `RecyclerView` — `PopupMenu` will result in a menu that can appear fairly far away from the mouse pointer, which will be aggravating.

`PopupWindow` and `ListPopupWindow` both allow for fine-grained positioning, which make them better candidates for our purposes. Of the two, `ListPopupWindow` handles the notion of a scrolling list, which may be useful for longer menus. And, we can populate its contents from a simple `ListAdapter`, like an `ArrayAdapter`. The `KBMouse/Context` sample project is a clone of the `KBMouse/Hotkeys` sample app that adds in a `ListPopupWindow` for a mouse-driven context menu... but it takes a bit of work.

First, we need to define what goes in the list of the `ListPopupWindow`. A simple solution for that is to use a string-array resource:

```xml
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <string-array name="popup">
    ...
  </string-array>
</resources>
```
Here, the two items are references to string resources, for internationalization purposes (in theory, at least).

All of our business logic for adding the context menu lies in the RowController — just as it handles clicks (to play the video in a standalone player) and long-clicks (to initiate a drag-and-drop), it can now handle context menus.

First, in the RowController constructor, we register the RowController as handling touch events for the row, via setOnTouchListener:

```java
RowController(View row, ChoiceCapableAdapter<?> adapter) {
    super(row);
    this.adapter = adapter;

    title = (TextView)row.findViewById(android.R.id.text1);
    thumbnail = (ImageView)row.findViewById(R.id.thumbnail);

    row.setOnClickListener(this);
    row.setOnLongClickListener(this);
    row.setOnTouchListener(this);
}
```

That requires RowController to implement the View.OnTouchListener interface, and therefore requires RowController to override onTouch:

```java
@Override
public boolean onTouch(View v, MotionEvent event) {
    if ((event.getButtonState() & MotionEvent.BUTTON_SECONDARY)!=0 &&
        event.getAction()==MotionEvent.ACTION_DOWN) {
        adapter.onChecked(position, true, true);

        String[] items =
            itemView
                .getContext()
                .getResources()
                .getStringArray(R.array.popup);
        ArrayAdapter<String> adapter =
```

2262
To determine if a given MotionEvent is a trigger for the context menu, we check two things:

1. Is the BUTTON_SECONDARY pressed?
2. Is this a “down” event (ACTION_DOWN)?

If yes, we tell our ChoiceCapableAdapter to check this row, so it is clear to the user
what they have right-clicked over.

Then, we load in the string array from the resources and wrap that in a standard ArrayAdapter. At that point, we can begin configuring the ListPopupWindow.

The constructor for the ListPopupWindow takes a Context. We grab the Context from the itemView field of this ViewHolder, which represents our row.

We then call five configuration methods to set up the look-and-feel of the ListPopupWindow. The first four are fairly straightforward:

- `setAnchorView()` specifies the View that this popup is anchored to. In this case, we use the row itself (itemView).
- `setHorizontalOffset()` and `setVerticalOffset()` indicate, from the upper-left corner of the anchor view, where to place the upper-left corner of the ListPopupView. We want the ListPopupView to be adjacent to the mouse pointer, and the `getX()` and `getY()` values of the MotionEvent tell us where inside the itemView the user clicked. However, the default position of the ListPopupWindow is to be anchored to the lower left corner of the anchor view, not the upper left corner. To adjust the horizontal position, we can simply use `getX()`, since both `getX()` and the default horizontal position of the ListPopupWindow are on the left. However, the offset for the vertical position needs to be a negative value, as we want to raise the ListPopupWindow to where the mouse pointer is. That value is the difference between the Y coordinate of the mouse pointer (`getY()`) and the height of the row (`itemView.getHeight()`).
- `setAdapter()` provides the ArrayAdapter to populate the list in the ListPopupWindow.

The fifth method — `setWidth()` — is more complex than it should be, due to a bug. Ideally, we would call `setWidth(ListPopupWindow.WRAP_CONTENT)`. According to the documentation, this will set the width of the ListPopupWindow to be the width of the content of the adapter. Unfortunately, this does not work. And, since that bug has been outstanding since 2013, it is unlikely that it will ever work.

The workaround — as documented in Stack Overflow — is to calculate the maximum width of our adapter rows ourselves, then call `setWidth()` with that pixel value. This is isolated in a `measureContentWidth()` method:

```java
// based on http://stackoverflow.com/a/26814964/115145
```
This implementation iterates over the items in the adapter, has the adapter create row views for each row (using a bit of light caching to try to recycle row views in simple adapters), then determines the measured width of those rows. The longest measured width is then used as the result. This works for simple rows and short lists, which is all we really need here anyway.

Then, we call `setOnItemClickListener()` to register a listener to find out when rows in the list in the `ListPopupWindow` are clicked. This works the same as with a
ListView. In our case, we look at the passed-in position, and route to the activity’s `playVideo()` or `showLargeThumbnail()` methods according to which list item the user clicked upon. We then `dismiss()` the `ListPopupWindow`, so it goes away after the user clicked on one of the list items.

Finally, we can `show()` the `ListPopupWindow`, so it displays its list to the user.

From the user’s perspective, right-clicking over one of the videos in the list offers the context menu:

![Figure 691: Right-Mouse Context Menu](image)

What is missing is the ability for the user to dismiss the context menu. If the user clicks outside the `ListPopupWindow`, it goes away as expected. However, the underlying click event is still processed. So, if the user clicks over the `VideoView` or large thumbnail `ImageView`, everything looks fine. If the user clicks over one of the `RecyclerView` rows… the clicked-upon video starts playing back in a standalone video player, rather than just dismissing the `ListPopupWindow`. This will be addressed in a future edition of this sample app.

Also note that API Level 23 offers `setOnContextClickListener()` on `View`. This works like `setOnClickListener()` and `setOnLongClickListener()`, letting you know via an `OnContextClickListener` that the view was “context-clicked”. However, you do not get details of the touch event, and so you have no good means of positioning the popup to be near where it should go.
Offering Tooltips

Users of desktop operating systems, and even Web apps, are used to having tooltips available on key UI elements (e.g., buttons). In a mouse-driven environment, these usually appear after the mouse has hovered over the UI element for a short while.

Touchscreens can also offer similar contextual help. For example, if the user long-presses on an action bar item's icon, a Toast will appear with the item's title.

So, there are two pieces to the puzzle of offering tooltips:

1. How do you decide when to show a tooltip?
2. What is the UI for the tooltip itself?

As with many things in Android, there are two options, depending on what version of Android you are running on.

Android 7.1 and Older

This section will focus on the first piece — how you decide when to show a tooltip — using a simple Toast for the tooltip UI. There are many Android libraries for tooltip UIs, which you may wish to investigate.

Hover Events

API Level 14 added setOnHoverListener() to View. This, and the corresponding OnHoverListener interface, allow developers to find out when the user is “hovering” over a widget. This can be triggered by a mouse or by some styluses.

The onHover() method of your OnHoverListener will be called when a change in the state of hovering occurs. You are given the affected View, along with the MotionEvent that triggered the state change. The MotionEvent should have one of three actions:

- ACTION_HOVER_ENTER, meaning that the user has begun hovering over the view
- ACTION_HOVER_MOVE, meaning that the user was already hovering over the view, but has moved the mouse pointer, so the hover position within the view bounds has changed
- ACTION_HOVER_EXIT, meaning that the user is no longer hovering over the view
The KBMouse/Tooltip sample project is a clone of the KBMouse/Hotkeys sample app that adds in tooltip support for long-clicks and hovers. MainActivity now implements the OnLongClickListener and OnHoverListener interfaces, so we can register those listeners on our VideoView and large thumbnail ImageView:

```java
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);

    player = findViewById(R.id.player);

    if (player != null) {
        player.setOnDragListener(this);
        player.setOnHoverListener(this);
        player.setOnLongClickListener(this);
    }

    thumbnailLarge = findViewById(R.id.thumbnail_large);

    if (thumbnailLarge != null) {
        thumbnailLarge.setOnDragListener(this);
        thumbnailLarge.setOnHoverListener(this);
        thumbnailLarge.setOnLongClickListener(this);
    }

    setLayoutManager(new LinearLayoutManager(this));
    adapter = new VideoAdapter(getRecyclerView());
    setAdapter(adapter);
    getRecyclerView().requestFocus();

    if (state != null) {
        isInPermission = state.getBoolean(STATE_IN_PERMISSION, false);
    }

    if (hasFilesPermission()) {
        loadVideos();
    } else if (!isInPermission) {
        isInPermission = true;

        ActivityCompat.requestPermissions(this, 
                new String[]{Manifest.permission.READ_EXTERNAL_STORAGE}, 
                REQUEST_PERMS);
    }
}
We will see why we are not registering for events on the RecyclerView a bit later in this chapter.

The `onLongClick()` method for the `OnLongClickListener` forwards the event to a `showTooltip()` method, providing a string resource with the particular message to show:

```java
@override
public boolean onLongClick(View v) {
    if (v==thumbnailLarge) {
        showTooltip(R.string.tooltip_thumbnail);
    } else if (v==player) {
        showTooltip(R.string.tooltip_player);
    } else {
        return(false);
    }
    return(true);
}
```

`showTooltip()` shows a Toast... with a slight wrinkle:

```java
private void showTooltip(@StringRes int message) {
    if (tooltip!=null) {
        tooltip.cancel();
    }
    tooltip=Toast.makeText(this, message, Toast.LENGTH_LONG);
    tooltip.show();
}
```

If, while a tooltip Toast is showing, the user long-clicks on a different widget, we want to show that tooltip immediately. By default, we would have to wait until the first Toast completed its duration. Toast has a `cancel()` method that does one of three things:

1. If the Toast has not yet been shown, it removes the Toast from the roster of pending Toasts
2. If the Toast is presently showing, it gets rid of the Toast  
3. If the Toast was shown previously, it does nothing, as nothing is needed

So, we hold onto the most-recent tooltip Toast in a field named tooltip, and we cancel() it before showing the next tooltip.

The onHover() method for the OnHoverListener forwards the event to a private onHover(), where we supply the string resource of the tooltip message:

```java
@Override
public boolean onHover(View v, MotionEvent event) {  
  if (v==player) {
    onHover(event, R.string.tooltip_player, player);
  }
  else if (v==thumbnailLarge) {
    onHover(event, R.string.tooltip_thumbnail, thumbnailLarge);
  }
  else {
    return(false);
  }
  return(true);
}
```

(from KBMouse/Tooltip/app/src/main/java/com/commonsware/android/kbmouse/hotkeys/MainActivity.java)

And that is where things start to get complicated.

**Detecting a Long-Enough Hover**

The problem is that while we can find out when the user starts and stops hovering over a view, we need additional code to determine when some time has elapsed between those two events. So, for example, if you want to show a tooltip one second after the user begins hovering over a view, you need to:

- Arrange to find out when one second has elapsed after the user starts hovering over the view
- Cancel that work if the user stops hovering over that view, either preventing the tooltip from appearing (if it has not done so yet) or perhaps causing the tooltip to vanish immediately (if it is presently being displayed)

postDelayed() provides a nice cheap way of handling this. We can schedule a Runnable to be invoked after our one-second delay, and we can use
removeCallbacks() to cancel the Runnable if the user stops hovering over that widget.

However, we do not know the exact sequence of hover events. It may be that we are given an ACTION_HOVER_ENTER event for a new widget prior to ACTION_HOVER_EXIT of the previous widget. Hence, we need to track per-widget state.

In this case, the sample app holds onto a Runnable per widget for which we are displaying tooltips, in a SparseArray object:

```java
private SparseArray<Runnable> hoverTimers = new SparseArray<>();
```

A SparseArray is a data structure that allows ArrayList-style indexed access to objects, but it does not assume that the index values are consecutive. Basically, it replaces a HashMap of Integer objects. The SparseArray allows us to use widget IDs as the index values, so as long as each of our tooltip-enabled widgets have unique IDs, we can track their state in the SparseArray.

Our private edition of onHover() uses this SparseArray:

```java
private void onHover(MotionEvent event, @StringRes final int message, final View anchor) {
    Runnable hover = hoverTimers.get(anchor.getId());

    if (hover == null &&
        (event.getAction() == MotionEvent.ACTION_HOVER_ENTER ||
         event.getAction() == MotionEvent.ACTION_HOVER_MOVE)) {
        hover = new Runnable() {
            @Override
            public void run() {
                showTooltip(message);
            }
        };

        hoverTimers.put(anchor.getId(), hover);
        thumbnailLarge.postDelayed(hover, TOOLTIP_DELAY);
    } else if (hover != null &&
        event.getAction() == MotionEvent.ACTION_HOVER_EXIT) {
        thumbnailLarge.removeCallbacks(hover);
        hoverTimers.remove(anchor.getId());
    }
```
There are two scenarios that we care about:

1. The user starts hovering over a widget, and we have not yet set up the timer Runnable, as it does not exist in the SparseArray. So, we create the Runnable to show our tooltip (via `showTooltip()`), stuff it in the SparseArray, and use `postDelayed()` to trigger the Runnable after a second.

2. The user stops hovering over a widget, and we already have the timer Runnable. In this case, we call `removeCallbacks()` to ensure that this Runnable is not run (if it has not run already), plus remove it from the SparseArray.

The net effect is that our Runnable will be invoked if one second elapses after the user starts hovering over a widget and the user has not stopped hovering over that same widget.

`showTooltip()` raises a `Toast` to serve as a crude tooltip:

```java
private void showTooltip(@StringRes int message) {
    if (tooltip!=null) {
        tooltip.cancel();
    }

    tooltip=Toast.makeText(this, message, Toast.LENGTH_LONG);
    tooltip.show();
}
```

However, it is possible that the user displays one tooltip, then quickly hovers over another widget, and that our one-second delay is shorter than the `Toast` display duration. So, we hold onto each `Toast` that we display, and we `cancel()` it before showing the next one. That way, if one `Toast` is outstanding when we need to show a different `Toast`, we can make the switch immediately, rather than having to wait for the rest of the first `Toast` display duration to elapse before showing the next one.

**What We Are Missing**

However, the tooltip for the `VideoView` will not display. `VideoView` is an odd widget,
Keyboard and Mouse Input

Consuming a lot of touch events for no really good reason. Most likely, for a sophisticated Android app, you will want to skip VideoView and use something else, such as a MediaPlayer tied to your own SurfaceView or TextureView.

This sample app does not attempt to provide tooltips for the rows in the RecyclerView. Even though we are set up to show a tooltip for the RecyclerView overall, the hover events are for the rows, not the RecyclerView, as the RecyclerView itself is not visible. If you wanted tooltips here, your choices are:

- Have the tooltip for the whole RecyclerView, forwarding hover events from rows up to your tooltip-management logic
- Have tooltips per row, using some different system than our SparseArray, as the row widget IDs will all be the same by default

Android 8.0+

Android has had the occasional tooltip-like feature, such as the tooltip that you get on action bar items when long-pressing them. Android 8.0 extends this to all widgets. Simply provide the desired text via android:tooltipText or setTooltipText(). A tooltip will then appear when either the user long-presses the widget or if the user hovers over the widget. In both cases, though, if the long-press or hover event is consumed by something else, the tooltip is not shown.

The KBMouse/TooltipO sample project is a clone of the preceding sample app, where we switch to using the tooltip implementation in Android 8.0+.

Specifically, our large-screen layout has tooltips for the VideoView and ImageView widgets, using android:tooltipText:

```xml
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal">

    <android.support.v7.widget.RecyclerView android:id="@+id/video_list"
        xmlns:android="http://schemas.android.com/apk/res/android"
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="1" />

    <LinearLayout
        android:layout_width="0dp"
```
KEYBOARD AND MOUSE INPUT

(from KBMouse/TooltipO/app/src/main/res/layout-w800dp/main.xml)
The result are tooltips reminiscent of those from the original sample:

![Figure 692: Tooltip From Long-Press of ImageView](image)

Hovering over either widget, or long-pressing either widget, will bring up the tooltip.

**Pointer Capture**

On a desktop operating system, the “pointer” refers to the mouse cursor. This feature is normally handled by the operating system. “Pointer capture” refers to when a widget blocks the normal mouse cursor, typically because it is going to use the mouse in some way for which the normal pointer would be inappropriate.

In Android 8.0+, you can call `requestPointerCapture()` and `releasePointerCapture()` to have a widget operate in pointer-capture mode or not.

The vast majority of Android apps should not need this.
The Portable Document Format — better known as PDF — has been around for over two decades, and it is still going strong today. As a result, we often have a need to show PDF files to users, whether those files are:

- Shipped with the app, such as documentation
- Downloaded by the app, such as email attachments for the mail client that you are writing
- Otherwise managed by the app, such as with PDF files held in cloud storage that your app is managing on behalf of the user
- And so on

This is another one of those topics that seems fairly simple on the surface, but can get complicated based on your requirements. In particular, if you want to try to present the PDF to the user in your app, as opposed to launching some external PDF viewing app, while you have a few options, they all have their issues.

In this chapter, we will review several ways of displaying a PDF to the user, so you can choose what approach (or approaches) are the best fit for your requirements.

**Prerequisites**

Understanding this chapter requires that you have read the core chapters of this book.

**The Criteria**

If there are several ways of displaying a PDF, we need some criteria by which to
evaluate those options and make our choice. Here are some likely criteria to use, though you may have others that are more specific to your app’s requirements.

**Where is the PDF?**

Most of the PDF-viewing options assume that the PDF is on the device already. However, even within that, there are a few possibilities as to where the PDF might be:

- Internal storage (e.g., `getFilesDir()`) of your app
- External storage (e.g., `getExternalFilesDir()`) associated with your app
- Common locations on external storage, such as the standard `Documents` directory
- Some `Uri` that you obtained via `ACTION_GET_CONTENT` or `ACTION_OPEN_DOCUMENT`
- An asset or raw resource within your app

And, occasionally, developers get boxed into a corner, with a requirement to show a PDF without downloading the PDF.

**Does It Work Offline?**

The opposite problem is the offline viewing experience. If the PDF is on the device already, ideally, the PDF-viewing technology can show that PDF without having to have an active Internet connection. After all, many users do not have continuous Internet access.

**How Complex is the PDF?**

While the PDF file format has been around for years and years, it has expanded over that time. In the beginning, PDF did not offer things like form fields, annotations, and the like. The more feature-rich your PDF is, the more likely it is that some PDF viewers may be incapable of handling all of those features.

This is not restricted to in-app viewing solutions. PDF viewing apps vary in capability, and there will be some that either do not support your desired features (e.g., allow the user to fill in forms) or only will if the user unlocks the feature through some purchase.
How Stable is the Solution?

Many PDF-viewing apps are continuously updated. If the user happens to choose one that is not, that is the user's fault, not yours.

However, when you build in PDF viewing into your app, now you need to ensure that your solution is up to date and likely to stay stable for the duration of your app's use.

How Private is the PDF?

The big one, in terms of the major options for viewing the PDF, is the degree of privacy that is tied to that PDF.

If the document comes from the user — for example, it came in an email attachment to the user's inbox that you are managing — you should assume a modest level of privacy. Do not ship that PDF to other servers without the user's approval. However, if the user wants to view the PDF, you should not be afraid of allowing the user to do so using the user's chosen PDF viewing app.

If the document is more tightly controlled by your app — for example, it came as an attachment to some secure messaging client that you are writing — you may be nervous about granting other apps access to that PDF. After all, you do not necessarily know what those other apps might do with the PDF.

Where things get very messy is when the developers think that they “own” the PDF, and therefore are trying to restrict that PDF's access, much as how a DRM solution tries to restrict access to videos. Many PDF-viewing apps offer printing, sharing, and other things that the user might want, but that the developers do not want. In truth, it is rather likely that the user can get to the PDF anyway, whether the developers like it or not, by various means (e.g., extracting PDFs packaged in the APK using an ordinary ZIP file utility). But, this seems to be the #1 reason why some developers are trying to view PDF files within their own app: treating the user as the enemy.

The Classic Solution: ACTION_VIEW

The quintessential solution — and the one that you should focus on first — is to use startActivity() with an ACTION_VIEW Intent, where the Uri in that Intent points to your PDF file:

```java
startActivity(new Intent(Intent.ACTION_VIEW, uriToThePdf));
```
This is quick, easy, and gives the user control over how the PDF is rendered, as they can (usually) choose the PDF viewer to use.

However, this is not a universal solution:

- Android itself does not ship with a PDF viewer app, and therefore some devices will not ship with a PDF viewer app. You wind up with an `ActivityNotFoundException` from your `startActivity()` call, and then you need to guide the user to install a PDF viewer app.
- The user may not be able to install such an app, due to limitations imposed by device owner APIs or because the user is using the device on a secondary user account that lacks app-installation capability.
- For maximum compatibility, you will need to set up a `FileProvider` (or the equivalent) and serve your PDF through it, particularly on Android 7.0+ devices, where the file scheme for `Uri` values is banned, in effect.

If you are concerned that the user might choose a PDF viewer app that is malware, or is one that has features that you dislike, you could use `PackageManager` and `queryIntentActivities()` to find all activities that support `ACTION_VIEW` for your PDF file. From there, you can find out the apps associated with those activities, and filter that based on a whitelist (or blacklist) of PDF viewer apps. Then, present your own “chooser”-style UI to allow the user to choose from among the valid options.

**The Really Bad Idea: Google Docs**

Some developers, though, try desperately to avoid using external PDF viewer apps.

The approach that many of those developers try is the worst available option: have Google Docs render the PDF in a `WebView`, using code reminiscent of:

```java
WebView webview=(WebView)findViewById(R.id.webview);
webview.getSettings().setJavaScriptEnabled(true);
webview.loadUrl("http://drive.google.com/viewerNg/
viewer?embedded=true&url=" + urlToYourPdf);
```

This has many poor characteristics:

- It requires that the PDF be available publicly on the Web, for Google Docs to be able to access it. From a security standpoint, many more attackers can
access the PDF online than can on an Android device.

• If the PDF is not already available publicly on the Web, you would need to run a server, or employ some cloud storage or similar service, to host that PDF, adding to your complexity.

• If the PDF needs to be uploaded, now you are consuming lots of extra bandwidth. Not only did you (probably) download the PDF from somewhere, but now you have to re-upload it somewhere, then download whatever bits and bytes the WebView winds up using to display it, as served from Google Docs.

• There is no requirement that Google keep this Google Drive view-an-arbitrary-PDF URL working. As soon as they change it, your app breaks. As soon as they discontinue it, this approach has to be replaced anyway.

• This approach requires a live Internet connection. There is no offline option.

Pretty much anything else will be better than this solution.

## The Built-In Option: PdfRenderer

Routinely, developers are astonished that Android does not ship with some sort of PDF-viewing app, the way that desktop operating systems do.

The closest thing that Android has to a built-in PDF viewer is PdfRenderer. This class was added in API Level 21 (Android 5.0), and it allows you to render pages of a PDF to Bitmap objects. In turn, you can then use those Bitmap objects to present the pages to the user, by one means or another.

This solution has severe limitations:

• As noted, it requires Android 5.0, leaving out older devices.

• It requires a seekable stream on the content, in the form of a ParcelFileDescriptor. The net effect of this is that you can only reliably render something backed by a file. Conversely, you cannot render something backed by a pipe. This means that you cannot render assets, raw resources, a PDF that you decrypt into a memory buffer, and so on.

• It chokes on complex PDF files. For example, the author of this book started testing it with [this short research paper](#), only to determine (eventually) that PdfRenderer simply cannot render that PDF. PdfRenderer was added with an eye towards print preview, and so its implementation may be focused on the sorts of PDFs that you can generate for printing, as opposed to arbitrary PDFs.
VIEWING PDFS

- It only gives you Bitmap objects. You still have to implement a UI to present those Bitmap objects to the user.

The PDF/PdfRenderer sample project illustrates the use of PdfRenderer.

The RecyclerView

We need to present pages to the user. In a typical PDF viewer, the user can scroll or swipe to move between pages. One could use a ViewPager for that role. However, large Bitmap objects really should be reused, and ViewPager does not make it easy to reuse objects. A RecyclerView would be a better choice.

The chapter on advanced RecyclerView uses demonstrates setting up a RecyclerView as a replacement for ViewPager for page-at-a-time presentations. The PdfRenderer sample app uses one of those techniques, involving SnapHelper, for presenting the pages to the user.

Hence, our UI is a RecyclerView with a light gray background:

```xml
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.RecyclerView
    android:id="@+id/pager"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="#CCCCCCCC"
    android:clipToPadding="false" />
```

(from PDF/PdfRenderer/app/src/main/res/layout/main.xml)

In onCreate(), our MainActivity sets up that RecyclerView with a LinearLayoutManager, along with a PagerSnapHelper named snapperCarr:

```java
pager.setLayoutManager(new LinearLayoutManager(this,
    LinearLayoutManager.HORIZONTAL, false));
snapperCarr.attachToRecyclerView(pager);
```

(from PDF/PdfRenderer/app/src/main/java/com/commonsware/android/pdfrenderer/MainActivity.java)

Eventually, we will tie in a RecyclerView.Adapter and RecyclerView.ViewHolder classes, named PageAdapter and PageController. However, there is nothing to render at the outset, as we do not have a PDF to use.
Getting the PDF

Later samples in this chapter happen to use PDF rendering technologies that can work with ordinary streams. In those cases, we can package some PDFs as assets, to provide sample behavior without the user having to rummage around and find a PDF.

Alas, that is not an option with PdfRenderer. So, we need to let the user find a PDF on external or removable storage.

To do that, we have an action bar item named “Open” that leads to an open() method on MainActivity:

```java
Intent i = new Intent()
    .setType("application/pdf")
    .setAction(Intent.ACTION_OPEN_DOCUMENT)
    .addCategory(Intent.CATEGORY_OPENABLE);

startActivityForResult(i, REQUEST_OPENDOOPEN);
```

Here, we use the Storage Access Framework, invoking an ACTION_OPEN_DOCUMENT Intent, requesting PDF files.

We get control again in onActivityResult():

```java
protected void onActivityResult(int requestCode, int resultCode, Intent data) {
    if (resultCode == Activity.RESULT_OK) {
        pickedDocument = data.getData();
        show(pickedDocument);
    }
}
```

If the user chose a PDF, we stuff its Uri into a pickedDocument field, plus call a private show() method:

```java
try {
    adapter = new PageAdapter(getLayoutInflater(),
```
show() creates a PageAdapter, giving it a LayoutInflater and a ParcelFileDescriptor on the Uri, obtained by calling openFileDescriptor() on a ContentResolver. We then attach PageAdapter to our pager-style RecyclerView.

To handle configuration changes, we hold onto pickedDocument in the saved instance state Bundle:

```
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putParcelable(STATE_PICKED, pickedDocument);
}
```

...and restore it in onCreate():

```
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    pager=(RecyclerView)findViewById(R.id.pager);
    pager.setLayoutManager(new LinearLayoutManager(this,
        LinearLayoutManager.HORIZONTAL, false));
    snapperCarr.attachToRecyclerView(pager);

    if (savedInstanceState!=null) {
        pickedDocument=savedInstanceState.getParcelable(STATE_PICKED);

        if (pickedDocument!=null) {
            show(pickedDocument);
        }
    }
}
```
In `onDestroy()`, we call a `close()` method on `PageAdapter` — we will see the role of `close()` shortly:

```java
protected void onDestroy() {
    if (adapter!=null) {
        adapter.close();
    }
    super.onDestroy();
}
```

---

**Adding the PdfRenderer**

`PageAdapter` is surprisingly short and mostly is focused on implementing the `RecyclerView.Adapter` API:

```java
package com.commonsware.android.pdfrenderer;

import android.graphics.pdf.PdfRenderer;
import android.os.ParcelFileDescriptor;
import android.support.v7.widget.RecyclerView;
import android.view.LayoutInflater;
import android.view.ViewGroup;
import java.io.IOException;

class PageAdapter extends RecyclerView.Adapter<PageController> {
    private final LayoutInflater inflater;
    private final PdfRenderer renderer;

    PageAdapter(LayoutInflater inflater, ParcelFileDescriptor pfd)
        throws IOException {
        this.inflater=inflater;
        renderer=new PdfRenderer(pfd);
    }

    @Override
    public PageController onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new PageController(inflater.inflate(R.layout.page, parent, false)));
    }

    @Override
    public void onBindViewHolder(PageController holder, int position) {
```
In the constructor, we create an instance of a PdfRenderer, passing in the ParcelFileDescriptor on our PDF file.

In onCreateViewHolder(), we create an instance of a PageController, passing it an inflated layout representing the page contents — we will examine this in greater detail shortly.

In onBindViewHolder(), we ask the PdfRenderer to give us a PdfRenderer.Page for the page identified by our position, via an openPage() method. We then pass that to the PageController via a setPage() method, before we close() the Page. It is the responsibility of PageController to ensure that it does everything that it needs to do with that page before returning from setPage().

getItemCount() returns the number of pages in the PDF, as determined by getPageCount().

Finally, close() calls close() on the PdfRenderer, to let it release any resources that it is holding onto, such as that ParcelFileDescriptor.

**Showing the Pages**

The real fun, of course, is in PageController, for rendering a page of the PDF into a Bitmap to be shown in a page of our pager-style RecyclerView.

To allow for pinch-to-zoom functionality, the PdfRenderer sample app uses Dave Morrissey's SubsamplingScaleImageView:
This has a 16dp margin on all four sides, causing each page of the PDF to appear to be floating over the light gray background of the RecyclerView itself. Android's PdfRenderer does not put any frame around its rendered page, leaving that up to you.

PageController grabs the SubsamplingScaleImageView in the constructor, then uses PdfRenderer.Page and a Bitmap to populate it in setPage():

```java
package com.commonsware.android.pdfrenderer;

import android.graphics.Bitmap;
import android.graphics.pdf.PdfRenderer;
import android.os.Environment;
import android.support.v7.widget.RecyclerView;
import android.view.View;
import android.widget.ImageView;
import com.davemorrissey.labs.subscaleview.ImageSource;
import com.davemorrissey.labs.subscaleview.SubsamplingScaleImageView;
import java.io.File;
import java.io.FileNotFoundException;
import java.io.FileOutputStream;

class PageController extends RecyclerView.ViewHolder {
    private final SubsamplingScaleImageView iv;
    private Bitmap bitmap;

    PageController(View itemView) {
        super(itemView);

        iv=(SubsamplingScaleImageView)itemView.findViewById(R.id.page);
    }

    void setPage(PdfRenderer.Page page) {
        if (bitmap==null) {
            int height=2000;
            int width=height * page.getWidth() / page.getHeight();

            bitmap=Bitmap.createBitmap(width, height, Bitmap.Config.ARGB_8888);
        }
    }
}
```
In setPage(), we lazy-create a Bitmap, set to 2000 pixels high and whatever width would be appropriate based on the aspect ratio of the page. This is a simple implementation, suitable for a PDF where all pages have the same aspect ratio. A more sophisticated sample would use some form of object pool for Bitmap objects based on aspect ratio.

Note that the Bitmap needs to be ARGB_8888, exacerbating its memory usage. Attempts to use RGB_565 — thereby cutting memory usage in half per page — fail with an error from PdfRenderer.

Actually rendering the page to the Bitmap is performed by the render() method on the Page. It takes the Bitmap, an optional Rect indicating a subset of the page to be rendered, an optional Matrix to be applied to transform the rendering, and a “render mode” to indicate if this is for use on a screen or (somehow) on a printed page.

However, render() does not do anything to the Bitmap other than render the page's contents. In particular, it does not clear the Bitmap ahead of time. Since we are reusing the Bitmap objects, by default, as those Bitmap objects get reused, they would accumulate page contents, which is not what we want. Also, render() does not assume any particular background color for pages, if such a color was not specified in the PDF. Instead, it just renders the “ink” on top of the Bitmap, with everything else left alone. So, we use eraseColor() to reset the Bitmap to white before we call render(), so we clear out any previous page's content, and so we have a solid white background for our pages.

Not only are we reusing the Bitmap, but we are reusing the SubsamplingScaleImageView. If the user used pinch-to-zoom and panned around a previous page, the SubsamplingScaleImageView will retain those settings. So, we call resetScaleAndCenter() to switch back to the starting point, then call setImage() to hand the SubsamplingScaleImageView the page to render. setImage() takes an ImageSource, and in this case we need to use cachedBitmap(), to indicate both that the image is in the form of an existing Bitmap and that we are caching the Bitmap.
ourselves (so the SubsamplingScaleImageView should not attempt to recycle() the Bitmap).

The result is a PDF viewer, where we can pick a PDF from the “Open” action bar item, then swipe through the pages:

![Figure 693: PdfRenderer Sample App](image)

**The Thunder Lizard Choice: PDF.js**

PdfRenderer has many limitations, none bigger than the fact that it fails to render complex PDFs.

If you have used the Firefox Web browser on your desktop or notebook in the past few years, you may have noticed that its built-in PDF viewer is actually written in JavaScript, in the form of PDF.js. This is designed to handle more complex PDF files, and so it is a more complete solution than is PdfRenderer.

However, PDF.js requires a fairly robust Web rendering engine to work. On Android, that means we are limited to Android 4.4+, when the original WebView was replaced by the “Android System WebView” app’s implementation, which shares more of its
guts with Chromium.

The PDF/PdfJS sample project demonstrates the use of PDF.js.

PDF.js needs a WebView, so we put one in our layout file:

```xml
<?xml version="1.0" encoding="utf-8"?>
<WebView
    android:id="@+id/webview"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent" />
```

(from PDF/PdfJS/app/src/main/res/layout/activity_main.xml)

Not surprisingly, it needs JavaScript to be enabled for that WebView. However, we also need to give JavaScript the ability to read from arbitrary URLs when we load the JavaScript itself from a file URL, as our PDF might come from somewhere else (e.g., content scheme for a document opened via ACTION_OPEN_DOCUMENT):

```java
wv = (WebView) findViewById(R.id.webview);
wv.getSettings().setJavaScriptEnabled(true);
wv.getSettings().setAllowUniversalAccessFromFileURLs(true);
```

(from PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java)

PDF.js itself is stored in assets/pdfjs/ in our main source set. This consists of the JavaScript library (build/ directory) and the stock Web-based viewer wrapped around that library (web/ directory). Combined, these two directories represent 4.6MB of material. While some of that could be stripped out or tweaked for mobile use, this highlights one of the problems with the PDF.js solution: it is large. Those assets will compress somewhat — expect about 2MB added to your APK file.

This sample app now gives the “Open” action bar item a submenu, where the user can choose from two pre-packaged PDFs as assets (a set of presentation slides and the infamous 1040(A) tax form from the United States Internal Revenue Service) or to pick one from the filesystem:

```xml
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/pdfs"
        android:icon="@drawable/ic_folder_open_white_24dp"
        android:showAsAction="always"
        android:title="@string/menu_pdf_files"/>
</menu>
```

(from PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java)
In onOptionsItemSelected() of MainActivity, we route to loadPdf() methods for the two assets and the open() method for the “Pick” option:

```java
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.preso) {
        loadPdf("MultiWindowAndYourApp.pdf");
        return(true);
    } else if (item.getItemId()==R.id.taxes) {
        loadPdf("f1040a.pdf");
        return(true);
    } else if (item.getItemId()==R.id.open) {
        open();
    }
    return(super.onOptionsItemSelected(item));
}
```

open() still uses ACTION_OPEN_DOCUMENT to allow the user to pick a PDF file. onActivityResult() still saves the Uri in the pickedDocument field but then calls a loadPdfUri() method with the string representation of that Uri:

```java
@Override
protected void onActivityResult(int requestCode, int resultCode, Intent data) {
    if (resultCode==Activity.RESULT_OK) {
        pickedDocument=data.getData();
        loadPdfUri(pickedDocument.toString());
    }
}
```

Similarly, the loadPdf() method used by onOptionsItemSelected() for the assets
VIEWING PDFS

stores the chosen asset name in a chosenAsset field, then calls `loadPdfUri()` with the proper `file:///android_asset/` URL:

```java
private void loadPdf(String name) {
    chosenAsset = name;
    loadPdfUri("file:///android_asset/"+name);
}
```

`loadPdfUri()` then uses `loadUrl()` to load up the Web-based PDF viewer in assets, supplying the URL to the PDF in the file query parameter:

```java
private void loadPdfUri(String uri) {
    try {
        wv.loadUrl("file:///android_asset/pdfjs/web/viewer.html?file=" +
                    URLEncoder.encode(uri, "UTF-8"));
    } catch (UnsupportedEncodingException e) {
        e.printStackTrace();
    }
}
```

This works “out of the box” for the assets, as both the Web viewer and the PDFs come from file URLs. To get the content scheme to work, you have to add `file://` to `HOSTED_VIEWER_ORIGINS` in `web/viewer.js`, to tell the Web viewer that `file://` is a valid origin for the viewer and that any reachable URL should be tried:

```javascript
var HOSTED_VIEWER_ORIGINS = [
    'null',
    'http://mozilla.github.io',
    'https://mozilla.github.io',
    'file://'
];
```

We also need to hold onto `chosenAsset` in our saved instance state:

```java
@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);
    outState.putString(STATE_ASSET, chosenAsset);
}
```
outState.putParcelable(STATE_PICKED, pickedDocument);
}

And we restore the PDF in `onCreate()`:

```java
@SuppressLint("SetJavaScriptEnabled")
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    wv=(WebView)findViewById(R.id.webview);
    wv.getSettings().setJavaScriptEnabled(true);
    wv.getSettings().setAllowUniversalAccessFromFileURLs(true);

    if (savedInstanceState!=null) {
        chosenAsset=savedInstanceState.getString(STATE_ASSET);

        if (chosenAsset==null) {
            pickedDocument=savedInstanceState.getParcelable(STATE_PICKED);

            if (pickedDocument!=null) {
                loadPdfUri(pickedDocument.toString());
            } else {
                loadPdf(chosenAsset);
            }
        }
    }
}
```

(From PDF/PdfJS/app/src/main/java/com/commonsware/android/pdfjs/MainActivity.java)
The result is PDF.js's stock PDF viewer, in our WebView, where the user can scroll vertically to browse all the pages in the PDF:

![PDF.js Rendering IRS 1040 Form](image)

**Figure 694: PDF.js Rendering IRS 1040 Form**

The Native Approach: Pdfium

The major downside to both PdfRenderer and PDF.js as in-process PDF viewing solutions is the required API level. Both work with Android 5.0+, and PDF.js works with Android 4.4. However, you may have a minSdkVersion below 19. One approach would be to use an external PDF viewer for those older devices, but if that were an option, you may be better off using that for all Android versions, not just older ones.

Your remaining options involve using some C/C++ code for rendering PDFs.

One popular native code base for PDF rendering is Pdfium, from Google, used in Chromium and Chrome. Roughly speaking, it fills the same role there as PDF.js does with Firefox.

Bartosz Schiller's AndroidPdfViewer library wraps Pdfium in a View that handles rendering and standard gestures (e.g., horizontal swipes to move between pages).
**VIEWING PDFS**

On the plus side, Pdfium works well on older Android versions. The author of this book tested it back to Android 4.1 (API Level 16) and had no problems, and the library itself claims to support back to API Level 11.

However, there is a cost: APK size. By default, AndroidPdfViewer gives you NDK binaries that support the major CPU architectures: 32- and 64-bit ARM and x86, plus MIPS. As a result, the native binaries take up 30MB of space in your APK. Dropping support for CPU architectures that are less important to you (e.g., ARM) can help, and you can drop the per-APK cost to ~5MB if you use ABI splits and ship separate APKs per supported CPU architecture (on distribution channels where that is an option).

The PDF/Pdfium sample project demonstrates the use of AndroidPdfViewer and Pdfium. It is very similar to the PDF.js sample.

However, we need to pull in the AndroidPdfViewer library:

```groovy
apply plugin: 'com.android.application'

android {
    compileSdkVersion 25
    buildToolsVersion '26.0.2'

    defaultConfig {
        applicationId "com.commonsware.android.pdfium"
        minSdkVersion 16
        targetSdkVersion 25
        versionCode 1
        versionName "1.0"
    }
}

dependencies {
    implementation 'com.github.barteksc:android-pdf-viewer:2.3.0'
}
```

(From PDF/Pdfium/app/build.gradle)

Our layout now uses a PDFView widget, instead of a RecyclerView or WebView:

```xml
<?xml version="1.0" encoding="utf-8"?>
<com.github.barteksc.pdfviewer.PDFView android:id="@+id/viewer"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent" />
```
We also need `open()` to support `ACTION_GET_CONTENT`, since `ACTION_OPEN_DOCUMENT` is not supported prior to API Level 19:

```java
private void open() {
    if (Build.VERSION.SDK_INT < Build.VERSION_CODES.KITKAT) {
        Intent i = new Intent()
            .setType("application/pdf")
            .setAction(Intent.ACTION_GET_CONTENT)
            .addCategory(Intent.CATEGORY_OPENABLE);

        startActivityForResult(i, REQUEST_GET);
    } else {
        Intent i = new Intent()
            .setType("application/pdf")
            .setAction(Intent.ACTION_OPEN_DOCUMENT)
            .addCategory(Intent.CATEGORY_OPENABLE);

        startActivityForResult(i, REQUEST_OPEN);
    }
}
```

Then, instead of `loadPdf()` or `loadPdfUri()` methods, we use a `configureViewer()` method. That method takes a `PDFView.Configurator` object, which we get by calling `fromUri()` on the `PDFView` itself, such as from our `onActivityResult()` method:

```java
@override
protected void onActivityResult(int requestCode, int resultCode, Intent data) {
    if (resultCode == Activity.RESULT_OK) {
        pickedDocument = data.getData();
        chosenAsset = null;
        configureViewer(viewer.fromUri(pickedDocument));
    }
}
```

`configureViewer()` then teaches the `PDFView` how we want to render this document:

```java
private void configureViewer(PDFView.Configurator configurator) {
```
Here, we:

- Enable horizontal swiping to move between pages
- Enable a scroll handle as an alternative for moving between pages
- Enable a double-tap gesture for toggling between a few different zoom levels

The result is similar to the PDF.js result, since Pdfium can handle similarly-complex PDF files:
### Viewing PDFs

**What To Choose?**

So, what do you choose?

For most apps, for most situations, using an external PDF viewer is the simplest solution. Use one that already exists, and be in position to suggest one to the user if there is no PDF viewer app available.

If you are certain that you need to keep the PDFs within your own app, and your \( \text{minSdkVersion} \) is 19 or higher, PDF.js offers the best rendering with a modest increase in app size. If, however, you need to support older devices than that, Pdfium will be a solid choice... but be prepared for some distribution complexity as you deal with the ABI splits to keep your APK size down to a reasonable level.
Trail: Home Screen Effects
App widgets are live elements that the user can add to her home screen. Android ships with a variety of app widgets, such as a music player, and device manufacturers frequently add more. However, developers can add their own — in this chapter, we will see how this is done.

For the purposes of this book, “app widgets” will refer to these items that go on the home screen. Other uses of the term “widget” will be reserved for the UI widgets, subclasses of View, usually found in the android.widget Java package.

**Prerequisites**

Understanding this chapter requires that you have read the core chapters, particularly the chapters on:

- basic widgets
- broadcast Intents
- services

**App Widgets and Security**

Creating app widgets looks little like creating an activity. That is because the home screen is showing your app widget, whereas your own app shows your own activities. Having a third-party app (a home screen) show a UI from your app has some security ramifications.

Android’s security model is based heavily on Linux user, file, and process security. Each application is (normally) associated with a unique user ID. All of its files are
owned by that user, and its process(es) run as that user. This prevents one
application from modifying the files of another or otherwise injecting their own
code into another running process. It would be dangerous for the home screen to
run arbitrary code itself or somehow allow its UI to be directly manipulated by
another process.

The app widget architecture, therefore, is set up to keep the home screen application
independent from any code that puts app widgets on that home screen, so bugs in
one cannot harm the other.

The Big Picture for a Small App Widget

The way Android pulls off this bit of security is through the use of RemoteViews.

The application component that supplies the UI for an app widget is not an
Activity, but rather a BroadcastReceiver (often in tandem with a Service). The
BroadcastReceiver, in turn, does not inflate a normal View hierarchy, like an
Activity would, but instead inflates a layout into a RemoteViews object.

RemoteViews encapsulates a limited edition of normal widgets, in such a fashion that
the RemoteViews can be “easily” transported across process boundaries. You
configure the RemoteViews via your BroadcastReceiver and make those
RemoteViews available to Android. Android in turn delivers the RemoteViews to the
app widget host (usually the home screen), which renders them to the screen itself.

This architectural choice has many impacts:

- You do not have access to the full range of widgets and containers. You can
  use FrameLayout, LinearLayout, and RelativeLayout for containers, and
  AnalogClock, Button, Chronometer, ImageButton, ImageView, ProgressBar,
  and TextView for widgets. And, on API Level 11 and higher, you can use some
  AdapterView-based widgets, like ListView, as we will examine in the next
  chapter. And, as of API Level 16 (Android 4.1), you can use GridLayout... but
  not its backport on earlier devices.
- The only user input you can get is clicks of the Button and ImageButton
  widgets. In particular, there is no EditText for text input.
- Because the app widgets are rendered in another process, you cannot simply
  register an OnClickListener to get button clicks; rather, you tell
  RemoteViews a PendingIntent to invoke when a given button is clicked.
- You do not hold onto the RemoteViews and reuse them yourself. Rather, you
create and send out a brand-new RemoteViews whenever you want to change the contents of the app widget. This, coupled with having to transport the RemoteViews across process boundaries, means that updating the app widget is expensive in terms of CPU time, memory, and battery life, when compared to equivalent UI updates of one of your own activities.

- Because the component handling the updates is a BroadcastReceiver, you have to be quick (lest you take too long and Android consider you to have timed out), you cannot use background threads, and your component itself is lost once the request has been completed. Hence, if your update might take a while, you will probably want to have the BroadcastReceiver start a Service and have the Service do the long-running task and eventual app widget update.

Crafting App Widgets

This will become somewhat easier to understand in the context of some sample code. In the AppWidget/PairOfDice project, you will find an app widget that displays a roll of a pair of dice. Clicking on the app widget re-rolls, in case you want a better result.

The Manifest

First, we need to register our BroadcastReceiver implementation in our AndroidManifest.xml file, along with a few extra features:

```xml
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonsware.android.appwidget.dice"
    android:versionCode="1"
    android:versionName="1.0">
    <supports-screens
to="true"
    android:normalScreens="true"
    android:smallScreens="false"/>
    <uses-feature
        android:name="android.software.app_widgets"
        android:required="true"/>
    <application
        android:allowBackup="false"
        android:icon="@drawable/ic_launcher"
        android:icon="@drawable/ic_launcher"
    </application>
</manifest>
```
Here, along with a do-nothing activity, we have a `<receiver>`. Of note:

1. Our `<receiver>` has `android:label` and `android:icon` attributes, which are not normally needed on BroadcastReceiver declarations. However, in this case, those are used for the entry that goes in the roster of available widgets to add to the home screen. Hence, you will probably want to supply values for both of those, and use appropriate resources in case you want translations for other languages.

2. Our `<receiver>` has an `<intent-filter>` for the `android.appwidget.action.APPWIDGET_UPDATE` action. This means we will get control whenever Android wants us to update the content of our app widget. There may be other actions we want to monitor — more on this in a later section.

3. Our `<receiver>` also has a `<meta-data>` element, indicating that its `android.appwidget.provider` details can be found in the `res/xml/widget_provider.xml` file. This metadata is described in greater detail.
The uses-feature Element

If the central point of your application is to provide an app widget, you should strongly consider adding a `<uses-feature>` element to advertise this fact to markets like the Play Store:

```xml
<uses-feature android:name="android.software.app_widgets" android:required="true"/>
```

In principle, having this element means that markets should block the installation of your app on devices where there is no app-widget-capable home screen or other known places for supporting app widgets.

If, however, your app has an app widget, but it is an adjunct to other forms of UI (typically a launcher activity), then you may wish to leave off this `<uses-feature>` element, or set it to `android:required="false"`.

The Metadata

Next, we need to define the app widget provider metadata. This has to reside at the location indicated in the manifest — in this case, in `res/xml/widget_provider.xml`:

```xml
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="144dip"
    android:minHeight="72dip"
    android:updatePeriodMillis="900000"
    android:initialLayout="@layout/widget"
/>
```

Here, we provide a few pieces of information:

1. The minimum width and height of the app widget (`android:minWidth` and `android:minHeight`). These are approximate — the app widget host (e.g., home screen) will tend to convert these values into “cells” based upon the overall layout of the UI where the app widgets will reside. However, they should be no smaller than the minimums cited here. Also, ideally, you use `dip` instead of `px` for the dimensions, so the number of cells will remain constant regardless of screen density.
2. The frequency in which Android should request an update of the widget's
HOME SCREEN APP WIDGETS

contents (android:updatePeriodMillis). This is expressed in terms of milliseconds, so a value of 3600000 is a 60-minute update cycle. Note that the minimum value for this attribute is 30 minutes — values less than that will be “rounded up” to 30 minutes. Hence our 15-minute (900000 millisecond) request will actually result in an update every 30 minutes.

3. The initial layout to use for the app widget, for the time between when the user requests the app widget and when onUpdate() of our AppWidgetProvider gets control.

Note that the calculations for determining the number of cells for an app widget varies. The dip dimension value for an N-cell dimension was \((74 \times N) - 2\) (e.g., a 2x3 cell app widget would request a width of 146dip and a height of 220dip). The value as of API Level 14 (a.k.a., Ice Cream Sandwich) is now \((70 \times N) - 30\) (e.g., a 2x3 cell app widget would request a width of 110dip and a height of 180dip). To have your app widgets maintain a consistent number of cells, you will need two versions of your app widget metadata XML, one in res/xml-v14/ (with the API Level 14 calculation) and one in res/xml/ (for prior versions of Android).

The Layout

Eventually, you are going to need a layout that describes what the app widget looks like. You need to stick to the widget and container classes noted above; otherwise, this layout works like any other layout in your project.

For example, here is the layout for the PairOfDice app widget:

```xml
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
>
    <ImageView android:id="@+id/left_die"
        android:layout_centerVertical="true"
        android:layout_alignParentLeft="true"
        android:src="@drawable/die_5"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginLeft="7dip"
    />

    <ImageView android:id="@+id/right_die"
        android:layout_centerVertical="true"
        android:layout_alignParentLeft="true"
        android:src="@drawable/die_6"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginLeft="7dip"
    />
</RelativeLayout>
```
All we have is a pair of ImageView widgets (one for each die), inside of a RelativeLayout. The RelativeLayout has a background, specified as a nine-patch PNG file. This allows the RelativeLayout to have guaranteed contrast with whatever wallpaper is behind it, so the user can tell the actual app widget bounds.

### The BroadcastReceiver

Next, we need a BroadcastReceiver that can get control when Android wants us to update our RemoteViews for our app widget. To simplify this, Android supplies an AppWidgetProvider class we can extend, instead of the normal BroadcastReceiver. This simply looks at the received Intent and calls out to an appropriate lifecycle method based on the requested action.

The one method that frequently needs to be implemented on the provider is `onUpdate()`. Other lifecycle methods may be of interest and are discussed later in this chapter.

For example, here is the implementation of the AppWidgetProvider for PairOfDice:

```java
package com.commonsware.android.appwidget.dice;

import android.app.PendingIntent;
import android.appwidget.AppWidgetManager;
import android.appwidget.AppWidgetProvider;
import android.content.ComponentName;
import android.content.Context;
import android.content.Intent;
import android.widget.RemoteViews;

public class AppWidget extends AppWidgetProvider {
    private static final int[] IMAGES={R.drawable.die_1, R.drawable.die_2,
        R.drawable.die_3, R.drawable.die_4,
        R.drawable.die_5, R.drawable.die_6};

    @Override
    public void onUpdate(Context ctxt, AppWidgetManager mgr,
        int[] appWidgetIds) {
        ComponentName me=new ComponentName(ctxt, AppWidget.class);
```
mgr.updateAppWidget(me, buildUpdate(ctxt, appWidgetIds));
}

private RemoteViews buildUpdate(Context ctxt, int[] appWidgetIds) {
    RemoteViews updateViews = new RemoteViews(ctxt.getPackageName(),
     R.layout.widget);

    Intent i = new Intent(ctxt, AppWidget.class);
    i.setAction(AppWidgetManager.ACTION_APPWIDGET_UPDATE);
    i.putExtra(AppWidgetManager.EXTRA_APPWIDGET_IDS, appWidgetIds);

    PendingIntent pi = PendingIntent.getBroadcast(ctxt, 0, i,
     PendingIntent.FLAG_UPDATE_CURRENT);

    updateViews.setImageViewResource(R.id.left_die,
     IMAGES[(int)(Math.random() * 6)]);
    updateViews.setOnClickListener(PendingIntent.getBroadcast(ctxt, R.id.left_die, pi));
    updateViews.setImageViewResource(R.id.right_die,
     IMAGES[(int)(Math.random() * 6)]);
    updateViews.setOnClickListener(PendingIntent.getBroadcast(ctxt, R.id.right_die, pi));
    updateViews.setOnClickListener(PendingIntent.getBroadcast(ctxt, R.id.background, pi));

    return updateViews;
}

To update the RemoteViews for our app widget, we need to build those RemoteViews (delegated to a buildUpdate() helper method) and tell an AppWidgetManager to update the widget via updateAppWidget(). In this case, we use a version of updateAppWidget() that takes a ComponentName as the identifier of the widget to be updated. Note that this means that we will update all instances of this app widget presently in use — the concept of multiple app widget instances is covered in greater detail later in this chapter.

Working with RemoteViews is a bit like trying to tie your shoes while wearing mittens — it may be possible, but it is a bit clumsy. In this case, rather than using methods like findViewById() and then calling methods on individual widgets, we need to call methods on RemoteViews itself, providing the identifier of the widget we wish to modify. This is so our requests for changes can be serialized for transport to the home screen process. It does, however, mean that our view-updating code looks a fair bit different than it would if this were the main View of an activity or row of a ListView.

To create the RemoteViews, we use a constructor that takes our package name and the identifier of our layout. This gives us a RemoteViews that contains all of the widgets we declared in that layout, just as if we inflated the layout using a
LayoutInflater. The difference, of course, is that we have a RemoteViews object, not a View, as the result.

We then use methods like:

1. `setImageViewResource()` to set the image for each of our ImageView widgets, in this case a randomly chosen die face (using graphics created from a set of SVG files from the OpenClipArt site)
2. `setOnClickPendingIntent()` to provide a PendingIntent that should get fired off when a die, or the overall app widget background, is clicked

We then supply that RemoteViews to the AppWidgetManager, which pushes the RemoteViews structure to the home screen, which renders our new app widget UI.

**The Result**

If you compile and install all of this, you will have a new app widget entry available. How you add app widgets to the home screen varies based upon Android version and the home screen implementation, and there are too many possibilities to try to list here.
HOME SCREEN APP WIDGETS

No matter how you add the Pair of Dice, the app widget will appear on the home screen:

![Figure 696: Pair of Dice, In Action](image)

Another and Another

As indicated above, you can have multiple instances of the same app widget outstanding at any one time. For example, one might have multiple picture frames, or multiple “show-me-the-latest-RSS-entry” app widgets, one per feed. You will distinguish between these in your code via the identifier supplied in the relevant AppWidgetProvider callbacks (e.g., onUpdate()).

If you want to support separate app widget instances, you will need to store your state on a per-app-widget-identifier basis. You will also need to use an appropriate version of updateAppWidget() on AppWidgetManager when you update the app widgets, one that takes app widget identifiers as the first parameter, so you update the proper app widget instances.

Conversely, there is nothing requiring you to support multiple instances as independent entities. For example, if you add more than one PairOfDice app widget
to your home screen, nothing blows up – they just show the same roll. That is because PairOfDice uses a version of updateAppWidget() that does not take any app widget IDs, and therefore updates all app widgets simultaneously.

**App Widgets: Their Life and Times**

There are three other lifecycle methods that AppWidgetProvider offers that you may be interested in:

1. **onEnabled()** will be called when the first widget instance is created for this particular widget provider, so if there is anything you need to do once for all supported widgets, you can implement that logic here.
2. **onDelete()** will be called when a widget instance is removed from the home screen, in case there is any data you need to clean up specific to that instance.
3. **onDisabled()** will be called when the last widget instance for this provider is removed from the home screen, so you can clean up anything related to all such widgets.

You will need to add appropriate action strings to your `<intent-filter>` for each of these events, such as ACTION_APPWIDGET_ENABLED to be notified about enabled events via onEnabled().

**Controlling Your (App Widget’s) Destiny**

As PairOfDice illustrates, you are not limited to updating your app widget only based on the timetable specified in your metadata. That timetable is useful if you can get by with a fixed schedule. However, there are cases in which that will not work very well:

1. If you want the user to be able to configure the polling period (the metadata is baked into your APK and therefore cannot be modified at runtime).
2. If you want the app widget to be updated based on external factors, such as a change in location.

The recipe shown in PairOfDice will let you use AlarmManager (described in another chapter) or proximity alerts or whatever to trigger updates. All you need to do is:

1. Arrange for something to broadcast an Intent that will be picked up by the BroadcastReceiver you are using for your app widget provider.
2. Have the provider process that Intent directly or pass it along to a Service (such as an IntentService)

Also, note that the updatePeriodMillis setting not only tells the app widget to update every so often, it will even wake up the phone if it is asleep so the widget can perform its update. On the plus side, this means you can easily keep your widgets up to date regardless of the state of the device. On the minus side, this will tend to drain the battery, particularly if the period is too fast. If you want to avoid this wakeup behavior, set updatePeriodMillis to 0 and use AlarmManager to control the timing and behavior of your widget updates.

Note that if there are multiple instances of your app widget on the user’s home screen, they will all update approximately simultaneously if you are using updatePeriodMillis. If you elect to set up your own update schedule, you can control which app widgets get updated when, if you choose.

**One Size May Not Fit All**

It may be that you want to offer multiple app widget sizes to your users. Some might only want a small app widget. Some might really like what you have to offer and want to give you more home screen space to work in.

**Android 1.x/2.x**

The good news: this is easy to do.

The bad news: it requires you, in effect, to have one app widget per size.

The size of an app widget is determined by the app widget metadata XML file. That XML file is tied to a <receiver> element in the manifest representing one app widget. Hence, to have multiple sizes, you need multiple metadata files and multiple <receiver> elements.

This also means your app widgets will show up multiple times in the app widget selection list, when the user goes to add an app widget to their home screen. Hence, supporting many sizes will become annoying to the user, if they perceive you are “spamming” the app widget list. Try to keep the number of app widget sizes to a reasonable number (say, one or two sizes).
Android 3.0+

As of API Level 11, it is possible to have a resizeable app widget. To do this, you can have an `android:resizeMode` attribute in your widget metadata, with a value of `horizontal`, `vertical`, or both (e.g., `horizontal|vertical`). When the user long-taps on an existing widget, they should see handles to allow the widget to be resized:

![Figure 697: API Demos App Widget, Resizing](image)

You can also have `android:minResizeWidth` and `android:minResizeHeight` attributes, measured in dp, that indicate the approximate smallest size that your app widget can support. These values will be interpreted in terms of “cells”, as with the `android:minWidth` and `android:minHeight` attributes, and so the dp values you supply will not be used precisely.

However, for Android 3.x and 4.0 (API Level 11-15), your code would not be informed about being resized. You had to simply ensure that your layout would intelligently use any extra space automatically. Hence, resizing tended to be used primarily with adapter-driven app widgets, as will be discussed in the next chapter.

Starting with API Level 16, though, you can find out when the user resizes your app widget, so you can perhaps use a different layout for a different size, or otherwise
adapt to the available space. Finding out about resize events takes a bit more work, as is illustrated in the AppWidget/Resize sample project.

This app widget project is similar to PairOfDice, described earlier in this chapter. However, our layout skips the dice, replacing them with a TextView widget in the RelativeLayout:

```xml
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
    android:orientation="horizontal">

    <TextView
        android:id="@+id/size"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerInParent="true"
        android:textColor="@android:color/white"
        android:textAppearance="?android:attr/textAppearanceMedium">
    </TextView>

</RelativeLayout>
```

(from AppWidget/Resize/app/src/main/res/layout/widget.xml)

Our widget_provider.xml resource stipulates our desired android:resizeMode and minimum resize dimensions:

```xml
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="180dip"
    android:minHeight="110dip"
    android:minResizeWidth="110dip"
    android:minResizeHeight="40dip"
    android:initialLayout="@layout/widget"
    android:resizeMode="horizontal|vertical" />
```

(from AppWidget/Resize/app/src/main/res/xml/widget_provider.xml)

Finding out about app widget resizing is a different event than finding out about app widget updates. Hence, we need to add a new <action> element to the <intent-filter> of our <receiver> in the manifest, indicating that we want...
HOME SCREEN APP WIDGETS

APPWIDGET_OPTIONS_CHANGED as well as ACTION_UPDATE:

```xml
<receiver
    android:name="AppWidget"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
  <intent-filter>
    <action android:name="android.appwidget.action.APPWIDGET_UPDATE"/>
    <action android:name="android.appwidget.action.APPWIDGET_OPTIONS_CHANGED"/>
  </intent-filter>
  <meta-data
      android:name="android.appwidget.provider"
      android:resource="@xml/widget_provider"/>
</receiver>
```

(from AppWidget/Resize/app/src/main/AndroidManifest.xml)

Then, our app widget implementation can override an onAppWidgetOptionsChanged() method:

```java
@Override
public void onAppWidgetOptionsChanged(Context ctxt, AppWidgetManager mgr, int appWidgetId, Bundle newOptions) {
    RemoteViews updateViews =
        new RemoteViews(ctxt.getPackageName(), R.layout.widget);
    String msg =
        String.format(Locale.getDefault(), "[\%d-%d] x [\%d-%d]",
                      newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MIN_WIDTH),
                      newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MAX_WIDTH),
                      newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MIN_HEIGHT),
                      newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MAX_HEIGHT));
    updateViews.setTextViewText(R.id.size, msg);
    mgr.updateAppWidget(appWidgetId, updateViews);
}
```

(from AppWidget/Resize/app/src/main/java/com/commonsware/android/appwidget/resize/AppWidget.java)

You will notice that we skip onUpdate(). We will be called with onAppWidgetOptionsChanged() when the app widget is added and resized. Hence, in the case of this app widget, we can define what the app widget looks like from onAppWidgetOptionsChanged(), avoiding onUpdate(). That being said, more typical app widgets will wind up implementing both methods, especially if they are supporting lower API levels than 16, where onAppWidgetOptionsChanged() will not be called.
Also remember that your process may well be terminated in between calls to app widget lifecycle methods like `onUpdate()` and `onAppWidgetOptionsChanged()`. Hence, if there is data from one method that you want in the other, be sure to persist that data somewhere.

In the `AppWidget` implementation of `onAppWidgetOptionsChanged()`, we can find out about our new app widget size by means of the `Bundle` supplied to our method. What we cannot find out is our exact size. Rather, we are provided minimum and maximum dimensions of our app widget via four values in the `Bundle`:

- `AppWidgetManager.OPTION_APPWIDGET_MIN_WIDTH`
- `AppWidgetManager.OPTION_APPWIDGET_MAX_WIDTH`
- `AppWidgetManager.OPTION_APPWIDGET_MIN_HEIGHT`
- `AppWidgetManager.OPTION_APPWIDGET_MAX_HEIGHT`

In our case, we grab these `int` values and pour them into a `String` template, using that to fill in the `TextView` of the app widget's contents.

When our app widget is initially launched, we show our initial size ranges:

![Figure 698: Resize Widget, As Initially Added](image)

---
When the user resizes our app widget, we show the new size ranges:

![Figure 699: Resize Widget, During Resize Operation](image)

However, not all home screen implementations will necessarily send the APPWIDGET_OPTIONS_CHANGED when an app widget is added to the home screen, only when the user resizes it later. For example, while the emulator’s home screen for Android 4.1 broadcasts APPWIDGET_OPTIONS_CHANGED, it does not for 4.2 or 4.3. Hence, you may want to also examine the size information in `onUpdate()` as well, so that you react to the initial size as well as any future sizes. One way to do this is to simply iterate over the supplied app widget IDs and invoke your own `onAppWidgetOptionsChanged()` method:

```java
// based on http://stackoverflow.com/a/18552461/115145

@Override
public void onUpdate(Context context, AppWidgetManager appWidgetManager, int[] appWidgetIds) {
    super.onUpdate(context, appWidgetManager, appWidgetIds);

    for (int appWidgetId : appWidgetIds) {
        Bundle options = appWidgetManager.getAppWidgetOptions(appWidgetId);
    }
}
```
Lockscreen Widgets

Android's lockscreen (a.k.a., the keyguard) had long been unmodifiable by developers. This led to a number of developers creating so-called “replacement lockscreens”, which generally reduce device security, as they can be readily bypassed. However, on Android 4.2 through 4.4, developers can create app widgets that the user can deploy to the lockscreen, helping to eliminate the need for “replacement lockscreens”.

However, note that this capability was dropped with Android 5.0. As a result, this particular app widget feature may not be something that you want to worry about. That being said, it is available for those versions, and you are welcome to support it for those versions.

Declaring that an app widget supports being on the lockscreen instead of (or in addition to) the home screen is very easy. All you must do is add an android:widgetCategory attribute to your app widget metadata resource. That attribute should have a value of either keyguard (for the lockscreen), home_screen, or both (e.g., keyguard|home_screen), depending upon where you want the app widget to be eligible. By default, if this attribute is missing, Android assumes a default value of home_screen.

Users cannot resize the lockscreen widgets at this time. However, you still will want to specify an android:resizeMode attribute in your app widget metadata, as whether or not you include vertical resizing will affect the height of your app widget. Lockscreen widgets without vertical will have a fixed small height on tablets, while lockscreen widgets with vertical will fill the available height. Lockscreen widgets on phones will always be small (to fit above the PIN/password entry area), and lockscreen widgets on all devices will stretch to fill available space horizontally.

You can also specify a different starting layout to use when your app is added to the lockscreen, as opposed to being added to the home screen. To do this, just add an android:initialKeyguardLayout attribute to your app widget metadata, pointing to the lockscreen-specific layout to use.
HOME SCREEN APP WIDGETS

To see this in action, take a look at the AppWidget/TwoOrThreeDice sample project. This is a revised clone of the PairOfDice sample, allowing the dice to be added to the lockscreen, and showing three dice on the lockscreen instead of the two on the home screen.

Our app widget metadata now contains the lockscreen-related attributes: android:widgetCategory and android:initialKeyguardLayout:

```xml
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
    android:minWidth="144dip"
    android:minHeight="72dip"
    android:updatePeriodMillis="900000"
    android:initialLayout="@layout/widget"
    android:initialKeyguardLayout="@layout/lockscreen"
    android:widgetCategory="keyguard|home_screen"
/>  
```

(from AppWidget/TwoOrThreeDice/app/src/main/res/xml/widget_provider.xml)

Our lockscreen layout simply adds a third die, middle_die:

```xml
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
>
    <ImageView android:id="@+id/left_die"
        android:layout_centerVertical="true"
        android:layout_alignParentLeft="true"
        android:src="@drawable/die_3"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginLeft="7dip"
    />

    <ImageView android:id="@+id/middle_die"
        android:layout_centerInParent="true"
        android:src="@drawable/die_2"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_marginLeft="7dip"
        android:layout_marginRight="7dip"
    />

    <ImageView android:id="@+id/right_die"
```
HOME SCREEN APP WIDGETS

```xml
android:layout_centerVertical="true"
android:layout_alignParentRight="true"
android:src="@drawable/die_2"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:layout_marginRight="7dip"

</RelativeLayout>
```

(from AppWidget/TwoOrThreeDice/app/src/main/res/layout/lockscreen.xml)

However, by specifying a different layout for the lockscreen widget, we have a problem. We need to know, in our Java code, what layout to use for the RemoteViews and how many dice need to be updated. And, ideally, we would handle this in a backwards-compatible fashion, so our app widget will have its original functionality on older Android devices. Plus, supporting the lockscreen makes it that much more likely that the user will have more than one instance of our app widget (e.g., one on the lockscreen and one on the homescreen), so we should do a better job than PairOfDice did about handling multiple app widget instances.

To deal with the latter point, our new `onUpdate()` method iterates over each of the app widget IDs supplied to it and calls a private `updateWidget()` method for each, so we can better support multiple instances:

```java
@Override
public void onUpdate(Context ctxt, AppWidgetManager mgr,
                      int[] appWidgetIds) {

    for (int appWidgetId : appWidgetIds) {
        updateWidget(ctxt, mgr, appWidgetId);
    }

}(from AppWidget/TwoOrThreeDice/app/src/main/java/com/commonsware/android/appwidget/dice/AppWidget.java)
```

The `updateWidget()` method is a bit more complicated than the `PairOfDice` equivalent code:

```java
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private void updateWidget(Context ctxt, AppWidgetManager mgr,
                          int appWidgetId) {

    int layout=R.layout.widget;

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        int category=
            mgr.getAppWidgetOptions(appWidgetId)
                .getInt(AppWidgetManager.OPTION_APPWIDGET_HOST_CATEGORY,
```
First, we need to choose which layout we are working with. We assume that we are to use the original R.layout.widget resource by default. But, if we are on API Level 17 or higher, we can call getAppWidgetOptions() on the AppWidgetManager, to get the Bundle of options — the same options that we could be delivered in onAppWidgetOptionsUpdate() as described in the previous section. One value that will be in this Bundle is AppWidgetManager.OPTION_APPWIDGET_HOSTCATEGORY, which will be an int with a value of AppWidgetProviderInfo.WIDGET_CATEGORY_KEYGUARD if our app widget is on the lockscreen. In that case, we switch to using R.layout.lockscreen. In addition, we know then we need to update the middle_die when we are updating the other dice.
There is also a subtle change in our `getBroadcast()` call to `PendingIntent`: we pass in the app widget ID as the second parameter, whereas in `PairOfDice` we passed 0. `PendingIntent` objects are cached in our process, and by default we will get the same `PendingIntent` when we call `getBroadcast()` for the same `Intent`. However, in our case, we may want two or more different `PendingIntent` objects for the same `Intent`, with differing extras (`EXTRA_APPWIDGET_ID`). Since extras are not considered when evaluating equivalence of `Intent` objects, just having different extras is insufficient to get different `PendingIntent` objects for those `Intent` objects. The second parameter to `getBroadcast()` (and `getActivity()` and `getService()` on `PendingIntent`) is a unique identifier, to differentiate between two otherwise equivalent `Intent` objects, forcing `PendingIntent` to give us distinct `PendingIntent` objects. This way, we can support two or more app widget instances, each having their own `PendingIntent` objects for their click events.

On an Android 4.2+ lockscreen, you should be able to swipe to one side (e.g., a bezel swipe from left to right), to expose an option to add an app widget:

![Figure 700: Lockscreen Add-A-Widget Panel, On a 4.2 Emulator](image)
HOME SCREEN APP WIDGETS

Tapping the “+” indicator (and, if needed, entering your device PIN or password), brings up an app widget chooser:

Figure 701: Lockscreen Widget Selection List, On a 4.2 Emulator
HOME SCREEN APP WIDGETS

Choosing TwoOrThreeDice will then add the app widget to the lockscreen, with three dice, not two:

*Figure 702: Lockscreen with TwoOrThreeDice, On a 4.2 Emulator*
Preview Images

App widgets can have preview images attached. Preview images are drawable resources representing a preview of what the app widget might look like on the screen. On tablets, this will be used as part of an app widget gallery, replacing the simple context menu presentation you used to see on Android 1.x and 2.x phones:

*Figure 703: App Widget Gallery, on Android 5.0*
To create the preview image itself, the Android 3.0+ emulator images contain a Widget Preview application that lets you run an app widget in its own container, outside of the home screen:

![Widget Preview application](image)

*Figure 704: The Widget Preview application, showing a preview of the Analog Clock app widget*

From here, you can take a snapshot and save it to external storage, copy it to your project's `res/drawable-nodpi/` directory (indicating that there is no intrinsic density assumed for this image), and reference it in your app widget metadata via an `android:previewImage` attribute. We will see an example of such an attribute in the chapter on advanced app widgets.

**Being a Good Host**

In addition to creating your own app widgets, it is possible to host app widgets. This is mostly aimed for those creating alternative home screen applications, so they can take advantage of the same app widget framework and all the app widgets being built for it.

This is not very well documented, but it involves the `AppWidgetHost` and
AppWidgetHostView classes. The latter is a View and so should be able to reside in an app widget host's UI like any other ordinary widget.
API Level 11 introduced a few new capabilities for app widgets, to make them more interactive and more powerful than before. The documentation lags a bit, though, so determining how to use these features takes a bit of exploring. Fortunately for you, the author did some of that exploring on your behalf, to save you some trouble.

Prerequisites

Understanding this chapter requires that you have read the preceding chapter and all of its prerequisites.

AdapterViews for App Widgets

In addition to the classic widgets available for use in app widgets and RemoteViews, five more were added for API Level 11:

1. GridView
2. ListView
3. StackView
4. ViewFlipper
5. AdapterViewFlipper

2329
Three of these (GridView, ListView, ViewFlipper) are widgets that existed in Android since the outset. StackView was added in API Level 11 to provide a “stack of cards” UI:

![Figure 705: The Google Books app widget, showing a StackView](image)

AdapterViewFlipper works like a ViewFlipper, allowing you to toggle between various children with only one visible at a time. However, whereas with ViewFlipper all children are fully-instantiated View objects held by the ViewFlipper parent, AdapterViewFlipper uses the Adapter model, so only a small number of actual View objects are held in memory, no matter how many potential children there are.

With the exception of ViewFlipper, the other four all require the use of an Adapter. This might seem odd, as there is no way to provide an Adapter to a RemoteViews. That is true, but API Level 11 added new ways for Adapter-like communication between the app widget host (e.g., home screen) and your application. We will take an in-depth look at that in an upcoming section.

**Building Adapter-Based App Widgets**

In an activity, if you put a ListView or GridView into your layout, you will also need to hand it an Adapter, providing the actual row or cell View objects that make up the contents of those selection widgets.

In an app widget, this becomes a bit more complicated. The host of the app widget does not have any Adapter class of yours. Hence, just as we have to send the
 vient. Android, starting with API Level 11, has a RemoteViewsService and RemoteViewsFactory that you can use for this purpose.

Let’s take a look, in the form of the AppWidget/LoremWidget sample project, which will put a ListView of 25 Latin words into an app widget.

**The AppWidgetProvider**

At its core, our AppWidgetProvider (named WidgetProvider, in a stunning display of creativity) still needs to create and configure a RemoteViews object with the app widget UI, then use `updateAppWidget()` to push that RemoteViews to the host via the AppWidgetManager. However, for an app widget that involves an AdapterView, like ListView, there are two more key steps:

- You have to tell the RemoteViews the identity of a RemoteViewsService that will help fill the role that the Adapter would in an activity
- You have to provide the RemoteViews with a “template” PendingIntent to be used when the user taps on a row or cell in the AdapterView, to replace the `onListItemClick()` or similar method you might have used in an activity

For example, here is `WidgetProvider` for our Latin-word app widget:

```java
package com.commonsware.android.appwidget.lorem;

import android.app.PendingIntent;
import android.appwidget.AppWidgetManager;
import android.appwidget.AppWidgetProvider;
import android.content.Context;
import android.content.Intent;
import android.net.Uri;
import android.widget.RemoteViews;

public class WidgetProvider extends AppWidgetProvider {
    public static String EXTRA_WORD =
        "com.commonsware.android.appwidget.lorem.WORD";

    @Override
    public void onUpdate(Context ctxt, AppWidgetManager appWidgetManager,
                         int[] appWidgetIds) {
        Intent svcIntent = new Intent(ctxt, WidgetService.class);
        svcIntent.putExtra(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetIds[0]);
        svcIntent.setData(Uri.parse(svcIntent.toUri(Intent.URI_INTENT_SCHEME)));
    }
}
```
The call to `setRemoteAdapter()` is where we point the `RemoteViews` to our `RemoteViewsService` for our `AdapterView` widget. The main rules for the `Intent` used to identify the `RemoteViewsService` are:

1. The service must be identified by its data (Uri), so even if you create the `Intent` via the `Context-and-Class` constructor, you will need to convert that into a Uri via `toUri(Intent.URI_INTENT_SCHEME)` and set that as the Uri for the `Intent`. Why? While your application has access to your `RemoteViewsService` Class object, the app widget host will not, and so we need something that will work across process boundaries. You could elect to add your own `<intent-filter>` to the `RemoteViewsService` and use an `Intent` based on that, but that would make your service more publicly visible than you might want.

2. Any extras that you package on the `Intent` — such as the app widget ID in this case — will be on the `Intent` that is delivered to the `RemoteViewsService` when it is invoked by the app widget host.

Note that there are two flavors of `setRemoteAdapter()`. An older deprecated one takes the app widget ID as the first parameter. The current one does not. The current one, though, is only available on API Level 14 and higher.
**Adapter-Based App Widgets**

The call to `setPendingIntentTemplate()` is where we provide a `PendingIntent` that will be used as the template for all row or cell clicks. As we will see in a bit, the underlying `Intent` in the `PendingIntent` will have more data added to it by our `RemoteViewsFactory`.

In all other respects, our `WidgetProvider` is unremarkable compared to other app widgets. It will need to be registered in the manifest as a `<receiver>`, as with any other app widget.

**The RemoteViewsService**

Android supplies a `RemoteViewsService` class that you will need to extend, and this class is the one you must register with the `RemoteViews` for an `AdapterView` widget. For example, here is `WidgetService` (once again, a highly creative name) from the LoremWidget project:

```java
package com.commonsware.android.appwidget.lorem;

import android.content.Intent;
import android.widget.RemoteViewsService;

public class WidgetService extends RemoteViewsService {
  @Override
  public RemoteViewsFactory onGetViewFactory(Intent intent) {
    return (new LoremViewsFactory(this.getApplicationContext(), intent));
  }
}
```

(from AppWidget/LoremWidget/app/src/main/java/com/commonsware/android/appwidget/lorem/WidgetService.java)

As you can see, this service is practically trivial. You have to override one method, `onGetViewFactory()`, which will return the `RemoteViewsFactory` to use for supplying rows or cells for the `AdapterView`. You are passed in an `Intent`, the one used in the `setRemoteAdapter()` call. Hence, if you have more than one `AdapterView` widget in your app widget, you could elect to have two `RemoteViewsService` implementations, or one that discriminates between the two widgets via something in the `Intent` (e.g., custom action string). In our case, we only have one `AdapterView`, so we create an instance of a `LoremViewFactory` and return it. Google has suggested using `getApplicationContext()` here to supply the `Context` object to `RemoteViewsFactory`, instead of using the `Service` as a `Context`, though it is unclear why this is.
Another thing different about the RemoteViewsService is how it is registered in the manifest:

```xml
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonsware.android.appwidget.lorem"
    android:versionCode="1"
    android:versionName="1.0">
    <uses-feature
        android:name="android.software.app_widgets"
        android:required="true"/>
    <application
        android:allowBackup="false"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name="LoremActivity"
            android:label="@string/app_name"
            android:theme="@android:style/Theme.Translucent.NoTitleBar">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>
                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
        <receiver
            android:name="WidgetProvider"
            android:icon="@drawable/ic_launcher"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.appwidget.action.APPWIDGET_UPDATE"/>
            </intent-filter>
            <meta-data
                android:name="android.appwidget.provider"
                android:resource="@xml/widget_provider"/>
        </receiver>
        <service
            android:name="WidgetService"
            android:permission="android.permission.BIND_REMOTEVIEWS"/>
    </application>
</manifest>
```
Note the use of android:permission, specifying that whoever sends an Intent to WidgetService must hold the BIND_REMOTEVIEWS permission. This can only be held by the operating system. This is a security measure, so arbitrary applications cannot find out about your service and attempt to spoof being the OS and cause you to supply them with RemoteViews for the rows, as this might leak private data.

The RemoteViewsFactory

A RemoteViewsFactory interface implementation looks and feels a lot like an Adapter. In fact, one could imagine that the Android developer community might create CursorRemoteViewsFactory and ArrayRemoteViewsFactory and such to further simplify writing these classes.

For example, here is LoremViewsFactory, the one used by the LoremWidget project:

```java
package com.commonsware.android.appwidget.lorem;

import android.appwidget.AppWidgetManager;
import android.content.Context;
import android.content.Intent;
import android.os.Bundle;
import android.widget.RemoteViews;
import android.widget.RemoteViewsService;

public class LoremViewsFactory implements RemoteViewsService.RemoteViewsFactory {
    private Context ctxt=null;
    private int appWidgetId;

    public LoremViewsFactory(Context ctxt, Intent intent) {
        this.ctxt=ctxt;
        appWidgetId=
            intent.getIntExtra(AppWidgetManager.EXTRA_APPWIDGET_ID,
                               AppWidgetManager.INVALID_APPWIDGET_ID);
    }

    @Override
    public void onCreate() {
```
ADAPTER-BASED APP WIDGETS

// no-op
}

@Override
public void onDestroy() {
    // no-op
}

@Override
public int getCount() {
    return (items.length);
}

@Override
public RemoteViews getViewAt(int position) {
    RemoteViews row =
        new RemoteViews(ctx.getPackageName(), R.layout.row);
    row.setTextViewText(android.R.id.text1, items[position]);
    Intent i = new Intent();
    Bundle extras = new Bundle();
    extras.putString(WidgetProvider.EXTRA_WORD, items[position]);
    extras.putInt(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetId);
    i.putExtras(extras);
    row.setOnClickFillInIntent(android.R.id.text1, i);
    return (row);
}

@Override
public RemoteViews getLoadingView() {
    return (null);
}

@Override
public int getViewTypeCount() {
    return (1);
}

@Override
public long getItemId(int position) {
    return (position);
}

@Override
public boolean hasStableIds() {

You need to implement a handful of methods that have the same roles in a RemoteViewsFactory as they do in an Adapter, including:

1. getCount()
2. getViewTypeCount()
3. getItemId()
4. hasStableIds()

In addition, you have onCreate() and onDestroy() methods that you must implement, even if they do nothing, to satisfy the interface.

You will need to implement getLoadingView(), which will return a RemoteViews to use as a placeholder while the app widget host is getting the real contents for the app widget. If you return null, Android will use a default placeholder.

The bulk of your work will go in getViewAt(). This serves the same role as getView() does for an Adapter, in that it returns the row or cell View for a given position in your data set. However:

1. You have to return a RemoteViews, instead of a View, just as you have to use RemoteViews for the main content of the app widget in your AppWidgetProvider
2. There is no recycling, so you do not get a View (or RemoteViews) back to somehow repopulate, meaning you will create a new RemoteViews every time

The impact of the latter is that you do not want to put large data sets into an app widget, as scrolling may get sluggish, just as you do not want to implement an Adapter without recycling unused View objects.

In LoremViewsFactory, the getViewAt() implementation creates a RemoteViews for a custom row layout, cribbed from one in the Android SDK:
Then, `getViewAt()` pours in a word from the static `String` array of Latin words into that `RemoteViews` for the `TextView` inside it. It also creates an `Intent` and puts the Latin word in as an `EXTRA_WORD` extra, then provides that `Intent` to `setOnClickFillInIntent()`. In addition, it adds the app widget instance ID as an extra, reusing the framework’s own `AppWidgetManager.EXTRA_APPWIDGET_ID` as the key. The contents of the “fill-in” `Intent` are merged into the “template” `PendingIntent` from `setPendingIntentTemplate()`, and the resulting `PendingIntent` is what is invoked when the user taps on an item in the `AdapterView`. The fully-configured `RemoteViews` is then returned.

The Rest of the Story

The app widget metadata needs no changes related to Adapter-based app widget contents. However, `LoremWidget` does add the `android:previewImage` attribute:
This points to the res/drawable-nodpi/preview.png file that represents a “widgetshot” of the app widget in isolation, obtained from the Widget Preview application:

![Figure 706: The preview of LoremWidget](image)

Also, the metadata specifies android:resizeMode="vertical". This attribute is new to Android 3.1, and allows the app widget to be resized by the user (in this case, only in the vertical direction, to show more rows). Older versions of Android will ignore this attribute, and the app widget will remain in your requested size. You can use vertical, horizontal, or both (via the pipe operator) as values for android:resizeMode.
When the user taps on an item in the list, our `PendingIntent` is set to bring up `LoremActivity`. This activity has `android:theme="@android:style/Theme.Translucent.NoTitleBar"` set in the manifest, meaning that it will not have its own user interface. Rather, it will extract our `EXTRA_WORD` — and the app widget ID — out of the Intent used to launch the activity and displays it in a `Toast` before finishing:

```
package com.commonsware.android.appwidget.lorem;

import android.app.Activity;
import android.appwidget.AppWidgetManager;
import android.os.Bundle;
import android.widget.Toast;

public class LoremActivity extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        String word=getIntent().getStringExtra(WidgetProvider.EXTRA_WORD);
        if (word == null) {
            word="We did not get a word!";
        }

        Toast.makeText(this,
                String.format("#%d: %s",
                    getIntent().getIntExtra(AppWidgetManager.EXTRA_APPWIDGET_ID,
                                     AppWidgetManager.INVALID_APPWIDGET_ID),
                    word), Toast.LENGTH_LONG).show();

        finish();
    }
}
```

(from AppWidget/LoremWidget/app/src/main/java/com/commonsware/android/appwidget/lorem/LoremActivity.java)

The Results

When you compile and install the application, nothing new shows up in the home screen launcher, because we have no activity defined to respond to `ACTION_MAIN` and `CATEGORY_HOME`. This would be unusual for an application distributed through the Play Store, as users often get confused if they install something and then do not know how to start it. However, for the purposes of this example, we should be fine, as readers of programming books never get confused about such things.
However, if you bring up the app widget gallery (e.g., long-tap on the home screen of an Android 6.0 device or emulator), you will see LoremWidget there, complete with preview image. You can drag it into one of the home screen panes and position it. When done, the app widget appears as expected:

![LoremWidget on Android Home Screen](image)

The ListView is live and can be scrolled. Tapping an entry brings up the corresponding Toast.
If the user long-taps on the app widget, they will be able to reposition it. On Android 3.1 and beyond, when they lift their finger after the long-tap, the app widget will show resize handles on the sides designated by your `android:resizeMode` attribute:

![LoremWidget on Android Home Screen, with Resize Handles](image)

*Figure 708: LoremWidget on Android Home Screen, with Resize Handles*
The user can then drag those handles to expand or shrink the app widget in the specified dimensions:

*Figure 709: Resized LoremWidget on Android Home Screen*
In 2018, Google introduced the concept of slices, as a way for apps to publish information to be embedded in the UI of other apps. Google is expected to make a major push for apps to publish slices. This chapter explores how this is done.

What’s a Slice?

What a slice actually is depends on your perspective.

From the user's standpoint, when they are in another app — such as Google Assistant — as part of their use of that app, they see data and UI elements that are tied to your app. So, for example, if your app helps users book hotel rooms, and the user asks the Assistant about a particular city, the Assistant might ask your app for a slice, to show the user hotel options in that city.

From the standpoint of your app, a slice is structured data, roughly analogous to publishing JSON from a Web service. While you get to specify text and images, and while you get to suggest particular types of user interactions (e.g., “allow the user to toggle this value between on and off”), the actual UI is rendered by another app. In some respects, this is reminiscent of app widgets, but RemoteViews give you much more direct control over the actual UI than do slices.

What Slices Contain

The data that makes up a slice is a combination of a generic UI structure and the user-facing elements (e.g., text, images) that should go into that UI structure. So, for example, you can create a list or grid, by saying that you want a series of rows and providing the text and images to go into those rows.
Elements in that UI structure can also be associated with `PendingIntent` objects to let you know when the user interacts with them, from simple clicks on image buttons, to being notified when the user changes values of toggles and sliders.

However, while you indicate in your code that you want a grid, the actual details of what that grid really looks like (margins, padding, colors, etc.) is up to the app that displays your slice. You do not get a vote.

### Where Slices Get Used

In many respects, this is the big mystery at the moment.

Google has indicated that some of their products — Search and Assistant — will support slices. Google has also published code to allow other apps to display slices. However, as with Google's code for allowing apps to host app widgets, the code is largely undocumented. It remains to be seen how widespread slices become. They could be huge, or they could be a little-used feature — only time will tell.

### A Tale of Two Slices

There are two implementations of the slice API: the one that you will use, and the other one.

The one that you will use is in the AndroidX family of libraries. This works back to API Level 19 (Android 4.4), covering the vast majority of Android devices in use today.

The other one is native to Android 9.0. It is not completely clear why this exists, given that there is a library version, and given that Google has been trending away from having duplicate implementations of things (see the deprecated native implementations of fragments and loaders). Regardless, until your `minSdkVersion` rises to 28 or higher, you will want to use the AndroidX slice API.

As a result, this chapter focuses on the AndroidX slice API.

### Slice Sizes

When another app (the “hosting app”) elects to show a slice from your app, in principle, that slice will show up in one of three sizes.
It could show up in what amounts to a shortcut-style icon:

![Figure 710: Slice, “Shortcut” Rendering](image)

It could show up as a single “row”:

![Figure 711: Slice, “Small” Rendering](image)
It could show up as a list of rows:

![Figure 712: Slice, “Large” Rendering](image)

You do not really have control over which size the hosting app uses. You simply provide the data for the slice, and the hosting app decides how to render it. As a result, the slice API is designed to allow you to define the “large” rendering with a series of built-in fallbacks for how that is displayed in the “small” or “shortcut” sizes.

In theory, all hosting apps will render slices the same way. In practice, you should make no assumptions about how your slices will be rendered.

**Setting Up a Slice**

In theory, Android Studio 3.2 offers a wizard for setting up the code to allow your app to publish slices. In practice, as of Android Studio 3.2 Canary 15, that wizard is rather buggy, and it will be better if you avoid it for now.

What you need are:

- The dependencies and other Gradle settings to allow you to use the
PUBLISHING SLICES

AndroidX slice API
• A SliceProvider implementation
• The <provider> element for that SliceProvider

The Gradle Settings

The AndroidX slice API has dependencies on some things that are only a part of Android 9.0. As a result, you need to have compileSdkVersion 28 at the moment in order to be able to use either slice API (native or AndroidX).

Also, the AndroidX family of libraries does not play nicely with the previous set of artifacts from the Android Support Library and related areas (e.g., the Architecture Components). You will need to:

• Use the androidx artifacts yourself
• Avoid any third-party libraries that depend upon the Android Support Library artifacts (until such time as the promised Jetifier tool starts to work)

For example, the Slices/SamplerX sample project has this app/build.gradle file:

```groovy
apply plugin: 'com.android.application'

android {
  compileSdkVersion 'android-P'

  defaultConfig {
    applicationId "com.commonsware.android.slice.sampler"
    minSdkVersion 21
    targetSdkVersion 27
    versionCode 1
    versionName "1.0"
  }
}

dependencies {
  implementation 'androidx.appcompat:appcompat:1.0.0-beta01'
  implementation 'androidx.slice:slice-builders:1.0.0-beta01'
}
```

Here, in addition to compileSdkVersion 28, we have two androidx dependencies:
using the AndroidX slice API

- androidx.appcompat:appcompat, which is the AndroidX edition of appcompat-v7, which your app will need to use, for reasons that will become clearer later in this chapter

**The SliceProvider**

Your code that defines the slice will go in a subclass of SliceProvider. SliceProvider is supplied by the slice API. As its name suggests, it is a subclass of ContentProvider, but one where the API that you implement is tied to slices.

The method that you will almost always implement is `onBindSlice()`, where your job is to return the Slice to be shown:

```java
@override
public Slice onBindSlice(Uri sliceUri) {
    Context ctxt = getContext();

    if (ctxt == null) {
        return null;
    }

    ListBuilder builder = new ListBuilder(ctxt, sliceUri, ListBuilder.INFINITY)
        .setAccentColor(ctxt.getResources().getColor(R.color.colorAccent))
        .addAction(buildIconAction(ctxt, "Top-level Action",
                                  R.drawable.ic_looks_two_black_24dp));

    builder
        .setHeader(buildHeader(ctxt))
        .addRow(buildSimpleRow(ctxt))
        .addInputRange(buildRangeRow(ctxt));

    return builder.build();
}
```

(from Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java)

We will explore this code in greater detail shortly.

The other required method is `onCreateSliceProvider()`, where you can perform any up-front one-time initialization that you might need. Return true when this work — if any — is done:

```java
@override
public boolean onCreateSliceProvider() {
```
The Manifest Entry

Since a SliceProvider is a ContentProvider, you will need a corresponding <provider> element in the manifest:

```xml
<provider
    android:name="SamplerSliceProvider"
    android:authorities="${applicationId}.provider"
    android:exported="true" />
```

As with every <provider>, the android:authorities must hold one or more unique values. Here, we use manifest merging placeholders to base our authority string off of the applicationId that we are defining in Gradle.

The <provider> must also be exported, via android:exported="true" and not have any permission-related attributes (e.g., android:permission). Normally, from a security standpoint, this is really bad, as it means that any app at any time can work with this provider, without user involvement. As it turns out, the slice API has its own permission system “baked into” the SliceProvider implementation.
The Activity That You Didn’t Write

Part of that permission system comes in the form of an activity that is automatically added to your manifest. If you open the manifest for your slice-enabled project and look at the “Merged Manifest” tab, you will see an `<activity>` element for an activity that you did not write, named `androidx.slice.compat.SlicePermissionActivity`:

```
<activity
    android:name="androidx.slice.compat.SlicePermissionActivity"
    android:theme="@style/YourAppCompatTheme" />
```

By default, this activity will use the theme that you have established in your `<application>` element. Since `SlicePermissionActivity` uses `appcompat`, your theme would need to be based on `Theme.AppCompat`, or else this activity will crash when started. If the rest of your app is not using `appcompat`, you will need to use the manifest merger process to override the `android:theme` attribute for this added `<activity>`, pointing to a theme that does inherit from `Theme.AppCompat`:

```
<activity
    android:name="androidx.slice.compat.SlicePermissionActivity"
    android:theme="@style/YourAppCompatTheme" />
```

We will see where this activity gets used later in this chapter.

Binding a Slice

The bulk of your business logic for your slice will either be in your `onBindSlice()` method or called from that method:

```java
@override
public Slice onBindSlice(Uri sliceUri) {
```
The first thing that all of Google's examples do is check to see if `getContext()` returns `null`. In theory, this should never happen in a `ContentProvider`, and so it is unclear why they are doing this check. However, the check is cheap, and there is a chance that there is something odd about `SliceProvider` and `onBindSlice()` that causes `getContext()` to return `null` in some scenarios. So, just check it, and return `null` from `onBindSlice()` if `getContext()` returns `null`.

For simple providers, you can then start building your slice. Complex providers, though, might want to return different slices in different scenarios. A slice for showing the weather might want to show different results based on a location (e.g., weather in New York City versus weather in Chennai). You can examine the path portion of the `Uri` that is supplied to `onBindSlice()`, examine its path segments, and create different slices for different values (e.g., `/weather/cities/newyork` might return a different slice than does `/weather/cities/chennai`). In this case, though, you will need to decide what you are going to do if you get a `Uri` that is unexpected (e.g., no path segments, unrecognized city name).

Most slices will be constructed based on a `ListBuilder`. The `ListBuilder` allows you to build a list of rows that form the “large” representation of your slice. One of those rows will be designated the “header”, and that will be what forms the “small” representation of your slice. Also, you can associate an action with the `ListBuilder` itself, and that action's icon will be what shows up for the “shortcut” representation of your slice.
To create a ListBuilder, use the three-parameter constructor that takes:

- a Context, which you get from `getContext()` in your `SliceProvider`
- the Uri associated with this slice
- the “time to live” for the data in this slice, expressed in milliseconds

The “time to live” would appear to be used to trigger automatic refreshes of your slice, though it is unclear how this will be handled in hosting apps. If your slice data is not particularly time-sensitive, pass `ListBuilder.INFINITY` for the third parameter to the ListBuilder constructor.

The two methods that you will want to call for your initial ListBuilder setup are:

- `setAccentColor()`, to teach the ListBuilder how to tint the icons and widgets when your slice is rendered, and
- `addAction()`, to supply a SliceAction

This particular SliceAction is made up of three things:

- A message to be displayed, when relevant (e.g., as a content description for accessibility)
- An icon, using `IconCompat`, which usually comes from a bitmap or resource
- A PendingIntent to identify what should happen if the user triggers this action (e.g., taps on the shortcut icon)

Here, we use our own `buildIconAction()` method to create the SliceAction:

```java
SliceAction buildIconAction(Context ctxt, String msg, @DrawableRes int iconRes) {
    return SliceAction.create(buildActionPI(ctxt, msg, iconRes),
                             buildIcon(ctxt, iconRes), ListBuilder.ICON_IMAGE, msg);
}
```

That, in turn, uses `buildActionPI()` and `buildIcon()` methods:

```java
PendingIntent buildActionPI(Context ctxt, String msg, int id) {
    Intent i = new Intent(ctxt, SliceActionReceiver.class)
             .putExtra(SliceActionReceiver.EXTRA_MSG, msg);

    return PendingIntent.getBroadcast(ctxt, id, i, PendingIntent.FLAG_UPDATE_CURRENT);
}
```

We use a broadcast PendingIntent, pointing to a `SliceActionReceiver`, which will
just display a Toast with the text of our message, packaged into the Intent as EXTRA_MSG:

```
package com.commonsware.android.slice.sampler;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.widget.Toast;

public class SliceActionReceiver extends BroadcastReceiver {
    static final String EXTRA_MSG = "msg";
    
    @Override
    public void onReceive(Context context, Intent intent) {
        Toast.makeText(context, intent.getStringExtra(EXTRA_MSG), Toast.LENGTH_LONG).show();
    }
}
```

(from Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SliceActionReceiver.java)

A SliceAction can be configured in a few different ways — we will examine the details later in the chapter.

In truth, our ListBuilder does have rows, which we add via setHeader(), addRow(), and addInputRange() methods. We will examine those later in the chapter. For the moment, take it on faith that they add three rows to our list of rows, the first of which is our header.

## Trying a Slice

A slice is a data structure. What a hosting app will show is a rendered edition of that data structure. However, the rendering code is not in your slice-publishing app — that is in the hosting app. You have no built-in means of showing your slice.

To that end, Google has an open source Slice Viewer utility that you can use for testing your slice.

## Installing the Slice Viewer

Visit the Releases area of the Slice Viewer GitHub repo and find the latest release.
There should be an APK file associated with that release. Download it and install it on your test device or emulator. For example, you could download the APK with your development machine’s Web browser, then install the app via `adb`:

```adb install /path/to/slice-viewer.apk```

**Running Your Slice in the Viewer**

The simplest way to get your slice into the Slice Viewer is by setting up a custom run configuration in Android Studio. To do this:

1. Choose Run > Edit Configurations from the Android Studio main menu
2. Click the + icon and choose to add an Android App run configuration
3. Give the run configuration an obvious name (e.g., `run-slice`)
4. Choose the appropriate module from the “Module” drop-down (e.g., `app`)
5. Change the “Launch” drop-down in the “Launch Options” group to be “URL”
6. Fill in `slice-content://...` in the “URL” field in the “Launch Options” group, where the ... is replaced by your provider’s authority string and, if applicable, any path that you wish to receive in your `Uri`
1. Change anything else in the run configuration that you might normally change, if anything
2. Click “OK” to save the run configuration
3. Run that run configuration on a device or emulator that already has the Slice Viewer app installed

This will cause the Slice Viewer to display your slice... or, at least, display a permission request:

![Slice Viewer, Showing Permission Note](image)

**Figure 715: Slice Viewer, Showing Permission Note**

**The User Flow**

When the user is first presented with a slice from your app, the slice will not show any actual information. Instead, for “small” and “large” representations, it will show a message indicating that the hosting app wants to show a slice from your app. In the “shortcut” representation, the user just sees the icon.
**Publishing Slices**

When the user taps on the slice's UI, the `SlicePermissionActivity` will be displayed, asking the user to grant permission for the hosting app to show slices from your app:

![Figure 716: SlicePermissionActivity, Asking for Permission](image)

If the user clicks “Allow”, then the user will be taken back to the hosting app, which should now show the actual slice, instead of the permission-request placeholder.

Hence, if the slice system works as designed, the hosting app should not have access to any data from your app unless the user allows such access via that permission request.

However, bear in mind that this is not a system-level permission grant. While the dialog is styled to look a bit like system security dialogs, it is really coming from your app, by way of the slice API.

**The SliceAction**

The rows in your slice can contain `SliceAction` objects. We saw an example of this earlier, defining a `SliceAction` to be attached to the `ListBuilder`.
Many row types ("templates") can have a primary action. This usually will control what happens when the user taps on the body of the row... though that is not always the case.

Some row types take additional actions that will appear in the rows themselves. These actions come in one of two forms:

- Actions with an associated icon, where tapping the icon triggers the PendingIntent
- Actions that are tied to a Switch widget (or similar sort of “toggle”), where toggling the Switch on or off triggers the PendingIntent

In the latter case, the Intent inside of your PendingIntent will be augmented with a Slice.EXTRA_TOGGLE_STATE boolean extra, containing the checked state of the Switch. So, for example, if your PendingIntent is a broadcast, your BroadcastReceiver will receive an Intent that is set up as you have it in the PendingIntent, plus it will contain the Slice.EXTRA_TOGGLE_STATE extra.

The Slice Item Templates

The bulk of the content of a slice comes in the form of rows that you hand to the ListBuilder.

Those rows are defined using a fixed roster of “templates”. You describe the basic type of row (e.g., a simple row, a row showing a series of grid cells) and the data that should go into that row. The hosting app — typically in conjunction with some Google-supplied rendering code — will use that information to render your slice in the hosting app’s UI. As a result, you do not have pixel-level control over what the rows look like. You control some icons, the accent color, and the text to be displayed, and perhaps some actions, and that’s about it.

There are five row templates: “simple rows”, headers, range rows, input range rows, and grid rows.

Simple Rows

A simple row is defined using a ListBuilder.RowBuilder and added to a ListBuilder via its addRow() method.

Simple rows offer:
PUBLISHING SLICES

- A title and subtitle, as simple text
- A primary action, in the form of a SliceAction
- A start (“title”) item and one or more end items, each of which is either an icon, a SliceAction, or a timestamp

All of these are optional, though if you supply none of them, your row does not show up in the rendered output.

In the sample app, we are setting the title, subtitle, and primary action, along with one end item:

```java
RowBuilder buildSimpleRow(Context ctxt) {
    return new RowBuilder()
        .setTitle("Simple Row Title")
        .setSubtitle("This is the subtitle")
        .setPrimaryAction(buildIconAction(ctxt, "Simple Row Primary Action",
            R.drawable.ic_looks_4_black_24dp))
        .addEndItem(buildToggleAction(ctxt, "Simple Row End Item", R.id.toggle));
}
```

(from Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java)

The end item is a Switch, created via SliceAction.createToggle():

```java
SliceAction buildToggleAction(Context ctxt, String msg, int id) {
    return SliceAction.createToggle(buildActionPI(ctxt, msg, id), msg, false);
}
```

(from Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java)

In principle, our PendingIntent could point to something that will use the Slice.EXTRA_TOGGLE_STATE extra to react to the now-current Switch state; in this app, that extra is ignored.

**Headers**

A header row is created using a ListBuilder.HeaderBuilder and is attached to the ListBuilder via its setHeader() method. As the name suggests, a list-based slice has only one header, whereas it can have several of the other row templates.

In addition to the same sort of title and subtitle support as is seen in simple rows, HeaderBuilder has a setSummary() method, which provides text that may be used in circumstances where the entire list is not displayed:
**Publishing Slices**

```java
ListBuilder.HeaderBuilder buildHeader(Context ctxt) {
    return new ListBuilder.HeaderBuilder()
        .setTitle("Header Title")
        .setSubtitle("This is the subtitle")
        .setSummary("This is the summary", false)
        .setPrimaryAction(buildIconAction(ctxt, "Header Primary Action",
                                            R.drawable.ic_looks_one_black_24dp));
}
```

(from slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java)

In “small” mode, the summary is shown in place of the subtitle.

Headers can have actions. Those added via addAction() are simply shown in the header. The “primary action” behaves differently depending on circumstances, as was the case with simple rows. All actions on headers will appear at the end, after the title and subtitle.

**Range Rows and Input Range Rows**

“Range rows” show value on a numerical scale, by default using a ProgressBar or similar widget. An “input range row” uses a SeekBar or similar widget, to allow the user to choose something within the numerical range.

Despite the similar names, these are independent constructs:

- Use a ListBuilder.RangeBuilder to add a range row to a ListBuilder, via its addRange() method
- Use a ListBuilder.InputRangeBuilder to add an input range row to a ListBuilder, via its addInputRange() method

The builders have a similar API:

- setTitle(), setSubtitle(), and setPrimaryAction() akin to simple rows
- setValue() and setMax() to set the current value and the maximum value for the range (where the minimum is 0)

ListBuilder.InputRangeBuilder additionally has an oddly-named setInputAction() method, where you supply a PendingIntent to be sent when the user changes the SeekBar position. Your component responding to the PendingIntent will have access to a Slice.EXTRA_RANGE_VALUE extra with the new value of the Seekbar. Note that setInputAction() is required; you will crash at runtime if you fail to supply a PendingIntent via this method.
The SamplerX sample app offers an input range row:

```
ListBuilder.InputRangeBuilder buildRangeRow(Context ctxt) {
  return new ListBuilder.InputRangeBuilder()
    .setTitle("Range Title")
    .setSubtitle("This is the subtitle")
    .setMax(10)
    .setValue(5)
    .setPrimaryAction(buildIconAction(ctxt, "Range Primary Action",
      R.drawable.ic_looks_5_black_24dp))
    .setInputAction(buildActionPI(ctxt, "Range Selection Changed", R.id.range));
}
```

(from Slices/SamplerX/app/src/main/java/com/commonsware/android/slice/sampler/SamplerSliceProvider.java)

We will see an example of a range row later in this chapter.

### Grid Rows

A slice can also have a “grid row”. This template uses a series of cells for the content. Each cell is created by a `ListBuilder.GridRowBuilder.CellBuilder`, where the row overall is created by a `ListBuilder.GridRowBuilder`. The resulting row is added to the `ListBuilder` via its `addGridRow()` method.

Unlike the other row types, a grid row has no title, subtitle, or actions (other than a primary action). It simply has cells. Each cell can have some mix of:

- “title text” (which might be rendered in bold)
- text
- images

You can have up to two pieces of text and one image, but they can appear in whatever order you want. They will be vertically stacked within the cell, with the roster of cells laid out horizontally within the row.

The row might be horizontally scrollable. If there is not enough room to show all of your cells, your “see more” data (`setSeeMoreAction()` or `setSeeMoreCell()`) will be used to allow the user to do something to see the rest of the data, such as launch one of your activities.

We will see a grid row later in this chapter.

### Hey, What About…?

You cannot invent your own row templates, insofar as the slice API does not have an
extensible API for this. Bear in mind that any custom templates would have to be honored both by slice publishers and slice hosting apps, which limits the utility of any “home-grown” row templates.

However, it is likely that Google will add more row templates to the slice API over time. There are already hints that they will allow for text input, akin to how that is offered in notifications.

**Actions and Sizes**

Given those templates, plus the API of `ListBuilder`, it would seem that the rules for actions would be simple:

- Actions defined on the rows are used on those rows
- Actions defined on the `ListBuilder` would be used in other situations, such as shortcut mode, where there are no rows

Unfortunately, that is not how it works.

**Shortcut Mode**

When your slice is rendered as a shortcut, the primary action of the first row is used for the shortcut. It is that primary action’s icon that is displayed, and it is that primary action’s `PendingIntent` that is invoked when the user taps on that shortcut.

Actions defined on the `ListBuilder`, elsewhere on the first row, or on other rows, are ignored in this mode.

**Small and Large Modes**

When your slice is rendered in “small” mode, the first row of your list is what is shown. Typically, that will be the header row, but a header row is optional – whatever the first row is that you hand to the `ListBuilder` will be used.

When your slice is rendered in “large” mode, more of your rows are shown, though the exact number may depend on the amount of screen space allocated to the slice.

Actions that you define on the `ListBuilder` will show up as “end items” on the first row. The row’s primary action controls what happens if the user clicks on the body of the row itself, but the primary action’s icon is not used.
The primary action on the second and subsequent rows in “large” mode is simply used for handling the clicks on the row body. The icon for such actions is ignored.

**Asynchronous Slices**

The SamplerX project demonstrates the basics of showing a slice and illustrates how to use some common row templates. However, on the whole, it is not very realistic. Usually, there will be some application data that you wish to display in the slice, whether from a database, file, Web service, or other source.

In an ideal world, getting this data would be instantaneous. As Android developers know all too well, any form of I/O is slow, some slower than others.

In a nice-if-not-ideal world, the slice API would have a built-in system for allowing us to load data asynchronously, in a reliable fashion. Alas, it does not. In fact, `onBuildSlice()` is a blocking call — we need to return from it very quickly, or else the slice hosting app may freeze up or otherwise offer a poor user experience.

While we might offer an optimized path in `onBuildSlice()` for creating the “real” slice using data that is cached, we cannot assume that the data that we need will be cached in memory. It is likely that we have no process at all prior to the request for our slice leading to the `onBuildSlice()` call. As a result, we need to handle both the “we have the data” case and the “we need to load the data” case, which gets a bit complicated.

If you want to include images that come from the network, things get even more complicated. For privacy and security reasons — plus simplicity, most likely — you cannot put a URL to some hosted image in a slice. Instead, you need to create an `IconCompat` based on the `Bitmap` that you get from downloading the image identified by the URL. That, in turn, gets a bit interesting, because most of the popular image-loading libraries are designed for asynchronous use. Here, asynchronous APIs are not an option: we need the `Bitmap` to load into the slice, before `onBindSlice()` returns.

The Slices/WeatherSlice sample project will attempt to demonstrate all of this, though the details of asynchronously loading your app’s data will vary widely by app. This particular app will show the weather forecast for New York City, pulled from the US National Weather Service’s Web service API.
Dealing with No Data

If you have no data, you need to still return a slice from `onBindSlice()`. However, there is no requirement that the slice resemble the “real” slice that you would return when you do have your data. You are welcome to use whatever sort of row structure that you want to let the user know that you are busily fetching the data for their slice.

In `WeatherSliceProvider` - the `WeatherSlice` sample's `SliceProvider` subclass – when we have no data, we return a slice with a range bar that theoretically shows download progress:

```java
package com.commonsware.android.slice.weather;

import android.app.PendingIntent;
import android.content.Context;
import android.content.Intent;
import android.net.Uri;
import org.threeten.bp.OffsetDateTime;
import org.threeten.bp.format.DateTimeFormatter;
import org.threeten.bp.format.FormatStyle;
import androidx.annotation.DrawableRes;
import androidx.core.graphics.drawable.IconCompat;
import androidx.slice.Slice;
import androidx.slice.SliceProvider;
import androidx.slice.builders.GridRowBuilder;
import androidx.slice.builders.ListBuilder;
import androidx.slice.builders.SliceAction;
import static androidx.slice.builders.ListBuilder.LARGE_IMAGE;

public class WeatherSliceProvider extends SliceProvider {
    static final Uri NYC_FORECAST = Uri.parse("https://forecast.weather.gov/MapClick.php?lat=40.7146&lon=-74.0071");
    static final DateTimeFormatter FORMATTER = DateTimeFormatter.ofLocalizedDateTime(FormatStyle.SHORT);
    static final Uri WEATHER_URL = new Uri.Builder()
        .scheme("content")
        .authority(BuildConfig.APPLICATION_ID + ".provider")
        .build();

    @Override
    public boolean onCreateSliceProvider() {
        return true;
    }

    public Slice onBindSlice(Uri sliceUri) {
        Context ctxt = getContext();

        if (ctxt == null) {
            return null;
        }

        ListBuilder builder = new ListBuilder(ctxt, sliceUri, ListBuilder.INFINITY)
```
.setAccentColor(ctx.getResources().getColor(R.color.colorAccent));

builder.setHeader(buildHeader(ctx));

WeatherResponse weather=Forecaster.LATEST;

if(weather==null) {
    Forecaster.enqueueWork(getContext());
    builder.addRange(new ListBuilder.RangeBuilder()
        .setTitle(ctx.getString(R.string.downloading)));
} else {
    builder.addGridRow(buildGridRow());
}

return builder.build();

ListBuilder.HeaderBuilder buildHeader(Context ctx) {
    return new ListBuilder.HeaderBuilder()
        .setTitle(ctx.getString(R.string.header_title))
        .setPrimaryAction(
            buildIconAction(ctx, ctx.getString(R.string.msg_forecast),
                R.drawable.ic_wb_sunny_black_24dp));
}

GridRowBuilder buildGridRow() {
    GridRowBuilder row=new GridRowBuilder();

    for (int i=0; i<Forecaster.COUNT; i++) {
        WeatherResponse.Period period=Forecaster.LATEST.properties.periods.get(i);
        OffsetDateTime odt=OffsetDateTime.parse(period.startTime);

        row.addCell(new GridRowBuilder.CellBuilder()
            .addTitleText(odt.format(FORMATTER))
            .addImage(IconCompat.createWithBitmap(period.iconBitmap), LARGE_IMAGE)
            .addText((
                String.format("%d%s", period.temperature, period.temperatureUnit)));
    }

    return row;
}

SliceAction buildIconAction(Context ctx, String msg, @DrawableRes int iconRes) {
    return SliceAction.create(buildActionPI(ctx, iconRes),
        buildIcon(ctx, iconRes), ListBuilder.ICON_IMAGE, msg);
}

PendingIntent buildActionPI(Context ctx, int id) {
    Intent i=new Intent(Intent.ACTION_VIEW, NYC_FORECAST);

    return PendingIntent.getActivity(ctx, id, i,
        PendingIntent.FLAG_UPDATE_CURRENT);
}

IconCompat buildIcon(Context ctx, @DrawableRes int iconRes) {
    return IconCompat.createWithResource(ctx, iconRes);
}
We will explore what a `WeatherResponse` is and what a Forecaster is later. For the moment, we are focusing on the case where `Forecaster.LATEST` is `null`, in which case our slice has a header row plus the range row. When the slice is first run, we have not had a chance to download a weather forecast, so the range bar shows up:

![Slice Viewer App, Showing WeatherSlice, Without a Forecast](image)

**Loading the Data**

We cannot load our data in `onBindSlice()`, because it may take a while. In this sample, we offload that work to a Forecaster class. Forecaster is a `JobIntentService`, and its responsibility is to use Retrofit to download the weather forecast.

`WeatherResponse` and some related classes contain the forecast itself:

```java
package com.commonsware.android.slice.weather;

import android.graphics.Bitmap;
import java.util.List;
```
This is structured as the National Weather Service Web API returns it… with one slight difference. The Web service API returns a URL to an icon representing a forecast in the icon field of the Period class. However, for our slice, we need the actual image itself.

Hence, the onHandleWork() method of Forecaster not only uses Retrofit to retrieve the Web service response, but it also uses OkHttp to download the image for a given forecast Period and uses BitmapFactory to decode that image into a Bitmap:

```java
package com.commonsware.android.slice.weather;

import android.content.Context;
import android.content.Intent;
import android.graphics.BitmapFactory;
import android.util.Log;
import androidx.annotation.NonNull;
import androidx.core.app.JobIntentService;
import okhttp3.OkHttpClient;
import okhttp3.Request;
import okhttp3.ResponseBody;
import retrofit2.Retrofit;
import retrofit2.converter.gson.GsonConverterFactory;

public class Forecaster extends JobIntentService {

public class WeatherResponse {
  public final Properties properties=null;

  public static class Properties {
    public final List<Period> periods=null;
  }

  public static class Period {
    public final String startTime=null;
    public final int temperature;
    public final String temperatureUnit=null;
    public final String icon=null;
    public Bitmap iconBitmap;

    public Period() {
      temperature=0;
    }
  }
}

(from Slices/WeatherSlice/app/src/main/java/com/commonsware/android/slice/weather/WeatherResponse.java)
```
static WeatherResponse LATEST=null;
static final int COUNT=4;
private static final double NYC_LATITUDE=40.730610;
private static final double NYC_LONGITUDE=-73.935242;
private static final int UNIQUE_JOB_ID=1337;

static void enqueueWork(Context ctxt) {
    enqueueWork(ctxt, Forecaster.class, UNIQUE_JOB_ID,
    new Intent(ctxt, Forecaster.class));
}

@Override
public void onHandleWork(@NonNull Intent intent) {
    OkHttpClient ok=new OkHttpClient.Builder().build();
    Retrofit retrofit=new Retrofit.Builder()
        .client(ok)
        .baseUrl("https://api.weather.gov")
        .addConverterFactory(GsonConverterFactory.create())
        .build();
    NWSInterface nws=retrofit.create(NWSInterface.class);
    double roundedLat=(double)Math.round(NYC_LATITUDE*10000d)/10000d;
    double roundedLon=(double)Math.round(NYC_LONGITUDE*10000d)/10000d;

    try {
        WeatherResponse response=nws.getForecast(roundedLat, roundedLon).execute().body();

        for (int i=0;i<COUNT;i++) {
            WeatherResponse.Period period=response.properties.periods.get(i);
            ResponseBody body=ok
                .newCall(new Request.Builder().url(period.icon).build())
                .execute().body();

            period.iconBitmap=BitmapFactory.decodeStream(body.byteStream());
        }

        LATEST=response;
        getContentResolver().notifyChange(WeatherSliceProvider.ME, null);
    }
    catch (Throwable t) {
        Log.e(getClass().getSimpleName(),
            "Exception from Retrofit request to National Weather Service", t);
    }
}
Once we have our data, we need to let the slice hosting app know to reload the slice. To do that, we use `notifyChange()` on a `ContentResolver`, telling it that the data at our provider's `Uri` has changed. Through either a `ContentObserver` or `JobScheduler`, the slice hosting app will find out about our data change and will reload our slice, triggering a fresh call to `onBindSlice()` in `WeatherSliceProvider`.

### Using the Data

This time, `onBindSlice()` will see that `Forecaster.LATEST` has data, and it builds a slice with two rows: a header and a grid row:

```java
ListBuilder.HeaderBuilder buildHeader(Context ctxt) {
    return new ListBuilder.HeaderBuilder()
        .setTitle(ctxt.getString(R.string.header_title))
        .setPrimaryAction(
            buildIconAction(ctxt, ctxt.getString(R.string.msg_forecast),
                R.drawable.ic_wb_sunny_black_24dp));
}

GridRowBuilder buildGridRow() {
    GridRowBuilder row = new GridRowBuilder();
    for (int i=0; i<Forecaster.COUNT; i++) {
        WeatherResponse.Period period = Forecaster.LATEST.properties.periods.get(i);
        OffsetDateTime odt = OffsetDateTime.parse(period.startTime);
        row.addCell(new GridRowBuilder.CellBuilder()
            .addTitleText(odt.format(FORMATTER))
            .addImage(IconCompat.createFromBitmap(period.iconBitmap), LARGE_IMAGE)
            .addText(String.format("%d%s", period.temperature, period.temperatureUnit)));
    }
    return row;
}
```

We have one cell per forecast period, where `Forecaster` is only downloading the icons for `COUNT` periods (defined as 4 in the current code). Each cell contains:

- the date and time for the forecast period,
- the image of the forecast, from the downloaded `Bitmap`, and
- the forecasted temperature

The date and time come from the National Weather Service API in ISO-8601 format. This app uses Jake Wharton's `ThreeTenABP` library, which offers a set of Java classes that mimic the Java 8 `java.time` classes. We use `OffsetDateTime` to parse the date and time for the forecast period.
ISO-8601 string, then use a static DateTimeFormatter to create a better-formatted bit of text to show the user.

For each cell, we use a GridRowBuilder.CellBuilder to create the cell, add it to the row via addCell(), and add the overall GridRowBuilder to the ListBuilder via addGridRow().

For the image portion of the cells, we pass in LARGE_IMAGE as a flag, indicating that we want the image to be as large as possible. Alternatives are ICON_IMAGE (rendered small and tinted with your accent color) and SMALL_IMAGE (rendered small but not tinted).

Note that we add a primary action to the header. Slices require a primary action; otherwise the slice-building code will crash:

```
java.lang.IllegalArgumentException: A slice requires a primary action; ensure one of your builders has called #setPrimaryAction with a valid SliceAction.
    at androidx.slice.builders.impl.ListBuilderV1Impl.build(ListBuilderV1Impl.java:142)
    at androidx.slice.builders.ListBuilder.build(ListBuilder.java:235)
    at com.commonsware.android.slice.weather.WeatherSliceProvider.onBindSlice(WeatherSliceProvider.java:73)
    at androidx.slice.compat.SliceProviderWrapperContainer$SliceProviderWrapper.onBindSlice(SliceProviderWrapperContainer.java:73)
    at android.app.slice.SliceProvider.onBindSliceStrict(SliceProvider.java:545)
    at android.app.slice.SliceProvider.handleBindSlice(SliceProvider.java:459)
    at android.app.slice.SliceProvider.call(SliceProvider.java:365)
    at android.content.ContentProvider$Transport.call(ContentProvider.java:401)
    at android.content.ContentProviderNative.onTransact(ContentProviderNative.java:272)
    at android.os.Binder.execTransact(Binder.java:731)
```

In this case, the primary action brings up a Web browser to view a weather forecast for New York City.

**Warning: Make No Rendering Assumptions**

With an Android app’s own UI, given sufficient work, you can have pixel-perfect control. When an Android app contributes to other UI — such as a Notification — you lose that level of control. Slices work the same way, in that you provide the data to be displayed but do not have absolute control over the way it looks.

That lack of control will be visible in most, if not all, slice hosting apps. In part, this
is due to screen space, as the host gets to decide how much space to allocate to the slice, which in turn steers the design towards a particular rendering mode (e.g., “small” or “shortcut” for smaller areas).

However, while many slice hosts will just use the rendered output from Google’s supplied slice rendering code, other slice hosts will make changes to that view hierarchy or even process the slices themselves. In these cases, the look of your slice may vary radically from the normal output that you see in apps like the Slice Viewer.

All that you get to do is supply the data and related hints as to how you want things to be rendered, and the slice host decides what to do. So, for example, if your slice has lots of rows, the rendered slice may or may not support scrolling to view all of those rows. You can, if you wish, call `setSeeMoreAction()` to supply a `SliceAction` that the slice host can attach to some form of “see more” button. Or, you can call `setSeeMoreRow()` to provide a simple row that will be displayed when scrolling is disabled, where you can have actions that help the user to get to an activity or something that will show them all of the data.

For example, here is the output from the `WeatherSlice` sample, showing a forecast:
We supplied the text and image. However, we do not control the actual formatting, such as:

- How many cells to show (we supplied 4, but only 3 are rendered)
- What size font is used for the text
- How large the ImageView is for the forecast
- What aspect ratio is used for the ImageView
- How the vertical whitespace is allocated
- And so on

**Other Slice Viewer Features**

On the screen that appears in the Slice Viewer when you run your slice via your custom run configuration, an action bar item will allow you to switch between the three rendering modes (shortcut, small, large), so you can see what your slice looks like in all three modes.

If you launch the Slice Viewer directly from the home screen or other launcher, you will be presented with a list of all slices that you have run previously:

*Figure 719: Slice Viewer Launcher Activity, Showing Two Slices*
PUBLISHING SLICES

This screen has the same action bar option for switching between the three rendering modes. The action bar also has a SearchView (or something similar) where you can type in the ContentProvider Uri for a slice (e.g., content://com.commonsware.android.slice.sampler.provider), to load a slice that way. The arrow icons next to each Uri take you to the same screen that is displayed when you run your slice via the run configuration, showing just that one slice.
For a SliceProvider to be useful, something need to be able to request and display a slice served by that provider. In this chapter, we will explore what it takes to do just that: display in your app a slice obtained from some other app's SliceProvider.

What You Need to Know

Hosting slices is tied very closely to LiveData from the Architecture Components. In a nutshell, LiveData is a way for you to subscribe to updates to some source of data, akin to subscribing to an RxJava Observable. LiveData has the added benefit of being aware of the Android lifecycle, so it can cleanly unsubscribe from the data source when the hosting activity or fragment is destroyed. You can learn more about LiveData from CommonsWare's book, Android's Architecture Components.

The Slices/Inspector sample project shown in this chapter happens to be written in Kotlin. If you are not familiar with Kotlin, focus less on the syntax shown in the examples and more on the concepts outlined in the prose.

Why?

Just because somebody needs to host slices does not mean that you have to host slices in your app. So, why would you bother writing code to display other apps’ slices?

- Perhaps you are not interested in hosting slices from arbitrary apps, but instead wish to host slices from other apps in your app suite, as a form of integration.
- Perhaps you are interested in integrating slices from specific slice providers,
HOSTING SLICES

if they happen to be installed on the device. For example, someday, the Wikipedia app might offer slices tied to search terms, where the slice might have a sentence about the topic and perhaps an image. That slice could lead users over to the Wikipedia app to learn more. You might be interested in displaying their slices, rather than hooking up to some Wikipedia-specific API, to help users learn more about specific terms that they encounter in your app.

- Perhaps you maintain a home screen/launcher app, and you want to offer slices as another form of interactive content, alongside classic Android app widgets.
- Perhaps a firm like Amazon might offer slices based on products, where your request for their slice can include a referral code. Users who purchase products from your app (and your hosted Amazon slices) trigger you to earn referral fees, as another income source.

Depending on how the slice ecosystem evolves, there could be many good reasons to host slices. And, the good news is that for simple scenarios, hosting slices is not very difficult.

How?

You have two main approaches for hosting a slice. Most developers will take the simple approach, using some Google-supplied library code to display and update the slice. If needed, though, you can get at the raw information about the slice and build your own custom rendered edition of that information.

In both cases, for the moment, we will assume that we know the Uri of the SliceProvider. In the Inspector sample app, to keep it simple, this value is hard-coded in gradle.properties to be the SamplerX example from the chapter on publishing slices:

```
SLICE_URI=content://com.commonsware.android.slice.dice.provider
```

(from Slices/Inspector/gradle.properties)

You can test using the Inspector with any other slice provider simply by changing that line to provide the Uri that you wish to test. That Uri is then hoisted into BuildConfig via a buildConfigField statement in app/build.gradle:

```
buildConfigField "String", "SLICE_URI", '"' + SLICE_URI + '"'
```

(from Slices/Inspector/app/build.gradle)
So, the app's code can identify our SliceProvider via BuildConfig.SLICE_URI.

The Simple Way: SliceView

Only two classes are really needed to render a slice given the Uri:

- SliceView, which is a widget that knows how to display a slice, and
- SliceLiveData, which is a LiveData that knows how to communicate with a SliceProvider, given its Uri, and push slice data to a SliceView

The sample app has a ViewPager with four tabs. The first three tabs each show a slice from the provider identified by SLICE_URI. Those tabs each use a SliceView, centered inside of a ConstraintLayout:

```xml
<?xml version="1.0" encoding="utf-8"?>
<androidx.constraintlayout.widget.ConstraintLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@android:color/darker_gray">
    <androidx.slice.widget.SliceView
        android:id="@+id/slice"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_margin="8dp"
        android:background="@android:color/white"
        app:layout_constraintBottom_toBottomOf="parent"
        app:layout_constraintEnd_toEndOf="parent"
        app:layout_constraintStart_toStartOf="parent"
        app:layout_constraintTop_toTopOf="parent" />
</androidx.constraintlayout.widget.ConstraintLayout>
```

A SliceView has no intrinsic background. If you do nothing else, it will render text and images with no background. In this layout, we set the ConstraintLayout to have a gray background and the SliceView to have a white background, so you can see the bounds the SliceView.

The sample app has a TabAdapter serving as our PagerAdapter for the ViewPager. For those first three tabs, it creates instances of a SliceFragment:

```java
package com.commonsware.android.slice.inspector

import androidx.fragment.app.Fragment
import androidx.fragment.app.FragmentManager
import androidx.fragment.app.FragmentPagerAdapter
import androidx.slice.widget.SliceView
```

2377
The `newInstance()` factory method on `SliceFragment` takes a `SliceView` “mode” value, indicating whether we want a shortcut, a small view, or a large view. These modes were describe in the chapter on publishing slices.

In `onCreateView()`, the `SliceFragment` fills the mode into the `SliceView` via `setMode()` (via the `mode` property syntax in Kotlin), defaulting to large mode if for some reason we did not get a mode provided to us:
Then, we:

- Parse SLICE_URI into an actual Uri
- Pass that, along with our activity, to SliceLiveData.fromUri(), to get a SliceLiveData that is configured to pull slice data from the identified provider
- observe() that SliceLiveData, having its slice data be fed into the SliceView

And... that’s it.
At this point, SliceLiveData and SliceView take over to render the slice in the requested mode:

_Figure 720: Slice Inspector, Showing Shortcut Mode_
All of the actions included in the slice are handled by $\text{SliceView}$. In this case, all of
HOSTING SLICES

the SamplerX actions work, each showing a Toast with the appropriate message.

Also, so long as you SliceLiveData has an active observer, it will receive updates to the slice content if the SliceProvider publishes updates. So, for example, if you inspect a slice that needs to perform network I/O — such as the weather slice profiled in the chapter on publishing slices — you will first get whatever the “loading” slice content is, then you will get the real content. SliceLiveData simply pushes new slices to the SliceView, which updates its content accordingly.

The Fully-Custom Way: Slice

You do not need a SliceView to display the contents of a slice, if you want to decide how to display those contents yourself. Instead, have the SliceLiveData route to your own code. It will hand you Slice objects, which you can inspect and use for setting up your own UI.

Unfortunately, this is largely undocumented.

The fourth tab in the Slice Inspector brings up a graph showing the various pieces of a slice:

![Slice Inspector, Showing Graph of Slice Elements](image)

*Figure 723: Slice Inspector, Showing Graph of Slice Elements*
HOSTING SLICES

This is handled by a separate InspectorFragment, using a TreeView from this library.

A Slice is a tree structure, created using the various builders inside of the SliceProvider. The root Slice will contain one or more SliceItem objects, obtained via the getItems() method (or the items property in Kotlin). Each SliceItem has a getFormat() method indicating what sort of item it is and what it contains:

- FORMAT_TEXT contains some text to render, which you can get via getText() on the SliceItem
- FORMAT_IMAGE contains an image to render, which you can get via getIcon() on the SliceItem
- FORMAT_SLICE contains a nested Slice in the tree, which you can get via getSlice() and can then traverse as desired
- And so on

The sample app’s graph simply puts the format value into each of the nodes, since formats happen to be human-readable strings. A app that wanted to do its own rendering of a slice — such as a screen reader wanting to use text-to-speech — would need to make sense of what is all in these slices and how to use them.

Most such apps will leverage SliceMetadata to help. You can wrap a Slice in a SliceMetadata via the SliceMetadata.from() method. SliceMetadata will give you higher-order information about an individual slice, such as:

- The actions, toggles, and similar elements that may be a part of the slice
- The title, subtitle, summary, and other text that is part of the slice
- A isPermissionSlice(), which attempts to tell you if this slice is really a request for the user to grant permissions, instead of containing actual content
- And so on

The Catch: Discovering Slices

The Slice Inspector sample app cheats. It already knows the Uri of the slice provider, courtesy of that SLICE_URI value in gradle.properties.

In some cases, your app will be able to cheat as well. If you want to show slices from some particular app, you can “bake” the Uri to its provider into your code by one
means or another. You can use PackageManager and queryContentProviders() to determine if that provider exists, and if it does, you can arrange to display its slices.

But what if you do not know what slice providers to use?

Eventually, the slice ecosystem will work out options for discovering slice providers. There is already a partial mechanism in place, involving Intent objects, but it is largely undocumented as of July 2018. Plus, it is fairly abstract, moving the discovery question from “how do I get the Uri?” to “how do I create the correct Intent?”.

Slices… from the Web?

Most of the focus on slices assume that the Uri in question is tied to a SliceProvider.

However, there is code in Google’s Slice Viewer app that supports slice Uri values having http or https as a scheme, instead of content. This implies that slices might come directly from Web servers, in addition to from local slice providers.

A slice host will not really care about the difference, other than perhaps needing the INTERNET permission where it might not be required otherwise. SliceLiveData is already asynchronous, so whether the slice data is coming from another app on the device or is coming from a server is an implementation detail for SliceLiveData, not for the hosting app.

Right now, there is no documentation for how one would do this. It is entirely possible that this bit of code was from some experiments that will never be fully supported by the slice libraries. However, if you are implementing a slice host, you may wish to watch for any signs that slices are being served by Web sites — if nothing else, they would represent additional scenarios for your app’s test suite.
Adding basic permissions to your app to allow it to, say, access the Internet, is fairly easy. However, the full permissions system has many capabilities beyond simply asking the user to let you do something. This chapter explores other uses of permissions, from securing your own components to using signature-level permissions (your own or Android’s).

**Prerequisites**

Understanding this chapter requires that you have read the core chapters, particularly the chapter on permissions and the chapter on signing your app.

One of the sample apps uses RxJava and RxAndroid, which are introduced elsewhere in the book.

**Securing Yourself**

Principally, at least initially, permissions are there to allow the user to secure their device. They have to agree to allow you to do certain things, such as reading contacts, that they might not appreciate.

The other side of the coin, of course, is to secure your own application. If your application is mostly activities, security may be just an “outbound” thing, where you request the right to use resources of other applications. If, on the other hand, you put content providers or services in your application, you will want to implement “inbound” security to control which applications can do what with the data.

Note that the issue here is less about whether other applications might “mess up”
your data, but rather about privacy of the user’s information or use of services that might incur expense. That is where the stock permissions for built-in Android applications are focused – can you read or modify contacts, can you send SMS, etc. If your application does not store information that might be considered private, security is less an issue. If, on the other hand, your application stores private data, such as medical information, security is much more important.

The first step to securing your own application using permissions is to declare said permissions, once again in the AndroidManifest.xml file. In this case, instead of uses-permission, you add permission elements. Once again, you can have zero or more permission elements, all as direct children of the root manifest element.

Declaring a permission is slightly more complicated than using a permission. There are three pieces of information you need to supply:

- The symbolic name of the permission. To keep your permissions from colliding with those from other applications, you should use your application's Java namespace as a prefix
- A label for the permission: something short that would be understandable by users
- A description for the permission: something a wee bit longer that is understandable by your users

```xml
<permission
    android:name="vnd.tlagency.sekrits.SEE_SEKRITS"
    android:label="@string/see_sekrits_label"
    android:description="@string/see_sekrits_description" />
```

This does not enforce the permission. Rather, it indicates that it is a possible permission; your application must still flag security violations as they occur.

**Enforcing Permissions via the Manifest**

There are two ways for your application to enforce permissions, dictating where and under what circumstances they are required. The easier one is to indicate in the manifest where permissions are required.

Activities, services, and receivers can all declare an attribute named android:permission, whose value is the name of the permission that is required to access those items:

```xml
<activity
    android:permission="vnd.tlagency.sekrits.SEE_SEKRITS" />
```
Only applications that have requested your indicated permission will be able to access the secured component. In this case, “access” means:

1. Activities cannot be started without the permission
2. Services cannot be started, stopped, or bound to an activity without the permission
3. Intent receivers ignore messages sent via sendBroadcast() unless the sender has the permission

**Enforcing Permissions Elsewhere**

In your code, you have two additional ways to enforce permissions.

Your services can check permissions on a per-call basis via checkCallingPermission(). This returns PERMISSION_GRANTED or PERMISSION_DENIED depending on whether the caller has the permission you specified. For example, if your service implements separate read and write methods, you could require separate read versus write permissions in code by checking those methods for the permissions you need from Java.

Also, you can include a permission when you call sendBroadcast(). This means that eligible broadcast receivers must hold that permission; those without the permission are ineligible to receive it. We will examine sendBroadcast() in greater detail elsewhere in this book.

**Requiring Standard System Permissions**

While normally you require your own custom permissions using the techniques described above, there is nothing stopping you from reusing a standard system permission, if it would fit your needs.
For example, suppose that you are writing YATC (Yet Another Twitter Client). You decide that in addition to YATC having its own UI, you will design YATC to be a “Twitter engine” for use by third party apps:

- Send timeline updates via broadcast Intents
- Publish the timeline, the user’s own tweets, @-mentions, and the like via a ContentProvider
- Offer a command-based service interface for posting updates to the timeline
- And so on

You could, and perhaps should, implement your own custom permission. However, since any app can get to Twitter just by having the INTERNET permission, one could argue that a third-party app should just need that same INTERNET permission to use your API (rather than integrating JTwitter or another third-party JAR).

**Signature Permissions**

Each permission in Android is assigned a protection level, via an android:protectionLevel attribute on the <permission> element. By default, permissions are at a normal level, but they can also be flagged as dangerous, signatureOrSystem, or signature. In the latter two cases, “signature” means that the app requesting the permission and the app requiring the permission should have be signed by the same signing key. In the case of signatureOrSystem — only used by the firmware – the app requesting the permission either needs to be signed by the firmware’s signing key or reside on the system partition (e.g., come pre-installed with the device).

**Firmware-Only Permissions**

Most of Android’s permissions mentioned in this book are ones that any SDK application can hold, if they ask for them and the user grants them. INTERNET, READ_CONTACTS, ACCESS_FINE_LOCATION, and kin all are normal permissions.

BRICK is not.

There was a permission in Android, named BRICK, that, in theory, allows an application to render a phone inoperable (a.k.a., “brick” the phone). While there is no brickMe() method in the Android SDK tied to this permission, presumably there might be something deep in the firmware that was protected by this permission. Though, since Android 6.0 removed the BRICK permission from the SDK, it is clearly
not something Google expects us to use.

The BRICK permission could not be held by ordinary Android SDK applications. You could request it all you want, and it will not be granted.

However, applications that are signed with the same signing key that signed the firmware could hold the BRICK permission.

That is because the system's own manifest used to have the following <permission> element:

```xml
<permission
    android:name="android.permission.BRICK"
    android:label="@string/permlab_brick"
    android:description="@string/permdesc_brick"
    android:protectionLevel="signature"/>
```

Your Own Signature Permissions

You too can require signature-level permissions. That will restrict the holders of that permission to be other apps signed by your signing key. This is particularly useful for inter-process communication between apps in a suite — by using signature permissions, you ensure that only your apps will be able to participate in those communications.

One nice thing about these sorts of signature-level permissions is that the user is not bothered with them. It is assumed that the user will agree to the communication between the apps signed by the same signing key. Hence, the user will not see signature-level permissions at install or upgrade time.

Since in some cases, you may not be sure which app will be installed first, it is best to have all apps in the suite include the same <permission> element, in addition to the corresponding <uses-permission> element. That way, no matter which app is installed first, it can declare the permission that all will share.

Though, that has its own problems, as you will see in the next section.

The Custom Permission Vulnerability

(NOte: Some of the material in this section originally appeared in material hosted in the CWAC-Security project repository. In addition, the author would like to thank Mark Carter and "Justin Case" for their contributions in this topic area).
Unfortunately, custom permissions have some undocumented limitations that make them intrinsically risky. Specifically, custom permissions can be defined by anyone, at any time, and “first one in wins”, which opens up the possibility of unexpected behavior.

Here, we will walk through some scenarios and show where the problems arise, plus discuss how to mitigate them as best we can.

Scenarios

All of the following scenarios focus on three major app profiles.

App A is an app that defines a custom permission in its manifest, such as:

```xml
<permission
    android:name="com.commonsware.cwac.security.demo.OMG"
    android:description="@string/perm_desc"
    android:label="@string/perm_label"
    android:protectionLevel="normal"/>
```

App A also defends a component using the android:permission attribute, referencing the custom permission:

```xml
<provider
    android:name="FileProvider"
    android:authorities="com.commonsware.cwac.security.demo.files"
    android:exported="true"
    android:grantUriPermissions="false"
    android:permission="com.commonsware.cwac.security.demo.OMG">
    <grant-uri-permission android:path="/test.pdf"/>
</provider>
```

App B has a <uses-permission> element to declare to the user that it wishes to access components defended by that permission:

```xml
<uses-permission android:name="com.commonsware.cwac.security.demo.OMG"/>
```

App C has the same <uses-permission> element. The difference is that App B also has the <permission> element, just as App A does, albeit with different descriptive information (e.g., android: description) and, at times, a different protection level.

All three apps are signed with different signing keys, because in the real world they would be from different developers.
So, to recap:

- A defines a permission and uses it for defense
- B defines the same permission and requests to hold it
- C just requests to hold this permission

With all that in mind, let’s walk through some possible scenarios, focusing on two questions:

1. What is the user told, when the app is installed through normal methods (i.e., not via adb), regarding this permission?
2. What access, if any, does App B or App C have to the ContentProvider from App A?

The Application SDK Case (A, Then C)

Suppose the reason why App A has defined a custom permission is because it wants third-party apps to have the ability to access its secured components... but only with user approval. By defining a custom permission, and having third-party apps request that permission, the user should be informed about the requested permission and can make an informed decision.

Conversely, if an app tries to access a secured component but has not requested the permission, the access attempt should fail.

App C has requested the custom permission via the <uses-permission> element. If the permission — defined by App A — has an android:protectionLevel of normal or dangerous, the user will be informed about the requested permission at install time. If the user continues with the installation, App C can access the secured component.

If, however, the android:protectionLevel is signature, the user is not informed about the requested permission at install time, as the system can determine on its own whether or not the permission should be granted. In this case, App A and App C are signed with different signing keys, so Android silently ignores the permission request. If the user continues with installation, then App C tries to access App A’s secured component, App C crashes with a SecurityException.

In other words, this all works as expected.
The Application SDK Problem Case (C, Then A)

However, in many cases, there is nothing forcing the user to install App A before App C. This is particularly true for publicly-distributed apps on common markets, like the Play Store.

When the user installs App C, the user is not informed about the request for the custom permission, presumably because that permission has not yet been defined. If the user later installs App A, App C is not retroactively granted the permission, and so App C’s attempts to use the secured component fail.

This works as expected, though it puts a bit of a damper on custom permissions. One way to work around this would be for the user to uninstall App C, then install it again (with App A already installed). This returns us to the original scenario from the preceding section. However, if the user has data in App C, losing that data may be a problem (as in a “let’s give App C, or perhaps App A, one-star ratings on the Play Store” sort of problem).

The Peer Apps Case, Part One (A, Then B)

Suppose now we augment our SDK-consuming app (formerly App C) to declare the same permission that App A does, in an attempt to allow the two apps to be installed in either order. That is what App B is: the same app as App C, but where it has the same <permission> element as does App A in its manifest.

This scenario is particularly important where both apps could be of roughly equal importance to the user. In cases where App C is some sort of plugin for App A, it is not unreasonable for the author of App A to require App A to be installed first. But, if Twitter and Facebook wanted to access components of each others’ apps, it would be unreasonable for either of those firms to mandate that their app must be installed first. After all, if Twitter wants to be installed first, and Facebook wants to be installed first, one will be disappointed.

If the user installs App A (the app defending a component with the custom permission) before App B, the user will be notified at install time about App B’s request for this permission. Notably, the information shown on the installation security screen will contain App A’s description of the permission. And, if the user goes ahead and installs App B, App B can indeed access App A’s secured component, since it was granted permission by the user.

Once again, everything is working as expected. Going back to the two questions:
The user is informed when App B or App C requests the permission defined by App A.

App B and App C can hold that permission if and only if they meet the requirements of the protection level.

The Peer Apps Case, Part Two (B, Then A)

What happens if we reverse the order of installation? After all, if App A and App B are peers, from the standpoint of the user, there is roughly a 50% chance that the user will install App B before App A.

Here is where things go off the rails.

The user is not informed about App B’s request for the custom permission.

The user will be informed about any platform permissions that the app requests via other <uses-permission> elements. If there are none, the user is told that App B requests no permissions… despite the fact that it does.

When the user installs App A, the same thing occurs. Of course, since App A does not have a <uses-permission> element, this is not all that surprising.

However, at this point, even though the user was not informed, App B holds the custom permission and can access the secured component.

This is bad enough when both parties are ethical. App B could be a piece of malware, though, designed to copy the data from App A, ideally without the user’s knowledge. And, if App B is installed before App A, that would happen.

So, going to the two questions:

1. The user is not informed about App B’s request for the permission...
2. …but App B gets it anyway and can access the secured component

The Downgraded-Level Malware Case (B, Then A, Again)

You might think that the preceding problem would only be for normal or dangerous protection levels. If App A defines a permission as requiring a matching signature, and App A marks a component as being defended by that permission, Android must require the signature match, right?
Wrong.

The behavior is identical to the preceding case. Android does not use the defender's protection level. It uses the definer's protection level, meaning the protection level of whoever was installed first and had the <permission> element.

So, if App A has the custom permission defined as signature, and App B has the custom permission defined as normal, if App B is installed first, the behavior is as shown in the preceding section:

1. The user is not informed about App B's request for the permission...
2. ...but App B gets it anyway and can access the secured component, despite the signatures not matching

**The Peer Apps Case With a Side Order of C**

What happens if we add App C back into the mix? Specifically, what if App B is installed first, then App A, then App C?

When App C eventually gets installed, the user is prompted for the custom permission that App C requests via <uses-permission>. However, the description that the user sees is from App B, the one that first defined the custom <permission>. Moreover, the protection level is whatever App B defined it to be. So if App B downgraded the protection level from App A's intended signature to be normal, App C can hold that permission and access the secured App A component, even if it is signed by another signing key.

Not surprisingly, the same results occur if you install App B, then App C, then App A.

**Behavior Analysis**

The behavior exhibited in these scenarios is consistent with two presumed implementation “features” of Android's permission system:

1. First one in wins. In other words, the first app (or framework, in the case of the OS's platform permissions) that defines a <permission> for a given android:name gets to determine what the description is and what the protection level is.
2. The user is only prompted to confirm a permission if the app being installed has a <uses-permission> element, the permission was already defined by
some other app, and the protection level is not signature.

Risk Assessment

The “first one in wins” rule is a blessing and a curse. It is a curse, insofar as it opens up the possibility for malware to hold a custom permission without the user’s awareness of that, and even to downgrade a signature-level permission to normal. However, it is a blessing, in that the malware would have to be installed first; if it is installed second, either its request to hold the permission will be seen by the user (normal or dangerous) or the request to hold the permission will be rejected (signature).

This makes it somewhat unlikely for a piece of malware to try to sneakily make off with data. Eventually, if enough users start to ask publicly why App B needs access to App A’s data (for cases where App A was installed first and the user knows about the permission request), somebody in authority may eventually realize that this is a malware attack. Of course, “eventually” may be a rather long time.

However, there are some situations where Android’s custom permission behavior presents risk even greater than that. If the attacker has a means of being sure that their app was installed first, they can hold any permission from any third-party app they want to that was known at install time.

For example:

- Somebody could sell a used Android device, and the buyer could neglect to factory-reset it, and the malware could be installed by the seller
- Somebody could sell a used Android device with a ROM mod preinstalled, based on a normal ROM mod (e.g., CyanogenMod), but with an additional bit of malware installed, to prevent a factory reset from foiling the attack’
- Somebody could distribute devices to users who might think the device is “factory clean” and not laden with malware (e.g., devices given as gifts)
- Somebody could distribute devices to users who might think that the pre-installed malware is actually a legitimate app (e.g., devices given to employees by an employer wishing to monitor usage by examining protected data from third-party apps)

Android 5.0’s “Fix”

Android 5.0 now prevents two apps from defining the same <permission> (“same” based on android:name) unless they are signed by the same signing key. First one in
On the plus side:

- This solves the security problem, as an attacker (B) cannot get at a defender’s (A’s) data by virtue of having been installed first, as A simply cannot be installed in this case.
- This has no impact on developers using signature-level `<permission>` elements for their own app suite.

However, it does pose significant limitations on legitimate public uses of custom `<permission>` elements. Only the defender should have the `<permission>` element now. Some client of the defender’s app (C) should not have the `<permission>` element and should simply rely upon the fact that the defender should be installed first. If the client were to define the `<permission>`, then either the client or the defender cannot be installed, which is pointless.

This has usability issues:

- A client should check, on first run of their app, if an expected defender (and its `<permission>` element) exists. If not, the client should alert the user to this fact and perhaps stop the app from proceeding further. The user would have to uninstall the client, install the defender, then reinstall the client, to get everything working properly, and the more the user uses the client app, the more painful the uninstall might be.
- It is impossible for two apps to be clients of each other. By definition, one app has to be installed first and the other second, which means only the first-to-be-installed app can have a custom `<permission>`. If Facebook wanted to hold a custom Twitter permission, and Twitter wanted to hold a custom Facebook permission, one of them is out of luck — if Facebook is installed first, it cannot request Twitter’s permission (as it does not yet exist) nor can it define Twitter’s permission (as if it does, Twitter cannot be installed). This might be able to be overcome for apps that are pre-loaded as part of a ROM mod or other custom Android build.

And, of course, this fix is only for Android 5.0 and above.

**Mitigation Using PermissionUtils**

The “first one in wins” rule also leads us to a mitigation strategy: On first run of our app, see if any other app has defined permissions that we have defined. If that has
happened, then we are at risk, and take appropriate steps. If, however, no other app has defined our custom permissions, then the Android permission system should work for us, and we can proceed as normal.

The CWAC-Security library provides some helper code, in the form of the PermissionUtils class, to detect other apps defining the same custom permissions that you define.

The idea is that you call checkCustomPermissions() — a static method on PermissionUtils — on the first run of your app. It will return details about what other apps have already defined custom permissions that your app defines. If checkCustomPermissions() returns nothing, you know that everything is fine, and you can move ahead. Otherwise, you can:

- Check to see if the offending app is on some whitelist, or otherwise meets criteria that suggests that it is OK
- Alert the user, indicating that these already-installed apps will have access to your app secured components
- Upload details about the offending apps to your server, so you can try to track down whether they are legitimate users of some API that you are exposing or are malware
- Whatever else you feel is necessary

**Custom Dangerous Permissions, and Android 6.0**

Android 6.0 introduced the concept of runtime permissions, where dangerous permissions need to be requested at runtime in addition to being requested in the manifest. This is covered back in the introductory chapter on permissions.

However, what happens if you define a custom dangerous permission?

The good news is that it works. However, you will want to test it, in part to see what it looks like to users, so you can get the phrasing of your permission-related string resources correct.

The Permissions/CustomDangerous sample project contains two application modules:

- app is an app that defends an activity using a custom dangerous permission
- client is an app that wishes to request that permission and start that
The `<permission>` element is unremarkable, other than the `protectionLevel` being set to `dangerous`:

```xml
<permission
    android:name="com.commonsware.android.perm.custdanger.SOMETHING"
    android:description="@string/perm_desc"
    android:label="@string/perm_label"
    android:protectionLevel="dangerous" />
```

(from Permissions/CustomDangerous/app/src/main/AndroidManifest.xml)

The label and description come from string resources:

```xml
<string name="perm_label">Custom Dangerous Permission</string>
<string name="perm_desc">This is a description. No, really.</string>
```

(from Permissions/CustomDangerous/app/src/main/res/values/strings.xml)

The client module uses the same `AbstractPermissionActivity` seen elsewhere in this book to request that `com.commonsware.android.perm.custdanger.SOMETHING` permission at runtime.
If you install the app application, then install and run the client application, what you see is the description, not the label, appear in the runtime permission dialog:

![Custom Dangerous Permission, As Shown In Runtime Permission Dialog, on Android 6.0.1](image)

Figure 724: Custom Dangerous Permission, As Shown In Runtime Permission Dialog, on Android 6.0.1
If you go into Settings > Apps > Custom Dangerous Client > Permissions, the custom dangerous permission does not show up immediately, due to a poorly-designed UI:

Figure 725: App Permissions in Settings, Showing Nothing Useful
Instead, the user needs to tap on the “Additional permissions” row to have that be replaced by the custom dangerous permission:

![Figure 726: App Permissions in Settings, Showing Custom Dangerous Permission](image)

Here, the label is what shows up, not the description.

Hence, you will want to tailor your phrasing of these string resources to make sense in their respective use cases.

**Finding the Available Permissions**

On the one hand, developers should try to stick to documented permissions.

On the other hand, documentation is sometimes lacking. This is particularly true for permissions other than those defined by the OS itself, ones that come from other apps that change more frequently, including the Play Services SDK and framework.

You might find that you need to determine what permissions have been defined on a given device. Perhaps that need is at runtime — if you request a permission that does not exist, you cannot actually get it, and that may lead to problems in the
future. Perhaps that need is just during development itself, to inspect some device and determine what it does and does not have in terms of permissions.

PackageManager offers methods to allow you to examine the device’s permissions and permission groups. The Permissions/PermissionReporter sample app uses these methods to build up a tabbed UI listing the defined permissions, broken down by protection level.

getAllPermissionGroups() on PackageManager will return a list of PermissionGroupInfo objects. This method takes an int value; 0 generally will be fine for your use cases.

On its own, PermissionGroupInfo is not especially useful. However, you can turn around and call queryPermissionsByGroup() on PackageManager, passing in the name from the PermissionGroupInfo, to get all of the permissions in that group. This method also takes an int value as the second parameter, where once again 0 will be fine.

queryPermissionsByGroup() returns a List of PermissionInfo objects. PermissionInfo has a few interesting values:

- name, which is the fully-qualified name of the permission
- descriptionRes, which is the string resource ID from the permission’s android:description attribute
- protectionLevel, which is a set of flags indicating the nature of the permission’s security

Note that to get the actual text of the description, there is a loadDescription() method on PermissionInfo that will do all the work to find the actual string for the description, based upon the app that defined the permission and the current locale.

To get the details of all the permissions defined on a device, we will have to call queryPermissionsByGroup() for each permission group. Each of those calls will involve IPC, and so this might be slow enough to warrant its own thread.

With that in mind, MainActivity in the PermissionReporter sample app has a PermissionSource that collects information about the permissions on the system. That information is aggregated in a PermissionRoster, which the data emitted by this Observable:

```java
private static class PermissionSource implements ObservableOnSubscribe<PermissionRoster> {
    private Context ctxt;
```
private PermissionSource(Context ctxt) {
    this ctxt=ctxt.getApplicationContext();
}

@Override
public void subscribe(ObservableEmitter<PermissionRoster> emitter)
throws Exception {
    PackageManager pm=ctxt.getPackageManager();
    final PermissionRoster result=new PermissionRoster();
    addPermissionsFromGroup(pm, null, result);
    for (PermissionGroupInfo group : pm.getAllPermissionGroups(0)) {
        addPermissionsFromGroup(pm, group.name, result);
    }
    emitter.onNext(result);
    emitter.onComplete();
}

private void addPermissionsFromGroup(PackageManager pm, String groupName,
                                      PermissionRoster result)
            throws PackageManager.NameNotFoundException {
    for (PermissionInfo info : pm.queryPermissionsByGroup(groupName, 0)) {
        int coreBits=
            info.protectionLevel &
            PermissionInfo.PROTECTION_MASK_BASE;
        switch (coreBits) {
            case PermissionInfo.PROTECTION_NORMAL:
                result.add(PermissionType.NORMAL, info);
                break;
            case PermissionInfo.PROTECTION_DANGEROUS:
                result.add(PermissionType.DANGEROUS, info);
                break;
            case PermissionInfo.PROTECTION_SIGNATURE:
                result.add(PermissionType.SIGNATURE, info);
                break;
            default:
                result.add(PermissionType.OTHER, info);
                break;
        }
    }
}

(from Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/MainActivity.java)

The subscribe() method loops over the permission groups:
As it turns out, not all permissions are part of a group. To find out the details of these un-grouped permissions, you need to call `queryPermissionsByGroup()` with a null permission group name.

For each permission group (plus the magic `null` group), we call a private `addPermissionsFromGroup()` method (shown above) to collect the details of the permissions in that group.

The `protectionLevel` field on a `PermissionInfo` contains a number of different sorts of flags. The `PROTECTION_MASK_BASE` is a bitmask that restricts the bits we are looking at to the ones for basic protections. We then divide the permissions into four groups based on protection level:

- normal
- dangerous
- signature
- other (which, on older devices, will include system or `signatureOrSystem` permissions)

Those `PermissionInfo` objects are then poured into the `PermissionRoster` object:
ADVANCED PERMISSIONS

```java
ArrayList<PermissionInfo> getListForType(PermissionType type) {
    return roster.get(type);
}
```

PermissionType is an enum defined by this project for the four groups and includes some Java shenanigans for being able to convert back and forth between integer values and the enum values:

```java
package com.commonsware.android.permreporter;

import android.util.SparseArray;

enum PermissionType {
    NORMAL(0),
    DANGEROUS(1),
    SIGNATURE(2),
    OTHER(3);

    private final int value;

    PermissionType(int value) {
        this.value = value;
    }

    static PermissionType forValue(int value) {
        return BY_VALUE.get(value);
    }
}
```

(from Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/PermissionRoster.java)
Restricted Profiles and UserManager

Android 4.2 introduced the concept of having multiple distinct users of a tablet. Each user would get their own portion of internal and external storage, as if they each had their own tablet.

Android 4.3 extends this a bit further, with the notion of setting up restricted profiles. As the name suggests, a restricted profile is restricted, in terms of what it can do on the device. Some restrictions will be device-wide (e.g., can the user install apps?), and some restrictions will be per-app. You can elect to allow your app to be restricted, where you define the possible ways in which your app can be restricted, and the one setting up the restricted profile can then configure the desired options for some specific profile.

This chapter will explain how users set up these restricted profiles, what you can learn about the device-wide restrictions, and how you can offer your own restrictions for your own app.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly the chapter on files and its section on multiple user accounts.

Android Tablets and Multiple User Accounts

The theory is that tablets are likely to be shared, whether among family members, among team members in a business, or similar sorts of group settings. There are three levels of “user” in an Android 4.3+ tablet that we will need to consider.
Primary User

The primary user is whoever first set up the tablet after initial purchase. In a family, this is probably a parent; in a corporate setting, this might be an IT administrator.

Prior to Android 4.2, there was only one user per device, and that user could (generally) do anything. In Android 4.2+, the primary user holds this role.

One thing that the primary user can do is set up other users, via the Users option in the Settings app:

![Figure 727: Users Screen in Settings](image-url)
Tapping the “Add user or profile” entry allows the primary user to set up another user or restricted profile:

Figure 728: Add Dialog in Users Screen in Settings
Secondary User

Choosing “User” from the Add dialog will define a secondary user of the device. This user has much of the same control as the primary user, in terms of being able to install and run whatever apps are desired.

Figure 729: Add New User Warning Dialog in Users Screen in Settings
Restricted Profile

A restricted profile is akin to a secondary user, in that it gets its own separate portion of internal and external storage. Beyond that, though, the primary user can further configure what the restricted profile can access:

![Restricted Profile Configuration Screen in Settings](image)

*Figure 730: Restricted Profile Configuration Screen in Settings*

The bulk of the restricted profile configuration screen is a list of apps, with Switch widgets to allow the primary user to allow or deny access to each app.
Some apps will have the “settings” icon to the left of the Switch. Tapping that will either bring up a dedicated activity for restricting operations within that app, or it will add new rows to the list with individual restriction options for that app. For example, tapping the settings icon for the Settings app adds a row where the primary user can block location sharing:

![Image of settings icon and restricted apps]

*Figure 731: Location Sharing Restrictions*

The “settings” icon in the first row, for the profile itself, will allow the primary user to control things for the entire profile, notably its name.
Switching to the restricted profile (e.g., via the lockscreen) will show the constrained set of available apps:

![Figure 732: Apps in a Restricted Profile](image)

**Determining What the User Can Do**

Your app can find out what device-level restrictions were placed on the current user by means of the `UserManager` system service. Specifically, as you can see in `MainActivity` of the `RestrictedProfiles/Device` sample project, all you need to do is:

- Acquire an instance of a `UserManager` by calling `getSystemService()` on a `Context`, passing in `USER_SERVICE` as the service's name
- Calling `getUserRestrictions()` on the `UserManager`

```java
package com.commonsware.android.profile.device;

import android.support.v4.app.FragmentActivity;
import android.os.Bundle;
import android.os.UserManager;
import android.widget.Toast;

public class MainActivity extends FragmentActivity {

```
getUserRestrictions() returns a Bundle, whose keys are documented on UserManager for various device-level restrictions that theoretically can be placed on the user. Here, “theoretically” means that while UserManager documents several DISALLOW_* constants, only two seem to be directly accessible to the primary user for configuration via Settings:

- DISALLOW_MODIFY_ACCOUNTS, to prevent a restricted profile from, among other things, modifying restricted profiles
- DISALLOW_SHARE_LOCATION, to prevent the apps run in this restricted profile from gathering location data

MainActivity examines the Bundle and, if it is empty, just displays a Toast and exits via finish(). This is the behavior you will see if you run this sample app on a non-restricted profile, such as the primary user. If, however, the Bundle has one or more keys, we inflate an activity_main layout that contains a RestrictionsFragment in a <fragment> element:
We then retrieve the `RestrictionsFragment` from the `FragmentManager` and call `showRestrictions()` on it, passing in the Bundle.

`RestrictionsFragment` is a `ListFragment` employing a custom `RestrictionsAdapter`. The `RestrictionsAdapter` wraps around the Bundle and an `ArrayList` of its keys. The `RestrictionsAdapter` constructor creates the `ArrayList` by sorting the `keySet()` of the Bundle. `getView()` on `RestrictionsAdapter` lets the superclass handle inflating the row (`android.R.layout.simple_list_item_1`), then puts an icon on the right side by using `setCompoundDrawablesWithIntrinsicBounds()`, which can tuck a drawable resource onto any of the four sides of a `TextView`.

The resulting list will show green icons for keys where the Bundle has stored a `true` Boolean value, and a red icon for `false`:

![Figure 733: Default Device Restrictions, on a Nexus 7 (2013)](image)

Since the keys are negative in tone (e.g., `DISALLOW_MODIFY_ACCOUNTS`), `true` means that the restriction is enforced and the underlying operation (e.g., modifying accounts) cannot be done.
Impacts of Device-Level Restrictions

Your app’s functionality may be limited by these device-level restrictions. This section outlines some of the results you should expect from a restricted profile.

Restricting Location Access

If a restricted profile is prevented from sharing the device’s location with apps, those apps simply will not receive location updates. There is no good way to detect this via the location API (e.g., `isProviderEnabled()` returns `true`), so you will have to detect this via `getUserRestrictions()` on `UserManager` as noted above.

Uninstalling Apps

Even without specific configuration, the restricted profile can only uninstall apps that they are available to that profile. However, since apps are really shared between profiles, this only removes that app from the restricted profile; it does not actually uninstall the app from the device as a whole.

Enabling Custom Restrictions

As noted earlier, the list of apps that is shown on the restricted profile configuration screen in Settings can have “settings” icons. The Settings app itself will have a settings icon, to allow the primary user to configure device-level restrictions.

But, what if you want your app to have such a settings icon? Maybe it makes sense for your app to allow the primary user to restrain restricted profiles from doing certain things within your app:

- Block in-app purchases
- Only show certain categories of content, not the full roster
- Only allow operation during certain times of the day

The means by which the Settings app restricts profiles is also available to you. You can declare to Android what aspects of your app can be restricted. Android will then collect that restriction data for you. Your app, at runtime, can then determine what restrictions are in place (if any) and take appropriate steps.

All of this will be illustrated using the `RestrictedProfiles/App` sample project.
Stating Your Restrictions

The biggest thing that you need to do to restrict your app is teach Android how to collect restrictions. In other words, you need to tell Android what to do when the user taps that settings icon in the restricted profile entry for your app.

You have two major options:

• Provide a list of the restrictions that Android should render and collect itself, or
• Provide an Intent that can be used to start up an activity of your own design where you collect those restrictions

Either approach will require you to set up a manifest-registered BroadcastReceiver, set to respond to the android.intent.action.GET_RESTRICTION_ENTRIES action:

```xml
<receiver android:name="RestrictionEntriesReceiver">
    <intent-filter>
        <action android:name="android.intent.action.GET_RESTRICTION_ENTRIES"/>
    </intent-filter>
</receiver>
```

(from RestrictedProfiles/App/app/src/main/AndroidManifest.xml)

That BroadcastReceiver will be called with sendOrderedBroadcast(), not so much to affect ordering, but to allow the BroadcastReceiver to send back a result via its setResultExtras() method. This provides a Bundle that the broadcaster can eventually retrieve, in this case providing details of what restrictions we wish to collect from the primary user to restrict the profile.

Option #1: RestrictionEntry List

To collect restrictions the way the Settings app does — with restriction rows appearing below your app in the restricted profile screen in Settings – your BroadcastReceiver will need to put an entry into the return Bundle, under the key of EXTRA_RESTRICTIONS_LIST (a constant defined on the Intent class). The value needs to be an ArrayList of RestrictionEntry objects, with each RestrictionEntry describing one restriction to collect.

Another thing that the RestrictionEntry objects contain is their current value. Android itself retains these values and supplies them to your BroadcastReceiver via an EXTRA_RESTRICTIONS_BUNDLE extra on the incoming Intent. Your app needs to
In `onReceive()`, RestrictionEntriesReceiver pulls out the Bundle of current restrictions, by retrieving the `EXTRA_RESTRICTIONS_BUNDLE` extra from the Intent passed into `onReceive()`. Note that this Bundle could very well be empty, if this is the first time we are being asked for restrictions.

RestrictionEntriesReceiver creates an empty `ArrayList` of `RestrictionEntry` objects, then calls a series of builder methods to create a total of three such `RestrictionEntry` objects, adding each to the list. `onReceive()` goes on to create a Bundle representing the results to be returned, packages the `ArrayList` in that Bundle under the `EXTRA_RESTRICTIONS_LIST` key, and returns that Bundle to the caller by means of `setResultExtras()`.

The three builder methods are each responsible for defining a single...
RestrictionEntry, including populating it with the current value from the current Bundle.

There are three types of RestrictionEntry, for boolean, single-selection lists ("choice"), and multi-selection lists. The RestrictionEntry constructor takes two parameters:

- The String key under which we will later retrieve this restriction value
- The current value of the restriction

The current value is:

- A boolean for boolean restrictions
- A String for choice restrictions
- A String array for multi-select restrictions

Our first builder, buildBooleanRestriction(), populates and returns a RestrictionEntry designed to collect a boolean value from the primary user, via a CheckBox:

```java
private RestrictionEntry buildBooleanRestriction(Context ctxt, Bundle current) {
    RestrictionEntry entry = new RestrictionEntry(RESTRICTION_BOOLEAN, current.getBoolean(RESTRICTION_BOOLEAN, false));
    entry.setTitle(ctxt.getString(R.string.boolean_restriction_title));
    entry.setDescription(ctxt.getString(R.string.boolean_restriction_desc));
    return entry;
}
```

buildBooleanRestriction() retrieves the current value from current Bundle to use with the RestrictionEntry constructor. In this case, if there is no such entry in the Bundle, the overall default value is false.

Each RestrictionEntry can have a title (setTitle()), supplying a string which will be displayed to describe what this restriction is. A boolean restriction can also have a description (setDescription()), containing another string with a bit more text. Note that, at the present time, the other two types of restrictions will ignore any
description that you include. Also note that the values supplied to setTitle() and setDescription() need to be strings, and so if you wish to use a string resource, you will need to get the actual string value yourself via getString().

The remaining two builder methods have a similar structure:

```java
private RestrictionEntry buildChoiceRestriction(Context ctxt, Bundle current) {
    RestrictionEntry entry =
        new RestrictionEntry(RESTRICTION_CHOICE,
            current.getString(RESTRICTION_CHOICE));
    entry.setTitle(ctxt.getString(R.string.choice_restriction_title));
    entry.setChoiceEntries(ctxt, R.array.display_values);
    entry.setChoiceValues(ctxt, R.array.restriction_values);
    return(entry);
}

private RestrictionEntry buildMultiSelectRestriction(Context ctxt, Bundle current) {
    RestrictionEntry entry =
        new RestrictionEntry(RESTRICTION_MULTI,
            current.getStringArray(RESTRICTION_MULTI));
    entry.setTitle("A Multi-Select Restriction");
    entry.setChoiceEntries(ctxt, R.array.display_values);
    entry.setChoiceValues(ctxt, R.array.restriction_values);
    return(entry);
}
```

(from RestrictedProfiles/App/app/src/main/java/com/commonsware/android/profile/app/RestrictionEntriesReceiver.java)

As with a ListPreference, you provide two string arrays to the RestrictionEntry, representing the values the primary user sees (setChoiceEntries()) and the corresponding values to be supplied to your app based upon the choice(s) (setChoiceValues()). You can supply these either as Java string arrays or as <string-array> resources – RestrictionEntriesReceiver goes with the latter approach.

**Option #2: Custom Restriction Activity**

It may be that what you want to collect, in terms of restrictions, cannot readily be represented in the form of Switch widgets and list dialogs. For example, to restrict
use of your app based on time, it would be nice to use a TimePickerDialog or the equivalent.

The alternative to returning an EXTRA_RESTRICTIONS_LIST roster of RestrictionEntry objects from your BroadcastReceiver is to have the result Bundle contain EXTRA_RESTRICTIONS_INTENT. This key should point to an Intent that identifies the activity that you want to start up when the user taps the settings icon. Android will call startActivityForResult() on that Intent when the user taps on the settings icon.

Your job is to collect the restrictions from the user, using the EXTRA_RESTRICTIONS_BUNDLE from the incoming Intent to pre-populate your activity, if desired. When the user is done, you should call setResult(), passing in an Intent that contains another EXTRA_RESTRICTIONS_BUNDLE with the revised data, or optionally a EXTRA_RESTRICTIONS_LIST (with the RestrictionEntry objects containing the values to be used).
What the Primary User Sees

Given the `RestrictionEntriesReceiver` described above, when the primary user goes to configure a restricted profile, your app will appear with a settings icon next to it:

![Restricted Profile, Showing App Settings Icon]

*Figure 734: Restricted Profile, Showing App Settings Icon*
Tapping that settings icon will “unfold” and display the restrictions that you configured via the RestrictionEntry objects:

Figure 735: Restricted Profile, Showing App Restrictions
The primary user can then interact with your restrictions, toggling checkboxes and popping up the list dialogs:

![Restricted Profiles and UserManager](image_url)

*Figure 736: Restricted Profile, Showing Choice Restriction*
Finding Out the Current Restrictions

Now, the rest of your app needs to find out what restrictions are placed upon it, so behavior can be tailored accordingly. To do this, call `getApplicationRestrictions()` on `UserManager`, passing in your package name, as seen here in `MainActivity`:

```java
package com.commonsware.android.profile.app;

import android.support.v4.app.FragmentActivity;
import android.os.Bundle;
import android.os.UserManager;
import android.widget.Toast;

public class MainActivity extends FragmentActivity {

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        UserManager mgr=(UserManager) getSystemService(USER_SERVICE);
        Bundle restrictions=mgr.getApplicationRestrictions(getPackageName());

        if (restrictions.keySet().size() > 0) {
            setContentView(R.layout.activity_main);
            RestrictionsFragment f=
```
This Bundle could be empty, or it could have values specified by the primary user to restrict the profile that is running your app.

In the case of this sample, we once again set up a RestrictionsAdapter to show the results, if the Bundle is not empty. However, our adapter is a bit more complicated, as there are more than boolean restrictions now. getView() has been updated to handle all three possible restrictions, showing the icon for the boolean restriction, and showing the value(s) from the lists in the other restrictions:
Collections.sort(keys);
addAll(keys);
	histo.this.restrictions=restrictions;
}

@Override
public View getView(int position, View convertView, ViewGroup parent) {
    TextView row=(TextView)super.getView(position, convertView, parent);
    String key=item(position);

    if (RestrictionEntriesReceiver.RESTRICTION_BOOLEAN.equals(key)) {
        int icon=
            restrictions.getBoolean(key) ? R.drawable.ic_true
            : R.drawable.ic_false;

        row.setCompoundDrawablesWithIntrinsicBounds(0, 0, icon, 0);
    } else if (RestrictionEntriesReceiver.RESTRICTION_CHOICE.equals(key)) {
        row.setText(String.format("%s (%s)\n", key,
            restrictions.getString(key)));
    } else {
        String value=
            TextUtils.join(" | ", restrictions.getStringArray(key));

        row.setText(String.format("%s (%s)\n", key, value));
    }

    return(row);
}
}
The result, when run on a restricted profile with restrictions placed upon our app, is to show those restrictions:

![Image](image_url)

*Figure 738: App Restrictions Demo, on a Restricted Profile*

**Implicit Intents May Go “Boom”**

The primary user of a tablet, when setting up a restricted profile, can control what apps are available to that profile. In many cases, if the user is setting up a restricted profile in the first place, the list of apps available to that profile will be fairly limited, such as only allowing a young child to access a few games and educational apps.

`startActivity()` always has the chance of throwing an `ActivityNotFoundException`. However, for certain Intent actions, we often ignore this possibility, because we are certain that there will be an app that can handle our request:

- All Android devices have Web browsers, right?
- All Android devices have some sort of mapping application, right?
- All Android devices let you pick a contact, right?
Now, with restricted profiles, you will need to deal with the ActivityNotFoundException case all of the time. You have three basic approaches for this:

1. Wrap all `startActivity()` and `startActivityForResult()` calls in a `try/catch` block that catches `ActivityNotFoundException` and intelligently handle the problem.
2. Use `PackageManager` and `resolveActivity()` before trying to start the activity, where if `resolveActivity()` returns `null`, you know that there is no activity available to handle your desired operation.
3. Switch out some of your `startActivity()` and `startActivityForResult()` calls for implementations in your app (e.g., embed Maps V2 rather than try to launch a potentially-nonexistent activity).

You might consider implementing a `safeStartActivity()` utility method that wraps up your particular plan, so you can debug it once.
Android devices have supported device authentication since the beginning. Users could lock their devices with a PIN, passphrase, or “pattern”, to help deter unauthorized use. Nowadays, fingerprint sensors are available on some Android devices as another authentication option.

For the vast majority of apps, none of this matters.

Some apps have sensitive content (e.g., password manager) or offer sensitive services (e.g., banking app). These apps may want to tie more tightly into the device authentication options, to ensure that the person working with the app right now is the device's authorized user.

In this chapter, we will look at how to perform this sort of integration.

**Prerequisites**

One of the examples in this chapter makes use of [RxJava](https://reactivex.io). 

**Is the Device Secure?**

You cannot validate the identity of the user on a device that is not secured by something (PIN, passphrase, pattern, fingerprint, etc.). So, one of the first things you may wish to determine is whether or not such a lock has been applied to the device.

Android has two separate ways of accomplishing this, with slightly different feature sets.
The DevicePolicyManager Approach

In the chapter on device administration, we cover a number of APIs for managing the lock quality. In particular, DevicePolicyManager has the concept of “password quality”. Any app — not just designated device admin apps — can call getPasswordQuality() on a DevicePolicyManager instance to find out the designated minimum required quality. A value of PASSWORD_QUALITY_UNSPECIFIED indicates that “anything goes”. PASSWORD_QUALITY_SOMETHING indicates that the device needs some form of authentication, but does not establish any criteria beyond that. Other values start to put restrictions on the authentication option, such as PASSWORD_QUALITY_ALPHABETIC, indicating that the authentication cannot be in the form of a simple PIN.

Other methods let you get minimum required password lengths, minimum required characters of certain classes (e.g., symbols), and so forth.

It is fairly likely that the current authentication option in force adheres to the password criteria exposed by those methods.

The KeyguardManager Approach

The KeyguardManager system service has a simpler API... with a couple of wrinkles.

- isDeviceSecure() returns true if the device is secured with a PIN, pattern, or password. However, this method is new to API Level 23.
- isKeyguardSecure() returns true if the device is secured with a PIN, pattern, password, or SIM card lock. A “SIM card lock” amounts to a PIN associated with the SIM card, one that follows the SIM card around if you move it between devices. Conversely, a device that is secured solely by a SIM card lock can be accessed simply by removing the SIM card. This method is available on API Level 16 and higher devices.

Since SIM card locks do not seem very common, the two methods will tend to return the same result. However, since SIM card lock security is fairly weak, on Android 6.0+, use isDeviceSecure(), so SIM card locks are not taken into account with the result.

The DeviceAuth/SecureCheck sample application demonstrates the use of these methods (and of a few others that we will see shortly).

Our activity’s UI consists of two big icons with those two KeyguardManager method
names as captions.

(from DeviceAuth/SecureCheck/app/src/main/res/layout/activity_main.xml)
In onCreate(), we retrieve a KeyguardManager system service and set the images on those icons based on the KeyguardManager results:

- If the method returns true, we show a locked icon
- If the method returns false, we show an unlocked icon
- If the method cannot be called (isDeviceSecure() on pre-Android 6.0 devices), we show a question mark icon, indicating that we do not know the result.

```java
private KeyguardManager mgr;

@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    mgr = (KeyguardManager) getSystemService(KEYGUARD_SERVICE);

    ImageView device = findViewById(R.id.device);
    ImageView keyguard = findViewById(R.id.keyguard);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.M) {
        if (mgr.isDeviceSecure()) {
            device.setImageResource(R.drawable.ic_lock_black_24dp);
        } else {
            device.setImageResource(R.drawable.ic_lock_open_black_24dp);
        }
    } else {
        device.setImageResource(R.drawable.ic_help_black_24dp);
    }

    if (mgr.isKeyguardSecure()) {
        keyguard.setImageResource(R.drawable.ic_lock_black_24dp);
    } else {
        keyguard.setImageResource(R.drawable.ic_lock_open_black_24dp);
    }
}
```

(from DeviceAuth/SecureCheck/app/src/main/java/com/commonsware/android/auth/check/MainActivity.java)
Running the app will show the results of those calls:

*Figure 739: Secure Check, As Run On Secure Android 5.0 Device*
Reconfirming the User

Those methods are interesting, but they do not tell you much about the current user. Obviously, if the device is not secure, you have no idea who the current user is. However, even if the device has a PIN/password/pattern lock, it is possible that the real user unlocked device, but somebody else now has that unlocked device. Some apps will want a way to re-authenticate the user, to confirm that the person working with the device right now is the real user, not somebody else who has their hands on the unlocked device.

KeyguardManager has a `createConfirmDeviceCredentialIntent()` method that helps with this. This method returns an Intent that can be used with `startActivityForResult()`. What then appears is a system-supplied activity that requires the user to re-authenticate the device. In `onActivityResult()`, a RESULT_OK result means that the user successfully re-authenticated. Anything else means that the user failed to re-authenticate and eventually pressed BACK to return to your app.

The SecureCheck sample app has an action bar icon that, when tapped, invokes an `authenticate()` method, one that uses `createConfirmDeviceCredentialIntent()`.
createConfirmDeviceCredentialIntent() takes two parameters: a title and a description. In principle, these should appear on the authentication activity, to provide context to the user as to why this screen appeared. In reality, the description may or may not appear, so do not assume that the user will be able to see whatever you put there.

Since this Intent is designed for use with startActivityForResult(), we cannot directly put it into a PendingIntent or anything. If for some reason you needed to re-authenticate from a Notification or app widget or something, you can use a Theme.Translucent.NoTitleBar-themed activity for the PendingIntent, as such activities are effectively invisible. That activity, in turn, can call startActivityForResult() with the Intent from createConfirmDeviceCredentialIntent().

Here, we just call startActivityForResult() directly, showing a Toast in onActivityResult() based upon the user's response:
DEVICE AUTHENTICATION

On some devices (e.g., Nexus 5X running Android 8.1), the authentication activity uses FLAG_SECURE and cannot be captured in a screenshot. Other devices have no such restriction:

![Re-Authentication Activity on a Samsung Galaxy Note 3](image)

*Figure 741: Re-Authentication Activity on a Samsung Galaxy Note 3*

Note that only the title appears here; on the Nexus 5X with Android 8.1, both the title and the description appear.

`createConfirmDeviceCredentialIntent()` has a significant limitation: the Intent that you create always triggers authentication when started. Sometimes, this is a feature, if you absolutely want to ensure that the user is authenticated before proceeding. Sometimes, this is a bug, if your flow keeps forcing the user to re-authenticate. There is a way to use `createConfirmDeviceCredentialIntent()` to have an authentication timeout, so a successful authentication skips future authentication for some amount of time. This is a bit complex to set up, as it requires custom use of the keystore, and so we will explore it in greater detail in the next chapter.
Fingerprints

Android 6.0 added APIs for fingerprint sensors. For most users, and for most apps, fingerprints are just another aspect of unlocking a device. However, apps can more deeply integrate with the fingerprint sensor if desired.

Note that the libraries and classes related to fingerprints are only supported on API Level 23 and higher.

Authenticating the User

One obvious use of the fingerprint sensor is to authenticate the current user, ensuring that the person holding the device is who we think it is.

There are a few options for doing this, with varying levels of complexity.

Via KeyguardManager

The simplest solution is to not worry about fingerprints, but instead to use the techniques shown earlier in this chapter to authenticate the user.

When a user sets up a fingerprint to use for unlocking a device, that is an adjunct to a more traditional PIN or passphrase. When you start the activity identified by the Intent returned by createConfirmDeviceCredentialIntent(), you are requesting that the user authenticate by whatever means is appropriate. If a fingerprint is an option, the user will be able to use a fingerprint to authenticate.

This is cheap and easy, but it does not require that the user use a fingerprint. The user could type in their PIN or passphrase instead.

Using RxFingerprint

It is possible that you will want to use a fingerprint specifically. For example, perhaps you are using fingerprints as part of a multi-factor authentication system, where the user needs to provide some sort of passphrase for your app and authenticate with a fingerprint.

The simplest way to do this is to use one of the many third-party libraries that exist to simplify Android’s fingerprint API. For example, the DeviceAuth/FingerCheck sample application uses RxFingerprint, which offers an RxJava-compatible API for
Device Authentication

authenticating a user via a registered fingerprint.

The first requirement for working with fingerprints explicitly is to request the USE_FINGERPRINT permission:

```xml
<uses-permission android:name="android.permission.USE_FINGERPRINT" />
```

(from DeviceAuth/FingerCheck/app/src/main/AndroidManifest.xml)

This is not a dangerous permission, so you do not need to request it at runtime using requestPermissions(). But, you have to have it, so that users that investigate the full slate of permissions requested by your app will know that you wish to work with fingerprints.

Android 9.0 introduced a new permission, USE_BIOMETRIC, to better reflect the migration from simple fingerprints to more biometric authentication options (e.g., iris scan). You may wish to request both USE_FINGERPRINT and USE_BIOMETRIC, knowing that the latter will be ignored on pre-Android 9.0 devices.

RxFingerprint itself is just another artifact to request as part of your dependencies:

```groovy
dependencies {
    implementation 'com.android.support:support-vector-drawable:27.0.2'
    implementation 'com.android.support.constraint:constraint-layout:1.0.2'
    implementation 'io.reactivex.rxjava2:rxjava:2.1.7'
    implementation 'io.reactivex.rxjava2:rxandroid:2.0.1'
    implementation 'com.mtramin:rxfingerprint:2.2.1'
}
```

(from DeviceAuth/FingerCheck/app/build.gradle)

When you want to authenticate the user, you can use isAvailable() and authenticate() static methods on the RxFingerprint class:

```java
if (RxFingerprint.isAvailable(this)) {
    disposable=RxFingerprint.authenticate(this)
        .subscribe(this::onAuthResult,
        t -> {
            Log.e(getClass().getSimpleName(), "Exception authenticating", t);
        });
} else {
    Toast.makeText(this, R.string.msg_not_available, Toast.LENGTH_LONG).show();
}
```
**Device Authentication**

You need to call `isAvailable()` first. If this returns false, you cannot authenticate using a fingerprint, for any number of reasons, including:

- The device is running on less than API Level 23, which you can validate yourself using `Build.VERSION.SDK_INT`
- The device does not have a fingerprint sensor — you can also check this by calling `hasSystemFeature(PackageManager.FEATURE_FINGERPRINT)` on a `PackageManager` and seeing if it returns true or false
- The user has not registered a fingerprint

Assuming that there is a fingerprint eligible for authentication, `authenticate()` turns on the fingerprint sensor. There is no visible indication of this, and so you will need to do something in your app to let the user know that it is time for them to scan their fingerprint.

There are four possible outcomes. The unexpected one is some sort of crash. In that case, your RxJava stream will contain a `Throwable` representing the crash. In the code shown above, `subscribe()` routes that `Throwable` to some code that logs the message to LogCat (and, ideally, should do other things as well, to let the user know that something went wrong).

Everything else routes through a `FingerprintAuthenticationResult` object that is the output of the RxJava stream set up by `isAvailable()`. You can call `getResult()` on that to get an enum value that indicates what happened:

```java
private void onAuthResult(FingerprintAuthenticationResult authResult) {
    String msg = getString(R.string.msg_not_possible);

    switch (authResult.getResult()) {
    case FAILED:
        msg = getString(R.string.msg_failed);
        button.setImageDrawable(R.drawable.off);
        unsub();
        break;
    case HELP:
        msg = authResult.getMessage();
        break;
    case AUTHENTICATED:
        msg = getString(R.string.msg_authenticated);
        button.setImageDrawable(R.drawable.off);
        unsub();
        break;
    }
```

2441
If we get a HELP event, the user can try to scan their fingerprint again. The 
getMessage() method on the FingerprintAuthenticationResult provides a 
message to show the user to hint at what they might do to get a better scan. 
Otherwise, AUTHENTICATED means that the user successfully authenticated using a 
fingerprint, and FAILED means that the user failed authentication.

In all three cases, the fingerprint sensor is still active, and will remain so until we 
dispose() of the Disposable representing this RxJava subscription, handled here by 
the unsub() method:

```java
private void unsub() {
    if (disposable!=null) {
        disposable.dispose();
        disposable=null;
    }
}
```

In this sample app, the layout consists of a single ImageButton, showing a vector 
drawable of a stylized fingerprint. That fingerprint will show up in one of two colors: 
black normally, but blue when the fingerprint sensor is active. In onCreate(), we set 
up tinted editions of the vector drawable, plus hook up an authenticate() method 
to the button:

```java
@override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    off=DrawableCompat.wrap(VectorDrawableCompat.create(getResources(),
            R.drawable.ic_fingerprint_black_24dp, null));
    off.setTint(getResources().getColor(android.R.color.black, null));

    on=DrawableCompat.wrap(VectorDrawableCompat.create(getResources(),
            R.drawable.ic_fingerprint_black_24dp, null));
    on.setTint(getResources().getColor(R.color.primary, null));

    button=findViewById(R.id.fingerprint);
    button.setImageDrawable(off);
    button.setOnClickListener(view -> authenticate());
```
authenticate() contains the RxFingerprint calls from earlier, but with some additional manipulation of the button drawable, to toggle it blue while the scan is going on and toggle it black if an exception occurs:

```java
private void authenticate() {
    unsub();

    if (RxFingerprint.isAvailable(this)) {
        button.setImageDrawable(on);
        disposable=RxFingerprint.authenticate(this)
            .subscribe(this::onAuthResult,
                     t -> {
                        Log.e(getClass().getSimpleName(), "Exception authenticating", t);
                        button.setImageDrawable(off);
                    });
    } else {
        Toast.makeText(this, R.string.msg_not_available, Toast.LENGTH_LONG).show();
    }
}
```
The layout sets the ImageButton to be approximately one inch square:

Figure 742: Finger Check Sample, As Initially Launched
When you tap that button, the fingerprint turns blue:

*Figure 743: Finger Check Sample, As Initially Launched*
From there, what happens depends on the user, but ideally involves a successful authentication:

![Figure 744: Finger Check Sample, As Initially Launched](image)

**Directly**

The `FingerprintManager` system service is the Android gateway to the fingerprint-specific APIs. It has only three methods, at least as of Android 8.1.

Two of these simply indicate whether or not you can bother using the third method:

- `isHardwareDetected()` returns `true` if the device has a fingerprint sensor that is set up for use by the Android SDK, `false` otherwise
- `hasEnrolledFingerprints()` returns `true` if the user has set up one or more fingerprints in Settings, `false` otherwise

If either of those methods return `false`, you cannot authenticate the user by fingerprint.

If they both return `true`, though, you can use the third method — `authenticate()` — to authenticate the user with a fingerprint.
authenticate() takes five parameters:

- A CryptoObject, which for simple authentication can be null
- A CancellationSignal object that you can use to cancel the attempt to authenticate
- Some currently-unused flags (pass in 0 for now)
- A callback object, to find out what is happening with the authentication attempt
- A Handler, if you want the callback methods to be called on some other thread (otherwise, pass null to be called back on the main application thread)

Your AuthenticationCallback implementation can be called with four methods:

- onAuthenticationSucceeded(), if the user did indeed pass the authentication
- onAuthenticationFailed(), if the sensor detected a fingerprint, but it was not one of the registered fingerprints (e.g., from some other person)
- onAuthenticationHelp(), when there was a problem in scanning the fingerprint, but the user can try again (e.g., the finger moved too much)
- onAuthenticationError(), when something goes wrong that does not represent a failure (i.e., mismatched fingerprint) and is not recoverable

RxFingerprint simply wraps all of this in an RxJava-friendly API.

Encrypting Data Using Fingerprints and Libraries

The CryptoObject that you can pass into authenticate() is tied to the device keystore for use with digitally signing and encrypting data securely. You do not have to use FingerprintManager to work with the keystore, but it is one option. However, as we will see in the chapter on the keystore, working with the keystore is a bit complex.

RxFingerprint

RxFingerprint offers simple encrypt() and decrypt() methods. Each return an Observable for you to be able to react to the results of the cryptography.

Both methods have three parameters in common:

1. An EncryptionMethod enum value, which is either AES (for AES-256
symmetric key encryption) or RSA (for public-key encryption)

2. The Activity requesting this work
3. A “key name”, which must be unique within your app, to identify the
   encryption key(s) that are generated and securely stored as part of this work

The advantage of RSA is that the user only needs to scan their fingerprint when data
is decrypted. Encryption can occur at any time without a fingerprint. With AES, a
fingerprint is needed for both encryption and decryption. However, AES should be a
bit faster, particularly for larger amounts of data.

The encrypt() method takes a fourth parameter, which is a String representing the
data to be encrypted. It is your job to marshal your data into a String by one means
or another. What you get, reactively, from the encrypt() process is another String,
representing the encrypted value. It is your job to save this somewhere, such as in a
file.

The decrypt() method then works in reverse:

- Its fourth parameter is the encrypted String
- The result of the decryption is the original “plaintext” value that you
  supplied to encrypt() originally

the DeviceAuth/FingerKey sample application illustrates the use of these two
methods.

The value that we are saving is a randomly-generated passphrase, for reasons that
will become clearer later in this chapter. Specifically, it is 128 characters of random
alphanumeric values, generated via a SecureRandom instance:

```java
private char[] generatePassphrase() {
    char[] result = new char[128];

    for (int i=0; i<result.length; i++) {
        result[i] = BASE36_SYMBOLS.charAt(rng.nextInt(BASE36_SYMBOLS.length()));
    }

    return result;
}
```

(from DeviceAuth/FingerKey/app/src/main/java/com/commonsware/android/key/MainActivity.java)

Here, BASE36_SYMBOLS is simply a String of the candidate characters to use in the
random passphrase:
Device Authentication

```java
private static final String BASE36_SYMBOLS="abcdefghijklmnopqrstuvwxyz0123456789";
```

rng is a SecureRandom instance:

```java
private final SecureRandom rng=new SecureRandom();
```

That passphrase is generated as part of starting up the activity and is held onto in a passphrase field.

The UI is the same as in the FingerAuth sample shown above, with a large fingerprint button. This time, when the user taps the button, we will encrypt the passphrase using RSA encryption, then turn around and decrypt the value. The decryption will require the user to scan their fingerprint.

The button is now tied to a `doTheWork` method, which confirms that we have fingerprint access, then calls `encrypt()` on the `RxFingerprint` instance:

```java
private void doTheWork() {
    unsub();

    if (RxFingerprint.isAvailable(this)) {
        disposable=RxFingerprint.encrypt(EncryptionMethod.RSA, this, KEY_NAME,
            new String(passphrase)).subscribe(this::onEncResult,
            t -> {
                Log.e(getClass().getSimpleName(), "Exception authenticating", t);
                button.setImageDrawable(off);
            });
    } else {
        Toast.makeText(this, R.string.msg_not_available, Toast.LENGTH_LONG).show();
    }
}
```

Here, `KEY_NAME` is just a simple constant. The passphrase is held onto as a char array, so we need to convert that to a `String` before passing it to `encrypt()` as the value to be encrypted.

The subscribe() call on the Observable routes control to an `onEncResult()` method in normal cases, or logs an Exception to LogCat in case of a serious failure.

There are three possible outcomes from `onEncResult()`... in theory. In reality, it will depend on the encryption algorithm. AES requires fingerprint authentication for
both encryption and decryption, and so there is a chance that the user fails the fingerprint authentication step. RSA — which this sample app uses — does not require fingerprint authentication for encryption. This means that everything should succeed (a result of AUTHENTICATED, or we should get a Throwable).

So, if we are AUTHENTICATED, our data has been encrypted, and so we can get that encrypted value via getEncrypted() on the FingerprintEncryptionResult. In a real app, you would save this somewhere for long-term use. Here, we just turn right around and:

- Show the “on” state for the ImageButton, with a blue fingerprint
- Clean up the previous subscription via unsub()
- Pass the getEncrypted() value to RxFingerprint.decrypt() to decrypt this value

```
private void onEncResult(FingerprintEncryptionResult encResult) {
    if (encResult.getResult() == FingerprintResult.AUTHENTICATED) {
        button.setImageDrawable(on);
        unsub();
        String encryptedValue = encResult.getEncrypted();

        disposable = RxFingerprint.decrypt(EncryptionMethod.RSA, this, KEY_NAME,
                                           encryptedValue)
            .subscribe(this::onDecResult,
                       t -> {
                           Log.e(getClass().getSimpleName(), "Exception decrypting", t);
                           button.setImageDrawable(off);
                       });
    } else {
        Toast.makeText(this, "This was unexpected...", Toast.LENGTH_LONG).show();
    }
}
```

(from DeviceAuth/FingerKey/app/src/main/java/com/commonsware/android/key/MainActivity.java)

decrypt() takes the same first three parameters as does encrypt():

1. The EncryptionMethod enum value corresponding with how you encrypted the value
2. The Activity requesting this work
3. The same “key name” that you used with encrypt()
The fourth parameter is the encrypted data to be decrypted.

decrypt() returns an Observable of FingerprintDecryptionResult. We use the
same pattern as before, routing the normal case to an onDecResult() method and
logging any exceptions to LogCat.

onDecResult() will need to deal with all three possible fingerprint scan outcomes
(FAILED, HELP, and AUTHENTICATED), since any decryption requires a fingerprint scan.
The first two of those scenarios we handle the same as in FingerAuth; the third one
just confirms that our decrypted data matches the plaintext that we supplied to
encrypt() back in the beginning:

```java
private void onDecResult(FingerprintDecryptionResult decResult) {
    String msg = getString(R.string.msg_not_possible);

    switch (decResult.getResult()) {
        case FAILED:
            msg = getString(R.string.msg_failed);
            button.setImageDrawable(off);
            unsub();
            break;
        case HELP:
            msg = decResult.getMessage();
            break;
        case AUTHENTICATED:
            button.setImageDrawable(off);
            unsub();

            if (decResult.getDecrypted().equals(new String(passphrase))) {
                msg = getString(R.string.msg_match);
            } else {
                msg = getString(R.string.msg_mismatch);
            }
            break;
    }

    Toast.makeText(this, msg, Toast.LENGTH_LONG).show();
}
```

(from DeviceAuth/FingerKey/app/src/main/java/com/commonsware/android/key/MainActivity.java)

In a real app, of course, you would use this decrypted data for something useful.
Whorlwind

Square — authors of a seemingly-infinite number of open source Android libraries — has their take on fingerprints and encryption, in the Whorlwind library.

This is simpler to use than RxFingerprint, if you do not need control over the encryption algorithm that is used or the storage location for the encrypted data. That is handled for you by Whorlwind. It uses the RSA algorithm, which avoids the need for fingerprint authentication for encrypting the data. And, it provides a Storage abstraction for persisting the encrypted data in a key-value store. Whorlwind ships with a SharedPreferencesStorage, or you can create another implementation of the Storage interface that meets your needs.

OK, So What Was That All About?

Encrypting a random string seems to be a bit esoteric. Developers are used to encrypting things of value, and a random string would not appear to be of value.

On its own, a random string is useless.

However, there are encrypted data stores for Android that rely on a passphrase, such as SQLCipher for Android. Those data stores have no means of integrating with a fingerprint scanner directly.

The encrypted random string, therefore, serves as a bridge between the fingerprint authentication — or, as we will see, the keystore — and the passphrase-based data store:

• We generate the long random string
• We use that string as the passphrase with the data store
• We encrypt that string using RxFingerprint, Whorlwind, etc.
• We save that encrypted string somewhere (inside a Whorlwind Storage, in a file, in SharedPreferences, etc.)

Later on, to access the passphrase-based data store, we:

• Load the encrypted string
• Decrypt it, which will involve user authentication
• Use the decrypted random string as our passphrase

The net result is an encrypted data store (e.g., SQLCipher for Android) with device-
based authentication, instead of (or in addition to) a user-entered passphrase.

We will explore this pattern in greater detail in the next chapter.

Limitations of Fingerprint-Based Encryption

Under the covers, all of this winds up using the keystore for handling the encryption securely. Using the keystore has many benefits, but it also has some limitations, particularly when it comes to changes to the lockscreen. The next chapter has a section that reviews these limitations.
The Java Cryptography Architecture (JCA) has been available in Java since Java 1.1, though it has expanded over the years. It gives us KeyStore objects that can manage cryptographic keys for a variety of symmetric and asymmetric ciphers. You can create keys, then use those keys to encrypt, decrypt, sign, and validate data. The actual algorithms that implement the cryptography come from service provider implementations (SPIs) that plug into the JCA. You do not need to know all of the details of the cryptography – you treat the algorithms mostly as a black box.

Android extends JCA by offering a KeyStore that is integrated into the Android architecture. In particular, on some Android 7.0+ devices, the keys can be tied to hardware, as part of the so-called Trusted Execution Environment (TEE, presumably named by a golfer). This dramatically reduces the likelihood of your keys somehow getting leaked to some malicious actor. The Android-supplied KeyStore also offers hooks to tie keys to device authentication, where you can require the user to authenticate the device before you can use the key to decrypt the data.

In this chapter, we will explore the basics of using this Android-specific KeyStore. The important word in the preceding sentence is “basics”, as this is not a complete treatment of how to use the JCA. The JCA is part of standard Java; other educational resources can show you how to implement effective cryptography using the JCA.

Also note that many of the Android-specific APIs shown in this chapter have a minSdkVersion of 23.

**Prerequisites**

To understand this chapter, please read the preceding chapter on device authentication first. Also, the examples in this chapter make extensive use of RxJava.
**Keys and the Keystore**

**Terminology**

First, let’s review some...ummmm... “key” terms that will be used in this chapter.

**Keys**

To encrypt, decrypt, sign, or validate some data, you need a key and a corresponding algorithm.

From a `javax.crypto` standpoint, the Java class that we use to represent keys is `SecretKey`. Whether this is the “real” key, or is merely an identifier to “key material” held elsewhere (e.g., in hardware), depends on the SPI and `KeyStore` implementation.

**KeyStore**

A `KeyStore`, as the name suggests, is a storage location for keys. There are several implementations of `KeyStore`, based on the storage location and format of the keys in the store.

In Android, we are particularly interested in one known as `AndroidKeyStore`. It offers two benefits:

1. The “key material” — the actual bytes representing the key — never make it into our application process. Instead, the cryptography is performed by a system process. The APIs that we use make it appear that everything is local, but in reality IPC is occurring under the covers to pass our data and key identifier to this system process. The benefit here is that even if our process gets attacked, the attacker cannot get the “key material” to be able to decrypt encrypted data away from this device.

2. On supported devices, and for supported key/algorithm combinations, the key material may “bound” to the device itself. This means that even the system process that normally does the cryptography does not have the bytes representing the key itself. Instead, the cryptography is performed by dedicated hardware, as part of the TEE. The key material held in the `AndroidKeyStore` needs to be blended with secure data held in hardware to get the real key to use with the cryptography. As a result, even if an attacker is able to hack core system processes, the attacker will not be able to retrieve a key that can be used outside of this device.
**KeyChain**

If you rummage around the Android SDK, you will also see a separate KeyChain class. This offers a stripped down system similar to the KeyStore. However, the KeyChain is for device-wide keys, and as such is usually not what developers of an individual app need.

**Getting a KeyStore**

The AndroidKeyStore is merely the name of a JCA KeyStore that you obtain using standard javax.crypto APIs:

```java
ks = KeyStore.getInstance("AndroidKeyStore");
ks.load(null);
```

The static getInstance() method returns an instance of the KeyStore, and load() is used to populate it. With traditional JCA KeyStore implementations, load() is used to load the keys from a file. The AndroidKeyStore does not need this, and so we can pass null into the load() method.

Note that these methods throw a variety of checked exceptions, and so you will need to be in position to catch those and do something useful. In practice, nothing should go wrong, as those checked exceptions are mostly for cases where:

- You provide an invalid KeyStore type name (e.g., `KeyStore.getInstance("this does not exist"))
- There are problems loading the keys from a file (file not found, file corrupt, etc.)

**Creating a Key**

Android has a dedicated KeyGenParameterSpec class, with a corresponding Builder, that is used to create secret keys for symmetric encryption, stored in the AndroidKeyStore:

```java
KeySpec spec =
    new KeyGenParameterSpec.Builder("thisIsMyKey",
        KeyProperties.PURPOSE_ENCRYPT | KeyProperties.PURPOSE_DECRYPT)
    .setBlockModes(KeyProperties.BLOCK_MODE_CBC)
    .setEncryptionPaddings(KeyProperties.ENCRYPTION_PADDING_PKCS7)
    .build();
```
**Keys and the KeyStore**

```java
KeyGenerator keygen =
    KeyGenerator.getInstance(KeyProperties.KEY_ALGORITHM_AES, "AndroidKeyStore");
keygen.init(spec);
SecretKey secretKey = keygen.generateKey();
```

Grafting the Android-specific AndroidKeyStore onto the JCA base results in a few oddities. For example, we do not need to do anything to save this key in the AndroidKeyStore — saving it is a side effect of creating the key using a KeyGenerator backed by the AndroidKeyStore (via the getInstance() static method).

Each of your app’s keys has a name (“thisIsMyKey” in the above example). You will use this name to reference the key later on. This name needs to be unique for your app, though it does not need to be unique for the entire device.

Most of the methods on the KeyGenParameterSpec.Builder are tied to the JCA, such as the block modes, encryption paddings, and so forth. The above configuration – when coupled with KEY_ALGORITHM_AES when creating the KeyGenerator – is for AES/CBC/PKCS7Padding, which is a fairly typical symmetric key setup. Most of the details of setting up the Builder, therefore, are tied to the specific form of encrypting or digital signature that you wish to employ. The details of this are well out of scope for this book and are best left to educational resources dedicated to Java cryptography.

The JCA KeyStore is designed around symmetric keys (e.g., SecretKey) classes, though asymmetric encryption has been grafted onto the original KeyStore API, so RSA-style public-key encryption can also be performed using the AndroidKeyStore.

**Tying the Key to Device Authentication**

Part of the reason for an Android-specific KeyGenParameterSpec class is to be able to offer Android-specific features to extend the JCA. A prominent example of this is tying a generated key to device authentication, such that your app can only use the key if the user is currently authenticated.

The two primary Builder methods for this are:

- `setUserAuthenticationRequired(true)`, to indicate that the key being generated requires user authentication
• `setUserAuthenticationValidityDurationSeconds()`, to indicate how long we have, after user authentication, to be able to use the key, before the user needs to re-authenticate

The default validity period is, in effect, zero seconds. Every use of the key requires an immediately-preceding authentication. This may be excessive, and you will want to consider whether setting a longer validity period (e.g., one minute) is more appropriate for your situation.

So, in this sample, we generate a key with user authentication required, with a 60-second timeout:

```java
KeyGenParameterSpec spec =
    new KeyGenParameterSpec.Builder("thisIsMyKey",
        KeyProperties PURPOSE_ENCRYPT | KeyProperties PURPOSE_DECRYPT)
    .setBlockModes(KeyProperties BLOCK_MODE_CBC)
    .setEncryptionPaddings(KeyProperties ENCRYPTION_PADDING_PKCS7)
    .setUserAuthenticationRequired(true)
    .setUserAuthenticationValidityDurationSeconds(60)
    .build();

KeyGenerator keygen =
    KeyGenerator.getInstance(KeyProperties.KEY_ALGORITHM_AES, "AndroidKeyStore");

keygen.init(spec);
SecretKey secretKey = keygen.generateKey();
```

Later on, when we try to use the key for encryption, decryption, etc., we may get a `UserNotAuthenticatedException`. This means that the user has not authenticated against the device within the timeout period, and so we need to re-authenticate the user (e.g., `createConfirmDeviceCredentialIntent()`) before trying the cryptographic operation again. The preceding chapter outlines how to use `createConfirmDeviceCredentialIntent()` to authenticate the user.

**Learning More About Your Key**

For keys created in the `AndroidKeyStore`, you can use a somewhat clunky set of APIs to find out more details about the key, in particular whether the key is backed by any sort of hardware security (e.g., the TEE). This information is available through an Android-specific `KeyInfo` class. Unfortunately, you have to get one of those by means of a `SecretKeyFactory` and a cast, as shown below:

```java
SecretKey key = (SecretKey) ks.getKey(keyName, null);
```
Given the SecretKey, you can get the associated SecretKeyFactory, based on the algorithm and keystore name. That SecretKeyFactory has a getKeySpec() method, which takes the SecretKey and the spec class (KeyInfo.class in this case). That needs to be cast to a KeyInfo, this JCA code probably pre-dates Java's support for generics.

The sample code shown above checks one specific characteristic of the key: does the key reside inside of secure hardware. You get that from a call to isInsideSecureHardware().

## Encrypting Data

So, with all of that as background, let's look at actually encrypting some data using all of this stuff.

The DeviceAuth/SecureNote sample application has a single activity with a really big EditText widget, for you to type in a note. We will store that note in an encrypted form, using a key that requires device authentication.

And to do that, we will spend some time in a bodega.

## Introducing RxKeyBodega

The RxKeyBodega class in this project implements a small RxJava-based API wrapped around the relevant javax.crypto and android.security.keystore classes. The idea is to isolate most of the “hard core” encryption logic in this class, but allow for composability, so that the calling app can control things like:

- Where the encrypted data comes from, and what happens to it after it is decrypted
- Where the encrypted data goes, after it is encrypted
The only aspect that RxKeyBodega cannot handle itself is device authentication, since that involves a UI.

(this is far smaller than a key “store”; hence, a key “bodega”)

**Encrypting the Note**

First, let’s look at the encryption path. Our MainActivity not only has the really big EditText, but it has a “save” action bar item that, when clicked, will save the contents of the EditText in an encrypted form.

**RxKeyBodega Client**

That action bar item is tied to a save() method on MainActivity, which uses RxKeyBodega to set up an RxJava chain to process our encryption:

```java
private void save() {
    final Context app = getApplicationContext();
    byte[] toEncrypt = note.getText().toString().getBytes.UTF8();

    RxKeyBodega.encrypt(toEncrypt, KEY_NAME, TIMEOUT_SECONDS)
        .subscribeOn(Schedulers.io())
        .map(result -> {
            File f = new File(app.getFilesDir(), FILENAME);

            RxKeyBodega.save(f, result);

            return f;
        })
        .observeOn(AndroidSchedulers.mainThread())
        .subscribe(
            file -> Toast.makeText(MainActivity.this, R.string.saved, Toast.LENGTH_SHORT).show(),
            t -> {
                if (t instanceof UserNotAuthenticatedException) {
                    requestAuth(REQUEST_SAVE);
                } else {
                    Toast.makeText(MainActivity.this, t.getMessage(), Toast.LENGTH_LONG).show();
                    Log.e(getString(R.string.app_name), "Exception saving encrypted file", t);
                }
            });
}
```

(from DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/MainActivity.java)

We will take a look at RxKeyBodega.encrypt() in the next section, but it returns an Observable of an EncryptionResult object, which itself is part of RxKeyBodega. We
supply the data to be encrypted as a byte array, which we encode using UTF8 from the Editable returned by the EditText and its getText() method. We pass that, along with a unique name for the encryption key to use and how long the device authentication timeout should be. That encryption key will be lazy-created if it does not already exist.

After routing this work to the io() thread, we use map() to process the EncryptionResult. We create a File pointing to where we want the encrypted data to be stored on internal storage, then call RxKeyBodega.save() to save the EncryptionResult to that file. This File is then supplied downstream to our subscriber lambda, which:

- Shows a Toast if everything seems OK
- Calls requestAuth() if we got a UserNotAuthenticatedException, indicating that we need the user to re-authenticate with the device before we can encrypt
- Shows an error Toast if something else went wrong

requestAuth() takes a request code as a parameter and kicks off device authentication using createConfirmDeviceCredentialIntent():

```java
private void requestAuth(int requestCode) {
    Intent i = mgr.createConfirmDeviceCredentialIntent("title", "description");

    if (i == null) {
        Toast.makeText(this, "No authentication required?!!", Toast.LENGTH_SHORT).show();
    } else {
        startActivityForResult(i, requestCode);
    }
}
```

(from DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/MainActivity.java)

In onActivityResult(), if the user authenticated, we try save() again:

```java
@Override
protected void onActivityResult(int requestCode, int resultCode, Intent data) {
    if (resultCode == RESULT_OK) {
        if (requestCode == REQUEST_SAVE) {
            save();
        }
    }
}
```
else if (requestCode==REQUEST_LOAD) {
    load();
}
else {
    Toast.makeText(this, R.string.sorry, Toast.LENGTH_SHORT).show();
    finish();
}

If the user declined to authenticate, we show a Toast and finish() the activity, since there is nothing useful that we can do.

RxKeyBodega Implementation

Overall, RxKeyBodega follows the implementation approach used by RxFingerprint, profiled in the previous chapter. So, for example, the encrypt() method on RxKeyBodega does not encrypt anything itself, but rather creates an Observable — named EncryptObservable — that will handle the encryption work itself:

```java
static Observable<EncryptionResult> encrypt(byte[] toEncrypt, String keyName, int timeout) {
    return Observable.create(new EncryptObservable(keyName, timeout, toEncrypt));
}
```

This way, the consumer of RxKeyBodega can control the thread on which the encryption work is performed.

EncryptObservable extends a BodegaObservable class. It lazy-initializes a KeyStore, where KEYSTORE is "AndroidKeyStore", so we get access to the (potentially) hardware-backed keystore:

```java
private abstract static class BodegaObservable {
    KeyStore ks;
    Exception initException;

    BodegaObservable() {
        try {
            ks=KeyStore.getInstance(KEYSTORE);
            ks.load(null);
        }
    }
```
Nothing should go wrong in that initialization, but getInstance() and load() throw some checked exceptions. If one occurs, it is held onto in an initException field.

EncryptObservable implements the ObservableOnSubscribe interface, so the bulk of its logic goes into the subscribe() method, called when something eventually subscribes to this Observable:

```java
@override
public void subscribe(ObservableEmitter<EncryptionResult> emitter) throws Exception {
    if (initException==null) {
        createKey(keyName, timeout);
        SecretKey secretKey=(SecretKey)ks.getKey(keyName, null);
        Cipher cipher=Cipher.getInstance("AES/CBC/PKCS5Padding");
        SecureRandom rand=new SecureRandom();
        byte[] iv=new byte[BLOCK_SIZE];
        rand.nextBytes(iv);
        IvParameterSpec ivParams=new IvParameterSpec(iv);
        cipher.init(Cipher.ENCRYPT_MODE, secretKey, ivParams);
        emitter.onNext(new EncryptionResult(ivParams.getIV(), cipher.doFinal(toEncrypt)));
    } else {
        throw initException;
    }
}
```

If initException is not null, we throw it here, so that the exception works its way through the RxJava chain and can be picked up by a Throwable handler in MainActivity.

If initException is null, though, we start off by lazy-creating our key, in a createKey() method:

```java
private void createKey(String keyName, int timeout) throws Exception {
    KeyStore.Entry entry=ks.getEntry(keyName, null);
```
This uses the approach outlined earlier in this chapter, creating an AES/CBC/PKCS7Padding key. In particular, it is tied to device authentication, so the user will have had to entered their PIN, passcode, fingerprint, etc. within the timeout period, or else the encryption cannot be performed.

Once we are sure that we have a key, subscribe() creates a Cipher for that key, uses doFinal() to pass along the data to be encrypted, and passes that doFinal() response, along with an “initialization vector”, to an EncryptionResult constructor. The EncryptionResult is what gets emitted by this Observable and is what is picked up by MainActivity in the first step of its RxJava chain.

The save() utility method on RxKeyBodega, used by MainActivity, writes the initialization vector data and the encrypted data to the supplied file:

```java
static void save(File f, EncryptionResult result) throws IOException {
    BufferedSink sink=Okio.buffer(Okio.sink(f));

    sink.write(result.iv);
    sink.write(result.encrypted);
    sink.close();
}
```
Some Quick Initialization Vector Notes

Some encryption schemes use an initialization vector (IV). This is a series of random bytes that serves as the initial input into the encryption algorithm. The bytes do not have to be secret, which is why it is safe for us to save them as part of the encrypted data, as we did in the `subscribe()` method of `EncryptObservable` above.

However, the bytes do have to be random. This has been a problem with Android.

Early versions of Android had a hard-coded default IV value, rather than randomly generating a value. This is bad, and it forced developers to have to create their own IV using `SecureRandom`.

Google apparently has fixed the default IV behavior. In fact, to use your own IV, you have to call `setRandomizedEncryptionRequired()` on the `KeyGenParameterSpec.Builder`, as part of creating your key in the `AndroidKeyStore`. If you fail to do this, when you go to supply your own IV bytes for encryption, you crash, with an exception whose message reads: “Caller-provided IV not permitted when encrypting”.

So, as of API Level 23, Google wants you to use their random IV implementation, rather than supply your own IV bytes. But, on older Android devices, you cannot rely on Google's implementation.

So, now what?

The safest course of action is to do what we are doing in the `SecureNote` sample: provide a random IV and tell Android that we intend to do this, via the `setRandomizedEncryptionRequired()` method. This way, even if some device manufacturer screws something up and their device winds up with non-random default IV values, you are covered.

Escaping If Device Is Insecure

Lazy-creating that key — in fact, this entire app — only makes sense if the device has a secure keyguard. Otherwise, we cannot have the key be tied to device authentication.

So, part of what we do in `onCreate()` is get a `KeyguardManager` and see if the...
If it is not secure, we show a Toast and `finish()` our activity to leave the app.

**Starting Decryption in `onCreate()`**

If we do have a secure keyguard, we call a `load()` method, which will kick off loading the encrypted data and decrypting it.

You might wonder why we do not take a similar approach for encrypting and saving the note. Rather than force the user to click a “save” action bar item, we could call `save()` from `onDestroy()`, or perhaps from `onStop()`.

The problem is that we may need the user to re-authenticate, if they have not authenticated since before the timeout window. That requires us to start an activity and get a result. However, that is not safe to do once our activity is destroyed. So what happens is that the user presses BACK to exit the app, we determine that we need to authenticate the user, and then:

- We have to fail to save the note, possibly with an error message, or
- We can try to show the authentication activity, get a result, and then save the note, but that is quite likely to fail, given that our activity will be destroyed along the way

As a result, while we can automatically decrypt the note, we cannot automatically...
Encrypt it.

**Decrypting the Note**

Now, let's turn our attention to the `load()` method.

**RxKeyBodega Client**

`load()` implements another RxJava `Observable` chain, to take what we wrote to the file, decrypt it, and show the results in the `EditText` for possible changes by the user:

```java
private void load() {
    Observable.just(new File(getFilesDir(), FILENAME))
        .subscribeOn(Schedulers.io())
        .observeOn(AndroidSchedulers.mainThread())
        .filter(File::exists)
        .flatMap(toDecrypt -> RxKeyBodega.decrypt(toDecrypt, KEY_NAME))
        .subscribe(bytes -> note.setText(new String(bytes, UTF8)),
            t -> {
                if (t instanceof UserNotAuthenticatedException) {
                    requestAuth(REQUEST_LOAD);
                } else {
                    Toast.makeText(MainActivity.this, t.getMessage(), Toast.LENGTH_LONG).show();
                    Log.e(getString(R.string.app_name), "Exception loading encrypted file", t);
                }
            });
}
```

The `Observable` starts out with a `File` pointing to where the note is saved on internal storage. We then use the `filter()` operator to only continue if the file exists — if it doesn't, that means we have no notes to load, and so the empty `EditText` is a fine starting point.

We then use a static `load()` method on `RxKeyBodega` to do the file I/O to read in the file. We pass the result from `load()` to the `RxKeyBodega.decrypt()` method, supplying the same `KEY_NAME` that we will want to use for encryption.

At that point, there are three possibilities:

1. Everything succeeds, in which case we get the decrypted bytes, so we can turn them into a `String` (using the `UTF8` charset) and apply that to the `EditText`
2. We get a `UserNotAuthenticatedException`, in which case we request that the user authenticate, and if that succeeds, `onActivityResult()` will try the `load()` again.

3. We get some other exception, in which case we just show a `Toast` and log the exception.

**RxKeyBodega Implementation**

The `load()` method on `RxKeyBodega` simply reads in the data that we wrote out:

```java
static EncryptionResult load(File f) throws Exception {
    BufferedSource source = Okio.buffer(Okio.source(f));
    byte[] iv = source.readByteArray(BLOCK_SIZE);
    byte[] encrypted = source.readByteArray();

    source.close();

    return new EncryptionResult(iv, encrypted);
}
```

(from `DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/RxKeyBodega.java`)

To read in the initialization vector, we need to know how many bytes it should be. That is based on the choice of encryption cipher, but the value is a constant for any given cipher. So, we get that in a `static` initialization block, and pray to the high heavens that JCA does not thrown an unexpected exception:

```java
private static final int BLOCK_SIZE;

static {
    int blockSize=-1;

    try {
        blockSize=Cipher.getInstance("AES/CBC/PKCS7Padding").getBlockSize();
    }
    catch (Exception e) {
        Log.e("RxKeyBodega", "Could not get AES/CBC/PKCS7Padding cipher", e);
    }

    BLOCK_SIZE=blockSize;
}
```

(from `DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/RxKeyBodega.java`)

(a production-grade app would do something with the exception besides logging it)
Keys and the Keystore

to LogCat)

load() then wraps the initialization vector and encrypted data in an EncryptionResult, which becomes input for the decrypt() method, which turns around and hands it to a DecryptObserverable:

```java
static Observable<byte[]> decrypt(EncryptionResult toDecrypt, String keyName) {
    return Observable.create(new DecryptObservable(keyName, toDecrypt));
}
```

(from DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/RxKeyBodega.java)

DecryptObservable then uses JCA to decrypt the encrypted data, using the chosen Cipher and initialization vector, emitting the decrypted data:

```java
private static class DecryptObservable extends BodegaObservable implements ObservableOnSubscribe<byte[]>
    final private String keyName;
    final private EncryptionResult toDecrypt;

private DecryptObservable(String keyName, EncryptionResult toDecrypt) {
    this.keyName=keyName;
    this.toDecrypt=toDecrypt;
}

@Override
public void subscribe(ObservableEmitter<byte[]> emitter)
    throws Exception {
    if (initException==null) {
        SecretKey secretKey=(SecretKey)ks.getKey(keyName, null);
        Cipher cipher=Cipher.getInstance("AES/CBC/PKCS7Padding");

        cipher.init(Cipher.DECRYPT_MODE, secretKey, new IvParameterSpec(toDecrypt.iv));
        emitter.onNext(cipher.doFinal(toDecrypt.encrypted));
    } else {
        throw initException;
    }
}
```

(from DeviceAuth/SecureNote/app/src/main/java/com/commonsware/android/auth/note/RxKeyBodega.java)

Time-Limited Device Authentication

In the previous chapter, we saw the use of createConfirmDeviceCredentialIntent() to force the user to re-authenticate before proceeding with something in your app. As noted then, the problem is that createConfirmDeviceCredentialIntent() always forces re-authentication, even if the user authenticated just moments ago (e.g., just unlocked their device).
However, for working with AndroidKeyStore-backed keys, we can require device authentication... but with a timeout. That way, the user only needs to re-authenticate if they have not authenticated recently, for whatever value of “recently” we want when setting up the key.

So, if you want to use createConfirmDeviceCredentialIntent(), but you want a timeout, one solution is silly, but works: encrypt something with a timeout-enabled, authenticated key. What you encrypt does not matter — you can throw away the results of the encryption. You are simply leveraging the timeout facility to let you know whether authentication is really needed or not.

The DeviceAuth/SecureTimeout sample application demonstrates this. It is based on the SecureCheck sample from the preceding chapter, but now uses the encryption technique outlined above.

In onCreate(), we set up the AndroidKeyStore:

```java
try {
    ks = KeyStore.getInstance(KEYSTORE);
    ks.load(null);
} catch (Exception e) {
    Toast.makeText(this, "Ummm... this shouldn't happen", Toast.LENGTH_LONG).show();
    Log.e(getClass().getSimpleName(), "Exception initializing keystore", e);
}
```

We only enable the authentication action bar item if we have a secure keyguard, as otherwise we cannot set up the key that we want to use:

```java
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
    menu.findItem(R.id.auth).setEnabled(mgr.isKeyguardSecure());

    return super.onCreateOptionsMenu(menu);
}
```

As before, tapping that action bar item invokes an authenticate() method. Before, that just blindly called createConfirmDeviceCredentialIntent() and forced authentication. Now... it's a bit different:

```java
private void authenticate() {
    try {
```
We start by invoking the same sort of lazy-create-the-key logic that we used in SecureNote, this time in a `createKeyForTimeout()` method:

```java
private void createKeyForTimeout() throws Exception {
    KeyStore.Entry entry=ks.getEntry(KEY_NAME, null);
    if (entry==null) {
        KeyGenParameterSpec spec=
            new KeyGenParameterSpec.Builder(KEY_NAME,
            KeyProperties.PURPOSE_ENCRYPT | KeyProperties.PURPOSE_DECRYPT)
                .setBlockModes(KeyProperties.BLOCK_MODE_CBC)
                .setEncryptionPaddings(KeyProperties.ENCRYPTION_PADDING_PKCS7)
                .setUserAuthenticationRequired(true)
                .setUserAuthenticationValidityDurationSeconds(TIMEOUT_SECONDS)
                .build();
        KeyGenerator keygen=
            KeyGenerator.getInstance(KeyProperties.KEY_ALGORITHM_AES, KEYSTORE);
        keygen.init(spec);
        keygen.generateKey();
    }
}
```

If that works, we call a `needsAuth()` method to see if we need authentication or not:
private boolean needsAuth(boolean isRecheck) {
    boolean result=false;
    try {
        SecretKey secretKey=(SecretKey)ks.getKey(KEY_NAME, null);
        Cipher cipher=Cipher.getInstance("AES/CBC/PKCS7Padding");
        cipher.init(Cipher.ENCRYPT_MODE, secretKey);
        cipher.doFinal(POINTLESS_DATA);
        if (!isRecheck) {
            Toast.makeText(this, "Already authenticated!", Toast.LENGTH_LONG).show();
        }
    } catch (UserNotAuthenticatedException e) {
        result=true;
    } catch (KeyPermanentlyInvalidatedException e) {
        Toast.makeText(this, "You reset the lock screen!", Toast.LENGTH_LONG).show();
    } catch (Exception e) {
        Toast.makeText(this, "Could not validate the key", Toast.LENGTH_LONG).show();
        Log.e(getClass().getSimpleName(), "Exception validating key", e);
    }
    return result;
}

This just encrypts a pointless bit of data:

    private static final byte[] POINTLESS_DATA=new byte[] {1, 2, 3};

There are several possible outcomes of this. The biggest one is that we could catch a UserNotAuthenticatedException, meaning that the user has not authenticated within our timeout. In that case, needsAuth() returns true, and authenticate() uses createConfirmDeviceCredentialIntent() to trigger authentication. onActivityResult() then calls needsAuth() again, to confirm that we did successfully authenticate the user:

    protected void onActivityResult(int requestCode, int resultCode, Intent data) {
        if (requestCode==REQUEST_CODE) {
            if (requestCode==RESULT_OK) {
                if (needsAuth(true)) {
                    Toast.makeText(this, "Good authentication... but still needs auth!",Toast.LENGTH_SHORT).show();
                } else {
                    Toast.makeText(this, "Authenticated!", Toast.LENGTH_SHORT).show();
                }
            } else if (requestCode==RESULT_CANCELED) {
                Toast.makeText(this, "User canceled authentication!", Toast.LENGTH_SHORT).show();
            }
        }
    }

KEYS AND THE KEYSTORE
Keys and the Keystore

The boolean parameter to needsAuth() simply indicates whether we are checking on the first or second pass. If we can successfully encrypt the pointless data, we know that the user has authenticated within our timeout period. If it’s the first pass through needsAuth(), we show a Toast here, otherwise we show it in onActivityResult().

This sample specifically checks for KeyPermanentlyInvalidatedException. This will be thrown if we had a key from before, but the user reset their lock screen, and that key is now no longer valid. If there was data encrypted using that key... the user is now in big trouble. From a JCA standpoint, you should be able to use deleteEntry() on the KeyStore to remove the old key under your key name and create a new one, if desired.

Encrypting Passphrases

The AndroidKeyStore is good for some scenarios, such as your own encrypted files. However, other things will need passphrases and do not integrate with the JCA. A prominent example is SQLCipher for Android. SQLCipher is an extension to SQLite, and SQLite is not tied to Android. Hence, SQLCipher is not tied to Android, and the SQLCipher for Android distribution is focused more on providing a near-clone of the Android SQLite classes (e.g., SQLiteDatabase).

However, you can integrate anything that takes a passphrase with the AndroidKeyStore – and, by extension, with fingerprint-based device authentication — by generating the passphrase and encrypting it. This works akin to encrypting notes, as seen in the earlier example, in that you are encrypting and decrypting from files. However, rather than the files being the actual data, they are merely the keys with which to access that actual data, which has its own security solution.

The DeviceAuth/CipherNote sample application is a clone of the SecureNote sample. There, the note was encrypted and saved as a file. In this sample, the note is saved in SQLCipher for Android, with a generated passphrase being encrypted and saved as a file. In this case, this approach is overkill. However, there are plenty of scenarios where you need a SQLite-like solution for querying and such, but you also
want to give the user the option of tying their security to device authentication, instead of having to type in a passphrase themselves.

From a UI standpoint, CipherNote works the same as SecureNote:

- The existing content is decrypted when the activity starts up, if that content exists, and possibly involving device authentication if needed
- When the user taps the “save” action bar item, the content is saved in an encrypted form

A NoteRepository

We start off with a simple SQLiteOpenHelper subclass named DatabaseHelper:

```java
package com.commonsware.android.auth.note;

import android.content.Context;
import net.sqlcipher.database.SQLiteDatabase;
import net.sqlcipher.database.SQLiteOpenHelper;

public class DatabaseHelper extends SQLiteOpenHelper {
    private static final String DATABASE_NAME = "note.db";
    private static final int SCHEMA = 1;

    DatabaseHelper(Context context) {
        super(context, DATABASE_NAME, null, SCHEMA);
        SQLiteDatabase.loadLibs(context);
    }

    @Override
    public void onCreate(SQLiteDatabase db) {
        db.execSQL("CREATE TABLE note (_id INTEGER PRIMARY KEY AUTOINCREMENT, content TEXT);" );
    }

    @Override
    public void onUpgrade(SQLiteDatabase db, int oldVersion, int newVersion) {
        throw new RuntimeException("How did we get here?" );
    }
}
```

This sets up a trivial table (`note`) with a primary key and the content. It also initializes SQLCipher for Android, by means of `SQLiteDatabase.loadLibs(context)`.

That is then wrapped in a NoteRepository, which provides us with an RxJava-based API for loading and saving notes from the encrypted database, given a passphrase. As with many repository-style classes — and as with many things that work with
SQLite or SQLCipher for Android — NoteRepository is a singleton. Its sole instance is lazy-created, as it needs a Context for use with DatabaseHelper:

```java
private static volatile NoteRepository INSTANCE;
private SQLiteDatabase db;

private synchronized static NoteRepository init(Context ctxt, char[] passphrase) {
    if (INSTANCE==null) {
        INSTANCE=new NoteRepository(ctxt.getApplicationContext(), passphrase);
    }
    return INSTANCE;
}

private synchronized static NoteRepository get() {
    return INSTANCE;
}

private NoteRepository(Context ctxt, char[] passphrase) {
    DatabaseHelper helper=new DatabaseHelper(ctxt);
    db=helper.getWritableDatabase(passphrase);
}
```

(from DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/NoteRepository.java)

The NoteRepository holds onto the SQLiteDatabase opened from the DatabaseHelper. More importantly, it does not hold onto the passphrase. Ideally, that passphrase should be cleared out of memory after the database is opened, as SQLCipher for Android no longer needs it, and the longer the passphrase is in memory, the more likely it is that somebody is going to find a way to extract it.

Our model object representing the note is named Note:

```java
static class Note {
    final long id;
    final String content;

    private Note(long id, String content) {
        this.id=id;
        this.content=content;
    }
}
```

(from DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/NoteRepository.java)

Loading the Note is reactive. We have a static load() method that returns an Observable based on a LoadObservable:

```java
static Observable<Note> load(Context ctxt, char[] passphrase) {
```
Keys and the Keystore

```java
return Observable.create(new LoadObservable(ctxt, passphrase));
```

(from DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/NoteRepository.java)

LoadObservable does as its name suggests: it loads the note from the database:

```java
private static class LoadObservable implements ObservableOnSubscribe<Note> {
    private final Context app;
    private final char[] passphrase;

    LoadObservable(Context ctxt, char[] passphrase) {
        this.app=ctxt.getApplicationContext();
        this.passphrase=passphrase;
    }

    @Override
    public void subscribe(ObservableEmitter<Note> e) throws Exception {
        Cursor c=NoteRepository.init(app, passphrase).db
            .rawQuery("SELECT _id, content FROM note", null);

        if (c.isAfterLast()) {
            e.onNext(EMPTY);
        } else {
            c.moveToFirst();
            e.onNext(new Note(c.getLong(0), c.getString(1)));
            Arrays.fill(passphrase, '\u0000');
        }

        c.close();
    }
}
```

(from DeviceAuth/CipherNote/app/src/main/java/com/commonsware/android/auth/note/NoteRepository.java)

While LoadObservable holds onto the passphrase, it does not make its own copy. Instead, it uses Arrays.fill() to clear out that char array as part of loading the note.

If there are no rows in the database, that means this was the first run of the app (or the user cleared the app's data). RxJava does not like an ObservableEmitter emitting a null value, so we have a magic EMPTY constant Note to use that signifies that we had no note:

```java
private static final Note EMPTY=new Note(-1, null);
```
Otherwise, this code is unremarkable: it queries the database, gets the values out of the Cursor to create a Note, and emits the Note.

There is a corresponding save() method. It is not reactive, but instead is designed to be added to some external RxJava chain. It takes the existing Note and the revised content from the EditText, either inserts or updates the database with the content, and returns a fresh Note instance:

```java
static Note save(Note note, String content) {
    ContentValues cv = new ContentValues(1);
    cv.put("content", content);
    if (note == EMPTY) {
        long id = NoteRepository.get().db.insert("note", null, cv);
        return new Note(id, content);
    } else {
        NoteRepository.get().db.update("note", cv, "_id=?", new String[]{String.valueOf(note.id)});
        return new Note(note.id, content);
    }
}
```

This way, clients can blindly request a save(), and the repository can determine if that requires an insert or an update, based on whether we are starting with the EMPTY note or not.

**RxPassphrase**

This sample modifies RxKeyBodega from earlier into RxPassphrase. Here, we have a reactive API to get our passphrase for use with our SQLCipher for Android database... including lazy-creating (and encrypting) that passphrase if it does not already exist.

The public API is a simple static get() method. It takes the file to use for storing the passphrase, the key name for our key in the AndroidKeyStore, and our desired authentication timeout as parameters. It just creates a PassphraseObservable to do
the real work:

```java
static Observable<char[]> get(File encryptedFile, String keyName, int timeout) {
    return Observable.create(new RxPassphrase.PassphraseObservable(encryptedFile, keyName, timeout));
}
```

...subscribe() initializes our KeyStore, then sees if the encrypted passphrase file exists, branching to load() or create() methods accordingly:

```java
@override
public void subscribe(ObservableEmitter<char[]> emitter) throws Exception {
    KeyStore ks=KeyStore.getInstance(KEystore);
    ks.load(null);
    if (encryptedFile.exists()) {
        load(ks, emitter);
    } else {
        create(ks, emitter);
    }
}
```

create() first creates a 128-character passphrase, using the same base36 algorithm used in an example from the preceding chapter:

```java
private void create(KeyStore ks, ObservableEmitter<char[]> emitter) throws Exception {
    SecureRandom rand=new SecureRandom();
    char[] passphrase=new char[128];
    for (int i=0; i<passphrase.length; i++) {
        passphrase[i]=BASE36_SYMBOLS.charAt(rand.nextInt(BASE36_SYMBOLS.length()));
    }
    createKey(ks, keyName, timeout);
    SecretKey secretKey=(SecretKey)ks.getKey(keyName, null);
    Cipher cipher=Cipher.getInstance("AES/CBC/PKCS7Padding");
    byte[] iv=new byte[BLOCK_SIZE];
    rand.nextBytes(iv);
    IvParameterSpec ivParams=new IvParameterSpec(iv);
    cipher.init(Cipher.ENCRYPT_MODE, secretKey, ivParams);
    byte[] toEncrypt=toBytes(passphrase);
```
create() then lazy-creates our key in our KeyStore, using the same createKey() method as was used previously:

```java
private void createKey(KeyStore ks, String keyName, int timeout) throws Exception {
    KeyStore.Entry entry = ks.getEntry(keyName, null);
    if (entry == null) {
        KeyGenParameterSpec spec = new KeyGenParameterSpec.Builder(keyName,
                KeyProperties.PURPOSE_ENCRYPT | KeyProperties.PURPOSE_DECRYPT)
                .setBlockModes(KeyProperties.BLOCK_MODE_CBC)
                .setEncryptionPaddings(KeyProperties.ENCRYPTION_PADDING_PKCS7)
                .setUserAuthenticationRequired(true)
                .setUserAuthenticationValidityDurationSeconds(timeout)
                .setRandomizedEncryptionRequired(false)
                .build();

        KeyGenerator keygen = KeyGenerator.getInstance(KeyProperties.KEY_ALGORITHM_AES, KEYSTORE);
        keygen.init(spec);
        keygen.generateKey();
    }
}
```

We then create a random initialization vector, and use that to help create our Cipher for encryption. We encrypt the passphrase and IV bytes, writing the results to the designated file, before returning the cleartext passphrase. That passphrase can then be passed to the NoteRepository for the purposes of creating our encrypted database.

Note that encryption might throw a UserNotAuthenticatedException, which the client needs to catch and route through the

---

**Keys and the Keystore**

```java
byte[] encrypted = cipher.doFinal(toEncrypt);

BufferedSink sink = Okio.buffer(Okio.sink(encryptedFile));
sink.write(iv);
sink.write(encrypted);
sink.close();
emitter.onNext(passphrase);
```
createConfirmDeviceCredentialIntent()-based UI for authenticating the user.

If our encrypted passphrase file already exists, we can just open and decrypt it:

```java
private void load(KeyStore ks, ObservableEmitter<char[]> emitter)
    throws Exception {
    BufferedSource source=Okio.buffer(Okio.source(encryptedFile));
    byte[] iv=source.readByteArray(BLOCK_SIZE);
    byte[] encrypted=source.readByteArray();
    source.close();
    SecretKey secretKey=(SecretKey)ks.getKey(keyName, null);
    Cipher cipher=Cipher.getInstance("AES/CBC/PKCS7Padding");
    cipher.init(Cipher.DECRYPT_MODE, secretKey, new IvParameterSpec(iv));
    byte[] decrypted=cipher.doFinal(encrypted);
    char[] passphrase=toChars(decrypted);
    emitter.onNext(passphrase);
}
```

We do not use createKey() here, as by definition our key should already exist, as we used it to encrypt the file. If for some reason our key is lost, then our data is lost, and we have to start over from scratch anyway.

**Using the NoteRepository and RxPassphrase**

The overall flow of MainActivity has not changed: we still call load() from onCreate() and still call save() from the action bar item click. Merely their implementations have changed, to blend NoteRepository and RxPassphrase.

load() starts an RxJava chain by asking RxPassphrase to get() the passphrase:

```java
private void load() {
    final Context app=getApplicationContext();
    File encryptedFile=new File(getFilesDir(), FILENAME);
    RxPassphrase.get(encryptedFile, KEY_NAME, TIMEOUT_SECONDS)
        .observeOn(AndroidSchedulers.mainThread())
        .subscribeOn(Schedulers.io())
        .flatMap(chars -> NoteRepository.load(app, chars))
        .subscribe(this::onNoteReady,
```
That passphrase is then used with NoteRepository.load() to get the note from the encrypted database, usingflatMap() to attach the Observable from NoteRepository.load() onto the existing chain. Then, if everything succeeds, we call onNoteReady() to hold onto the Note object and populate the EditText:

```java
private void onNoteReady(NoteRepository.Note note) {
    this.note = note;
    textarea.setText(note.content);
}
```

If we get a UserNotAuthenticatedException, we go through the same requestAuth() as before, triggering authentication. In onActivityResult(), we call load() again to try to get the Note, now that the user has authenticated.

The passphrase is stored on internal storage, ingetFilesDir()(new File(getFilesDir(), FILENAME)). Hence, in principle, it will only get deleted if the database itself gets deleted, such as the user choosing “Clear Data” for our app in Settings. This is important, as our data will be lost if either the database or the encrypted passphrase file are lost.

save() does not need to use RxPassphrase, as NoteRepository should already have the open database. So, we can just use NoteRepository.save() to persist the note:

```java
private void save() {
    Observable.just(textarea.getText().toString())
        .map(content -> NoteRepository.save(note, content))
        .subscribeOn(Schedulers.io())
        .observeOn(AndroidSchedulers.mainThread())
        .subscribe(this::onNoteSaved,
            t -> {
                if (t instanceof UserNotAuthenticatedException) {
                    requestAuth(REQUEST_LOAD);
                }
            } else {
                Toast.makeText(MainActivity.this, t.getMessage(), Toast.LENGTH_LONG).show();
        });
```
Here, `onNoteSaved()` just shows the “Saved!” Toast, plus calls `onNoteReady()` to ensure that we have the Note for any subsequent `save()` call:

```java
private void onNoteSaved(NoteRepository.Note note) {
    Toast.makeText(this, R.string.saved, Toast.LENGTH_LONG).show();
    onNoteReady(note);
}
```

**A Key(Store) Limitation**

The keys in the `AndroidKeyStore` are tied to a secure keyguard. That is why these samples check for a secure keyguard before proceeding.

But what if the user *had* a secure keyguard, then downgrades to merely swipe-to-unlock?

When they downgrade, they should get a system warning that they will lose some information. In particular, on fingerprint-enabled devices, they should get a note about losing stored fingerprints. However, the system warning may not be a sufficient deterrent, and the user may downgrade their keyguard security anyway.

If that happens, your keys in the `AndroidKeyStore` get wiped out. Even if the user turns right around and sets up a secure keyguard again, whatever had been in the `AndroidKeyStore` is gone, and anything encrypted with one of those keys will be unrecoverable.

Changing between different types of security — such as switching between a PIN and a passphrase — is fine and will not affect the `AndroidKeyStore`. 
This chapter outlines some additional security measures that you can consider for your applications that do not necessarily warrant a full chapter on their own at this time.

In other words, it’s just a pile of interesting security stuff.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. In addition, you should review the app signing chapter if you are unfamiliar with the signing process.

Public Key Validation

We sign our apps with signing keys all the time. By default, we are signing with a so-called “debug signing key”, created automatically by the build tools. For production, we sign with a different signing key. The primary use of that signing key is to determine equivalence of authorship:

- Is this APK, representing an upgrade to an already-installed app, signed by the same signing key that signed that app?
- Is this APK, that requests firmware-defined signature-level permissions, signed by the same signing key that signed the firmware?

However, as it turns out, information about the public key that signed an APK is visible to us, for our own APK as well as for any other APK on the device. We can leverage that to help determine whether a given APK was signed by something we
recognize. This goes above and beyond using Android’s built-in signature-based defenses (e.g., using a custom signature-level permission).

**Scenarios**

There are several scenarios in which we might imagine that we could employ our own public key validation. How well the technique will work, though, depends on what we are checking and the nature of the attack we are defending against.

**Checking Yourself**

You might consider checking your own app’s public key. After all, if your app is not signed with your production signing key, something very strange is going on, and the natural reaction is that “something strange” is unlikely to be a good thing for you.

However, there are some issues here.

First and foremost, checking your own signing key assumes that whatever caused you to not be signed by that key did not also modify your validation algorithm. For example, suppose that you validate your signing key to determine if somebody perhaps reverse-engineered and modified your app, perhaps to remove some license checks. This will only catch an attacker that removed the licensing checks and did not also remove your signature validation, or modify the validation to use the attacker’s signing key. While it is possible that an attacker will modify one part but not another, it remains unclear how well this defense will work in practice.

Also, bear in mind that you, as a developer, may be opting into services that intentionally change your app’s signature. Various providers will “wrap” your app, whether for interstitial ad banners or for quasi-DRM. There are three possible ways that they wrap your app:

1. They sign it with their signing key, which means that your runtime validation of the key will fail, as your app is now signed by their key, not yours. This is also very risky, as if for whatever reason you are no longer able to use their service (e.g., they go out of business), you may have difficulty in upgrading your app, as you will not have the right key to use.
2. They sign it with your signing key, either one that you upload, or one that they generate for you. In this case, your runtime public key validation logic could still work. On the other hand, now this other firm is perfectly capable
of upgrading your app, or shipping other apps, signed with your production signing key, and this has its own set of risks.

3. They allow you to download the “wrapped” app and have you sign it yourself with your own signing key. This is the best alternative from a security standpoint, but it is the most tedious, as now you have additional work to do to publish your app.

Checking Arbitrary Other Apps

What will tend to be more reliable is to check other applications’ public keys. While they might have been cracked, it is unlikely that the same attacker also attacked your app, and so you can help detect problems in others.

For example, let us consider a specific scenario: a client-side JAR for integration to a third-party app.

This book outlines many forms of IPC, from content providers to remote services to broadcast Intent objects. If you are creating an app that offers such IPC endpoints, you may wish to consider also shipping a JAR to make using those endpoints a bit easier. You might create a library that handles all of the details of sending commands to your remote service, or you might create a library that provides a wrapper around the AIDL-generated Java proxy classes for remote binding.

Another thing such a JAR could do is check the integrity of your app. The JAR’s code is in the client’s app, not yours, and while your app might be cracked, the client’s app might not. You could check the validity of the public key of your own app from the client’s app, and fail if there is a detected problem.

This might be especially important depending upon the nature of the app and the JAR that is providing access to it. If the app is an app offering on-device payments (e.g., a Google Wallet sort of app), and the app offers an API for other apps to do payments, it is fairly important that those other apps can trust the payment app. By checking the public key, your JAR can help provide that level of trust... or at least ensure that nobody else has done something specifically to degrade that trust.

This is particularly important for avoiding device-hosted man-in-the-middle attacks on your IPC from client apps to your app. In an ideal world, you would only allow IPC via signature-level permissions, but that will not work in cases where third parties are writing the clients.

If your IPC is based upon a service (command pattern or binding pattern), if
multiple service implementations all advertise the same \texttt{<intent-filter>}, Android needs to decide which service will handle the request. First, it will take into account the \texttt{android:priority} value on the \texttt{<intent-filter>} (even though this behavior is currently undocumented). For multiple services with the same priority (e.g., no priority specified), the first one that was installed will be the one that is chosen. In either case, the client has no way to know, short of examining the service’s public key, whether the service that will respond to the requests for IPC is the legitimate service or something else advertising that it supports the same Intent action. Even with Android 5.0 blocking your ability to bind via an implicit Intent, you wind up with the same sorts of problems when you use \texttt{resolveService()} to try to determine the \texttt{ComponentName} of the service to make an explicit Intent for it.

**The Easy Solution: SignatureUtils**

The author of this book has published the CWAC-Security library. Among other things, this library has a \texttt{SignatureUtils} class that makes it relatively easy for you to compare the signature of some Android app to a known good value.

All you need to do is call the static \texttt{getSignatureHash()} method, supplying some Context (any will do) and the package name of the app that you wish to check. This will return the SHA-256 hash of the signing key of the app, as a set of capitalized, colon-delimited hex values.

You can get the same sort of hash by running the Java 7 version of \texttt{keytool}. Hence, if the app you wish to test is another one of yours, perhaps signed with a different signing key, you can use \texttt{keytool} to get the value to compare with the result of \texttt{getSignatureHash()}. Or, during development, create a little utility app that will dump the \texttt{getSignatureHash()} value for the third-party app, and run it on a device containing a known good version of that app (i.e., one that does not appear to have been replaced by malware).

Ideally, over time, we will be able to get app developers to publish their SHA-256 hashes on their Web sites, as another means of getting a known value of the hash to compare at runtime.

If you determine that \texttt{getSignatureHash()} does not return the right value, this means that the app that is installed on the device is written by somebody other than the app’s original author. Often times, this will mean the app has malware in it. It is up to you to determine how you wish to respond to this scenario:

- Alert the user?
Send data back to your server, or to your analytics collection point, with details of the bad APK?
• Block usage of your app, or usage of features that depend upon the flawed third party?
• Something else?

Examining Public Keys

Under the covers, SignatureUtils uses PackageManager and related classes to examine what they somewhat erroneously refer to as “signatures”. The MiscSecurity/SigDump sample project will allow us to browse the list of installed packages, see a decoded public key on the screen for a package that we select, plus dump the “signature” as a binary file for later comparison using another app.

The UI Structure

This app has a single activity, whose UI consists of:

• a RecyclerView to show the list of packages, and
• a set of labeled TextView widgets to show details of the last-clicked-upon package

These are wrapped in a ConstraintLayout, which uses Barrier objects to organize the TextView widgets into a table:

```xml
<layout>
  <data>
    <variable
      name="model"
      type="com.commonsware.android.signature.dump.MainActivity.DetailModel" />
  </data>
  <android.support.constraint.ConstraintLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <android.support.v7.widget.RecyclerView
      android:id="@+id/packages"
      android:layout_width="0dp"
      android:layout_height="0dp"
      android:layout_margin="4dp"
      android:background="#11000000"
      app:layout_constraintBottom_toTopOf="@id/selected"
      app:layout_constraintEnd_toEndOf="parent"
      app:layout_constraintStart_toStartOf="parent"/>
  </android.support.constraint.ConstraintLayout>
</layout>
```
MISCELLANEOUS SECURITY TECHNIQUES

app:layout_constraintTop_toTopOf="parent" />

<TextView
android:id="@+id/selected"
android:text="@{model.selected}"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:textStyle="bold"
app:layout_constraintBottom_toTopOf="@id/top_row"
app:layout_constraintStart_toStartOf="parent" />

<android.support.constraint.Barrier
android:id="@+id/column"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
app:barrierDirection="end"
app:constraint_referenced_ids="subject_caption,issuer_caption,valid_caption" />

<android.support.constraint.Barrier
android:id="@+id/top_row"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
app:barrierDirection="top"
app:constraint_referenced_ids="subject_caption,subject" />

<TextView
android:id="@+id/subject_caption"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:layout_margin="4dp"
android:text="@string/subject"
app:layout_constraintBottom_toTopOf="@id/middle_row"
app:layout_constraintStart_toStartOf="parent" />

<TextView
android:id="@+id/subject"
android:text="@{model.sigModel.subject}"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:layout_margin="4dp"
app:layout_constraintBottom_toTopOf="@id/middle_row"
app:layout_constraintStart_toStartOf="@id/column" />

<android.support.constraint.Barrier
android:id="@+id/middle_row"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
app:barrierDirection="top"
app:constraint_referenced_ids="issuer_caption,issuer" />

<TextView
android:id="@+id/issuer_caption"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:layout_margin="4dp"
android:text="@string/issuer"
app:layout_constraintBottom_toTopOf="@id/bottom_row"
app:layout_constraintStart_toStartOf="parent" />
The TextView contents use data binding expressions to pull information in from a DetailModel, which we will examine shortly.

But, given this structure, the job of the activity is to show the list of packages in the RecyclerView and, when a list item is clicked, update the DetailModel to fill in the remaining widgets.

### Listing the Packages

MainActivity holds a DetailModel object in a field:

```java
private final DetailModel detailModel = new DetailModel();
```

2491
In `onCreate()` of `MainActivity`, we set up the data binding and bind that data model, plus populate the `RecyclerView`:

```java
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    ActivityMainBinding binding = DataBindingUtil.setContentView(this, R.layout.activity_main);

    binding.setModel(detailModel);

    binding.packages.setLayoutManager(new LinearLayoutManager(this));
    binding.packages.addItemDecoration(new DividerItemDecoration(this, LinearLayoutManager.VERTICAL));
    binding.packages.setAdapter(new PackageAdapter(getLayoutInflater(), buildPackageList(), detailModel));
}
```

The `RecyclerView` uses a `PackageAdapter` to fill in its contents:

```java
private static class PackageAdapter extends RecyclerView.Adapter<RowHolder> {
    private final LayoutInflater inflater;
    private final List<PackageInfo> packages;
    private final DetailModel detailModel;

    private PackageAdapter(LayoutInflater inflater,
                             List<PackageInfo> packages,
                             DetailModel detailModel) {
        this.inflater = inflater;
        this.packages = packages;
        this.detailModel = detailModel;
    }

    @NonNull
    @Override
    public RowHolder onCreateViewHolder(ViewGroup parent, int viewType) {
        View row = inflater.inflate(android.R.layout.simple_list_item_1, parent, false);

        return new RowHolder(row);
    }
}
```

(from MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/MainActivity.java)
This wraps around a List of PackageInfo objects, which we get from PackageManager:

```java
public List<PackageInfo> buildPackageList() {
    List<PackageInfo> result = getPackageManager().getInstalledPackages(PackageManager.GET_SIGNATURES);
    Collections.sort(result, (a, b) -> a.packageName.compareTo(b.packageName));
    return result;
}
```

getPackageList() calls getInstalledPackages() on PackageManager, specifically requesting to retrieve signature information via the GET_SIGNATURES flag. The list we get back from getInstalledPackages() can be in any order, so we sort the results before returning it for display purposes.

**Decoding the Key**

We need to fill in those TextView widgets, and to do that, we need to have a DetailModel.

That class just holds onto a pair of ObservableField objects, one for the “selected” package name (whatever the user last clicked on), and one for a separate SigModel class:

```java
public static class DetailModel {
    public final ObservableField<String> selected = new ObservableField<>();
    public final ObservableField<SigModel> sigModel = new ObservableField<>();
}
```

We need to fill in those TextView widgets, and to do that, we need to have a DetailModel.
SigModel holds the formatted data to pour into the TextView widgets, populated from an X509Certificate object:

```java
public static class SigModel {
    public final String subject;
    public final String issuer;
    public final String validDates;

    private SigModel(X509Certificate cert) {
        this.subject = cert.getSubjectDN().toString();
        this.issuer = cert.getIssuerDN().toString();
        this.validDates =
            FORMAT.format(cert.getNotBefore()) + " to " +
            FORMAT.format(cert.getNotAfter());
    }
}
```

We are interested in three items from the X509Certificate. The subject is who the certificate is for and the issuer is who created the certificate. For a self-signed certificate — what we usually use for Android app development — the subject and the issuer usually are the same party. We also want to show the valid date range for the certificate, where we get the getNotBefore() and getNotAfter() dates and format them using a SimpleDateFormat object:

```java
private static final DateFormat FORMAT =
    DateFormat.getDateInstance();
```

So now we are left with the glue code: when the user clicks on a package in the list, we need to get an X509Certificate representing the contents of the signing key and use that to put a fresh SigModel into the DetailModel, so data binding can update the TextView widgets.

That is all taken care of by RowHolder, which is the ViewHolder for our RecyclerView:

```java
private static class RowHolder extends RecyclerView.ViewHolder {
    private final TextView title;
    private final View row;

    RowHolder(View itemView) {
        super(itemView);
    }
}
```
When we bind() a PackageInfo into the row, we also set up an click listener for the row itself, to find out when the user taps on it. There, we update the two fields of the
DetailModel, using `buildCertificate()` to get the X509Certificate for use with SigModel.

The `PackageInfo` object contains a `signatures` field with an array of `Signature` objects. Despite the name, those each are an encoded representation of an X509Certificate. Traditionally, Android apps have been signed with just one key, so we only look at the first element of the array. Then, using Java cryptography classes, we:

- Get the byte array of the encoded certificate, by calling `toByteArray()` on the `Signature`
- Get a `CertificateFactory` for the X509 format
- Wrap the bytes in a `ByteArrayInputStream`
- And ask the `CertificateFactory` to decode the certificate

### Dumping the Key

The click listener we applied to the row also has this line:

```java
SigSaver.enqueueWork(title.getContext(), packageInfo);
```

This invokes a `SigSaver` implementation of a `JobIntentService`. Its job is to write this “signature” to a file, so it could be transferred off of the device and perhaps examined using tools like `openssl`.

`SigSaver` uses `getPackageInfo()` on `PackageManager` to get the `PackageInfo` object for a specific package, then gets the same byte array that `buildCertificate()` does and writes it to a file on external storage:

```java
package com.commonsware.android.signature.dump;

import android.content.Context;
import android.content.Intent;
import android.content.pm.PackageManager;
import android.content.pm.Signature;
import android.support.annotation.NonNull;
import android.support.v4.app.JobIntentService;
import android.util.Log;
import java.io.File;
import java.io.FileOutputStream;
```

(from MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/MainActivity.java)
public class SigSaver extends JobIntentService {
    private static final int UNIQUE_JOB_ID = 1337;
    private static final String EXTRA_PACKAGE = "package";

    static void enqueueWork(Context ctxt, PackageInfo packageInfo) {
        Intent i = new Intent(ctxt, SigSaver.class)
                .putExtra(EXTRA_PACKAGE, packageInfo.packageName);

        enqueueWork(ctxt, SigSaver.class, UNIQUE_JOB_ID, i);
    }

    @Override
    protected void onHandleWork(@NonNull Intent intent) {
        String packageName = intent.getStringExtra(EXTRA_PACKAGE);

        try {
            PackageInfo packageInfo = getPackageManager().getPackageInfo(packageName,
                    PackageManager.GET_SIGNATURES);
            File output =
                    new File(getExternalFilesDir(null),
                            packageInfo.packageName.replace('.', '_') + "_.bin"){
                if (output.exists()) {
                    output.delete();
                }

                Signature[] signatures = packageInfo.signatures;
                byte[] raw = signatures[0].toByteArray();

                try {
                    FileOutputStream fos = new FileOutputStream(output.getPath());

                    fos.write(raw);
                    fos.close();
                }
                catch (java.io.IOException e) {
                    Log.e(getClass().getSimpleName(),
                            "Exception in writing signature file", e);
                }
            }
            catch (PackageManager.NameNotFoundException e) {
                Log.e(getClass().getSimpleName(),
                        "Exception loading package info: "+packageName, e);
            }
        }
    }
}
The Result

When you run the app, you will get a list of all of the installed packages, which will include system packages that have no activities (and, therefore, nothing in the app drawer of your launcher):

![Signature Dump Demo](image)

Figure 745: SigDump App, As Initially Launched
Scrolling to and clicking on a package will populate the bottom panel with the details of that package's signature:

![Figure 746: SigDump App, After Clicking on the SigDump Entry](image)

Also, a copy of the public signing key — as an encoded X.509 certificate — is written out to a file on external storage.

**Choosing Your Signing Keysize**

The documentation for app signing contains a small side note about the `-keysize` parameter to `keytool`, the utility used to generate our signing keys:

The size of each generated key (bits). If not supplied, Keytool uses a default key size of 1024 bits. In general, we recommend using a key size of 2048 bits or higher.

The reason for the 2,048-bit key size recommendation is that 1,024-bit RSA (the `keytool` default) has been considered at risk for a few years.

The recent revelations about state-sponsored decryption research should be
hammering this home. Even if today, forging a 1,024-bit digital signature is still impractical for all but the largest security agencies, it is well within reason that this will fall within the reach of large botnets in the not-too-distant future. Once signing keys can be cracked, apps will be able to be replaced with hacked editions, without tripping up the signature check, or signature-level permission checks might start passing due to forged signatures.

Switching to a larger keysize is not that hard... for new apps. Just specify -keysize 4096 when creating your production signing key, and you should be good for a long time, barring a major decryption breakthrough for RSA signatures.

For existing apps with existing signing keys, though, you cannot change the key without breaking your ability to update the app.

Create a new, stronger production signing key, as a separate key from whatever you are using for production. Make note to use that new signing key for any new apps you create. And, if you have other reasons why you are migrating an existing user base to a new app (e.g., free app for which you are now offering a paid-app option), consider using the new signing key.

If you are a consultant, and you create unique signing keys per project, just cut over to using a stronger key for new clients and projects.

And if you are creating apps for which security is paramount, you might consider whether it is worthwhile to move your user base to a new version of the app with a new signing key at some point, just for the added protection.

Avoiding Accidental APIs

One place where developers create their own security problems is with “accidental APIs”.

An API, of course, is where one code base exposes some interface that another code base can use. An accidental API is when one code base does not intend to expose an interface, but does anyway, possibly to the app’s detriment.

Bear in mind that if your app becomes popular, other developers will poke and prod at it, to see if they can connect to your app by one means or another. Perhaps they want to offer features that you have not gotten to yet. Perhaps they have more nefarious aims. Regardless, making sure that other code can only work with your
app the way that you intend for such code to work with your app.

**Export Only What’s Necessary**

A component of your app is only reachable by a third-party app if it is exported. Otherwise, it is inaccessible to third-party apps.

(Admittedly, content providers have an exception to this rule, which we will get to shortly)

You normally do not think about exporting components, except when it comes to content providers. However, your choices for how you implement your app may lead you to accidentally export things that you did not realize were exported.

**Export Defaults**

The official way to declare whether or not a component is exported is to have an android:exported attribute for that component in the manifest (e.g., on an <activity> element). However, many times, we do not have such an attribute, but instead rely on the default export behavior.

Activities, services, and broadcast receivers have a simple rule for the default: if the component has an <intent-filter>, it is exported by default. Otherwise, it is not exported by default.

This, in turn, leads to a fairly simple development rule: only use an <intent-filter> and implicit Intent objects for working with your components if you also want third party apps to work with those components. Otherwise, do not use <intent-filter>, and instead communicate with your components using explicit Intent objects (e.g., the kind that take a Java class as the second constructor parameter).

For example, the classic MAIN/LAUNCHER <intent-filter> on your launcher activity is specifically there because you want a third party app — the launcher — to be able to start your activity. Most, if not all, of your other activities probably do not need an <intent-filter>, as they are likely to be private to your app.

**The Chooser Bug**

Some developers choose to still use an <intent-filter> and implicit Intent objects for their own private activities, yet then use android:exported to enforce the
privacy.

This is not a good plan.

The rest of the system, notably PackageManager, does not pay much attention to android:exported until the time when the component is to be used, such as when the activity is to be started. Then, and only then, does Android realize that the component is not exported, and it fails the request, usually with a cryptic SecurityException.

A classic example of where this can cause problem came to light in 2012, with the UPS Mobile app. The rest of this section is an excerpt from the author’s blog post on this incident:

The UPS Mobile app allows you to track packages and do a handful of other things that you might ordinarily do via the UPS Web site. It generally seems to be well-regarded, but it has an annoying flaw:

It claims to be Barcode Scanner, and does a lousy job at it.

Barcode Scanner, from ZXing, is a favorite among Android developers for its integration possibilities. However, some people do not like having a dependence upon the Barcode Scanner app, so they grab the open source code and attempt to blend it into their own apps. This is neither endorsed nor supported by the ZXing team, but since it is open source, it is also perfectly legitimate.

However, UPS (or whoever they hired to build the app) screwed up. They not only copied the source code, but they copied the manifest entry for the scanning activity. And, their activity has:

```
<intent-filter>
    <action android:name="com.google.zxing.client.android.SCAN" />
    <category android:name="android.intent.category.DEFAULT" />
</intent-filter>
```

This means that on any device that has UPS Mobile installed, they will be an option for handling Barcode Scanner Intent objects. What happened was that the person asking the question was manually invoking startActivityForResult() to bring up Barcode Scanner, was getting a chooser with UPS Mobile in it, and then was crashing upon choosing UPS Mobile... because UPS Mobile declared this activity to be not exported.
There was a bug, in which Android would display non-exported activities in a chooser, despite the fact that they could never be successfully used by the user. This appears to have been fixed as of Android 4.2, despite the issue being declined.

So, what should we learn from this?

First, UPS Mobile should not have used that `intent-filter`. As Dianne Hackborn has pointed out, your `intent-filter` mix is effectively part of your app’s API, and so you need to think long and hard about every `intent-filter` you publish. UPS Mobile is not Barcode Scanner and should not be advertising that they handle such Intent objects, despite the activity being not exported.

Second, UPS Mobile probably should not have had any `intent-filter` elements for this activity, if they intend to use it purely internally. They could just as easily use an explicit Intent to identify the activity and avoid all of this nonsense.

Third, the person who filed the SO question ideally would have been using ZXing’s `IntentIntegrator`. As Sean Owen of the ZXing project noted in a comment on my answer, `IntentIntegrator` ensures that only Barcode Scanner or official brethren will handle any scan requests, so this problem would not have appeared.

Fourth, Android really should not be showing non-exported activities in a chooser, which means probably that `PackageManager` should be filtering out non-exported activities from methods like `queryIntentActivities()`, which I presume lies at the heart of the chooser.

In summary, if your component is truly private, do not have an `intent-filter` on it, lest you cause yourself, and your users, problems with other apps.

**The ContentProvider Behavior Change**

Content providers are a little different… in lots of ways. In the specific scenarios being covered here, there are two primary differences.

First, third-party apps can still access a provider that has `android:exported="false"`. However, they can only do so in response to some operation initiated by your application, using `android:grantUriPermissions` and flags like `FLAG_GRANT_READ_URI_PERMISSION`. A third-party app will have no independent access to your non-exported provider.

Second, the default value for `android:exported` not only does not depend upon
<intent-filter> (since few providers use one), but it has changed over the years:

- For apps with android:minSdkVersion and android:targetSdkVersion set to 16 or lower, the provider is exported by default
- All other apps, the provider is not exported by default

Lint will complain about your manifest having a <provider> without an android:exported attribute.

**Sanitize Your Input Extras**

If you do expose one or more of your components to third-party apps, and you are supporting certain Intent extras on any Intent objects used to talk to those components, make sure that the extras’ values make sense.

Even Google makes this error, as was seen in the PreferenceActivity bug. PreferenceActivity supports an extra, named :android:show_fragment, to indicate that the activity should immediately jump to a specific fragment, rather than start at the top level of the preference navigation. The problem is that PreferenceActivity did not — and, at the time, could not — validate that the fragment to be loaded is a fragment that is supposed to be loaded. This would allow attackers to force apps, like Settings, to load arbitrary fragments, including those not normally accessible to the current user. This is the reason why we now need to override isValidFragment() in our PreferenceActivity implementations, so we can declare whether or not a particular requested fragment is a legitimate choice or not.

The equivalent behavior for a ContentProvider is to sanitize the inputs to methods like query(), update(), openFile(), and so on, to make sure that you do not expose something that you should not. For example, blindly accepting paths to openFile() could get you in trouble, if the Uri contains relative paths (e.g., content://your.authority.here/../databases/your-private.db), perhaps allowing third parties to get at files that you did not intend for them to access.

**Secure Your Output Extras**

Similarly, if you send broadcasts or otherwise use IPC to talk to third-party apps, bear in mind that others might be able to see some of that interaction, depending on the IPC in question.

The obvious case is with a broadcast Intent for an implicit Intent. Any app with a registered receiver will be able to “tune into” that broadcast and get whatever data is
inside the Intent. In cases where you cannot use permissions to limit the scope of the broadcast, you need to make sure that there is nothing in the Intent that is private to the user.

Sometimes, though, non-obvious cases will emerge. For a few years, Intent extras on activities might be viewed by third-party apps that held the GET_TASKS permission, courtesy of the recent-tasks list. The Intent used to launch the task is available via ActivityManager and getRecentTasks(). While this specific problem was resolved in Android 4.1.1, there may be other similar scenarios lurking about.

**Other Ways to Expose Data**

Sometimes, we expose data to third-party apps by using standard Android APIs. We focus on the normal publisher and consumer of data using those APIs and forget about other apps that might be monitoring those communications. Or, we might not realize that one party in those communications may not have the user's best interests at heart. This section outlines some examples.

**App Widgets**

Any data that is put into the widgets inside of your RemoteViews for an app widget is visible to the home screen, lockscreen, or other app widget host. Those apps are the ones actually converting the RemoteViews into a view hierarchy, and they can inspect those views, reading the text in your TextViews, and so forth.

As a result, be careful about exposing potentially sensitive data via an app widget.

**Notifications**

Custom notifications also use RemoteViews and therefore could suffer from the same problem.

On the surface, you might not be worried quite so much about this, because the Notification object goes to the NotificationManager, for display by the OS itself.

However, as of Android 4.3 (API Level 18), apps can register to listen to added and removed notifications via a NotificationListenerService. Not only can such a service read the text from your Notification, but it can also access your RemoteViews. This includes any RemoteViews that may be generated for you by the expanded notification classes (e.g., BigPictureStyle).
As a result, be careful about exposing potentially sensitive data via a Notification.

**Clipboard**

Any app can retrieve text off of the clipboard. After all, that’s the point behind a clipboard.

However, this does mean that you need to be careful what you put on the clipboard in the first place. The quintessential problem case is a password manager: putting a password on the clipboard for easy pasting into an app’s EditText password field will be popular, but it allows that password to be retrieved by other apps.

You can attempt to help reduce the window of risk by clearing the clipboard after a period of time. However, bear in mind that your process might be terminated before that occurs. Also, only clear the clipboard if the clipboard text is still yours — do not clear the clipboard if another app has already put its own contents there, lest you confuse and irritate the user in the middle of some other paste operation.

**ServerSocket and Kin**

If you open up any sort of server-style socket connection — TCP/IP, Bluetooth, etc. — bear in mind that the Android security framework may not be able to help you much. You cannot secure a ServerSocket with an android:permission attribute, for example. It is up to you to validate whether a particular request is expected and allowed, or not.

**Jacking Attacks**

Jacking attacks, in general, refer to cases where what the user thinks they are interacting with on-screen is not actually what they are interacting with. Instead, something else has interposed itself between the user and the activity that the user is trying to use. That “something else” might be trying to intercept user input (tapjacking, activity jacking) or confuse the user about what is actually being interacted with (window jacking).

**Classic Tapjacking**

Tapjacking refers to another program intercepting and inspecting touch events that are delivered to your foreground activity (or related artifacts, such as the input method editor). At its worst, tapjackers could intercept passwords, PINs, and other
The term “tapjacking” seems to have been coined by Lookout Mobile Security, in a blog post that originally demonstrated this issue.

The Problem

You may recall that there are three axes to consider with Android user interfaces. The X and Y axes are the ones you typically think about, as they control the horizontal and vertical positioning of widgets in an activity. The Z axis — effectively “coming out the screen towards the user’s eyes” — can be used in applications for sophisticated techniques, such as a pop-up panel.

Normally, you think of the Z axis within the scope of your activity and its widgets. However, there are ways to display “system alerts” – widgets that can float over the top of any activity. A Toast is the one you are familiar with, most likely. A Toast displays something on the screen, yet touch events on the Toast itself will be passed through to the underlying activity. Lookout demonstrated that it is possible to create a fully-transparent Toast. However, the lifetime of a Toast is limited (3.5 seconds maximum), which would limit how long it can try to grab touch events.

However, any application holding the SYSTEM_ALERT_WINDOW permission can display their own “system alerts” with custom look and custom duration. By making one that is fully transparent and lives as long as possible, a tapjacker can obtain touch events for any application in the system, including lock screens, home screens, and any standard activity.

On the surface, this might not seem terribly useful, since the View cannot see what is being tapped upon.

However, a savvy malware author would identify what activity is in the foreground and log that information along with the tap details and the screen size, periodically dumping that information to some server. The malware author can then scan the touch event dumps to see what interesting applications are showing up. With a minor investment – and possibly collaboration with other malware authors — the author can know what touch events correspond to what keys on various input method editors, including the stock keyboards used by a variety of devices. Loading a pirated version of the APK on an emulator can indicate which activity has the password, PIN, or other secure data. Then, it is merely a matter of identifying the touch events applied to that activity and matching them up with the soft keyboard to determine what the user has entered. Over time, the malware author can perhaps
develop a script to help automate this conversion.

Hence, the on-device tapjacker does not have to be very sophisticated, other than trying to avoid detection by the user. All of the real work to leverage the intercepted touch events can be handled offline.

**How to Address This**

In principle, Android 4.0.3 fixed this, by preventing touch events from being delivered to two separate applications. Either the tapjacking View gets the touch event (and consumes it), or the tapjacking View does not get the touch event (and therefore does not know about it).

For Android 2.2 and 2.3 devices, you also have the option of `setFilterTouchesWhenObscured()`, which will be examined later in this chapter.

**Activity Jacking**

In August 2014, a number of media outlets reported on a research paper and USENIX conference presentation describing a way by which your users could be tricked into providing confidential information — passwords, credit card information, and such — to a piece of malware, rather than to your app. This flew in the face of conventional wisdom, which said that the tapjacking fixes from Android 4.0.3 cleared up this sort of problem.

The paper points out that there are ways of writing malware such that:

- the malware can pop an activity in front of yours, and
- do so at just the right time, to mimic one of your activities, such that the user thinks that the malware’s activity is actually yours and enters the confidential data into the malware activity

The authors describe it as a UI inference attack; to keep with the theme of this chapter, this section refers to it as “activity jacking”.

**The Problem**

The details of how to execute the attack are rather esoteric, using lots of curious approaches to find out when an activity comes onto the screen and, more specifically, which activity of an app being attacked it is. Readers are encouraged to
review the paper if you want details of exactly how to execute this sort of attack their way.

However, one simpler way of knowing this stuff is to implement an AccessibilityService. Officially, such services are supposed to help with accessibility, such as providing TalkBack-style audio announcements as the user navigates the UI by touch alone. In practice, a lot of apps use AccessibilityService to be able to monitor user inputs across the device and, in some cases, modify those inputs. Some password managers, for example, implement an AccessibilityService to help them auto-fill login dialogs. As a result, many users install and enable an AccessibilityService without really thinking about whether they can trust that service.

Given that you know when a particular activity appears on the screen, the attack is simple: launch your own activity that looks much like the original. The user might miss the fact that two activities just appeared, then go ahead and interact with your activity, thinking that it is from the real app. For example, you might interpose your own authentication dialog in front of the one for the banking app, thereby getting the user’s PIN or passcode.

You can further take steps to try to “cover your tracks” and deal with the fact that the real activity is waiting for user input:

- If you are using an AccessibilityService, you can use performGlobalAction() to initiate a BACK button press, right after dismissing your own activity, to dismiss the original activity.
- Otherwise, you can pretend that the user input is flawed and needs to be re-entered. In the case of an authentication dialog, you can pop up a regular AlertDialog that says that their password was not recognized. When the user dismisses that dialog, you also finish() your intercepting activity, returning the user to the real activity, where they can complete the real authentication.

How to Address This

An activity jack attack has two key weaknesses:

1. The attacker cannot see the screen, because on non-buggy devices, the attacker has no means of silently capturing a screenshot of our activity as it comes into the foreground. Hence, while the attacker can create an activity that tries to mimic ours, they can only do so statically, analyzing our
activity’s UI on their development machine and creating their own lookalike.
2. We know that our activity has left the foreground, as we are called with onPause() (and perhaps other lifecycle methods, depending upon the nature of the attacker).

Hence, one defense can be to include in our activity a **secure element** that cannot be mimicked ahead of time, then **hide that element** (or our whole UI) when we are no longer in the foreground.

This concept of a secure element is not new. Some financial services Web sites have taken this approach. As part of the user setting up their online banking account, the user chooses an image from a collection of clipart. On the Web page that collects the user’s passphrase, the page also shows this secure element. The user is taught that if they do not see their chosen image, then the Web page they are looking at is not really from their bank, and therefore they should not type in their passphrase.

This is not that hard to implement in Android. You too would allow the user to choose a piece of clipart, displaying that in an ImageView on your secure activity in onResume(). In onPause() you would hide that ImageView via setVisibility(View.INVISIBLE). That way:

- Since the image is chosen by the user, the attacker is unlikely to mimic the same image
- Since you are hiding the image when you are not in the foreground, the attacker cannot use a transparent region in their activity to have your image “peek through” their attacking activity

As a result, if the user is paying attention, the user should see either the wrong image or no image at all, and the user should realize that they are being activity jacked and therefore fail to proceed.

You might be tempted to do something else in response to your secure activity being replaced in the foreground by another app’s activity, such as pop up a warning dialog. However, there are plenty of valid scenarios when this would occur, such as an incoming phone call, and you have no reliable means of whitelisting all possible valid scenarios. There will be a high incidence of false positives, and that may not help the user. Having this as an user-selectable option is fine, but I would not go this route by default.
Window Jacking

Sometimes, the objective of the attacker is not to prevent the user from entering in information, or even to see what the user enters. Sometimes, the objective is to confuse the user, tricking them into clicking on things that they might not want to click on.

The Problem

A great example of this comes from Android 6.0’s runtime permission system.

Apps with targetSdkVersion of 23 or higher will need to call requestPermissions() at various points, to ask the user to grant runtime permissions not previously granted (or granted but later revoked). That brings up a system-supplied dialog-themed activity:

![Figure 747: Runtime Permission System Dialog](image)

Perhaps the attacker wants the user to agree to the permission but fears that the user might deny it instead. The attacker could use SYSTEM_ALERT_WINDOW to put a View on top of the system dialog, replacing the real permission explanation with something seemingly benign. The user — who may not have a lot of Android experience – clicks “Allow”, where if the user were presented with the real message,
the user might have clicked “Deny”.

**How to Address This**

Quoting [the Android documentation](https://developer.android.com): Sometimes it is essential that an application be able to verify that an action is being performed with the full knowledge and consent of the user, such as granting a permission request, making a purchase or clicking on an advertisement. Unfortunately, a malicious application could try to spoof the user into performing these actions, unaware, by concealing the intended purpose of the view. As a remedy, the framework offers a touch filtering mechanism that can be used to improve the security of views that provide access to sensitive functionality.

To enable touch filtering, call `setFilterTouchesWhenObscured(boolean)` or set the `android:filterTouchesWhenObscured` layout attribute to true. When enabled, the framework will discard touches that are received whenever the view’s window is obscured by another visible window. As a result, the view will not receive touches whenever a toast, dialog or other window appears above the view’s window.

For the runtime permission window jacking, using `setFilterTouchesWhenObscured()` would prevent the user from clicking on either the “Allow” or the “Deny” buttons. The alternative message would be in its own window, floating over the dialog. Hence, that should cause `FLAG_WINDOW_IS_OBSCURED` to be set on any `MotionEvents` delivered to the dialog, and those touch events would be dropped.

For example, take a look at the `res/layout/main.xml` file in the [Tapjacking/RelativeSecure](https://github.com/Android-Security-Tapjacking) sample project:

```xml
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:filterTouchesWhenObscured="true">
    <TextView android:id="@+id/label"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="URL:"
</RelativeLayout>
```
Here, we have android:filterTouchesWhenObscured="true" on the RelativeLayout at the root of the layout resource. This property cascades to a container's children, and so if a tapjacker (or Toast or whatever) is above any of the widgets in the RelativeLayout, none of the touch events will be processed.

More fine-grained control can be achieved in custom widgets by overriding onFilterTouchEventForSecurity(), which gets control before the regular touch event methods. You can determine if a touch event had been intercepted by looking for the FLAG_WINDOW_IS_OBSCURED flag in the MotionEvent passed to onFilterTouchEventForSecurity(), and you can make the decision of how to handle this on an event-by-event basis.

The Problem with the Solution

According to Iwo Banaś, this approach may not actually work due to bugs in Android's implementation. The filter-when-obscured logic depends upon a FLAG_WINDOW_IS_OBSCURED value being on the MotionEvent, and that may be getting lost somewhere along the way.

2513
The author of this book has not yet attempted to replicate Mr. Banaś’ findings.

**Google’s Line of Defense: Obscuring the Foreground**

Google’s focus, besides the fixes listed above, is to make it increasingly difficult for one app to find out when another app is in the foreground. This is a key component of jacking attacks, as the jacker needs to know what is behind it. For example, with window jacking, obscuring the permission message only makes sense when the permission dialog appears — having some floating message appear at other points in time will be a giveaway that something is amiss.

As a result, methods on `ActivityManager` that used to provide details of all running processes have been neutered, frequently only providing details about your own process. Similarly, in Android 7.0, attempts by apps to find out about other processes through Linux-isms, like `/proc`, are being locked down.

**Using FLAG_SECURE**

By default, your activity’s UI contents can be captured for any number of things:

- the overview screen (a.k.a., recent-tasks list)
- screenshots and screencasts, whether via the [media projection APIs](https://developer.android.com/reference/android/media/MediaProjection) or some other device-supplied means
- the [Assist API](https://developer.android.com/reference/android/support/v4/app/SupportInvisible_WindowInfo), such as Google’s “Now On Tap” feature

However, you may have some activities that should not be captured in this fashion, due to potential privacy issues.

For that, you can apply `FLAG_SECURE` to an `Activity`:

```java
public class FlagSecureTestActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        getWindow().setFlags(LayoutParams.FLAG_SECURE,
                             LayoutParams.FLAG_SECURE);

        setContentView(R.layout.main);
    }
}
```
Call `setFlags()` before `setContentView()`, in this case setting `FLAG_SECURE`.

In theory, this will prevent any of the aforementioned capture options from working.

Unfortunately, the Android framework sometimes creates its own `Window` instances, such as the drop-down in a `Spinner`. Even if you set `FLAG_SECURE` on the `Window` for an activity, the Android framework does not pass that flag to any other windows created on behalf of that activity, and those windows show up in:

- Screenshots and screencasts taken by the media projection APIs on Android 5.0+
- The Assist API (e.g., Now On Tap) on Android 6.0+
- Android Studio screen recordings on Android 4.4+

This has been demonstrated to affect:

- `AutoCompleteTextView`
- `Spinner` (both dropdown and dialog modes)
- the overflow menu of the framework-supplied action bar
- `ShareActionProvider`
- `Dialog` and subclasses (e.g., `AlertDialog`)
- `Toast`

Of these, only the `Dialog` offers us access to its `Window`, on which we could apply `FLAG_SECURE`, for developers that realize that this is required.

Google has officially stated that all of this is working as intended.

If you are using `FLAG_SECURE`, you should thoroughly exercise your app's UI on Android 4.4+ while recording a screencast — the Android Studio screen recorder would be a simple tool to use. Then, play back that screencast, see what windows show up, and identify those that contain sensitive information that should not appear. Some of the windows that appear will not contain sensitive information — here, the risk is that you might add sensitive information to them in the future but forget about this bug.

Then, you have two main courses of action: rewrite your UI to avoid the UI elements that are leaking this information, or attempt to patch the problem.
Trail: Data Storage and Retrieval
Content Provider Theory

Android publishes data to you via an abstraction known as a “content provider”. Access to contacts and the call log, for example, are given to you via a set of content providers. In a few places, Android expects you to supply a content provider, such as for integrating your own search suggestions with the Android Quick Search Box. And, content providers are one way for you to supply data to third party applications, or to consume information from third party applications. As such, content providers have the potential to be something you would encounter frequently, even if in practice they do not seem used much.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on working with local databases.

Using a Content Provider

Any Uri in Android that begins with the content:// scheme represents a resource served up by a content provider. Content providers offer data encapsulation using Uri instances as handles – you neither know nor care where the data represented by the Uri comes from, so long as it is available to you when needed. The data could be stored in a SQLite database, or in flat files, or retrieved off a device, or be stored on some far-off server accessed over the Internet.

Given a Uri, you may be able to perform basic CRUD (create, read, update, delete) operations using a content provider. Uri instances can represent either collections or individual pieces of content. Given a collection Uri, you may be able to create new pieces of content via insert operations. Given an instance Uri, you may be able to
read data represented by the Uri, update that data, or delete the instance outright. Or, given a Uri, you may be able to open up a handle to what amounts to a file, that you can read and, possibly, write to.

These are all phrased as “may” because the content provider system is a facade. The actual implementation of a content provider dictates what you can and cannot do, and not all content providers will support all capabilities.

**Pieces of a Uri**

A Uri for a ContentProvider is made up of two to four components.

A provider Uri always has a content scheme. So, when represented as a string, you will see the Uri start with `content://`.

After the scheme, where in an http:// URL you would find a domain name or IP address, a provider Uri always has the authority string. This is unique on the device — only one provider will be tied to a given authority string.

What comes after the authority string is up to the provider. It is structured like the path segments of an http:// URL, but what those path segments mean is up to the provider implementation. The one approximate rule is that a Uri pointing to an individual piece of content — such as a row of a table or view in a database — frequently has the Uri end in a number, where the number indicates a unique identifier of that content.

Most of the Android APIs expect these to be Uri objects, though in common discussion, it is simpler to think of them as strings. The Uri.parse() static method creates a Uri out of the string representation.

**Getting a Handle**

So, where do these Uri instances come from?

Some Uri values are part of the framework. For example, ContactsContract.Contacts.CONTENT_URI is a Uri pointing at the collection of contacts.

You might also get Uri instances handed to you from other sources, such as getting Uri handles for contacts via activities responding to ACTION_PICK or ACTION_GET_CONTENT Intent objects.
You can also hard-wire literal String objects (e.g., "content://contacts/people") and convert them into Uri instances via Uri.parse(). This is not an ideal solution, as the base Uri values could conceivably change over time. For example, while you used to access contacts via a Uri like content://contacts/people, that is no longer the case. ContactsContract.Contacts.CONTENT_URI is a different value and will give you better results.

The Database-Style API

Of the two flavors of API that a content provider may support, the database-style API is more prevalent. Using a ContentResolver, you can perform standard “CRUD” operations (create, read, update, delete) using what looks like a SQL interface.

Makin’ Queries

Given a base Uri, you can run a query to return data out of the content provider related to that Uri. This has much of the feel of SQL: you specify the “columns” to return, the constraints to determine which “rows” to return, a sort order, etc. The difference is that this request is being made of a content provider, not directly of some database (e.g., SQLite).

You have two main options for running a query:

1. Use the query() method on ContentResolver from some sort of background thread
2. Use a CursorLoader, as is discussed in an upcoming chapter

The standard query() method on ContentResolver takes five parameters:

- The base Uri of the content provider to query, or the instance Uri of a specific object to query
- An array of properties (think “columns”) from that content provider that you want returned by the query
- A constraint statement, functioning like a SQL WHERE clause
- An optional set of parameters to bind into the constraint clause, replacing any ? that appear there
- An optional sort statement, functioning like a SQL ORDER BY clause

This method returns a Cursor object, which you can use to retrieve the data returned by the query.
This will hopefully make more sense given an example. This chapter shows some sample bits of code from the ContentProvider/ConstantsPlus sample project. This is the same basic application as was first shown back in the chapter on database access, but rewritten to pull the database logic into a content provider, which is then used by a retained ListFragment.

As before, in `onViewCreated()`, we kick off a LoadCursorTask if we do not already have our Cursor, such as via a configuration change:

```java
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    SimpleCursorAdapter adapter =
        new SimpleCursorAdapter(getActivity(), R.layout.row,
            current.next, new String[] {
                DatabaseHelper.TITLE,
                DatabaseHelper.VALUE
            }, new int[] { R.id.title, R.id.value },
            0);

    setListAdapter(adapter);

    if (current == null) {
        task = new LoadCursorTask(getActivity()).execute();
    }
}
```

LoadCursorTask inherits from a BaseTask. BaseTask and its subclasses need a ContentResolver to be able to work with our ContentProvider. So, BaseTask takes a Context in its constructor and uses that to retrieve a ContentResolver:

```java
abstract private class BaseTask<T> extends AsyncTask<T, Void, Cursor> {
    final ContentResolver resolver;

    BaseTask(Context ctxt) {
        super();

        resolver = ctxt.getContentResolver();
    }
```

(From ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java)
CONTENT PROVIDER THEORY

In doInBackground(), LoadCursorTask calls a doQuery() method inherited from BaseTask, which in turn uses our ContentResolver to query our ContentProvider:

```java
protected Cursor doQuery() {
    Cursor result = resolver.query(Provider.Constants.CONTENT_URI,
                                    PROJECTION, null, null, null);
    result.getCount();
    return(result);
}
```

(from ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java)

In the call to query(), we provide:

1. The Uri for our provider (Provider.Constants.CONTENT_URI), in this case representing the collection of physical constants managed by the provider
2. A list of properties to retrieve
3. Three null values, indicating that we do not need a constraint clause (the Uri represents the instance we need), nor parameters for the constraint, nor a sort order (we should only get one entry back)

The biggest “magic” here is the list of properties. The lineup of what properties are possible for a given provider should be provided by the documentation (or source code) for the content provider itself. In this case, we define logical values on the Provider provider implementation class that represent the various properties (namely, the unique identifier, the display name or title, and the value of the constant), and we refer to them with our PROJECTION:

```java
private static final String[] PROJECTION = new String[] {
    Provider.Constants._ID, Provider.Constants.TITLE,
    Provider.Constants.VALUE
};
```

(from ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java)

Adapting to the Circumstances

Now that we have a Cursor via query(), we have access to the query results and can do whatever we want with them. You might, for example, manually extract data from the Cursor to populate widgets or other objects.

In our case, we are using the SimpleCursorAdapter, set up in onViewCreated(), to render our Cursor. This means that we need to take the Cursor that doQuery()
generates and arrange to hand that to the SimpleCursorAdapter. The 
onPostExecute() method on BaseTask handles this:

```
@Override
public void onPostExecute(Cursor result) {
    ((CursorAdapter)getListAdapter()).changeCursor(result);
    current = result;
    task = null;
}
```

(from ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java)

Give and Take

Of course, content providers would be astonishingly weak if you couldn’t add or 
remove data from them, and were instead limited to only update what is there. 
Fortunately, content providers offer these abilities as well.

To insert data into a content provider, you have two options available on the 
ContentProvider interface (available through getContentResolver() to your 
activity):

- Use `insert()` with a collection Uri and a ContentValues structure 
  describing the initial set of data to put in the row
- Use `bulkInsert()` with a collection Uri and an array of ContentValues 
  structures to populate several rows at once

The `insert()` method returns a Uri for you to use for future operations on that new 
object. The `bulkInsert()` method returns the number of created rows; you would 
need to do a query to get back at the data you just inserted.

For example, if the user chooses our “Add” overflow item, we pop up a dialog to 
collect a new constant:

```
private void add() {
    LayoutInflater inflater = getActivity().getLayoutInflator();
    View addView = inflater.inflate(R.layout.add_edit, null);
    AlertDialog.Builder builder = new AlertDialog.Builder(getActivity());

    builder.setTitle(R.string.add_title).setView(addView)
        .setPositiveButton(R.string.ok, this)
        .setNegativeButton(R.string.cancel, null).show();
}
```
Then, if the user taps the “OK” button in the dialog, our `onClick()` listener is called, where we collect the entered values from the user, pour them into a `ContentValues` structure, and pass that to an `InsertTask`:

```java
@Override
public void onClick(DialogInterface dialog, int which) {
    ContentValues values = new ContentValues(2);
    AlertDialog dlg = (AlertDialog) dialog;
    EditText title = (EditText) dlg.findViewById(R.id.title);
    EditText value = (EditText) dlg.findViewById(R.id.value);

    values.put(DatabaseHelper.TITLE, title.getText().toString());
    values.put(DatabaseHelper.VALUE, value.getText().toString());

    task = new InsertTask(getActivity()).execute(values);
}
```

`InsertTask`, in its `doInBackground()` method, calls `insert()` on a `ContentResolver` to insert this row:

```java
@Override
protected Cursor doInBackground(ContentValues... values) {
    resolver.insert(Provider.Constants.CONTENT_URI, values[0]);

    return doQuery();
}
```

Notice that we also call `doQuery()` again. That is because our `Cursor` is now out of date, and we need to obtain a fresh `Cursor` with fresh results. And, as with `LoadTask`, `InsertTask` inherits from `BaseTask`, not only providing us with that `doQuery()` method but also the `onPostExecute()` method that puts the `Cursor` into the `SimpleCursorAdapter`.

To delete one or more rows from the content provider, use the `delete()` method on `ContentResolver`. This works akin to a SQL `DELETE` statement and takes three parameters:

- A `Uri` representing the collection (or instance) from which you wish to delete rows
A constraint statement, functioning like a SQL WHERE clause, to determine which rows should be deleted
An optional set of parameters to bind into the constraint clause, replacing any ? that appear there

The Streaming API

Sometimes, what you are trying to retrieve does not look like a set of rows and columns, but rather looks like a stream. For example, the MediaStore provider manages the index of all music, video, and image files available on external storage, and you can use MediaStore to open up a stream to read in the contents of one of those files. Here, working with the Uri and the provider is much like working with a URL and a Web server.

Some content providers, like MediaStore, support both the database-style and streaming APIs — you query to find media that matches your criteria, then can open some file that matches. Other content providers might only support the streaming API.

Working with the Stream

Given a Uri that represents some file managed by the content provider, you can use openInputStream() and openOutputStream() on a ContentResolver to access an InputStream or OutputStream, respectively. Note, though, that not all content providers may support both modes. For example, if you are working with a content provider that serves files stored inside the application (e.g., assets in the APK file), you will not be able to get an OutputStream to modify the content.

Also note that openInputStream() and openOutputStream() work with both file:// and content:// Uri values — you do not need to manually inspect the Uri and handle files separately if you do not want to.

Retrieving Metadata

You can call getType() on a ContentResolver, supplying a Uri as a parameter. This will return the MIME type reported by the ContentProvider for the data at that Uri. For the streaming API, this will give you results reminiscent of a Web server — some specific MIME type if the provider knows it, otherwise probably some generic MIME type (e.g., application/octet-stream).
You can also call query() on the ContentResolver. Your projection (the list of columns to return) can include:

- OpenableColumns.SIZE, which will return the length of the file being streamed to you for that Uri, and
- OpenableColumns.DISPLAY_NAME, which should be some name for the file that the user might recognize

The DATA Anti-Pattern

However, the authors of MediaStore screwed up developer expectations, due to a legacy convention.

The legacy convention was that a content:// Uri might not be openable directly using something like openInputStream(). Instead, it pointed to a database row, retrievable via query(), and you would look in the DATA column for how to access the actual data. Some providers no doubt continue to use this pattern, as does MediaStore. The rules for what the DATA column would be were not well documented, but by convention they tended to be a path to a file. The problem is that this runs afoul of Google's current guidance, as there is no guarantee that other apps can access such a file.

Do not blindly assume that if you get a content:// Uri that it is for the DATA pattern. Try to open a stream on the Uri, and if that fails, then see if the DATA pattern is in play. Or, if you query() to get the size and/or display name first, also request the DATA column, and if it exists and is not null, try that if opening the stream directly does not work.

Building Content Providers

Building a content provider is a very tedious task. There are many requirements of a content provider, in terms of methods to implement and public data members to supply. And, until you try using it, you have no great way of telling if you did any of it correctly (versus, say, building an activity and getting validation errors from the resource compiler).

That being said, building a content provider is of huge importance if your application wishes to make data available to other applications. If your application is keeping its data solely to itself, you may be able to avoid creating a content provider, just accessing the data directly from your activities. But, if you want your data to
possibly be used by others — for example, you are building a feed reader and you want other programs to be able to access the feeds you are downloading and caching — then a content provider is right for you.

First, Some Dissection

The content Uri is the linchpin behind accessing data inside a content provider. When using a content provider, all you really need to know is the provider's base Uri; from there you can run queries as needed, or construct a Uri to a specific instance if you know the instance identifier.

When building a content provider, though, you need to know a bit more about the innards of the content Uri.

A content Uri has two to four pieces, depending on situation:

1. It always has a scheme (content://), indicating it is a content Uri instead of a Uri to a Web resource (http://).
2. It always has an authority, which is the first path segment after the scheme. The authority is a unique string identifying the content provider that handles the content associated with this Uri.
3. It may have a data type path, which is the list of path segments after the authority and before the instance identifier (if any). The data type path can be empty, if the content provider only handles one type of content. It can be a single path segment (foo) or a chain of path segments (foo/bar/go) as needed to handle whatever data access scenarios the content provider requires.
4. It may have an instance identifier, which is an integer identifying a specific piece of content. A content Uri without an instance identifier refers to the collection of content represented by the authority (and, where provided, the data path).

For example, a content Uri could be as simple as content://sekrits, which would refer to the collection of content held by whatever content provider was tied to the sekrits authority (e.g., SecretsProvider). Or, it could be as complex as content://sekrits/card/pin/17, which would refer to a piece of content (identified as 17) managed by the sekrits content provider that is of the data type card/pin.
Next, Some Typing

Next, you need to come up with some MIME types corresponding with the content your content provider will provide. There are three basic patterns.

For the streaming API, the MIME type that you will use should be the actual MIME type of the stream itself. Perhaps you already know the MIME type (e.g., you got it in an HTTP header when you downloaded the content from a Web server). Perhaps you will use MimeTypeMap to try to infer a MIME type based on a file extension. That is up to you, just as it is up to you to ensure that your Web server returns proper MIME types for streams that it serves up.

For the database-style API, even though the MIME type system is not really designed for this sort of thing, we still use MIME types. Each Uri will have an associated MIME type, indicating what is represented by that Uri. A Uri that points to a collection of content (e.g., a database table or view) will use one MIME type structure, while a Uri that points to an individual piece of content (e.g., a row in that database table or view) will use a different MIME type structure.

The collection MIME type should be of the form vnd.X.cursor.dir/Y, where X is the name of your firm, organization, or project, and Y is a dot-delimited type name. So, for example, you might use vnd.tlagency.cursor.dir/sekrits.card.pin as the MIME type for your collection of secrets.

The instance MIME type, for an individual piece of content, should be of the form vnd.X.cursor.item/Y, usually for the same values of X and Y as you used for the collection MIME type (though that is not strictly required).

Implementing the Database-Style API

Just as an activity and a receiver are both Java classes, so is a content provider. So, the big step in creating a content provider is crafting its Java class, with a base class of ContentProvider.

In your subclass of ContentProvider, you are responsible for implementing six methods that, when combined, perform the services that a content provider is supposed to offer to activities wishing to create, read, update, or delete content via the database-style API.
Implement `onCreate()`

As with an activity, the main entry point to a content provider is `onCreate()`. Here, you can do whatever initialization you want. In particular, here is where you should lazy-initialize your data store. For example, if you plan on storing your data in such-and-so directory on external storage, with an XML file serving as a “table of contents”, you should check and see if that directory and XML file are there and, if not, create them so the rest of your content provider knows they are out there and available for use.

Similarly, if you have rewritten your content provider sufficiently to cause the data store to shift structure, you should check to see what structure you have now and adjust it if what you have is out of date.

Implement `query()`

As one might expect, the `query()` method is where your content provider gets details on a query some activity wants to perform. It is up to you to actually process said query.

The query method gets, as parameters:

1. A `Uri` representing the collection or instance being queried
2. A `String` array representing the list of properties that should be returned
3. A `String` representing what amounts to a SQL `WHERE` clause, constraining which instances should be considered for the query results
4. A `String` array representing values to “pour into” the `WHERE` clause, replacing any `?` found there
5. A `String` representing what amounts to a SQL `ORDER BY` clause

You are responsible for interpreting these parameters however they make sense and returning a `Cursor` that can be used to iterate over and access the data.

As you can imagine, these parameters are aimed towards people using a SQLite database for storage. You are welcome to ignore some of these parameters (e.g., you elect not to try to roll your own SQL `WHERE` clause parser), but you need to document that fact so activities only attempt to query you by instance `Uri` and not by using parameters that you elect to ignore.
Implement insert()

Your insert() method will receive a Uri representing the collection and a ContentValues structure with the initial data for the new instance. You are responsible for creating the new instance, filling in the supplied data, and returning a Uri to the new instance.

Implement update()

Your update() method gets the Uri of the instance or collection to change, a ContentValues structure with the new values to apply, a String for a SQL WHERE clause, and a String array with parameters to use to replace ? found in the WHERE clause. Your responsibility is to identify the instance(s) to be modified (based on the Uri and WHERE clause), then replace those instances’ current property values with the ones supplied.

This will be annoying, unless you are using SQLite for storage. Then, you can pretty much pass all the parameters you received to the update() call to the database, though the update() call will vary slightly depending on whether you are updating one instance or several.

Implement delete()

As with update(), delete() receives a Uri representing the instance or collection to work with and a WHERE clause and parameters. If the activity is deleting a single instance, the Uri should represent that instance and the WHERE clause may be null. But, the activity might be requesting to delete an open-ended set of instances, using the WHERE clause to constrain which ones to delete.

As with update(), though, this is simple if you are using SQLite for database storage (sense a theme?). You can let it handle the idiosyncrasies of parsing and applying the WHERE clause — all you have to do is call delete() on the database.

Implement getType()

The last method you need to implement is getType(). This takes a Uri and returns the MIME type associated with that Uri. The Uri could be a collection or an instance Uri; you need to determine which was provided and return the corresponding MIME type.
Update the Manifest

The glue tying the content provider implementation to the rest of your application resides in your AndroidManifest.xml file. Simply add a <provider> element as a child of the <application> element, such as:

```xml
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
   package="com.commonsware.android.constants"
   android:versionCode="1"
   android:versionName="1.0">

   <supports-screens
      android:anyDensity="true"
      android:largeScreens="true"
      android:normalScreens="true"
      android:smallScreens="true"/>

   <uses-sdk
      android:minSdkVersion="14"
      android:targetSdkVersion="18"/>

   <application
      android:icon="@drawable/ic_launcher"
      android:label="@string/app_name">

      <provider
         android:name=".Provider"
         android:authorities="com.commonsware.android.constants.Provider"
         android:exported="false"/>

      <activity
         android:name=".ConstantsBrowser"
         android:label="@string/app_name">

         <intent-filter
            android:name="android.intent.action.MAIN">

            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
      </activity>
   </application>

</manifest>
```

The android:name property is the name of the content provider class, with a leading dot to indicate it is in the stock namespace for this application’s classes (just like you
use with activities).

The `android:authorities` property should be a semicolon-delimited list of the authority values supported by the content provider. Recall, from earlier in this chapter, that each content `Uri` is made up of a scheme, authority, data type path, and instance identifier. Each authority from each `CONTENT_URI` value should be included in the `android:authorities` list. Now, when Android encounters a content `Uri`, it can sift through the providers registered through manifests to find a matching authority. That tells Android which application and class implements the content provider, and from there Android can bridge between the calling activity and the content provider being called.

Several other attributes relate to security:

- `android:exported` indicates whether third-party apps are able to initiate communications with your provider on their own
- `android:readPermission` and `android:writePermission` allow you to defend your provider with permissions; third-party apps have to have `<uses-permission>` elements for those permissions to be able to work with your provider
- `android:grantUriPermissions` indicates whether you are able to selectively “poke pinholes in the firewall” of your provider security, to say that for specific IPC operations (e.g., starting a third-party activity), that third party has limited access to your provider’s content

These will be explored later in this book.

**Add Notify-On-Change Support**

A feature that your content provider can offer to its clients is notify-on-change support. This means that your content provider will let clients know if the data for a given content `Uri` changes.

For example, suppose you have created a content provider that retrieves RSS and Atom feeds from the Internet based on the user’s feed subscriptions (via OPML, perhaps). The content provider offers read-only access to the contents of the feeds, with an eye towards several applications on the phone using those feeds versus everyone implementing their own feed poll-fetch-and-cache system. You have also implemented a service that will get updates to those feeds asynchronously, updating the underlying data store. Your content provider could alert applications using the feeds that such-and-so feed was updated, so applications using that specific feed can
refresh and get the latest data.

On the content provider side, to do this, call notifyChange() on your ContentResolver instance (available in your content provider via getContext().getContentResolver()). This takes two parameters: the Uri of the piece of content that changed and the ContentObserver that initiated the change. In many cases, the latter will be null; a non-null value simply means that the observer that initiated the change will not be notified of its own changes.

On the content consumer side, an activity can call registerContentObserver() on its ContentResolver (via getContentResolver()). This ties a ContentObserver instance to a supplied Uri — the observer will be notified whenever notifyChange() is called for that specific Uri. When the consumer is done with the Uri, unregisterContentObserver() releases the connection.

Implementing the Streaming API

If you want to have a ContentProvider support streaming data via the streaming API, you will still need to set up the <provider> element, choose an authority, and create a subclass of ContentProvider as with the database-style API. From there, whether you are adding the streaming API to an existing provider or creating a new one, there is some additional work to be done.

Serving the Stream

If you want consumers of your ContentProvider to be able to call openInputStream() or openOutputStream() on a Uri, the most likely approach is to implement the openFile() method. The openFile() method returns a curious object called a ParcelFileDescriptor. Given that, the ContentResolver can obtain the InputStream or OutputStream that was requested. There are various static methods on ParcelFileDescriptor to create instances of it, such as an open() method that takes a File object as the first parameter. Note that this works for both files on external storage and files within your own project’s app-local file storage (e.g., getFilesDir()).

openFile() also gets a String parameter that is the “mode” for opening the file. This can be converted into appropriate flags for use with ParcelFileDescriptor and its open() method. Mostly, this is for determining whether we are opening the file for read or write operations.
Serving the Metadata

You should implement the query() method in your provider as well. If the Uri is pointing to one of your streams, you should create a one-row MatrixCursor and supply the OpenableColumns as the columns. OpenableColumns has two values: DISPLAY_NAME (for some human-readable name of the stream) and SIZE (the length of the stream in bytes). Based on the projection string array passed into query(), you can skip columns that the client is not requesting.

You also need to implement getType(). For the database-style API, you pretty much invent your own MIME types. For the streaming API, you should be returning MIME types for the Uri values that really represent the contents of that Uri. In other words, your getType() method should behave like you would expect a Web server to do with respect to the Content-Type header. If you know the MIME type for certain (e.g., you got it yourself in an HTTP or IMAP operation and saved it), use that. If you do not know the MIME type for certain, you can try the MimeMap class, which knows how to map common file extensions to their MIME type counterparts. Worst-case, return application/octet-stream.

The Rest of the Requirements

You also have to implement the following abstract methods:

- onCreate()
- insert()
- update()
- delete()

If you are not supporting the database-style API, you are welcome to have insert(), update(), and delete() throw some RuntimeException, to indicate that those operations are not supported.

Issues with Content Providers

Content providers are not without their issues.

The biggest complaint seems to be the lack of an onDestroy() companion to the onCreate() method you can implement. Hence, if you open a database in onCreate(), you close it... never. Sometimes, you can alleviate this by initializing things on demand and releasing them immediately, such as opening a database as
part of `insert()` and closing it within the same method. This does not always work, however — for example, you cannot close the database you query in `query()`, since the `Cursor` you return would become invalid. Holding onto an open `SQLiteDatabase` is not a problem, as all of your data changes are written to disk as part of committing transactions. So, many `ContentProvider` implementations settle for simply never closing the database.

The fact that `ContentProvider` is effectively a facade means that a consumer of a `ContentProvider` has no idea what to expect. It is up to documentation to explain what `Uri` values can be used, what columns can be returned, what query syntax is supported, and so on. And, the fact that it is a facade means that much of the richness of the SQLite interface is lost, such as `GROUP BY`. To top it off, the API supported by `ContentProvider` is rather limited — if what you want to share does not look like a database and does not look like a file, it may be difficult to force it into the `ContentProvider` API.

Another issue is the client’s dependence upon the provider itself. If, for whatever reason, the provider’s process is terminated while the client has an open `Cursor` on query results, the client’s process is also terminated. It is unclear if the same effect occurs when the client has an open stream from a provider through the streaming API, though it seems likely. Now, in theory, the importance of the provider’s process should be raised to the highest importance of any of its clients, though this behavior is not documented and may not occur in practice.

This behavior by Android is rather drastic, more drastic than what happens to HTTP clients when the Web server they are connected to crashes. There, the client winds up with some sort of exception and can move on. The moral of this story is: when working with a `ContentProvider`, it behooves you to use the data quickly, particularly if your app is in the background at the time.
The previous chapter focused on the concepts, classes, and methods behind content providers. This chapter more closely examines some implementations of content providers, organized into simple patterns.

Prerequisites

Understanding this chapter requires that you have read the preceding chapter, along with the chapter on permissions.

The Single-Table Database-Backed Content Provider

The simplest database-backed content provider is one that only attempts to expose a single table's worth of data to consumers. The CallLog content provider works this way, for example.

Step #1: Create a Provider Class

We start off with a custom subclass of ContentProvider, named, cunningly enough, Provider. Here we need the database-style API methods: query(), insert(), update(), delete(), and getType().
onCreate()

Here is the `onCreate()` method for `Provider`, from the [ContentProvider/ConstantsPlus](https://github.com/commonsware/android/contentprovider/tree/master/常数) sample application:

```java
@Override
public boolean onCreate()
{
    db=new DatabaseHelper(getContext());

    return(true);
}
```

(from [ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java](https://github.com/commonsware/android/contentprovider/tree/master/常数))

While that does not seem all that special, the “magic” is in the private `DatabaseHelper` object, a fairly conventional `SQLiteOpenHelper` implementation:

```java
package com.commonsware.android.constants;

import android.content.ContentValues;
import android.content.Context;
import android.database.Cursor;
import android.database.sqlite.SQLiteDatabase;
import android.database.sqlite.SQLiteOpenHelper;
import android.hardware.SensorManager;

class DatabaseHelper extends SQLiteOpenHelper {
    private static final String DATABASE_NAME="constants.db";
    static final String TITLE="title";
    static final String VALUE="value";

    public DatabaseHelper(Context context) {
        super(context, DATABASE_NAME, null, 1);
    }

    @Override
    public void onCreate(SQLiteDatabase db) {
        Cursor c=db.rawQuery("SELECT name FROM sqlite_master WHERE type='table' AND name='constants'", null);

        try {
            if (c.getCount()==0) {
                db.execSQL("CREATE TABLE constants (_id INTEGER PRIMARY KEY AUTOINCREMENT, title TEXT, value REAL);");

                ContentValues cv=new ContentValues();

                cv.put(Provider.Constants.TITLE, "Gravity, Death Star I");
                cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_DEATH_STAR_I);
                db.insert("constants", Provider.Constants.TITLE, cv);

                cv.put(Provider.Constants.TITLE, "Gravity, Earth");
                cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_EARTH);
                db.insert("constants", Provider.Constants.TITLE, cv);

```
cv.put(Provider.Constants.TITLE, "Gravity, Jupiter");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_JUPITER);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Mars");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MARS);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Mercury");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MERCURY);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Moon");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MOON);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Neptune");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_NEPTUNE);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Pluto");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_PLUTO);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Saturn");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_SATURN);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Sun");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_SUN);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, The Island");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_THE_ISLAND);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Uranus");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_URANUS);
db.insert("constants", Provider.Constants.TITLE, cv);

cv.put(Provider.Constants.TITLE, "Gravity, Venus");
cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_VENUS);
db.insert("constants", Provider.Constants.TITLE, cv);
}

finally {
    c.close();
}

@Override
public void onUpgrade(SQLiteDatabase db, int oldVersion, int newVersion) {
    android.util.Log.w("Constants", "Upgrading database, which will destroy all old data");
    db.execSQL("DROP TABLE IF EXISTS constants");
onCreate(db);
}
Note that we are creating the DatabaseHelper in onCreate() and are never closing it. That is because there is no onDestroy() (or equivalent) method in a ContentProvider. While we might be tempted to open and close the database on every operation, that will not work, as we cannot close the database and still hand back a live Cursor from the database. Hence, we leave it open and assume that SQLite’s transactional nature will ensure that our database is not corrupted when Android shuts down the ContentProvider.

**query()**

For SQLite-backed storage providers like this one, the query() method implementation should be largely boilerplate. Use a SQLiteQueryBuilder to convert the various parameters into a single SQL statement, then use query() on the builder to actually invoke the query and give you a Cursor back. The Cursor is what your query() method then returns.

For example, here is query() from Provider:

```java
@Override
public Cursor query(Uri url, String[] projection, String selection,
                     String[] selectionArgs, String sort) {
    SQLiteQueryBuilder qb = new SQLiteQueryBuilder();
    qb.setTables(TABLE);

    String orderBy;

    if (TextUtils.isEmpty(sort)) {
        orderBy = Constants.DEFAULT_SORT_ORDER;
    } else {
        orderBy = sort;
    }

    Cursor c =
        qb.query(db.getReadableDatabase(), projection, selection,
                 selectionArgs, null, null, orderBy);

    c.setNotificationUri(getContext().getContentResolver(), url);

    return (c);
}
```

(from ContentProvider/ConstantsPlus/app/src/main/java/com/commonsware/android/constants/Provider.java)
We create a SQLiteQueryBuilder and pour the query details into the builder, notably the name of the table that we query against and the sort order (substituting in a default sort if the caller did not request one). When done, we use the query() method on the builder to get a Cursor for the results. We also tell the resulting Cursor what Uri was used to create it, for use with the content observer system.

### insert()

Since this is a SQLite-backed content provider, once again, the implementation is mostly boilerplate: validate that all required values were supplied by the activity, merge your own notion of default values with the supplied data, and call insert() on the database to actually create the instance.

For example, here is insert() from Provider:

```java
@Override
public Uri insert(Uri url, ContentValues initialValues) {
    long rowID =
        db.getWritableDatabase().insert(TABLE, Constants.TITLE,
                                      initialValues);

    if (rowID > 0) {
        Uri uri =
            ContentUris.withAppendedId(Provider.Constants.CONTENT_URI,
                                        rowID);
        getContext().getContentResolver().notifyChange(uri, null);

        return uri;
    }

    throw new SQLException("Failed to insert row into 
" + url);
}
```

The pattern is the same as before: use the provider particulars plus the data to be inserted to actually do the insertion.

### update()

Here is update() from Provider:

```java
@Override
public int update(Uri url, ContentValues values, String where,
```

2541
In this case, updates are always applied across the entire collection, though we could have a smarter implementation that supported updating a single instance via an instance Uri.

**delete()**

Similarly, here is delete() from Provider:

```java
@Override
public int delete(Uri url, String where, String[] whereArgs) {
    int count = db.getWritableDatabase().delete(TABLE, where, whereArgs);
    getContext().getContentResolver().notifyChange(url, null);
    return count;
}
```

This is almost a clone of the update() implementation described above.

**getType()**

The last method you need to implement is getType(). This takes a Uri and returns the MIME type associated with that Uri. The Uri could be a collection or an instance Uri; you need to determine which was provided and return the corresponding MIME type.

For example, here is getType() from Provider:

```java
@Override
public String getType(Uri url) {
    if (isCollectionUri(url)) {
```
Step #2: Supply a Uri

You may wish to add a public static member... somewhere, containing the Uri for each collection your content provider supports, for use by your own application code. Typically, this is a public static final Uri put on the content provider class itself:

```java
public static final Uri CONTENT_URI =
    Uri.parse("content://com.commonsware.android.constants.Provider/constants");
```

You may wish to use the same namespace for the content Uri that you use for your Java classes, to reduce the chance of collision with others.

Bear in mind that if you intend for third parties to access your content provider, they will not have access to this public static data member, as your class is not in their project. Hence, you will need to publish the string representation of this Uri that they can hard-wire into their application.

Step #3: Declare the “Columns”

Remember those “columns” you referenced when you were using a content provider, in the previous chapter? Well, you may wish to publish public static values for those too for your own content provider.

Specifically, you may want a public static class implementing BaseColumns that contains your available column names, such as this example from Provider:

```java
public static final class Constants implements BaseColumns {
    public static final Uri CONTENT_URI =
        Uri.parse("content://com.commonsware.android.constants.Provider/constants");
    public static final String DEFAULT_SORT_ORDER = "title";
    public static final String TITLE = "title";
    public static final String VALUE = "value";
}
```

2543
Since we are using SQLite as a data store, the values for the column name constants should be the corresponding column names in the table, so you can just pass the projection (array of columns) to SQLite on a `query()`, or pass the `ContentValues` on an `insert()` or `update()`.

Note that nothing in here stipulates the types of the properties. They could be strings, integers, or whatever. The biggest limitation is what a `Cursor` can provide access to via its property getters. The fact that there is nothing in code that enforces type safety means you should document the property types well, so people attempting to use your content provider know what they can expect.

**Step #4: Update the Manifest**

Finally, we need to add the provider to the `AndroidManifest.xml` file, by adding a `<provider>` element as a child of the `<application>` element:

```xml
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonsware.android.constants"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="18"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <provider
            android:name=".Provider"
            android:authorities="com.commonsware.android.constants.Provider"
            android:exported="false"/>

        <activity
            android:name=".ConstantsBrowser"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```
The Local-File Content Provider

Implementing a content provider that supports serving up files based on Uri values is similar, and generally simpler, than creating a content provider for the database-style API. In this section, we will examine the ContentProvider/Files sample project. This project demonstrates a common use of the filesystem-style API: serving files from internal storage to third-party applications (who, by default, cannot read your internally-stored files).

Note that this sample project will only work on devices that have an application capable of viewing PDF files accessed via content:// Uri values.

The FileProvider Class

Our ContentProvider is named FileProvider. However, most of the logic is contained in an AbstractFileProvider that will be used for a handful of sample apps in this chapter. We will look at both of those classes, focusing first on the FileProvider.

onCreate()

We have an onCreate() method. In many cases, this would not be needed for this sort of provider. After all, there is no database to open. In this case, we use onCreate() to copy the file(s) out of assets into the app-local file store. In principle, this would allow our application code to modify these files as the user uses the app (versus the unmodifiable editions in assets/).

```java
@Override
public boolean onCreate() {
    File f = new File(getContext().getFilesDir(), "test.pdf");

    if (!f.exists()) {
```
AssetManager assets=getContext().getAssets();

    try {
        copy(assets.open("test.pdf"), f);
    } catch (IOException e) {
        Log.e("FileProvider", "Exception copying from assets", e);

        return(false);
    }

    return(true);

This uses a static copy() method, inherited from AbstractFileProvider, that can copy an InputStream from an asset to a local File. We will take a peek at this later in this chapter.

openFile()

We need to implement openFile(), to return a ParcelFileDescriptor corresponding to the supplied Uri:

@Override
public ParcelFileDescriptor openFile(Uri uri, String mode) throws FileNotFoundException {
    File root=getContext().getFilesDir();
    File f=new File(root, uri.getPath()).getAbsoluteFile();

    if (!f.getPath().startsWith(root.getPath())) {
        throw new SecurityException("Resolved path jumped beyond root");
    }

    if (f.exists()) {
        return(ParcelFileDescriptor.open(f, parseMode(mode)));
    }

    throw new FileNotFoundException(uri.getPath());
}
We are passed in a *nix-style string mode, which will be a value like \texttt{r} for read access, \texttt{wt} for write access (and truncate the file), etc. In API Level 19+, \texttt{ParcelFileDescriptor} has a convenience method for converting such modes into the equivalent \texttt{ParcelFileDescriptor} flag values. For older devices, you can simply use the \texttt{parseMode()} code that Google added:

\begin{verbatim}
// following is from ParcelFileDescriptor source code
// Copyright (C) 2006 The Android Open Source Project
// (even though this method was added much after 2006...)

private static int parseMode(String mode) {
    final int modeBits;
    if ("r".equals(mode)) {
        modeBits = ParcelFileDescriptor.MODE_READ_ONLY;
    } else if ("w".equals(mode) || "wt".equals(mode)) {
        modeBits =
            ParcelFileDescriptor.MODE_WRITE_ONLY
            | ParcelFileDescriptor.MODE_CREATE
            | ParcelFileDescriptor.MODE_TRUNCATE;
    } else if ("wa".equals(mode)) {
        modeBits =
            ParcelFileDescriptor.MODE_WRITE_ONLY
            | ParcelFileDescriptor.MODE_CREATE
            | ParcelFileDescriptor.MODE_APPEND;
    } else if ("rw".equals(mode)) {
        modeBits =
            ParcelFileDescriptor.MODE_READ_WRITE
            | ParcelFileDescriptor.MODE_CREATE;
    } else if ("rwt".equals(mode)) {
        modeBits =
            ParcelFileDescriptor.MODE_READ_WRITE
            | ParcelFileDescriptor.MODE_CREATE
            | ParcelFileDescriptor.MODE_TRUNCATE;
    } else {
        throw new IllegalArgumentException("Bad mode '" + mode + "'");
    }
    return modeBits;
}
\end{verbatim}

Our \texttt{openFile()} method then uses \texttt{parseMode()} in the call to the static \texttt{open()}
method on ParcelFileDescriptor, which opens the file (with the desired access mode) and gives us our ParcelFileDescriptor back that we can return. If the file is not found, we can throw a FileNotFoundException to indicate that.

However, we also check to see that the File that we are trying to access is inside getFilesDir(), by comparing paths. A Uri can have .. path segments to move up directory levels. Using that with the File constructor means that a rogue Uri could move outside of our designated root directory (getFilesDir()), to perhaps try to access other data on our internal storage (e.g., databases). getAbsoluteFile() will net out any path-traversal segments (e.g., ..). If getAbsoluteFile() lies within getFilesDir(), we go ahead, otherwise we throw a SecurityException.

**getDataLength()**

AbstractFileProvider gives us a callback — getDataLength() — where we can indicate how big a file is, given its Uri. That information will be made available to clients consuming this stream. The default will be to indicate that the file size is unknown... and that usually works. However, if it is easy for you to determine the file size, do so, and it will increase the compatibility of your app with possible consumers.

In this case, determining the size of a local file is easy:

```java
@Override
protected long getDataLength(Uri uri) {
    File f = new File(getContext().getFilesDir(), uri.getPath());
    return f.length();
}
```

(from ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/FileProvider.java)

**The AbstractFileProvider Class**

AbstractFileProvider is designed to handle a lot of common boilerplate for streaming providers like the one provided in this sample.

**getType()**

Just as our database-style ContentProvider needed to implement getType() to provide a MIME type given a Uri, so too do our streaming providers. The difference is that a streaming provider usually wants to use “real” MIME types, values that
third-party apps are likely to recognize. For example, a PDF file should use a MIME type of application/pdf, as that is what PDF viewing apps will expect.

Android has some convenience code for determining a likely MIME type. You can use MimeMap to convert a file extension to a MIME type, or you can use guessContentTypeFromName() onURLConnection to get a MIME type for a URL. Both use the same underlying database — the difference is mostly a matter of whether you have a bare file extension already or not. So, the default implementation of getType() in AbstractFileProvider uses guessContentTypeFromName():

```
@Override
public String getType(Uri uri) {
    return (URLConnection.guessContentTypeFromName(uri.toString()));
}
```

If you know that your MIME type is unlikely to be recognized by Android (e.g., you invented your own), a subclass of AbstractFileProvider could handle those cases, chaining to the superclass for other Uri values.

**insert(), update(), and delete()**

ContentProvider itself is abstract, requiring us to implement a variety of methods to satisfy the compiler. Three of them — insert(), update(), and delete() — have no role in a pure-streaming ContentProvider, so AbstractFileProvider has stub implementations:

```
@Override
public Uri insert(Uri uri, ContentValues initialValues) {
    throw new RuntimeException("Operation not supported");
}

@Override
public int update(Uri uri, ContentValues values, String where, String[] whereArgs) {
    throw new RuntimeException("Operation not supported");
}

@Override
public int delete(Uri uri, String where, String[] whereArgs) {
    throw new RuntimeException("Operation not supported");
}
```

Content Provider Implementation Patterns
A ContentProvider that supports both the database-style and streaming APIs will need real implementations of those methods for the database operations, perhaps throwing an Exception for requests to insert, update, or delete a Uri that represents a stream.

**query() and getFileName()**

We also need to implement query(). You can get by with having this be a stub similar to insert() and kin. However, for better compatibility, you should have a more robust query() implementation, as it will be used by ContentResolver to retrieve two pieces of metadata about a Uri:

- What is a valid filename to use to represent this Uri, should we need a human-readable name? After all, a ContentProvider Uri does not have to represent a human-readable path, and so the last segment of that Uri could be a cryptic string of hex digits or something, not a filename.
- What is the length of the data that should be delivered by the stream?

query() will be called with a projection that contains either OpenableColumns.DISPLAY_NAME, OpenableColumns.SIZE, or both. A streaming ContentProvider ideally supports returning a Cursor with this data. The AbstractFileProvider implementation of query() handles this for us:

```java
abstract class AbstractFileProvider extends ContentProvider {
    private final static String[] OPENABLE_PROJECTION = {
        OpenableColumns.DISPLAY_NAME, OpenableColumns.SIZE
    };

    @Override
    public Cursor query(Uri uri, String[] projection, String selection,
        String[] selectionArgs, String sortOrder) {
        if (projection == null) {
            projection=OPENABLE_PROJECTION;
        }

        final MatrixCursor cursor=new MatrixCursor(projection, 1);

        MatrixCursor.RowBuilder b=cursor.newRow();

        for (String col : projection) {
            if (OpenableColumns.DISPLAY_NAME.equals(col)) {
                b.add(getFileName(uri));
            } else if (OpenableColumns.SIZE.equals(col)) {
                b.add(getDataLength(uri));
            }
```
If the supplied projection is null, we assume that the caller wants the standard OpenableColumns; otherwise, we will use the supplied projection.

Our results will be packaged in a MatrixCursor. This amounts to a Cursor interface on a two-dimensional array, where you build up the rows in that array via a MatrixCursor.RowBuilder. In our case, there will only be one such row, for the relevant values for the file to be streamed in support of the requested Uri.

We iterate over the columns in the projection, calling out to getFileName() and getDataLength() methods for OpenableColumns.DISPLAY_NAME and OpenableColumns.SIZE respectively (and using null as the result for anything else). The default implementations of those methods return the last path segment of the Uri and AssetFileDescriptor.UNKNOWN_LENGTH, respectively:

```java
protected String getFileName(Uri uri) {
    return uri.getLastPathSegment();
}

protected long getDataLength(Uri uri) {
    return AssetFileDescriptor.UNKNOWN_LENGTH;
}
```

Subclasses can override those as needed, as we saw with getDataLength() in the concrete FileProvider class.

However, query() does not return the MatrixCursor directly. Instead, it wraps it in a LegacyCompatCursorWrapper. This class comes from the CWAC-Provider project, from the author of this book. LegacyCompatCursorWrapper is designed to try to improve compatibility with clients that are expecting query() results to include a _DATA column, the way that MediaStore does. Poorly-written clients will crash if this column does not exist. LegacyCompatCursorWrapper wraps a Cursor and serves up
an empty _DATA column for those clients that need one.

**copy()**

AbstractFileProvider also has a convenience copy() static method that copies an InputStream to a File, used from the FileProvider onCreate() method:

```java
static void copy(InputStream in, File dst) throws IOException {
    FileOutputStream out = new FileOutputStream(dst);
    byte[] buf = new byte[1024];
    int len;
    while ((len = in.read(buf)) >= 0) {
        out.write(buf, 0, len);
    }
    in.close();
    out.close();
}
```

(from ContentProvider/Files/app/src/main/java/com/commonsware/android/cp/files/AbstractFileProvider.java)

**The Manifest**

Finally, we need to add the provider to the AndroidManifest.xml file, by adding a <provider> element as a child of the <application> element, as with any other content provider:

```
<?xml version="1.0" encoding="utf-8"?
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonsware.android.cp.files"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name="com.commonsware.android.cp.files.FileProviderActivity"/>
    </application>
</manifest>
```
Note, however, that we have android:exported="true" set in our <provider> element. This means that this content provider can be accessed from third-party apps or other external processes (e.g., the media framework for playing back videos).

**Using this Provider**

The activity is fairly trivial, simply creating an ACTION_VIEW Intent on our PDF file and starting up an activity for it, then finishing itself:

```java
package com.commonsware.android.cp.files;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;

public class FilesCPDemo extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        startActivity(new Intent(Intent.ACTION_VIEW,
                                   Uri.parse(FileProvider.CONTENT_URI
                                             + "test.pdf")));

        finish();
    }
}
```
Here, we use a CONTENT_URI published by FileProvider as the basis for identifying the file:

```java
public static final Uri CONTENT_URI =
    Uri.parse("content://com.commonsware.android.cp.files/");
```

### The Protected Provider

The problem with the preceding example is that any app on the device, if it knows the right Uri to ask for, will be able to access the file. This may be desired, but often times it will not be. Instead, you may want to specifically indicate which apps, at specific points in time, can view the file.

Particularly if your objective is to start a third-party app to work with that file, setting up this sort of security is not that difficult. To see how that works, we will walk through the `ContentProvider/GrantUriPermissions` sample project. This is a clone of the `ContentProvider/Files` project with this extra security added on.

The way the defense works is by using Android's permission system. We will mark the ContentProvider as being not exported, then selectively grant that access to a specific Uri to the app that we want to view our file.

**Step #1: Mark the Provider as Not Exported**

Putting `android:exported="false"` on the `<provider>` element indicates that no app has the ability to make requests of your ContentProvider, except for specific cases where you authorize it:

```xml
<provider
    android:name="FileProvider"
    android:authorities="com.commonsware.android.cp.files"
    android:exported="false"
    android:grantUriPermissions="false">
    <grant-uri-permission android:path="/test.pdf"/>
</provider>
```

---

---

**2554**
With no other changes, if we tried to use the app, the third-party PDF viewer would crash when trying to read our PDF file from the Uri.

**Step #2: Grant Access to the Uri**

To allow third parties to get access only when we specify, we need to make a few more changes.

This `<provider>` element also has `android:grantUriPermissions="false"`. That is the default value for this attribute, shown here purely for illustration purposes. It also has a `<grant-uri-permissions>` child element, listing the local path (within the `ContentProvider`) to our PDF file.

The `<grant-uri-permissions>` element (or elements, plural) allow us to override the permission requirement for certain pieces of content, granting access to that content on a per-request basis. There are three possibilities:

1. If `android:grantUriPermissions` is `true`, then we will be able to grant access to any content within our provider
2. If `android:grantUriPermissions` is `false`, but we have `<grant-uri-permissions>` sub-elements, we can only grant access to the content identified by the `Uri` paths specified in those sub-elements
3. If `android:grantUriPermissions` is `false`, and we have no `<grant-uri-permissions>` sub-elements (the default case), we cannot grant access to any content within our provider

In this case, we specify that we will only grant access to `/test.pdf`. Since that is the only content in this provider, we could have the same net effect by setting `android:grantUriPermissions` to `true`.

Then, when we create an `Intent` used to interact with another component, we can include a flag indicating what permission we wish to grant:

```java
package com.commonsware.android.cp.perms;
import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;

public class FilesCPDemo extends Activity {
  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
  }
```
In this revised version of our activity, we add `FLAG_GRANT_READ_URI_PERMISSION` to the Intent used with `startActivity()`. This will grant the activity that responds to our Intent read access to the specific Uri in the Intent, overriding the exported status. That is why, when you run this app on a device, the PDF viewer will still be able to view the file.

There is also `FLAG_GRANT_WRITE_URI_PERMISSION` for granting write access, not needed here, as our provider only supports read access.

While this is most commonly used with `startActivity()` (e.g., allowing a mail program limited access to your attachments provider), this can also be used with `startService()`, `bindService()`, and the various flavors of sending broadcasts (e.g., `sendBroadcast()`).

**The Stream Provider**

Sometimes, we want a provider that looks like the local-file provider from the preceding section... but we do not have a file. Instead, we have data in some other form, such as a byte array, or a `String`, or an `InputStream`. Writing that material to a file may be problematic, or even counterproductive.

For example, imagine an app that stores data on the user’s behalf in an encrypted fashion. One such file is a PDF, that the user would like to view. There are PDF viewers that can view files served via `content://Uri` values, as the previous section demonstrated... but that assumes an unencrypted file. While we could decrypt the file, writing the decrypted results to another file, and serve the decrypted data to the PDF viewer, now we have a persistent decrypted version of the data. That opens a window of time when the data might be accessed by people with nefarious intent, which is something we are trying to avoid by using the encrypted store in the first place. Rather, it would be nice if we could decrypt the data on the fly and give that decrypted result to the PDF viewer. Of course, there are security risks intrinsic to that too — after all, we do not know what the PDF viewer might do with the unencrypted data — but it is at least an improvement.
The good news is that Android does support streaming options for openFile()-style ContentProvider implementations. However, as one might expect, they are not the simplest things to implement.

In this section, we will examine the ContentProvider/Pipe sample project. This is a near clone of the ContentProvider/Files sample from the preceding section. However, rather than simply handing the file to Android to serve as content, we will stream it in ourselves. In principle, as part of this streaming, we could be decrypting it from an encrypted state. Since this sample shares much code with the previous sample, we will focus solely on the changes here.

Note that this sample was inspired by the sample found at https://github.com/nandeeshwar/Pfd-Create-Pipe.

The Pipes

Starting with API Level 9, it is possible to create a pipe between two processes, from the Android SDK, via ParcelFileDescriptor. In the previous section, we saw how ParcelFileDescriptor could be used to open a local file and make that available to other processes — the createPipe() method gives us a pipe.

The “pipe” returned by createPipe() is a two-element array of ParcelFileDescriptor objects. The first element in the array represents the “read” end of the pipe. In our case, that is the end that should be used by a PDF viewer to read in the file contents. The second element of the array represents the “write” end of the pipe, which we will use to supply the file’s contents to the “read” end (and to the PDF viewer by extension).

The Revised openFile()

With that in mind, here is our revised openFile() method:

```java
@Override
public ParcelFileDescriptor openFile(Uri uri, String mode) throws FileNotFoundException {
    ParcelFileDescriptor[] pipe = null;

    try {
        pipe = ParcelFileDescriptor.createPipe();
        AssetManager assets = getContext().getAssets();

        new TransferThread(assets.open(uri.getLastPathSegment())),
```
We create our pipe via `createPipe()`, then get an `InputStream` on our PDF file stored as an asset — unlike the `ContentProvider/Files` sample, we do not need to copy the asset to a local file now. We then kick off a background thread, implemented in an inner class named `TransferThread`, to actually copy the data from the asset to the write end of the pipe.

Rather than supply `TransferThread` with a `ParcelFileDescriptor` for the write end of the pipe, we supply an `OutputStream`. Specifically, we pass in a `ParcelFileDescriptor.AutoCloseOutputStream`. This is an `OutputStream` that knows to close the `ParcelFileDescriptor` when we close the stream. Otherwise, it behaves like a fairly typical `OutputStream`.

**The Transfer**

`TransferThread` is a fairly conventional copy-data-from-stream-to-stream implementation:

```java
static class TransferThread extends Thread {
  InputStream in;
  OutputStream out;

  TransferThread(InputStream in, OutputStream out) {
    this.in=in;
    this.out=out;
  }

  @Override
  public void run() {
    byte[] buf=new byte[1024];
    int len;

    try {
```

(from `ContentProvider/Pipe/app/src/main/java/com/commonsware/android/cp/pipe/PipeProvider.java`)
Here, we read in data in 1KB blocks from the InputStream (our asset) and write the data to our OutputStream (obtained from the ParcelFileDescriptor).

The Results

Our activity logic has not substantially changed. We still create an ACTION_VIEW Intent on the content:// Uri from our provider, pointing to our test.pdf asset. Any PDF viewer capable of handling content:// Uri values will use a ContentResolver to open an InputStream for our Uri. In the ContentProvider/Files sample, that InputStream would receive the contents of the file directly from Android. In this new sample, that InputStream is reading in bytes off of our pipe, until such time as it has read in all the streamed data and we have closed the OutputStream.

Not every possible consumer of a Uri will be able to work with our stream, though. For example, MediaPlayer expects to be able to move forwards and backwards within the stream, and while that works for file-backed ParcelFileDescriptors, it does not work for those representing a pipe. Hence, MediaPlayer will crash when trying to use a Uri to a pipe-based stream, which is certainly unfortunate.

The author would like to thank Reuben Scratton for his assistance in tracking down this MediaPlayer limitation.

FileProvider

The Android Support package now contains its own implementation of a
FileProvider that greatly simplifies serving files from internal or external storage to another app.

Here, we will see Google's FileProvider in action via the ContentProvider/V4FileProvider sample project. This is a near clone of the ContentProvider/Pipe sample from the preceding section, just leveraging FileProvider to help us serve a file from internal storage.

**The Rationale**

The documentation for FileProvider states:

> Apps should generally avoid sending raw filesystem paths across process boundaries, since the receiving app may not have the same access as the sender. Instead, apps should send Uri backed by a provider like FileProvider.

This is not just an issue for passing files from internal storage to other apps. On Android 4.2+ tablets, it could even be an issue for external storage, as each user account gets its own portion of external storage. There may be scenarios in which your app (associated with one user) winds up needing to pass the contents of a file on external storage to another app (associated with another user). Regular filesystem paths will not work in this case, as one user account cannot directly access another user account’s files, even on external storage.

**The Sources of Files**

Google's FileProvider offers automatic serving of files from a few root points:

- `getFilesDir()` (i.e., the standard portion of internal storage for your app)
- `getCacheDir()` (i.e., internal storage, but files that the OS can purge if needed to free up disk space)
- `Environment.getExternalStorageDirectory()` (i.e., the root of external storage)
- `getExternalFilesDir(null)` and `getExternalCacheDir()` (i.e., unique directories on external storage for your app)

For each of these, you will be able to specify a specific subdirectory’s worth of files that should be served, if you do not want the entire directory’s contents published via FileProvider. You will also be able to specify an alias, which serves as the first path segment (after the authority in the content:// Uri) — FileProvider maps that path segment to a specific location of files to serve.
The Manifest Entry

The information about what files to serve comes in the form of an XML resource file. You can name the file whatever you like, but its content needs to be a root <paths> element, with a series of children for the different directories you wish to serve. Those directories will be denoted via child elements with specific names:

- <files-path> for getFilesDir()
- <cache-path> for getCacheDir()
- <external-path> for Environment.getExternalStorageDirectory()
- <external-files-path> for getExternalFilesDir(null)
- <external-cache-path> for getExternalCachePath()

Note that the latter two require version 24.2.0 or higher of the support library, as they are fairly new.

For example, our sample project has a res/xml/provider_paths.xml file with the following contents:

```xml
<?xml version="1.0" encoding="utf-8"?>
<paths>
  <files-path name="stuff" />
</paths>
```

(from ContentProvider/V4FileProvider/app/src/main/res/xml/provider_paths.xml)

Here, we are saying that we want to serve the contents of getFilesDir(), using a virtual root path of stuff. With an authority of com.commonsware.android.cp.v4file, this means that a Uri of content://com.commonsware.android.cp.v4file/stuff/test.pdf would serve up a test.pdf file in the getFilesDir() directory.

The optional path attribute of the <files-path>, etc. elements indicates a particular subdirectory, relative to the element-specific root, that should be used as the source of files. So, for example, had the provider_paths.xml file looked like:

```xml
<?xml version="1.0" encoding="utf-8"?>
<paths xmlns:android="http://schemas.android.com/apk/res/android">
  <files-path name="stuff" path="help/" />
</paths>
```

...then content://com.commonsware.android.cp.v4file/stuff/test.pdf would map to help/test.pdf inside of getFilesDir().
You then point to this XML resource from a `<meta-data>` element in the `<provider>` element in the manifest, teaching FileProvider what to serve. For example, our `<provider>` element in this sample app is:

```
<provider
    android:name="LegacyCompatFileProvider"
    android:authorities="com.commonsware.android.cp.v4file"
    android:exported="false"
    android:grantUriPermissions="true">
    <meta-data
        android:name="android.support.FILE_PROVIDER_PATHS"
        android:resource="@xml/provider_paths"/>
</provider>
```

(from ContentProvider/V4FileProvider/app/src/main/AndroidManifest.xml)

Here, our `android:name` points to a LegacyCompatFileProvider class that we will examine shortly. We still provide the `android:authorities` value, along with any permission rules that we want. Beyond that, we have a `<meta-data>` element, with an `android:name` of `android.support.FILE_PROVIDER_PATHS`, that points to our XML resource with the path information.

You will also notice that our `android:exported` attribute is set to `false`. As it turns out, `FLAG_GRANT_READ_URI_PERMISSION` trumps the exported status of a provider. If you pass a `Uri` to an activity using `FLAG_GRANT_READ_URI_PERMISSION`, the activity will be able to read the contents of that `Uri`, even if the provider itself is not exported.

**The Legacy Compatibility**

LegacyCompatFileProvider is a simple subclass of FileProvider, one that overrides `query()` and wraps its `Cursor` in a LegacyCompatCursorWrapper to try to improve compatibility with ill-behaved clients:

```
package com.commonsware.android.cp.v4file;

import android.database.Cursor;
import android.net.Uri;
import android.support.v4.content.FileProvider;
import com.commonsware.cwac.provider.LegacyCompatCursorWrapper;

public class LegacyCompatFileProvider extends FileProvider {

    @Override
    public Cursor query(Uri uri, String[] projection, String selection, String[] selectionArgs, String sortOrder) {
        return new LegacyCompatCursorWrapper(super.query(uri, projection, selection, selectionArgs, sortOrder));
    }
}
```
The Usage

At this point, the provider is ready for use, insofar as we can specify Uri values like content://com.commonsware.android.cp.v4file/stuff/test.pdf and get results. Of course, we actually need to have files in our internal storage, and we need to use such a Uri.

Hence, our activity combines the unpack-the-file-from-assets logic from our own providers in earlier samples, plus starts up a PDF viewer on our designated test.pdf file:

```
package com.commonsware.android.cp.v4file;

import android.app.Activity;
import android.content.Intent;
import android.content.res.AssetManager;
import android.os.Bundle;
import android.support.v4.content.FileProvider;
import android.util.Log;
import java.io.File;
import java.io.FileInputStream;
import java.io.IOException;
import java.io.InputStream;

public class FilesCPDemo extends Activity {
    private static final String AUTHORITY = "com.commonsware.android.cp.v4file";

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        File f = new File(getFilesDir(), "test.pdf");

        if (!f.exists()) {
            AssetManager assets = getAssets();

            try {
                copy(assets.open("test.pdf"), f);
            } catch (IOException e) {
                Log.e("FileProvider", "Exception copying from assets", e);
            }
        }
    }
}
```
FILE PROVIDER OFFERS A HANDY GETURI FOR FILE() STATIC HELPER METHOD THAT WILL RETURN A URI FOR A GIVEN FILE, INCORPORATING OUR SPECIFIED CONTENT PROVIDER AUTHORITY.

THE RESULT OF RUNNING THIS ACTIVITY IS THE SAME AS THE OTHER FILE-SERVING PROVIDER SAMPLES FROM THIS CHAPTER: A PDF VIEWER (IF ONE IS AVAILABLE) WILL DISPLAY THE TEST.PDF FILE.

**StreamProvider**

FILE PROVIDER IS RATHER NICE: YOU CAN SERVE UP TYPICAL FILE-BASED CONTENT WITHOUT HAVING TO ROLL YOUR OWN IMPLEMENTATION OF CONTENT PROVIDER AND OPENFILE(). HOWEVER, IT ONLY SUPPORTS A FEW SOURCES OF DATA.

THE AUTHOR OF THIS BOOK HAS WRITTEN STREAM PROVIDER, A FORK OF FILE PROVIDER THAT ADDS SUPPORT FOR SERVING CONTENT FROM ASSETS AND RAW RESOURCES. PLUS, THROUGH SUBCLASING, YOU CAN READILY SERVE UP CONTENT FROM OTHER SOURCES AS WELL.
StreamProvider can be found in the CWAC-Provider project.

You can add this library to your Android Studio project much in the same way as you can other CWAC libraries: add the CWAC repository and request the dependency:

```java
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}
dependencies {
    implementation 'com.commonsware.cwac:provider:0.5.0'
}
```

Once you have added the CWAC-Provider dependency to your project, you use it much the same as you would use FileProvider:

- Define an XML metadata file with a `<paths>` root element, containing one or more elements describing what you want the provider to serve
- Add `com.commonsware.cwac.provider.StreamProvider` as a `<provider>` to your manifest, under your own `android:authority`, with a `<meta-data>` element (with a name of `com.commonsware.cwac.provider.STREAM_PROVIDER_PATHS`), pointing to that XML metadata

```xml
<provider
    android:name="com.commonsware.cwac.provider.StreamProvider"
    android:authorities="...
    android:exported="false"
    android:grantUriPermissions="true">
    <meta-data
        android:name="com.commonsware.cwac.provider.STREAM_PROVIDER_PATHS"
        android:resource="@xml/..."/>
    <meta-data
        android:name="com.commonsware.cwac.provider.USE_LEGACY_CURSOR_WRAPPER"
        android:value="true"/>
</provider>
```

- Consider adding the `USE_LEGACY_CURSOR_WRAPPER` `<meta-data>` element, shown in the above example, to automatically add in LegacyCompatCursorWrapper support, described elsewhere in this chapter
- Use `FLAG_GRANT_READ_URI_PERMISSION` and
FLAG_GRANT_WRITE_URI_PERMISSION in Intent objects you use to have third parties use the files the StreamProvider serves, to allow those apps selective, temporary access to the file.

Exporting and Usage Patterns

If your StreamProvider is exported, all of your streams will be considered read-only, regardless of any other configuration. Mostly, this mode is here for cases where you need a streaming provider and cannot grant Uri permissions (e.g., implementing a ChooserTargetService).

If your StreamProvider is not exported, and it has android:grantUriPermissions set, then you can control, on a per-Uri basis, which clients get access to your streams. This works identically to how FileProvider works. Whether a particular source of streams is read-only or read-write will depend on whether the stream is a file and your metadata configuration.

Wherever possible, elect to not export the provider and use FLAG_GRANT_READ_URI_PERMISSIONS or similar techniques to selectively grant access to your content.

Note that the exported-and-read-only rule is on a per-provider basis. If you have some content that needs to be published globally and others that are not:

• Use StreamProvider and one <provider> element for one set of content, with one authority and android:exported setting
• Subclass StreamProvider and have a separate <provider> element for the other set of content, with a separate authority and android:exported setting

Metadata Elements

Google's FileProvider supports:

• <files-path> for serving files from your app's getFilesDir()
• <external-path> for serving files from Environment.getExternalStorageDirectory()
• <cache-path> for serving files from your app's getCacheDir()
• <external-files-path> for serving files from getExternalFilesDir()
• <external-cache-path> for serving files from getExternalCacheDir()

Each of those take a name attribute, indicating the first path segment of the Uri that
should identify this particular source of files. For example, a name of foo would mean that `content://your.authority.here/foo/...` would look for a ... file in that particular element's source of files.

Each of those optionally take a path attribute, indicating a subdirectory under the element-defined root to use as the source of files, rather than the root itself. So, a `<files-path>` with a path="stuff" attribute would serve files from the stuff/ subdirectory within `getFilesDir()`. Note that path can point to a file as well, to limit access to a single file rather than a directory. Note that path is required for `<files-path>`, so you do not accidentally serve everything under `getFilesDir()`.

Also, each can optionally take a readOnly attribute. If this is set to true, then the files will be readable, but not writeable.

`<external-files-path>` also can take an optional dir attribute. If missing, the files are served from `getExternalFilesDir()`. If a valid value of dir is supplied, that value is passed into `getExternalFilesDir()`. As such, dir is limited to be one of the `Environment.DIRECTORY_*` constants:

- Alarms
- DCIM
- Documents
- Download
- Movies
- Music
- Notifications
- Pictures
- Podcasts
- Ringtones

However, you cannot have both `<external-files-path>` with no dir (indicating that you are serving from `getExternalFilesDir(null)`) and one or more `<external-files-path>` elements with dir values, as they will conflict.

StreamProvider adds support for:

- `<raw-resource>` for serving a particular raw resource, where the path is the name of the raw resource (without file extension)
- `<asset>` for serving files from assets/
- `<dir-path>`, for serving files from locations identified by `getDir()`
- `<external-public-path>`, for serving files from locations identified by
Hence, StreamProvider is especially useful when you want to package some content — such as a PDF file for online help — that you want to serve from your app. Just drop the file in assets/ in your project, set up StreamProvider to serve up assets, and use an appropriate Intent with startActivity() to view that file.

In the case of `<dir-path>`, two attributes are required:

- `dir`, which indicates what directory to serve (this is passed into `getDir()`)
- `path`, which serves its normal role, to determine what to serve from the directory identified by `dir`

In the case of `<external-public-path>`, `dir` is required. It needs to be the string value of one of the `Environment.DIRECTORY_*` constants, listed above.

**Assets and Gradle**

For files you are looking to share from your app's assets/, you will need to teach the build system to avoid compressing those files. While annoying, it helps StreamProvider be more compatible with various client apps.

To do this, add an `aaptOptions` closure to your `android` closure in your module's `build.gradle` file. For example, you might have:

```java
android {
    compileSdkVersion 25
    buildToolsVersion "25.0.0"

    aaptOptions {
        noCompress 'pdf', 'mp4', 'ogg'
    }
}
```

This would tell Gradle and the build system to not compress files ending in `pdf`, `mp4`, and `ogg`. For your own project, you would choose the file extensions of relevance for the content that you are looking to serve out of assets/.

**I Can Haz Uri?**

FileProvider has the static `getUriForFile()` convenience method, to build a `Uri` pointing to the FileProvider, given the File that you wish to serve.
StreamProvider has a similar `getUriForFile()` method, with three key differences:

1. It only takes the authority string and the File; no Context is necessary
2. It only works for files, not assets or raw resources
3. Rather than throwing an exception for an unrecognized File (the way FileProvider does), StreamProvider just returns null, indicating that the File you requested is not one that the StreamProvider is configured to serve

So, you can call `StreamProvider.getUriForFile(AUTHORITY, f)`, for some String for your AUTHORITY and some File (here named f) to get a Uri pointing to that file, for the purposes of using that Uri in an Intent, etc.

**Uri Prefixes**

Activities that support ACTION_SEND through an appropriate `<intent-filter>` are likely to have a flaw: they probably do not validate the Uri being supplied via EXTRA_STREAM. The "surreptitious sharing" attack takes advantage of this, tricking the app into sharing its own content. While the researchers who reported this flaw focused on file: Uri schemes, content: is also vulnerable, if your provider's Uri values are predictable.

To help defeat this attack, StreamProvider automatically adds a per-install UUID to each Uri. So, instead of:

```
content://your.authority.here/something/and/a/relative/path.xml
```

the Uri will be something like:

```
content://your.authority.here/9b80af30-4507-4f34-956a-3b47e4a7f27f/something/and/a/relative/path.xml
```

By using a UUID unique for this installation of your app, it makes your Uri values dependent upon the device. This makes it more difficult for attackers to hand you a valid Uri to your own content to send somewhere that you might not want.

On the flip side, this makes constructing your own Uri values a bit more difficult. For files, you can use the `getUriForFile()` method. For assets and raw resources, you can call the static `getUriPrefix()` method to get the prefix that is being used, and add that to your Uri, such as by using a Uri.Builder:
getUriPrefix() takes the authority string of your StreamProvider and returns the prefix... or null, if by subclassing StreamProvider, you disabled this prefix.

**Extending StreamProvider**

You are welcome to create subclasses of StreamProvider, to extend its capabilities for things that you may want to do in your app. For example, the instrumentation tests for StreamProvider demonstrate creating a subclass that supports serving database files, via a custom <database-path> element in the metadata.

By and large, you just create a subclass of StreamProvider and use it in your <provider> element. Of importance are the hooks in StreamProvider to allow subclasses to change critical behavior.

**Customizing the Uri Prefix**

In your subclass, you have three options for changing the Uri prefix used by StreamProvider:

- If you want a per-install value, but just not a UUID, override buildUriPrefix() and return your own generated String
- If you want a fixed prefix, to be used for all installs of this provider, override getUriPrefix() and return your constant
- If you do not want a prefix, override getUriPrefix() and return null

**Supporting Other Stream Locations**

You may have content located in directories other than what StreamProvider supports out of the box, such as the path for SQLite databases. To handle that, you can add support for new XML elements in the <paths> element (e.g., <database-path> for serving up databases).

To do this, in your StreamProvider subclass, override buildStrategy() and return a StreamStrategy implementation that is configured for your scenario. For files located in unusual spots, LocalPathStrategy should work.
In the library’s androidTest/ source set, you will find a DatabaseProvider that, at the time of this writing, looks like this:

```java
public class DatabaseProvider extends StreamProvider {
    private static final String TAG = "database-path";

    @Override
    protected StreamStrategy buildStrategy(Context context,
                                            String tag, String name,
                                            String path, boolean readOnly,
                                            HashMap<String, String> attrs)
            throws IOException {
        if (TAG.equals(tag)) {
            return new LocalPathStrategy(name,
                                           context.getDatabasePath(path));
        }
        return super.buildStrategy(context, tag, name, path, attrs);
    }
}
```

The parameters to buildStrategy() are:

- a Context, should you need one (though do not assume it is any particular sort of Context)
- the tag we encountered (e.g., database-path)
- the value of the name attribute, which all of these need to have, as that is how we determine which StreamStrategy handles this request
- the value of the path attribute, which can be null
- a HashMap of all attributes, in case you wish to have some custom ones

Either return your own StreamStrategy instance based off of this information or chain to the superclass’ implementation, so StreamProvider can handle the stock tags.

If your provider is intrinsically read-only (i.e., it is impossible to modify the content), you can ignore the readOnly flag. If, however, your content could be modified, and you support modification, please honor the readOnly flag and block modifications/deletions when that is set to true.

**Supporting Other Stream Strategies**

You may have content located in things that are not files, such as BLOB columns in a
database. In theory, you can create a custom StreamStrategy implementation that handles this. However, this has not been tried much, and so there are likely to be some gaps in the implementation.

That being said, you can examine the built-in strategies (e.g., AssetStrategy, LocalPathStrategy) and their superclasses (e.g., AbstractPipeStrategy) to see how to implement strategies.

**Adding Columns to `query()`**

You may wish to add other columns in response to a `query()` call, beyond the OpenableColumns that StreamProvider handles itself and the _DATA and MIME_TYPE columns added by LegacyCompatCursorWrapper.

To do that, override `getValueForQueryColumn()` in your StreamProvider subclass. This is supplied the Uri of the content and the name of the column requested by the client. You can return an Object suitable for stuffing into a MatrixCursor to send back – typically, this will be a String, int, or long.

**Totally Overhauling Uri Handling**

StreamProvider itself holds onto a CompositeStreamStrategy, delegating all operations to it. If you wish to extend CompositeStreamStrategy and do things differently, also override `buildCompositeStrategy()` on your StreamProvider subclass, to return the instance of the CompositeStreamStrategy that you want the StreamProvider to use.

**Overriding Standard Methods**

You can override standard ContentProvider methods (e.g., `getType()`) if needed.

Alternatively, you can override the methods on a StreamStrategy, then use that alternative StreamStrategy implementation in your `buildStrategy()` method.

**Adding Support for `insert()` and `update()`**

By default, none of the StreamStrategy implementations support `insert()` or `update()`. However, your custom StreamStrategy can, whether you are extending one of the stock strategy classes or are implementing your own from scratch.
First, override canInsert() and/or canUpdate(), returning true for those operations you do support. Then, you can override insert() and update(), which have the same method signatures on StreamStrategy as they do on ContentProvider. There, you can do what you wish.
A perpetual problem in Android app development is getting long-running work off of the main application thread. In modern times, we have lots of flexible solutions for this.

Another problem in Android app development is holding onto data across configuration changes. In modern times, we have lots of flexible solutions for this as well.

However, back in 2011, we did not have nearly as many options. To try to fill the gap, Android 3.0 introduced the Loader framework. A Loader is an abstraction around loading data and retaining it across configuration changes.

In truth, the Loader framework never became particularly popular. The one scenario where it is worth exploring is when you are trying to query a ContentProvider from an activity or fragment. That scenario is what we will focus on in this chapter.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- database access
- content provider theory
- content provider implementations

Introducing the Loader Framework

There are three major pieces to the Loader framework: LoaderManager,
LoaderCallbacks, and the Loader itself.

And, for historical reasons, there are two implementations of all three of these:

- one in the framework classes (e.g., android.app.LoaderManager)
- one in the Support Library (e.g., android.support.v4.app.LoaderManager)

As with the framework implementation of Fragment, the framework implementation of Loader and kin is deprecated as of Android 9.0. The expectation is that you are using FragmentActivity (or things that extend from it, like AppCompatActivity) and therefore can use the library implementation of Loader.

**LoaderManager**

LoaderManager is your gateway to the Loader framework. You obtain one by calling getSupportLoaderManager() on your FragmentActivity or Fragment. Via the LoaderManager you can initialize a Loader, restart that Loader (e.g., if you have a different query to use for loading the data), etc.

**LoaderCallbacks**

Much of your interaction with the Loader, though, comes from your LoaderCallbacks object, such as your activity if that is where you elect to implement the LoaderCallbacks interface. Here, you will implement three “lifecycle” methods for consuming a Loader:

1. onCreateLoader() is called when your activity requests that a LoaderManager initialize a Loader. Here, you will create the instance of the Loader itself, teaching it whatever it needs to know to go load your data
2. onLoadFinished() is called when the Loader has actually loaded the data — you can take those results and pour them into your UI, such as calling swapCursor() on a CursorAdapter to supply the fresh Cursor’s worth of data
3. onLoaderReset() is called when you should stop using the data supplied to you in the last onLoadFinished() call (e.g., the Cursor is going to be closed), so you can arrange to make that happen (e.g., call swapCursor(null) on a CursorAdapter)

When you implement the LoaderCallbacks interface, you will need to provide the data type of whatever it is that your Loader is loading (e.g., LoaderCallbacks<Cursor>). If you have several loaders returning different data types, you may wish to consider implementing LoaderCallbacks on multiple objects.
THE LOADER FRAMEWORK

(e.g., instances of anonymous inner classes), so you can take advantage of the type safety offered by Java generics, rather than implementing LoaderCallbacks<Object> or something to that effect.

Loader

Then, of course, there is Loader itself.

Consumers of the Loader framework will use some concrete implementation of the abstract Loader class in their LoaderCallbacks onCreateLoader() method.

However, there is only one concrete implementation: CursorLoader, designed to perform queries on a ContentProvider, and described in a later section.

In theory, the Loader framework was designed to “load” arbitrary stuff, and while some projects have done that, it is not a particularly popular technique.

Using CursorLoader

Let’s start off by examining the simplest case: using a CursorLoader to asynchronously populate and update a Cursor retrieved from a ContentProvider. This is illustrated in the Loaders/LoaderRV sample project, which is the same basic show-the-list-of-gravity-constants sample application that we examined previously, updated to use the Loader framework.

In onViewCreated() of our ConstantsFragment, we ask our LoaderManager to initialize a loader:

```java
@Override
public void onViewCreated(View v, Bundle savedInstanceState) {
    super.onViewCreated(v, savedInstanceState);

    RecyclerView rv = v.findViewById(android.R.id.list);

    rv.setLayoutManager(new LinearLayoutManager(getActivity()));
    rv.addItemDecoration(new DividerItemDecoration(getActivity(), DividerItemDecoration.VERTICAL));
    rv.setAdapter(adapter);

    getActivity().getSupportLoaderManager().initLoader(0, null, this);
}
```

(from Loaders/LoaderRV/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java)
The initLoader() call on LoaderManager (retrieved via getLoaderManager()) takes three parameters:

- A locally-unique identifier for this loader
- An optional Bundle of data to supply to the loader
- A LoaderCallbacks implementation to use for the results from this loader (here set to be the ConstantsFragment itself, as it implements the LoaderManager.LoaderCallbacks<Cursor> interface)

Shortly thereafter, your onCreateLoader() method of the LoaderCallbacks will be called. Here, you need to initialize the Loader to use for this identifier. You are passed the identifier plus the Bundle (if any was supplied). In our case, we want to use a CursorLoader:

```java
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return new CursorLoader(getActivity(), Provider.Constants.CONTENT_URI,
        PROJECTION, null, null, null);
}
```

CursorLoader takes a Context plus all of the parameters you would ordinarily use with query() on a ContentResolver, such as the provider Uri.

At this point, the CursorLoader will query the provider, but do so on a background thread, so the main application thread is not tied up. When the Cursor has been retrieved, it is supplied to your onLoadFinished() method of your LoaderCallbacks:

```java
public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {
    adapter.changeCursor(cursor);
}
```

We are using a RecyclerView.Adapter named RVCursorAdapter as before, and we call its changeCursor() method to supply it the Cursor to use to populate the RecyclerView that is the UI of the fragment.

Your onLoadFinished() method will also be called whenever the data represented by your Uri changes. That is because the CursorLoader is registering a ContentObserver, so it will find out about data changes and will automatically query the Cursor and supply you with the updated data.
Eventually, `onLoaderReset()` will be called. You are passed a `Cursor` object that you were supplied previously in `onLoadFinished()`. You need to make sure that you are no longer using that `Cursor` at this point — in our case, we swap `null` back into our `RVCursorAdapter`:

```java
public void onLoaderReset(Loader<Cursor> loader) {
    adapter.changeCursor(null);
}
```

(from Loaders/LoaderRV/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java)

And that’s pretty much it, at least for using `CursorLoader`. Of course, you need a content provider to make this work, and creating a content provider involves a bit of work.

**What Else Is Missing?**

The `Loader` framework does an excellent job of handling queries in the background. What it does not do is help us with anything else that is supposed to be in the background, such as inserts, updates, deletes, or creating/upgrading the database. It is all too easy to put those on the main application thread and therefore possibly encounter issues. Moreover, since the thread(s) used by the `Loader` framework are an implementation detail, we cannot use those threads ourselves necessarily for the other CRUD operations.

**What Happens When…?**

Here are some common development scenarios and how the `Loader` framework addresses them.

**… the Data Behind the Loader Changes?**

According to the `Loader documentation`, “They monitor the source of their data and deliver new results when the content changes”.

The documentation is incorrect.

A `Loader` can “monitor the source of their data and deliver new results when the content changes”. There is nothing in the framework that requires this behavior. Moreover, there are some cases where it is clearly a bad idea to do this — imagine a `Loader` loading data off of the Internet, needing to constantly poll some server to
look for changes.

The documentation for a Loader implementation should tell you the rules. Android’s built-in CursorLoader does deliver new results, by means of a behind-the-scenes ContentObserver. However, it is not automatic that a Loader deliver new results, and it may be impractical for a Loader to deliver new results.

... the Configuration Changes?

Your Loader objects are retained across the configuration change automatically. Barring bugs in a specific Loader implementation, your Loader should then hand the new activity instance the data that was retrieved on behalf of the old activity instance (e.g., the Cursor).

Hence, you do not have to do anything special for configuration changes.

... the Activity is Destroyed?

The Loader framework triggers a reset of the Loader when the activity is destroyed, which obligates the Loader to release any loaded data.

Writing a Custom Loader

Perhaps, despite the above issues, and despite the author’s assertion that the Loader framework is a failed abstraction, you want to implement a custom Loader.

You have two main choices for doing that:

- If the API that you are using is intrinsically asynchronous, you can extend Loader
- If the API that you are using is synchronous, most likely you should extend AsyncTaskLoader, which manages an AsyncTask for you, giving you a background thread for loading the content

If your API can work either way — synchronously or asynchronously – either option works. In terms of getting the Loader implementation right, you may want to use AsyncTaskLoader, as it will ensure that everything is delivered on the right thread. On the other hand, you may have greater control over the nature of the asynchronous work using the API’s native asynchronous capability, such as configuring a thread pool.
The HTTP/RetroLoader sample project is a clone of the HTTP/Retrofit sample app from the chapter on Internet access. However, this time, the Retrofit work to load the most recent android Stack Overflow questions will be mediated by a QuestionsLoader.

**Changing the Retrofit Interface**

Retrofit offers both synchronous and asynchronous APIs. For the purposes of this sample, we will use the synchronous API, to see how one might implement an AsyncTaskLoader. That, in turn, requires us to modify StackOverflowInterface, having questions() return the SOQuestions directly, rather than by using a callback:

```java
package com.commonsware.android.retrofit;

import retrofit2.Call;
import retrofit2.http.GET;
import retrofit2.http.Query;

public interface StackOverflowInterface {
    @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
    Call<SOQuestions> questions(@Query("tagged") String tags);
}
```

(from HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/StackOverflowInterface.java)

Otherwise, this is unchanged from the original edition of this sample.

**Implementing QuestionsLoader**

QuestionsLoader is an implementation of AsyncTaskLoader. The documentation for Loader and AsyncTaskLoader leave a lot to be desired. QuestionsLoader is based on “triangulation” between the installed-applications loader included in the AsyncTaskLoader documentation and the source code to CursorLoader.

Loader uses Java generics. Its declaration requires the type of content being loaded by the Loader. So, QuestionsFragment is a Loader of SOQuestions:

```java
public class QuestionsLoader extends AsyncTaskLoader<SOQuestions> {
    ...
}
```

(from HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java)
The Constructor

A Loader needs to have a constructor that takes a Context as a parameter. So, QuestionsLoader has one, that chains to the superclass constructor, plus sets up the StackOverflowInterface using Retrofit:

```java
public QuestionsLoader(Context context) {
    super(context);

    Retrofit retrofit =
        new Retrofit.Builder()
            .baseUrl("https://api.stackexchange.com")
            .addConverterFactory(GsonConverterFactory.create())
            .build();
    so = retrofit.create(StackOverflowInterface.class);
}
```

Loading the Questions

The real work for loading the questions comes in loadInBackground(). Subclasses of AsyncTaskLoader need to implement this to return the content being loaded. As the name suggests, loadInBackground() is called on a background thread, so you can take time here.

The key piece of the loadInBackground() of QuestionsFragment is the call to questions() on the StackOverflowInterface, to retrieve the desired questions:

```java
@Override
synchronized public SOQuestions loadInBackground() {
    if (isLoadInBackgroundCanceled()) {
        throw new OperationCanceledException();
    }

    try {
        return so.questions("android").execute().body();
    } catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception loading questions", e);
        throw new OperationCanceledException();
    }
}
```
However, it is possible that before loadInBackground() is called, that something cancels the AsyncTask in the AsyncTaskLoader. A subclass of AsyncTaskLoader needs to check isLoadInBackgroundCanceled() in loadInBackground(), and throw an OperationCanceledException if isLoadInBackgroundCanceled() returns true.

Delivering Results

Not only do subclasses of AsyncTaskLoader have to load the content, they also have to cache the results of the previous load. So, QuestionsLoader has a lastResult field, holding onto an SOQuestions object.

In deliverResult(), we need to do three things:

1. If isReset() returns true, indicating that the Loader was reset, we need to clean up anything associated with the previous load results
2. We need to cache the new load results, which are passed into deliverResult() as a parameter
3. If the loader is started (isStarted() returns true), we need to chain to the superclass implementation of deliverResult() to actually deliver the data to the LoaderCallbacks implementation:

```java
@Override
public void deliverResult(SOQuestions data) {
    if (isReset()) {
        // actual cleanup, if any
    }

    lastResult=data;

    if (isStarted()) {
        super.deliverResult(data);
    }
}
```

(from HTTP/Retrofit/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java)

Here, lastResult is just a POJO holding onto other POJOs, so there is nothing specific for us to do in case the loader was reset. If our results were a Cursor, a Bitmap, or other objects with clear “close” or “release” semantics, you might do that work if onReset() returned true.
Starting, Stopping, and Resetting

You also need to implement three additional methods.

First is `onStartLoading()`. Here is where we use the cached result, delivering it via `deliverResults()`. If we do not have a cached result, we need to call `forceLoad()` to trigger the `AsyncTask` which, in turn, triggers `loadInBackground()` and the rest of the work to actually retrieve the results:

```java
@Override
protected void onStartLoading() {
    super.onStartLoading();

    if (lastResult!=null) {
        deliverResult(lastResult);
    } else {
        forceLoad();
    }
}
```

(from HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java)

There is a corresponding `onStopLoading()`, where we need to call `cancelLoad()`, to cancel the `AsyncTask`:

```java
@Override
protected void onStopLoading() {
    super.onStopLoading();

    cancelLoad();
}
```

(from HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsLoader.java)

Finally, there is `onReset()`, where we need to call `onStopLoading()` (as loading should stop if the Loader is reset), plus do any cleanup of our cached results as needed:

```java
@Override
protected void onReset() {
    super.onReset();

    onStopLoading();
    // plus any actual cleanup
}
```
Using QuestionsLoader

You might think that with 70-odd lines of QuestionsLoader code that we would have a corresponding savings in QuestionsFragment.

Alas, no, though it is a bit shorter.

QuestionsFragment now implements LoaderCallbacks instead of Retrofit's Callback interface:

```java
public class QuestionsFragment extends ListFragment implements LoaderManager.LoaderCallbacks<SOQuestions> {
  ...
}
```

In the original QuestionsFragment, we fired off the asynchronous Retrofit work in `onCreateView()`, and we processed the results in the `success()` and `failure()` methods.

Now, we just need to call `initLoader()`, in this case from `onViewCreated()`:

```java
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
  super.onViewCreated(view, savedInstanceState);

  getLoaderManager().initLoader(0, null, this);
}
```

Then, our LoaderCallbacks methods create the QuestionsLoader and apply the results:

```java
@Override
public Loader<SOQuestions> onCreateLoader(int id, Bundle args) {
  return new QuestionsLoader(getActivity());
}

@Override
public void onLoadFinished(Loader<SOQuestions> loader, SOQuestions data) {
  setListAdapter(new ItemsAdapter(data.items));
}
```
THE LOADER FRAMEWORK

@Override
public void onLoaderReset(Loader<SOQuestions> loader) {
    setListAdapter(null);
}

(from HTTP/RetroLoader/app/src/main/java/com/commonsware/android/retrofit/QuestionsFragment.java)

Considering the Loader Contract

As noted earlier in this chapter, there are three key pieces of the Loader contract: asynchronicity, data retention, and automatic delivery of updates on content changes.

So, how does QuestionsLoader stack up?

- AsyncTaskLoader provides the asynchronous operation for us, so we inherit that
- All loaders are automatically retained by the LoaderManager, so there is nothing specific that we need to do for that
- However, we are unaware of any changes in our content, such as new questions being asked, so we are not delivering updated content to clients of the QuestionsLoader

This is a common gap with loader implementations. Occasionally, we may be in position to find out when the content changes. More often, we are not, or the work to find out about content changes has to be handled by a much larger subsystem, beyond a simple Loader subclass.

For example, if we really wanted to have QuestionsLoader automatically deliver a fresh SOQuestions object when new Stack Overflow android questions were asked, we could: use some sort of timing mechanism (e.g., ScheduledExecutorService) to poll the Stack Exchange API every so often. However, then we would need to implement some sort of “diff” algorithm to determine if relevant data changed in the JSON response, so we knew to deliver a fresh SOQuestions to clients. However, our polling period would be somewhat arbitrary. Frequent polling would consume a fair amount of battery and bandwidth as well.
The ContactsContract and CallLog Providers

One of the more popular stores of data on your average Android device is the contact list. Ever since Android 2.0, Android tracks contacts across multiple different “accounts”, or sources of contacts. Some may come from your Google account, while others might come from Exchange or other services.

This chapter will walk you through some of the basics for accessing the contacts on the device. Along the way, we will revisit and expand upon our knowledge of using a ContentProvider.

First, we will review the contacts APIs, past and present. We will then demonstrate how you can connect to the contacts engine to let users pick and view contacts... all without your application needing to know much of how contacts work. We will then show how you can query the contacts provider to obtain contacts and some of their details, like email addresses and phone numbers. We wrap by showing how you can invoke a built-in activity to let the user add a new contact, possibly including some data supplied by your application.

In addition, we will take a peek at the CallLog provider, which, as the name suggests, gives you access to a log of calls made on the device.

Prerequisites

Understanding this chapter requires that you have read these chapters in addition to the core chapters:

- content provider theory
Introducing You to Your Contacts

Android makes contacts available to you via a complex ContentProvider framework, so you can access many facets of a contact’s data — not just their name, but addresses, phone numbers, groups, etc. Working with the contacts ContentProvider set is simple… only if you have an established pattern to work with. Otherwise, it may prove somewhat daunting.

Organizational Structure

The contacts ContentProvider framework can be found as the set of ContactsContract classes and interfaces in the android.provider package. Unfortunately, there is a dizzying array of inner classes to ContactsContract.

Contacts can be broken down into two types: raw and aggregate. Raw contacts come from a sync provider or are hand-entered by a user. Aggregate contacts represent the sum of information about an individual culled from various raw contacts. For example, if your Exchange sync provider has a contact with an email address of jdoe@foo.com, and your Facebook sync provider has a contact with an email address of jdoe@foo.com, Android may recognize that those two raw contacts represent the same person and therefore combine those in the aggregate contact for the user. The classes relating to raw contacts usually have Raw somewhere in their name, and these normally would be used only by custom sync providers.

The ContactsContract.Contacts and ContactsContract.Data classes represent the “entry points” for the ContentProvider, allowing you to query and obtain information on a wide range of different pieces of information. What is retrievable from these can be found in the various ContactsContract.CommonDataKinds series of classes. We will see examples of these operations later in this chapter.

A Look Back at Android 1.6

Prior to Android 2.0, Android had no contact synchronization built in. As a result, all contacts were in one large pool, whether they were hand-entered by users or were added via third-party applications. The API used for this is the Contacts ContentProvider.
The Contacts ContentProvider still works, as it is merely deprecated in Android 2.0.1, not removed. In practice, it has one big limitation: it will only report contacts added directly to the device (as opposed to ones synchronized from Microsoft Exchange, Facebook, or other sources). As a result, modern Android apps should not be using Contacts in general — use ContactsContract.

Pick a Peck of Pickled People

Back in the chapter on resource sets and configurations, we saw a series of examples of handling configuration changes. Those samples allowed the user to pick a contact and view a contact. There, we focused on the configuration change aspect. Here, let’s examine the actual pick and view logic a bit more closely.

Picking a Contact

When the user picks a contact, we call startActivityForResult() with an ACTION_PICK Intent:

```java
public void pickContact(View v) {
    Intent i = new Intent(Intent.ACTION_PICK,
                           ContactsContract.Contacts.CONTENT_URI);

    startActivityForResult(i, PICK_REQUEST);
}
```

The Intent has ContactsContract.Contacts.CONTENT_URI as its Uri. Here, ContactsContract.Contacts.CONTENT_URI is defined by the Android SDK and points to the contacts “table” inside the ContactsContract “database”, as it were. Whether there is really a database or a table involved is up to the implementation of ContactsContract, of course.

When we call startActivityForResult(), Android needs to find an activity to fulfill this request. However, at the outset, all it has is an action string and a Uri. There could be all sorts of activities on the device that advertise that they can pick from a collection identified by a Uri starting with the content scheme.

To help refine the request, Android asks the ContactsContract ContentProvider what the MIME type is for this Uri. Then, Android knows an action string, a MIME type, and a Uri. It so happens that the contacts apps that ship on Android have an
THE CONTACTS CONTRACT AND CALLLOG PROVIDERS

activity that has an <intent-filter> that indicates that it can handle ACTION_PICK of the relevant MIME type from a content Uri. And so that is the activity that the user sees.

The Uri that we get back in onActivityResult() not only points to the contact that the user picked, but also gives us temporary read access to that contact's personally identifying information. In effect, it is as if the normal READ_CONTACTS permission requirement was suspended, for this one Uri, for our app alone. Once our process terminates, we may no longer have the ability to get at details about that contact via its Uri, as this read access is temporary.

Viewing a Contact

As it turns out, the sample app does not take advantage of the temporary read access. Instead, when the user clicks the “View” button, the app just brings up an activity to go view that contact:

```java
public void viewContact(View v) {
    startActivity(new Intent(Intent.ACTION_VIEW, contact));
}
```

(from ConfigChange/Fragments/app/src/main/java/com/commonsware/android/rotation/frag/RotationFragment.java)

Once again, Android has an action string (ACTION_VIEW) and a Uri (the one that we got in response to the ACTION_PICK request). And, once again, Android asks ContactsContract for the MIME type of the data associated with this Uri, so that the MIME type can help identify the right activity to handle this request. The contacts app that comes on the device should have an activity that complies, and so we can view the contact.

In truth, the only reason why we as developers can count on these activities existing is because of Google Play Services and the Play Store. The Compatibility Definition Document (CDD) that manufacturers must comply with to get Google’s proprietary Android apps requires that the device ship with apps that fulfill all of the <intent-filter> elements supported by the apps in the Android Open Source Project (AOSP). Hence, for devices that legitimately have the Play Store on them, there should always be an app that offers activities to allow users to pick and view contacts. However, on devices that do not legitimately have the Play Store, those activities might not exist. Manufacturers who avoid Google's proprietary apps should still aim to comply with the CDD as much as possible, if they want third-party apps like yours to work successfully on those devices. However, there is no contractual requirement that they do, and so, as the saying goes, your mileage may vary
Spin Through Your Contacts

The preceding example allows you to work with contacts, yet not actually have any contact data other than a transient Uri. All else being equal, it is best to use the contacts system this way, as it means you do not need any extra permissions that might raise privacy issues.

Of course, all else is rarely equal.

Your alternative, therefore, is to execute queries against the contacts ContentProvider to get actual contact detail data back, such as names, phone numbers, and email addresses. The Contacts/Spinners sample application will demonstrate this technique.

Contact Permissions

Since contacts are privileged data, you need certain permissions to work with them. Specifically, you need the READ_CONTACTS permission to query and examine the ContactsContract content and WRITE_CONTACTS to add, modify, or remove contacts from the system. This only holds true if your code will have access to personally-identifying information, which is why the Pick sample above — which just has an opaque Uri — does not need any permission.

For example, here is the manifest for the Contacts/Spinners sample application:

```xml
<?xml version="1.0" encoding="utf-8"?>
<manifest
    package="com.commonsware.android.contacts.spinners"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-permission
        android:name="android.permission.READ_CONTACTS" />

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@style/Theme.Apptheme">

        <activity
            android:name=".ContactSpinners"
            android:label="@string/app_name">
        </activity>
    </application>
</manifest>
```
And, since this app has a targetSdkVersion of 26, we also need to deal with runtime permissions, as READ_CONTACTS has a protectionLevel of dangerous, so we need to ask the user for permission at runtime. To that end, we use the same AbstractPermissionActivity seen elsewhere in the book as the base class for our ContactSpinners activity, so we can delegate all of the runtime permission logic to AbstractPermissionActivity.

Pre-Joined Data

While the database underlying the ContactsContract content provider is private, one can imagine that it has several tables: one for people, one for their phone numbers, one for their email addresses, etc. These are tied together by typical database relations, most likely 1:N, so the phone number and email address tables would have a foreign key pointing back to the table containing information about people.

To simplify accessing all of this through the content provider interface, Android pre-joins queries against some of the tables. For example, you can query for phone numbers and get the contact name and other data along with the number — you do not have to do this join operation yourself.

The UI

The ContactSpinners activity has a RecyclerView along with a Spinner:
**The ContactsContract and CallLog Providers**

In `onReady()` of the activity, we load up the Spinner, plus configure the RecyclerView:

```java
@Override
public void onReady() {
    setContentView(R.layout.main);

    Spinner spin = findViewById(R.id.spinner);
    spin.setOnItemSelectedListener(this);

    ArrayAdapter<String> aa = new ArrayAdapter<String>(this,
        android.R.layout.simple_spinner_item,
        getResources().getStringArray(R.array.options));

    aa.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
    spin.setAdapter(aa);

    RecyclerView rv = findViewById(android.R.id.list);

    rv.setLayoutManager(new LinearLayoutManager(this));
    rv.addItemDecoration(new DividerItemDecoration(this,
        DividerItemDecoration.VERTICAL));
    adapter = new RVCursorAdapter(getLayoutInflater());
    rv.setAdapter(adapter);
}
```

In particular, we populate the Spinner based on a `<string-array>` resource from the `res/values/arrays.xml` file:

```xml
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <string-array name="options">
```

2593
The ContactsContract and CallLog Providers

<table>
<thead>
<tr>
<th>Contact Names</th>
<th>Contact Names &amp; Numbers</th>
<th>Contact Names &amp; Email Addresses</th>
</tr>
</thead>
</table>

Reacting to the Spinner

We set up the activity to be the OnItemSelectedListener for the Spinner, which means that we have to implement onItemSelected() and onNothingSelected():

```java
@Override
public void onItemSelected(AdapterView<?> parent, View v, int position, long id) {
    getSupportLoaderManager().initLoader(position, null, this);
}
```

@Override
public void onNothingSelected(AdapterView<?> parent) {
    // ignore
}
```

When the user selects something in the Spinner — and for the default selection — we will use the Loader framework and use a CursorLoader to query the ContactsContract ContentProvider. In this case, though, we want three different Cursor values, one for each option in the Spinner. That will mean that we need three different CursorLoader objects. To identify which loader we are going to initialize, we pass in the position of the Spinner to initLoader(), so the 0/1/2 value that we get as the position forms our loader ID.

Loading the Data

In onCreateLoader() of our LoaderCallbacks, we need to return a CursorLoader for whichever loaderId was passed in. What varies is the Uri that we want to query and the “projection” of “columns” that we want to get back. So, onCreateLoader() uses a switch statement to decide what Uri and projection to use, then creates a CursorLoader based upon that:

```java
@Override
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
```
The two case values are just constants tied to the positions from the Spinner, defined as static data members:

```java
private static final int LOADER_NAMES = 0;
private static final int LOADER_NAMES_NUMBERS = 1;
```

Similarly, the three projections are defined as static data members:

```java
private static final String[] PROJECTION_NAMES = new String[]{
    ContactsContract.Contacts._ID,
    ContactsContract.Contacts.DISPLAY_NAME,
};
private static final String[] PROJECTION_NUMBERS = new String[]{
    ContactsContract.Contacts._ID,
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Phone.NUMBER
};
private static final String[] PROJECTION_EMAILS = new String[]{
    ContactsContract.Contacts._ID,
```
For the “names” Spinner entry, we are going to retrieve the ID and display name of the contact, using the standard ContactsContract.Contacts.CONTENT_URI Uri value.

For the “names and phone numbers” Spinner entry, we still want the display name of the contact, but we also want phone numbers. Fortunately, as mentioned earlier, ContactsContract denormalizes its data in response to queries, so we can get the display name of the contact even when we are querying the “table” of phone numbers, via ContactsContract.CommonDataKinds.Phone.CONTENT_URI. The same basic process holds true for the “names and emails” entry, where we query ContactsContract.CommonDataKinds.Email.CONTENT_URI. Note that we will get somewhat redundant information back — if a contact has two phone numbers, we get two rows in our Cursor, both for the same contact, and one per phone number.

We can sort by DISPLAY_NAME for all three cases, courtesy of the aforementioned denormalization of the data.

Showing the Results

We also have to implement onLoadFinished(), to take in the Cursor that is the result of the query against ContactsContract and put the results in the RecyclerView. Once again, the rendering will differ a bit based upon whether we are showing just names or names along with other data (e.g., phone numbers). So, we have another switch statement, where we determine what columns we want, what layout ID to use, and what roster of widgets in that layout map to those columns:

```java
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    String[] columns = null;

    switch (loader.getId()) {
    case LOADER_NAMES:
        columns=COLUMNS_NAMES;
        break;

    case LOADER_NAMES_NUMBERS:
        columns=COLUMNS_NUMBERS;
```
The lists of columns and views are defined as static data members and map positionally (i.e., the first view is for the first column):

```java
private static final String[] COLUMNS_NAMES = new String[]{
    ContactsContract.Contacts.DISPLAY_NAME
};
private static final String[] COLUMNS_NUMBERS = new String[]{
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Phone.NUMBER
};
private static final String[] COLUMNS_EMAILS = new String[]{
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Email.DATA
};
```

Then, we update a RecyclerView.Adapter, named RVCursorAdapter, with the fresh Cursor and column list. That adapter, along with a RecyclerView.ViewHolder implementation named RowHolder, populate a framework-supplied simple_list_item_2 widget with the 1 or 2 columns that we want from the Cursor:

```java
private static class RVCursorAdapter extends RecyclerView.Adapter<RowHolder> {
    private Cursor cursor;
    private final LayoutInflater inflater;
    private String[] columns;
    
    private RVCursorAdapter(LayoutInflater inflater) {
        this.inflater = inflater;
    }

    @NonNull
    @Override
    public RowHolder onCreateViewHolder(@NonNull ViewGroup parent, int viewType) {
        View row = inflater.inflate(android.R.layout.simple_list_item_2, parent, false);
        return new RowHolder(row);
    }
    
    @Override
    public void onBindViewHolder(RowHolder holder, int position) {
        holder.setData(cursor, position, columns);
    }
    
    @Override
    public int getItemCount() {
        return cursor.getCount();
    }

    private static class RowHolder extends RecyclerView.ViewHolder {
        private TextView tv;
        private TextView tv2;
        
        private RowHolder(View itemView) {
            super(itemView);
            tv = itemView.findViewById(android.R.id.text1);
            tv2 = itemView.findViewById(android.R.id.text2);
        }
        
        public void setData(Cursor c, int position, String[] columns) {
            tv.setText(c.getString(position, columns[0]));
            tv2.setText(c.getString(position, columns[1]));
        }
    }
}
```
return new RowHolder(row);
}

@Override
public void onBindViewHolder(@NonNull RowHolder holder,
    int position) {
    cursor.moveToPosition(position);
    holder.bind(cursor, columns);
}

@Override
public int getItemCount() {
    return cursor==null ? 0 : cursor.getCount();
}

private void changeCursor(Cursor cursor, String[] columns) {
    if (this.cursor!=null) {
        this.cursor.close();
    }
    this.cursor=cursor;
    this.columns=columns;
    notifyDataSetChanged();
}

private void clearCursor() {
    cursor=null;
    notifyDataSetChanged();
}

private static class RowHolder extends RecyclerView.ViewHolder {
    private final TextView text1;
    private final TextView text2;

    RowHolder(View itemView) {
        super(itemView);
        text1=itemView.findViewById(android.R.id.text1);
        text2=itemView.findViewById(android.R.id.text2);
    }

    public void bind(Cursor cursor, String[] columns) {
        int index=cursor.getColumnIndex(columns[0]);
        text1.setText(cursor.getString(index));

        if (columns.length==2) {
            index=cursor.getColumnIndex(columns[1]);
            text2.setText(cursor.getString(index));
        }
    }
}

(from Contacts/Spinners/app/src/main/java/com/commonsware/android/contacts/spinners/ContactSpinners.java)
Makin’ Contacts

Let’s now take a peek at the reverse direction: adding contacts to the system. This was never particularly easy and now is... well, different.

First, we need to distinguish between sync providers and other apps. Sync providers are the guts underpinning the accounts system in Android, bridging some existing source of contact data to the Android device. Hence, you can have sync providers for Exchange, Facebook, and so forth. These will need to create raw contacts for newly-added contacts to their backing stores that are being sync’d to the device for the first time. Creating sync providers is outside of the scope of this book for now.

It is possible for other applications to create contacts. These, by definition, will be phone-only contacts, lacking any associated account, no different than if the user added the contact directly. The recommended approach to doing this is to collect the data you want, then spawn an activity to let the user add the contact — this avoids your application needing the WRITE_CONTACTS permission and all the privacy/data integrity issues that creates.

To that end, take a look at the Contacts/Inserter sample project. It defines a simple activity with a two-field UI, with one field apiece for the person’s first name and phone number:

```xml
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
android:orientation="vertical"
android:layout_width="match_parent"
android:layout_height="match_parent"
android:stretchColumns="1">
  <TableRow>
    <TextView android:text="First name:"
/>  
    <EditText android:id="@+id/name"
/>  
  </TableRow>
  <TableRow>
    <TextView android:text="Phone:"
/>  
    <EditText android:id="@+id/phone"
android:inputType="phone"
/>  
  </TableRow>
</TableLayout>
```
The trivial UI also sports a button to add the contact:

![ContactInserter sample application](image)

When the user clicks the button, the activity gets the data and creates an Intent to be used to launch the add-a-contact activity. This uses the `ACTION_INSERT_OR_EDIT` action and a couple of extras from the `ContactsContract.Intents.Insert` class:

```java
package com.commonsware.android.inserter;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.provider.ContactsContract.Contacts;
import android.provider.ContactsContract.Intents.Insert;
import android.view.View;
import android.widget.Button;
import android.widget.EditText;
```
public class ContactsInserter extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        Button btn=(Button)findViewById(R.id.insert);

        btn.setOnClickListener(onInsert);
    }

    View.OnClickListener onInsert=new View.OnClickListener() {
        public void onClick(View v) {
            EditText fld=(EditText)findViewById(R.id.name);
            String name=fld.getText().toString();

            fld=(EditText)findViewById(R.id.phone);

            String phone=fld.getText().toString();
            Intent i=new Intent(Intent.ACTION_INSERT_OR_EDIT);
            i.setType(Contacts.CONTENT_ITEM_TYPE);
            i.putExtra(Insert.NAME, name);
            i.putExtra(InsertPHONE, phone);
            startActivity(i);
        }
    };
}

(from Contacts/Inserter/app/src/main/java/com/commonsware/android/inserter/ContactsInserter.java)
We also need to set the MIME type on the Intent via `setType()`, to be `CONTENT_ITEM_TYPE`, so Android knows what sort of data we want to actually insert. Then, we call `startActivity()` on the resulting Intent. That brings up an add-or-edit activity:

![Image of contacts add-or-edit activity]

*Figure 749: The add-or-edit-a-contact activity*
... where if the user chooses “Create new contact”, they are taken to the ordinary add-a-contact activity, with our data pre-filled in:

![The edit-contact form, showing the data from the ContactInserter activity](image)

Note that the user could choose an existing contact, rather than creating a new contact. If they choose an existing contact, the first name of that contact will be overwritten with the data supplied by the ContactsInserter activity, and a new phone number will be added from those Intent extras.

**Looking at the CallLog**

A closely-related ContentProvider to ContactsContract is CallLog. As the name suggests, it contains a log of calls for this device, including things like the date/time of the call, the call duration, and the other party on the call (e.g., a phone number).

If you wish to give the user another look at their calls, independent from the UI available on the device (e.g., Dialer app), you might wish to query the CallLog, as we do in the [Contacts/CallLog](#) sample application
Pondering Permissions

In the beginning, there was no READ_CALL_LOG permission. To read the CallLog provider, you needed to hold READ_CONTACTS. The reason for the READ_CONTACTS permission is that the CallLog denormalizes the data, copying into its own table contact data about the other party, so that the CallLog can remain independent of ContactsContract.

In API Level 16, though, they added the READ_CALL_LOG permission. If your minSdkVersion is 16 or higher, you can just request READ_CALL_LOG. If your minSdkVersion is lower than that, though, you will want to request both permissions, to make sure that you are covered. You might consider using the android:maxSdkVersion attribute on the READ_CONTACTS <uses-permission> element, as you will not need it on newer devices, unless you are also working with ContactContract.

Both READ_CALL_LOG and READ_CONTACTS are dangerous permissions, and therefore if your targetSdkVersion is 23 or higher, you need to request those permissions at runtime. Of course, you only need to request the permissions that you need, and so if your minSdkVersion is 16 or higher and you are only using READ_CALL_LOG, you only need to request READ_CALL_LOG at runtime.

Our sample app uses the same AbstractPermissionActivity as did the first sample app in this chapter, though this time our CallLogConsumerActivity will request READ_CALL_LOG instead of READ_CONTACTS.

Contents of CallLog.Calls

The sample app requests the READ_CALL_LOG permission, so it can query the CallLog:

```xml
<uses-permission android:name="android.permission.READ_CALL_LOG" />
```

(from Contacts/CallLog/app/src/main/AndroidManifest.xml)

To request this permission when our app launches, this project uses the same AbstractPermissionActivity seen elsewhere in the book and profiled in the chapter on permissions. That logic gives us control in an onReady() method in our CallLogConsumerActivity when we can start setting up the UI and requesting the call log data.
THE CONTACTS CONTRACT AND CALL LOG PROVIDERS

In `onReady()` — among other bits of work that we will explore shortly — we call `initLoader()`, to query the CallLog via a `CursorLoader`. The activity itself implements the `LoaderManager.LoaderCallbacks` interface needed by `initLoader()`, and so the activity has the three required `LoaderCallbacks` methods:

```java
@Override
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return new CursorLoader(this, CallLog.Calls.CONTENT_URI,
        PROJECTION, null, null, CallLog.Calls.DATE
        + " DESC"));
}

@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {
    adapter.changeCursor(cursor);
}

@Override
public void onLoaderReset(Loader<Cursor> loader) {
    adapter.changeCursor(null);
}
```

(from Contacts/CallLog/app/src/main/java/com/commonsware/android/calllog/consumer/CallLogConsumerActivity.java)

Here, we retrieve the data from the `CallLog.Calls` “table” via its `CONTENT_URI`, asking for the “columns” indicated by the `PROJECTION`:

```java
private static final String[] PROJECTION=
    new String[] {
        CallLog.Calls.NUMBER, CallLog.Calls.DATE
    };
```

(from Contacts/CallLog/app/src/main/java/com/commonsware/android/calllog/consumer/CallLogConsumerActivity.java)

We sort the data descending by date. It would be nice if the documentation for CallLog included some indication that this approach was endorsed and supported. Based on the CallLog implementation, it should be stable.

**Showing the CallLog**

`onLoadFinished()` and `onLoaderReset()` each call a `changeCursor()` method on our adapter. That is an instance of `RVCursorAdapter`, set up in `onReady()`:

```java
@Override
public void onReady() {
    adapter=new RVCursorAdapter(getLayoutInflater());
}
```

2605
RVCursorAdapter wraps around the Cursor of calendar data:

```java
private static class RVCursorAdapter extends RecyclerView.Adapter<RowHolder> {
    private Cursor cursor;
    private final LayoutInflater inflater;

    private RVCursorAdapter(LayoutInflater inflater) {
        this.inflater = inflater;
    }

    @NonNull
    @Override
    public RowHolder onCreateViewHolder(@NonNull ViewGroup parent, int viewType) {
        View row = inflater.inflate(R.layout.row, parent, false);
        return new RowHolder(row);
    }

    @Override
    public void onBindViewHolder(@NonNull RowHolder holder, int position) {
        cursor.moveToPosition(position);
        holder.bind(cursor);
    }

    @Override
    public int getItemCount() {
        return cursor == null ? 0 : cursor.getCount();
    }

    private void changeCursor(Cursor cursor) {
        if (this.cursor != null) this.cursor.close();
        this.cursor = cursor;
        notifyDataSetChanged();
    }
}
```

(changeCursor()) closes the old Cursor (if there was one), holds onto the new one, and tells the RecyclerView to reload its contents, as our data has changed.
Our row layout (res/layout/row.xml) has two TextView widgets for the two pieces of data that we want to display:

```xml
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content">
    <TextView
        android:id="@+id/date"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_alignParentEnd="true"
        android:layout_alignParentRight="true"
        android:textSize="28sp" />
    <TextView
        android:id="@+id/number"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_alignParentLeft="true"
        android:layout_alignParentStart="true"
        android:textSize="28sp" />
</RelativeLayout>
```

Each row in the list is managed by a RowHolder:

```java
private static class RowHolder extends RecyclerView.ViewHolder {
    private final TextView date;
    private final TextView number;

    RowHolder(View itemView) {
        super(itemView);
        date = itemView.findViewById(R.id.date);
        number = itemView.findViewById(R.id.number);
    }

    public void bind(Cursor cursor) {
        number.setText(cursor.getString(0));

        long time = cursor.getLong(1);
        String formattedTime = DateUtils.formatDateTime(cursor.getContext(), time, DateUtils.FORMAT_ABBREV_RELATIVE);
        date.setText(formattedTime);
    }
}
```
The DATE columns is returned to use as milliseconds since the Unix epoch, so we use DateUtils.formatDateTime() to convert that into something that is human-readable and matches the user's chosen locale settings.

The results is a list of calls by date and phone number.
The CalendarContract Provider

The Android Open Source Project (AOSP) has had a Calendar application from its earliest days. This application originally was designed to sync with Google Calendar, later extended to other sync sources, such as Microsoft’s Exchange. However, this application was not part of the Android SDK, so there was no way to access it from your Android application.

At least, no officially documented and supported way.

Many developers poked through the AOSP source code and found that the Calendar application had a ContentProvider. Moreover, this ContentProvider was exported (by default). So many developers used undocumented and unsupported means for accessing calendar information. This occasionally broke, as Google modified the Calendar app and changed these pseudo-external interfaces.

Android 4.0 added official SDK support for interacting with the Calendar application via its ContentProvider. As part of the SDK, these new interfaces should be fairly stable — if nothing else, they should be supported indefinitely, even if new and improved interfaces are added sometime in the future. So, if you want to tie into the user’s calendars, you can. Bear in mind, though, that the new CalendarContract ContentProvider is not identical to the older undocumented providers, so if you are aiming to support pre-4.0 devices, you have some more work to do.

Of course, similar to the ContactsContract ContentProvider, the CalendarContract ContentProvider is severely lacking in documentation, and anything not documented is subject to change.
Prerequisites

Understanding this chapter requires that you have read the chapters on:

- content provider theory
- content provider implementations

You Can’t Be a Faker

While the Android emulator has the CalendarContract ContentProvider, it will do you little good. While you can define a Google account on the emulator, the emulator lacks any ability to sync content with that account. Hence, you cannot see any events for your calendars in the Calendar app, and you cannot access any calendar data via CalendarContract.

You may be able to use an outlook.com account, to sync with an Outlook calendar.

Otherwise, in order to test your use of CalendarContract, you will need to have hardware that runs Android 4.0 (or higher), with one or more accounts set up that have calendar data.

Do You Have Room on Your Calendar?

As a ContentProvider, CalendarContract is not significantly different from any other such provider that Android supplies or that you write yourself, in that there are Uri values representing collections of data, upon which you can query, insert, update, and delete as needed.

The two main collections of data that you are likely to be interested in are CalendarContract.Calendars (the collection of all defined calendars) and CalendarContract.Events (the collection of all defined events across all calendars). Each of those has a CONTENT_URI static data member that you would use with ContentResolver or a CursorLoader to perform operations on those collections. An entry in CalendarContract.Events points back to its corresponding calendar via a CALENDAR_ID column that you can query upon; the remaining columns on CalendarContract.Events have names apparently designed to match with the iCalendar specification (e.g., DTSTART and DTEND for the start and end times of the event).
Three other collections may be of interest:

1. CalendarContract.Instances has one entry per occurrence of an event, so recurring events get multiple rows
2. CalendarContract.Attendees has information about each attendee of an event
3. CalendarContract.Reminders has information about each reminder scheduled for an event (e.g., when to remind the user), for those events with associated reminders

Each of those ties back to its associated CalendarContract.Events row via an EVENT_ID column.

**Calendar Permissions**

There are two permissions for working with CalendarContract: READ_CALENDAR and WRITE_CALENDAR. As you might expect, querying CalendarContract requires the READ_CALENDAR permission; modifying CalendarContract data requires the WRITE_CALENDAR permission.

These permissions have existed since Android's earliest days, even in the SDK, as a side effect of the “meat cleaver” approach the core Android team employed to create the initial SDK. Hence, you can request these permissions in the manifest with any Android build target, without compiler errors. Of course, actually referring to CalendarContract will require a build target (i.e., compileSdkVersion in Android Studio) of API Level 14 or higher.

**Querying for Events**

For example, let’s populate a RecyclerView with the roster of all events the user has across all calendars, using a CursorLoader, showing the name of each event, the event’s start date, and the event’s end date. You can find this in the Calendar/Query sample project in the book’s source code.

**The Permission**

Our manifest has the READ_CALENDAR permission, as you would expect:
To request this permission when our app launches, this project uses the same AbstractPermissionActivity seen elsewhere in the book and profiled in the chapter on permissions. That logic gives us control in an onReady() method in our CalendarQueryActivity when we can start setting up the UI and requesting the calendar data.

The CursorLoader

As part of our onReady() work, we call initLoader() on a LoaderManager:

```java
getSupportLoaderManager().initLoader(0, null, this);
```

That triggers a call to our LoaderCallbacks methods:

```java
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return new CursorLoader(this, CalendarContract.Events.CONTENT_URI,
                              CalendarContract.Events.PROJECTION, null, null,
                              CalendarContract.Events.DTSTART);
}
```
**The CalendarContract Provider**

```java
public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {
    adapter.changeCursor(cursor);
}

public void onLoaderReset(Loader<Cursor> loader) {
    adapter.changeCursor(null);
}
```  

(from Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java)

onCreateLoader() requests data from `CalendarContract.Events.CONTENT_URI`, the Uri that represents the virtual table of calendar event data. We request three columns, identified by the **PROJECTION**:

```java
private static final String[] PROJECTION=
    new String[] {
        CalendarContract.Events.TITLE,
        CalendarContract.Events.DTSTART,
        CalendarContract.Events.DTEND
    };
```  

(from Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java)

onCreateLoader() also requests that the calendar data be sorted by starting date.

**The RecyclerView**

onLoadFinished() and onLoaderReset() each call a changeCursor() method on our adapter. That is an instance of RVCursorAdapter, set up in onReady():

```java
@Override
public void onReady() {
    adapter=new RVCursorAdapter(getLayoutInflater());

    RecyclerView rv=getRecyclerView();

    setLayoutManager(new LinearLayoutManager(this));
    rv.addItemDecoration(new DividerItemDecoration(this, DividerItemDecoration.VERTICAL));
    rv.setAdapter(adapter);

    getSupportLoaderManager().initLoader(0, null, this);
}
```  

(from Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java)

RVCursorAdapter wraps around the Cursor of calendar data:
changeCursor() closes the old Cursor (if there was one), holds onto the new one, and tells the RecyclerView to reload its contents, as our data has changed.

Our row layout (res/layout/row.xml) has three TextView widgets for the three pieces of data that we want to display:

```xml
  <TextView android:id="@+id/title" android:layout_width="wrap_content" android:layout_height="wrap_content" android:layout_gravity="center_vertical" />
</LinearLayout>
```
Each row in the list is managed by a RowHolder:

```java
private static class RowHolder extends RecyclerView.ViewHolder {
  private final TextView title, dtstart, dtend;

  RowHolder(View itemView) {
    super(itemView);
    title = itemView.findViewById(R.id.title);
    dtstart = itemView.findViewById(R.id.dtstart);
    dtend = itemView.findViewById(R.id.dtend);
  }

  public void bind(Cursor cursor) {
    title.setText(cursor.getString(0));
    dtstart.setText(getFormattedDate(cursor, 1));
  }
}
```

(from Calendar/Query/app/src/main/res/layout/row.xml)
The `CalendarContract.Provider`

```java
private String getFormattedDate(Cursor cursor, int column) {
    long time = cursor.getLong(column);
    return DateUtils.formatDateTime(dtstart.getContext(), time,
                                     DateUtils.FORMAT_ABBREV_RELATIVE);
}
```

(from Calendar/Query/app/src/main/java/com/commonsware/android/cal/query/CalendarQueryActivity.java)

The `DTSTART` and `DTEND` values are returned to use as milliseconds since the Unix epoch, so we use `DateUtils.formatDateTime()` to convert that into something that is human-readable and matches the user’s chosen locale settings.

**The Results**

If you run this on a device with available calendar data, you will get a list of those events:

![Calendar Query sample application, with some events redacted](image)

*Figure 751: The Calendar Query sample application, with some events redacted*
Penciling In an Event

What is rarely documented in the Android SDK is what activities might exist that support the MIME types of a given ContentProvider. In part, that is because device manufacturers have the right to remove or replace many of the built-in applications.

The Calendar application is considered by Google to be a “core” application. Quoting the Android 2.3 version of the Compatibility Definition Document (CDD):

The Android upstream project defines a number of core applications, such as a phone dialer, calendar, contacts book, music player, and so on. Device implementers MAY replace these applications with alternative versions. However, any such alternative versions MUST honor the same Intent patterns provided by the upstream project. For example, if a device contains an alternative music player, it must still honor the Intent pattern issued by third-party applications to pick a song.

Hence, in theory, so long as the CDD does not change and device manufacturers correctly honor it, those Intent patterns described by the Calendar application's manifest should be available across Android 4.0 devices. The Calendar application appears to support ACTION_INSERT and ACTION_EDIT for both the collection MIME type (vnd.android.cursor.dir/event) and the instance MIME type (vnd.android.cursor.item/event). Notably, there is no support for ACTION_PICK to pick a calendar or event, the way you can use ACTION_PICK to pick a contact.
The MediaStore Provider

Playing back media is a popular pastime on Android devices, one in which your app may want to participate. The easiest way for you to find out what media is available for you to display, edit, or otherwise work with is via the MediaStore content provider. MediaStore is part of the Android framework and allows you to query for images, audio files, and video files that are indexed on the device.

This chapter will review the general workings of MediaStore, plus work through an example of getting video files — and their thumbnails — from MediaStore.

**Prerequisites**

Understanding this chapter requires that you have read the chapters on:

- RecyclerView
- content provider theory
- content provider implementations

It is also a pretty good idea to have read the chapters on media recording and playback that might be of relevance, depending on what you intend to do with the MediaStore:

- Audio Playback
- Audio Recording
- Video Playback
- Using the Camera via 3rd-Party Apps
- Working Directly with the Camera

You might also wish to consider skimming through the chapter on files again, as it...
will be cross-referenced in several places in this chapter.

The MediaStore Provider

What Is the MediaStore?

The documentation for MediaStore describes it this way:

The Media provider contains meta data for all available media on both internal and external storage devices.

This definition... leaves a bit to be desired.

From our standpoint as Android developers, the MediaStore is a ContentProvider, supplied by Android. We can use it much like we use other system-supplied providers, like ContactsContract and CalendarContract. In this case, the primary role of MediaStore is for us to find media, just as the primary role of ContactsContract is for us to find contacts.

The “meta data” reference in the documentation refers to the fact that MediaStore itself does not store the media, even though that's what the name MediaStore would suggest. MediaMetadataStore would be a more accurate description. We can learn about available media — names, durations, etc. — and we can get a Uri from MediaStore pointing to the media, but the media itself lives as a file somewhere else.

Indexed Media

MediaStore has media as a primary focus. Here, “media” refers to:

- Images (typically photos)
- Audio (music, podcasts, etc.)
- Video (whether recorded by the device, downloaded from somewhere, etc.)

MediaStore has intrinsic knowledge of these, particularly for the file formats and codecs that Android supports. As a result, the index maintained by MediaStore will contain some metadata in common for all file types, such as:

- title
- MIME type
- dates (when the file was added, when the file was modified)

...and other metadata that will be unique to one or two of the major types, such as:
Indexed Non-Media

As was mentioned in passing in the chapter on files, Android uses MTP for Android 4.0+ as the USB protocol for sharing files with a desktop or notebook computer.

To power this, Android does not go straight to the filesystem, but rather works with MediaStore. MediaStore maintains an index of all files, not just “media”. Whatever shows up in MediaStore is what shows up to the user in their Windows drive letter, macOS mounted volume, etc.

You too can query MediaStore for non-media files. Android will try to maintain a MIME type — probably based on file extensions — and so you can find all indexed PDF files, for example, by querying MediaStore.

MediaStore and “Other” External Storage

In the chapter on files, we covered the difference between internal storage and external storage. Primarily, MediaStore maintains an index of external storage.

However, many Android devices today have multiple locations that could be considered “external storage”. While the vast majority of Android devices have “external storage” as a portion of on-board flash memory, Android device manufacturers are welcome to add other options, such as:

- card slots (typically microSD)
- USB host ports (capable of mounting thumb drives and the like)

From the standpoint of the Android SDK, such secondary storage locations are off-limits, in that there is nothing in the Android SDK to tell us if there are any such locations, where they are located (in terms of File objects to their roots), whether they can be read from, or whether they can be written to. You will find various blog posts and Stack Overflow answers where developers have attempted to catalog all of the possibilities, using a mix of low-level Linux information and manufacturer-based heuristics, but these techniques will be generally unreliable across thousands of device models.
However, many manufacturers who have added such secondary storage options will arrange to have that storage be indexed and be part of MediaStore. So, if the user slides in a microSD card containing audio files, on many devices, when you query MediaStore for available audio files, you will find those on the microSD card in addition to those on “traditional” external storage. From the user's standpoint, in terms of consuming media, this is sufficient.

**How Does My Content Get Indexed?**

As was noted back in the chapter on files, if you write files to external storage, you will want to use MediaScannerConnection to ensure that those files get indexed. In that chapter, the focus was on ensuring that your files would be visible to attached desktops/notebooks via MTP. However, what really happens is that MediaScannerConnection updates MediaStore, which in turn drives the MTP-served content.

Even if you fail to index content manually, at some point, Android is likely to pick up the files. For example, Android will scan external storage after a reboot. However, using MediaScannerConnection to “tap Android on the shoulder” and have it index your file means that it will show up in MediaStore more quickly. This is very important for multimedia assets — if you downloaded some media, you want that to be indexed as soon as possible, so the user can turn around and consume that media, whether through your app or another one on the user’s device.

**How Do I Retrieve Video from the MediaStore?**

Video players will need to find out what videos are available on the device, eligible for playback. They may wish to retrieve other details, such as the video title, duration, and so forth. And, of course, they will need something that they can use to actually play back the video itself.

In this section, we will examine elements of the RecyclerView/VideoList sample project. This project will show the roster of available videos; tapping on a video in the list will launch the user’s video player to watch that video. See also the chapter on advanced RecyclerView techniques for more about the RecyclerView aspects of this app.
**Requesting Permission**

Starting on API Level 19 devices, you need to hold the READ_EXTERNAL_STORAGE or WRITE_EXTERNAL_STORAGE permissions to be able to work with the MediaStore. Hence, the VideoList sample app has the READ_EXTERNAL_STORAGE permission in its manifest, as it has no need to write to external storage:

```xml
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.recyclerview.videolist"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <uses-permission android:name="android.permission.READ_EXTERNAL_STORAGE"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:theme="@style/Theme.Apptheme">

    <activity
      android:name=".MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>
        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

(from RecyclerView/VideoList/app/src/main/AndroidManifest.xml)

Since READ_EXTERNAL_STORAGE is a dangerous permission, we need to request this permission at runtime, in addition to requesting it in the manifest. MainActivity implements this logic, using the same basic approaches as is seen in the chapter on permissions.
**THE MEDIASTORE PROVIDER**

### Querying for Video

MainActivity uses the **Loader framework**, since MediaStore is a ContentProvider and Loader is a convenient way to asynchronously load content from a ContentProvider. MainActivity implements the LoaderManager.LoaderCallbacks interface.

Calling `initLoader()` is done in a `loadVideos()` method:

```java
private void loadVideos() {
    getSupportLoaderManager().initLoader(0, null, this);
}
```

(from RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/video/MainActivity.java)

That method, in turn, is called in two places:

- **onCreate()**, if we already have the READEXTERNAL_STORAGE permission

```java
@override
public void onCreate(Bundle state) {
    super.onCreate(state);

    setLayoutManager(new LinearLayoutManager(this));
    setAdapter(new VideoAdapter());

    if (state!=null) {
        isInPermission= state.getBoolean(STATE_IN_PERMISSION, false);
    }

    if (hasFilesPermission()) {
        loadVideos();
    } else if (!isInPermission) {
        isInPermission=true;

        ActivityCompat.requestPermissions(this,
             new String[]{Manifest.permission.READ_EXTERNAL_STORAGE},
             REQUEST_PERMS);
    }
}
```

(from RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/video/MainActivity.java)

- **onRequestPermissionsResult()**, if we were just granted the
The MediaStore Provider

READ_EXTERNAL_STORAGE permission

```java
@Override
public void onRequestPermissionsResult(int requestCode,
                                        String[] permissions,
                                        int[] grantResults) {
    isInPermission = false;
    if (requestCode == REQUEST_PERMS) {
        if (hasFilesPermission()) {
            loadVideos();
        } else {
            finish(); // denied permission, so we're done
        }
    }
}
```

The initLoader() call triggers a call to onCreateLoader(), where MainActivity creates a CursorLoader to query the MediaStore for videos:

```java
@Override
public Loader<Cursor> onCreateLoader(int arg0, Bundle arg1) {
    return new CursorLoader(this,
                            MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
                            null, null, null,
                            MediaStore.Video.Media.TITLE);
}
```

The Uri for video content from MediaStore is MediaStore.Video.Media.EXTERNAL_CONTENT_URI. Passing in null for the list of columns to return will return all available columns — not the most efficient approach, but it is convenient. The sort order of MediaStore.Video.Media.TITLE has the results sorted by the TITLE column, so the videos are returned alphabetically.

Our other LoaderManager.LoaderCallbacks methods are fairly conventional, updating a VideosAdapter that our RecyclerView uses for displaying the videos:

```java
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    (VideoAdapter) getAdapter().setVideos(c);
}
```
Showing the Thumbnails

If you have used a video player on Android, most have an activity (or fragment) akin to the one we are implementing in this section. And, most of those will show thumbnail images of the videos in question.

However, retrieving and showing those thumbnails is a bit complicated, because Android may need to generate the thumbnail, if there is not already a thumbnail for the video, or if its cache of thumbnails was cleared. Generating a thumbnail takes time, time that we do not want to spend on the main application thread. For that, we will use Picasso, as profiled in the chapter on Internet access.

The thumbnail will need to be displayed using some sort of ImageView. That is handled by RowController, which is the ViewHolder that we are using with VideosAdapter. It, in turn, uses Picasso to load the thumbnail:

```java
void bindModel(Cursor row) {
    title.setText(row.getString(
        row.getColumnIndex(MediaStore.Video.Media.TITLE)));

    videoUri =
        ContentUris.withAppendedId(
            MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
            row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));

    Picasso.with(thumbnail.getContext())
        .load(videoUri.toString())
        .fit().centerCrop()
        .placeholder(R.drawable.ic_media_video_poster)
        .into(thumbnail);

    int mimeTypeColumn =
        row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);

    videoMimeType = row.getString(mimeTypeColumn);
}
```

(from RecyclerView/VideoList/app/src/main/java/com/commonsware/android/recyclerview/videolist/RowController.java)
THE MEDIASTORE PROVIDER

We construct the Uri to the video using ContentUris.withAppendedId(). Picasso knows how to handle such Uri values, identifying them as coming from the MediaStore and using appropriate methods to retrieve a suitable thumbnail. That will be done in the background, with a placeholder image shown while the thumbnail is loading. The net result is that when we populate our RecyclerView with our videos, the rows will initially have the placeholder image, replaced by the actual video thumbnails as they get loaded.

Playing the Selection

RowController also sets itself up to find out about clicks on the list rows. The objective is to play back the video when the user clicks on a row. It simply constructs an Intent to view the video and starts an activity with it:

```java
@Override
public void onClick(View v) {
    Intent i = new Intent(Intent.ACTION_VIEW);
    i.setDataAndType(videoUri, videoMimeType);
    title.getContext().startActivity(i);
}
```

(videoUri and videoMimeType were populated in the bindModel() method shown above, so they will have the proper values for whatever row the user clicked upon.)
The Results

Running this on a device with videos available should show the list of those videos, complete with title and thumbnail:

![Video List Demo App](image)

*Figure 752: The Video List Demo App*

Tapping on any entry in the list should bring up a video player on your device, assuming that one or more such players (that are capable of supporting `content://Uri` values) are installed.
Android has long offered the ability for an app to pick some file or stream from another app and consume it. However, the original options were designed around an app loading content from another app. Even though our code would be requesting content based on abstractions like MIME types, the implementation and user experience would be based on the traditional “pick an app to fulfill this request” chooser.

Google, given its clear interest in cross-cutting storage engines like Google Drive, wanted something better. In Android 4.4, they added the Storage Access Framework (SAF) to provide a better user experience, with only modest changes to client code. With Android’s increasing reliance upon content and document providers for cross-app content sharing, understanding the Storage Access Framework is fairly important for modern app development.

In this chapter, we will examine what it takes to consume documents published via the SAF.

**Prerequisites**

This chapter assumes that you have read the chapter on ContentProvider patterns or have equivalent experience with consuming streams published by a ContentProvider.

**The Storage Access… What?**

Let’s think about photos for a minute.
A person might have photos managed as:

- on-device photos, mediated by an app like a gallery
- photos stored online in a photo-specific service, like Instagram
- photos stored online in a generic file-storage service, like Google Drive or Dropbox

Now, let’s suppose that person is in an app that allows the user to pick a photo, such as to attach to an email.

The classic Android solution would be for the user to have to first choose the app to use to find the photo (e.g., Gallery, Instagram, Google Drive, Dropbox), then find the photo using that app. Then, if all goes well, the original app would receive a \texttt{Uri} to that photo and be able to make use of it.

However, this flow has three main problems:

1. From the user’s standpoint, they need to know where they have the photo before they can go looking for it. Given the prominence of generic file-storage services, the user might not remember where the photo is stored, but might remember enough details about the photo (e.g., timeframe when taken, tags that might have been attached to the photo) to find it... but the user has to sequentially search each possible photo-storing app until the right one is found.

2. From the client app developer’s standpoint, too many apps screw up handling the classic \texttt{ACTION_PICK} and \texttt{ACTION_GET_CONTENT} activities, failing to return a result in all cases. Users then are as likely to blame the client app for the mistake as they are to blame the photo-storing app or Android itself.

3. None of this was designed with online file-sharing services in mind. What happens if an app knows about a possible file, but the file is not available on the device right now, because it has not been downloaded from the online service?

The Storage Access Framework is designed to address these issues. It provides its own “picker” UI to allow users to find a file of interest that matches the MIME type that the client app wants. File providers simply publish details about their available files — including those that may not be on the device but could be retrieved if needed. The picker UI allows for easy browsing and searching across all possible file providers, to streamline the process for the user. And, since Android is the one providing the picker, the picker should more reliably give a result to the client app based upon the user’s selection (if any).
The Storage Access Framework Participants

Providers are specialized ContentProvider implementations, usually extending DocumentsProvider, that can tell Android about the documents that are published by an app. This includes providing any sort of organizational structure (directory tree, tag cloud, etc.)

The clients are apps that wish to consume (or create) documents managed by providers. Clients will indicate what sort of document they want, in the form of a MIME type, where applicable.

The picker is the system UI that allows the user to pick a document (or documents) from among the documents published by all providers that meet the criteria established by a client requesting access to the document(s).

Picking How to Pick (a Peck of Pickled Pepper Photos)

ACTION_PICK would seem to be the Intent action to use to pick something. It works, but it is designed for the case where you know the specific collection of “somethings” you want to pick from. Use this, for example, to pick a contact specifically out of ContactsContract.

In cases where you know the MIME type you want, but you do not particularly know or care about the exact source of the file, use ACTION_GET_CONTENT on API Level 18 and below for everything.

For MIME types that clearly represent a document, file, or other sort of stream, use ACTION_OPEN_DOCUMENT (and the SAF) on API Level 19+. The SAF picker will incorporate both full-fledged SAF-compliant providers’ documents along with apps that only support ACTION_GET_CONTENT. However, since ACTION_OPEN_DOCUMENT is only available on API Level 19+ devices, if you are supporting older devices, you will need to check Build.VERSION.SDK_INT and choose an Intent action accordingly.

For MIME types that represent entries in a database (e.g., a calendar entry), use ACTION_GET_CONTENT, even on API Level 19+. Google also recommends using ACTION_GET_CONTENT on API Level 19+ “if you want your app to simply read/import data”, though it is unclear why they make this recommendation or why the user experience should differ based upon how the bytes would be used.
**CONSUMING DOCUMENTS**

### Opening a Document

Technically, we do not “open” a document using `ACTION_OPEN_DOCUMENT`. Instead, we are requesting a `Uri` pointing to some document that the user chooses.

To do that, create an Intent with:

- `ACTION_OPEN_DOCUMENT` as the action
- `CATEGORY_OPENABLE` as the category
- your desired MIME type

Then, use that Intent with `startActivityForResult()`.

For example, the `Documents/Consumer` sample application contains a `ConsumerFragment` that adds an “Open” item to the action bar overflow. Clicking on “Open” triggers a call to the `open()` method on the fragment. And, for API Level 19+ devices, that will in turn request to “open” a document:

```java
@TargetApi(Build.VERSION_CODES.KITKAT)
private void open() {
    Intent i = new Intent().setType("image/*");
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
        startActivityForResult(i.setAction(Intent.ACTION_OPEN_DOCUMENT)
            .addCategory(Intent.CATEGORY_OPENABLE), REQUEST_OPEN);
    } else {
        startActivityForResult(i.setAction(Intent.ACTION_GET_CONTENT)
            .addCategory(Intent.CATEGORY_OPENABLE), REQUEST_GET);
    }
}
```

(from `Documents/Consumer/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java`)

This `open()` method also gracefully degrades for older devices, falling back to `ACTION_GET_CONTENT`. In both cases, we are trying to allow the user to pick some image (MIME type of `image/*`). The two `startActivityForResult()` calls use different request IDs (REQUEST_OPEN versus REQUEST_GET), so that we can distinguish the sort of result that we get in `onActivityResult()`:

```java
@Override
public void onActivityResult(int requestCode, int resultCode,
```

2632
Both ACTION_GET_CONTENT and ACTION_OPEN_DOCUMENT should supply a Uri in the result Intent that points to the document the user chose, if the user actually chose one and we got RESULT_OK as the result code. This sample logs that Uri value to a "transcript" (TextView inside of a ScrollView) to show what we get back.

If the result is from an ACTION_OPEN_DOCUMENT request (REQUEST_OPEN request code), we can try to get some metadata about the document. The provider should support a query on the returned Uri that will give us the display name (OpenableColumns.DISPLAY_NAME) and possibly the size of the file (OpenableColumns.SIZE). So, we use the Loader framework to run this query, with our fragment implementing the LoaderCallbacks:

```java
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return new CursorLoader(getActivity(), uri, PROJECTION, null, null, null);
}

public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    transcript.setText(null);
    logToTranscript(uri.toString());

    if (c!=null && c.moveToFirst()) {
        int displayNameColumn=
        c.getColumnIndex(OpenableColumns.DISPLAY_NAME);

        if (displayNameColumn>=0) {
            logToTranscript("Display name: "+c.getString(displayNameColumn));
        }
    }
```
```java
int sizeColumn = c.getColumnIndex(OpenableColumns.SIZE);

if (sizeColumn < 0 || c.isNull(sizeColumn)) {
    logToTranscript("Size not available");
} else {
    logToTranscript(String.format("Size: %d", c.getInt(sizeColumn)));
}
```

```java
public void onLoaderReset(Loader<Cursor> loader) {
    // unused
}
```

(from Documents/Consumer/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java)

If we get results back, we try to read out these two values and record them to the transcript as well. Note, though, that:

- There is no guarantee that either column will be in the result set, or that the result set will have any rows
- The size might not be known, particularly if the file is not presently resident on the device (e.g., it is being downloaded now, given that the user chose the file), and so we need to call `isNull()` on the `Cursor` to see if we actually have a SIZE value before trying to get it as an integer
The user is presented with the system’s picker, to choose an image, complete with a navigation drawer to get to various spots within the picker:

*Figure 753: Storage Access Framework Picker, Showing Images*
When the user taps on an image, the results wind up in our transcript UI:

![Image](image.png)

*Figure 754: Uri, Display Name, and Size of Chosen File*

Note that the default behavior of ACTION_OPEN_DOCUMENT is to let the user choose a single file. If your Intent includes EXTRA_ALLOW_MULTIPLE, set to true, then the user can choose multiple documents. Rather than getting their Uri values via getData() on the result Intent, you will need to call getClipData() on the Intent and iterate over the “clipboard entries”.

The Uri itself can then be used to get an InputStream or OutputStream for the contents, using openInputStream() and openOutputStream() on ContentResolver, respectively. Note, though, that you cannot pass the Uri to other applications, as they may not have rights to work with that document the way that you do.

### Why We Want Things To Be Openable

You will notice that both the ACTION_OPEN_DOCUMENT and the ACTION_GET_CONTENT Intent objects created in the preceding example have CATEGORY_OPENABLE applied to them. This is supposed to guarantee that we can actually consume the content represented by the Uri that we get. In particular, we should be able to use a
ContentResolver and open streams on that content.

If we leave off CATEGORY_OPENABLE, it is possible that we will get a Uri that we cannot open ourselves.

The difference boils down to what use we intend to put the Uri toward:

- If all we plan to do is use that Uri for is to wrap it in an ACTION_VIEW Intent and start an activity on it, you could skip CATEGORY_OPENABLE and perhaps offer more choices to your user
- Otherwise, use CATEGORY_OPENABLE

The Rest of the CRUD

ACTION_OPEN_DOCUMENT will give you a Uri for a document that you can open for reading — the “R” in “CRUD”.

However, the other CRUD operations are also entirely possible.

Create

ACTION_CREATE_DOCUMENT will give you a Uri for a document that you can open for writing, as it is your document.

To do this, construct an Intent with:

- an action of ACTION_CREATE_DOCUMENT
- a category of CATEGORY_OPENABLE
- the MIME type of the content you wish to write
- an extra, named EXTRA_TITLE, containing your desired filename

Then, invoke startActivityForResult() on that Intent, and use the Uri supplied in the result Intent delivered to onActivityResult().

Update

The Uri returned from an ACTION_OPEN_DOCUMENT request may be writable. If it is, you can use openOutputStream() on a ContentResolver to write to that document. You can determine if a document is writable by examining the COLUMN_FLAGS value returned from a query() on the Uri — if it includes FLAG_SUPPORTS_WRITE, you can
CONSUMING DOCUMENTS

write to the document.

Delete

Similarly, if the COLUMN_FLAGS value includes FLAG_SUPPORTS_DELETE, you can delete the document by calling the static deleteDocument() method on the DocumentsContract class, supplying a ContentResolver plus the Uri of the document to be deleted.

The DocumentFile Helper

The support-core-utils library from the Android Support libraries contains a DocumentFile class. This provides a light File-like layer atop the low-level API offered through a ContentResolver or DocumentsContract. Of note, DocumentFile offers convenience methods for:

- determining read/write access (canRead() and canWrite())
- getting the display name (getName()) and length (length()) of the document
- getting the MIME type (getType())
- deleting the document (delete())
- and so on

DocumentFile can actually work with raw files — just create a DocumentFile using the static fromFile() method. More often, though, you will create a DocumentFile wrapped around the Uri that you get from ACTION_OPEN_DOCUMENT or ACTION_CREATE_DOCUMENT. For that, there is the static fromSingleUri() method.

CWAC-Document and DocumentFileCompat

There is one significant problem with DocumentFile, though: it only works on document Uri values on API Level 19 and higher. However, we can get such Uri values on older devices, and we can get Uri values from other places than a DocumentProvider (e.g., FileProvider).

The CWAC-Document library offers a DocumentFileCompat class. This is forked from the official DocumentFile but adds support for older devices and non-document Uri values. Specifically, for a non-document content Uri, you can get:
CONSUMING DOCUMENTS

- the display name, queried via the OpenableColumns
- the length, also from the OpenableColumns
- the MIME type, from ContentResolver and getType()

Also, some DocumentFile methods whose values can be safely hard-coded for legacy documents, like isVirtual()(false), isDirectory()(false), and.isFile()(true) are supported.

DocumentFileCompat also offers convenience methods for:

- Accessing streams (openInputStream(), openOutputStream())
- Copying the content to something else (copyTo())
- Copying something else into this content (copyFrom(), copyFromAsset())

We will see the use of DocumentFileCompat in the next couple of sample apps.

Getting Durable Access

By default, you will have the rights to read (and optionally write) to the document represented by the Uri until the activity that requested the document via ACTION_OPEN_DOCUMENT or ACTION_CREATE_DOCUMENT is destroyed.

If you pass the Uri to another component — such as a service – you will need to add FLAG_GRANT_READ_URI_PERMISSION and/or FLAG_GRANT_WRITE_URI_PERMISSION to the Intent used to start that component. That extends your access until that component is destroyed.

If, however, you need the rights to survive your app restarting, you can call takePersistableUriPermission() on a ContentResolver, indicating the Uri of the document and the permissions (FLAG_GRANT_READ_URI_PERMISSION and/or FLAG_GRANT_WRITE_URI_PERMISSION) that you want persisted. Those rights will then survive a reboot. However:

- They will not survive the document being deleted, so just because you have a saved Uri, do not assume that the Uri will still be valid
- Not every storage provider will grant such persistable permissions
- This will only work for Uri values that you get from ACTION_OPEN_DOCUMENT or ACTION_CREATE_DOCUMENT, not ones that you get by other means (e.g., ACTION_GET_CONTENT)
- You can revoke those rights by calling releasePersistableUriPermission()
CONSUMING DOCUMENTS

later on, and there is nothing stopping the storage provider from revoking those permissions itself at some time in the future

In addition, you can call `getPersistedUriPermissions()` to find out what persisted permissions your app has. This returns a List of `UriPermission` objects, where each one of those represents a `Uri`, what persisted permissions (read or write) you have, and when the permissions will expire.

If you do not have persistable permissions when you get the `Uri`, your primary recourse is to make a local copy of the content, while you still have temporary access to it. The Documents/Durable sample application illustrates this. It is based on the Documents/Consumer sample app from earlier in this chapter, with a few key changes:

- It provides menu options for opening a document via `ACTION_OPEN_DOCUMENT` or getting content via `ACTION_GET_CONTENT`
- It uses an `IntentService` (DurablizerService) to either obtain persistable permissions to the content or to make a local copy, delivering the results asynchronously via an event bus
- It uses `DocumentFileCompat` instead of direct `ContentResolver` queries to get the content metadata

For an event bus, we use greenrobot’s EventBus, added as a dependency via `build.gradle`, along with the CWAC-Document library:

```java
apply plugin: 'com.android.application'

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
        applicationId "com.commonsware.android.documents.durable"
    }
}

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}
```
CONSUMING DOCUMENTS

dependencies {
   implementation 'com.android.support:support-fragment:27.1.0'
   implementation 'org.greenrobot:eventbus:3.0.0'
   implementation 'com.commonsware.cwac:document:0.2.0'
}

(MainActivity is the same as in the Documents/Consumer sample app, as is the core UI of ConsumerFragment (ScrollView with a TextView inside). However, ConsumerFragment registers for events in onStart() and unregisters in onStop():

```java
@Override
public void onStart() {
   super.onStart();
   EventBus.getDefault().register(this);
}

@Override
public void onStop() {
   EventBus.getDefault().unregister(this);
   super.onStop();
}
```

The menu resource now has two items, open (for ACTION_OPEN_DOCUMENT) and get (for ACTION_GET_CONTENT):

```xml
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/get"
        android:showAsAction="never"
        android:title="@string/get" />
    <item
        android:id="@+id/open"
        android:enabled="false"
        android:showAsAction="never"
        android:title="@string/open" />
</menu>
```
The open one is disabled (android:enabled="false") at the outset, as ACTION_OPEN_DOCUMENT only works on API Level 19+ devices, and the minSdkVersion of this sample is 15.

In onCreateOptionsMenu(), we conditionally enable the open item, and in onOptionsItemSelected(), we route the menu items to open() and get() methods:

```java
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.actions, menu);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.KITKAT) {
        menu.findItem(R.id.open).setEnabled(true);
    }

    super.onCreateOptionsMenu(menu, inflater);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.open) {
        open();
    } else if (item.getItemId()==R.id.get) {
        get();
    }

    return(super.onOptionsItemSelected(item));
}
```

Those methods invoke their associated Intent actions, using */* this time for the MIME type:

```java
@TargetApi(Build.VERSION_CODES.KITKAT)
private void open() {
    Intent i =
        new Intent()
            .setType("*/")
            .setAction(Intent.ACTION_OPEN_DOCUMENT)
            .addCategory(Intent.CATEGORY_OPENABLE);

    startActivityForResult(i, REQUEST_OPEN);
}
```
private void get() {
    Intent i =
        new Intent()
            .setType("image/png")
            .setAction(Intent.ACTION_GET_CONTENT)
            .addCategory(Intent.CATEGORY_OPENABLE);

    startActivityForResult(i, REQUEST_GET);
}

@override
public void onActivityResult(int requestCode, int resultCode, Intent resultData) {
    if (resultCode == Activity.RESULT_OK) {
        getActivity()
            .startService(new Intent(getActivity(), DurablizerService.class)
                .setData(resultData.getData()))
            .addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION));
    }
}

@override
protected void onHandleIntent(Intent intent) {
    Uri document = intent.getData();
    boolean weHaveDurablePermission = obtainDurablePermission(document);

    // Handle Intent
}

However, whereas the Documents/Consumer sample app processed the resulting Uri directly in onActivityResult(), now we delegate that work to a DurablizerService that is responsible for ensuring that we have durable access to the content:

We pass the Uri via the data facet of the Intent (setData()), plus add the FLAG_GRANT_READ_URI_PERMISSION flag. This ensures that DurablizerService will have access to the content even if MainActivity is destroyed before our work is complete.

onHandleIntent() in DurablizerService has a basic flow:

- Try to obtain persistable permissions
- If that does not work, try to make a local copy
- If either of those work, deliver a DocumentFile to the UI layer via a ContentReadyEvent
The job of `obtainDurablePermission()` is to use `takePersistableUriPermission()` on a `ContentResolver` to request read and write access, at least on Android 4.4 or higher. So, we create a `perms` value that requests both `FLAG_GRANT_READ_URI_PERMISSION` and `FLAG_GRANT_WRITE_URI_PERMISSION`, and pass that to `takePersistableUriPermission()`, along with the document `Uri`:
Unfortunately, while `takePersistableUriPermission()` is synchronous, it does not actually tell us if we *have* those permissions. The only way to find out if we have access is to call `getPersistedUriPermissions()`, which returns a roster of `UriPermission` objects listing every persisted `Uri` permission held by our app. Then, we have to sift through those, looking for one matching our desired document `Uri`. `obtainDurablePermission()` then returns a boolean indicating whether or not our request for persistable permissions succeeded.

`makeLocalCopy()` will be called if `obtainDurablePermission()` returns false (e.g., we are on an older Android device or otherwise used `ACTION_GET_CONTENT`). Its job is to make a local copy of the content, so we have indefinite access:

```java
private Uri makeLocalCopy(Uri document) {
   DocumentFileCompat docFile=buildDocFileForUri(document);
   Uri result=null;

   if (docFile.getName()!=null) {
      try {
         String ext=MimeTypeMap.getInstance().getExtensionFromMimeType(docFile.getType());

         if (ext!=null) {
            ext="."+ext;
         }

         File f=File.createTempFile("cw_", ext, getFilesDir());
         docFile.copyTo(f);
         result=Uri.fromFile(f);
      }
      catch (Exception e) {
         Log.e(getClass().getSimpleName(), "Exception copying content to file", e);
      }
   }
   return(result);
}
```

We start off by getting a `DocumentFileCompat` for the document `Uri`, using a `buildDocFileForUri()` helper method:
CONSUMING DOCUMENTS

```java
private DocumentFileCompat buildDocFileForUri(Uri document) {
    DocumentFileCompat docFile;

    if (document.getScheme().equals(ContentResolver.SCHEME_CONTENT)) {
        docFile = DocumentFileCompat.fromSingleUri(this, document);
    } else {
        docFile = DocumentFileCompat.fromFile(new File(document.getPath()));
    }

    return (docFile);
}
```

(from Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/DurablizerService.java)

This handles both likely scenarios:

- We get a content: Uri, and so our DocumentFileCompat needs to be created using the fromSingleUri() factory method
- We get a file: Uri, and so our DocumentFileCompat needs to be created using the fromFile() factory method

Back in makeLocalCopy(), we get the file extension associated with the content’s MIME type, by way of MimeMap and getExtensionFromMimeType(). Calling getType() on the DocumentFileCompat will fail if, for some reason, we have a content: Uri but do not have any permission to work with it. For example, had we failed to include FLAG_GRANT_READ_URI_PERMISSION on the Intent that started DurablizerService and if the MainActivity were destroyed by this point, we would not have any rights to use the content, and getType() will fail to get the MIME type for the content.

But, if getType() succeeds, we try to get that file extension. That too might fail, returning null, if the MIME type is not recognized by MimeMap. We can live with a null file extension. However, if the file extension is not null, it will lack the leading ., so we add that. Then, we create a unique file in getFilesDir(), using that file extension and createTempFile() on File. From there, we use the convenient copyTo() method on DocumentFileCompat to copy that content into our temporary file.

The ContentReadyEvent simply wraps a DocumentFileCompat pointing to our final content: either the original Uri (if we obtained durable access to it) or on our local copy:
**CONSUMING DOCUMENTS**

```java
static class ContentReadyEvent {
    final DocumentFileCompat docFile;

    ContentReadyEvent(DocumentFileCompat docFile) {
        this.docFile = docFile;
    }
}

(From Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/DurablizerService.java)
```

Back in ConsumerFragment, when the ContentReadyEvent is received, we log the details to the transcript:

```java
@Subscribe(threadMode=ThreadMode.MAIN)
public void onContentReady(DurablizerService.ContentReadyEvent event) {
    logToTranscript(event.docFile.getUri().toString());
    logToTranscript("Display name: " + event.docFile.getName());
    logToTranscript("Size: " + Long.toString(event.docFile.length()));
}

(From Documents/Durable/app/src/main/java/com/commonsware/android/documents/consumer/ConsumerFragment.java)
```

For cases where we are granted persistable permissions, the output will show a content: Uri, as we can continue to use the original content:

![Durable Document Demo](image)

*Figure 755: Durable Document Demo, Showing Document Result*
CONSUMING DOCUMENTS

For cases where we were not granted persistable permissions — such as ACTION_GET_CONTENT — the output will show a file: Uri, representing the local copy of the content:

![Durable Document Demo](image)

*Figure 756: Durable Document Demo, Showing Content Result*

**Another Durable Example: Diceware**

Dealing with durable documents does not require a service. Services are a good idea when you might need to make a copy of the document (e.g., the ACTION_GET_CONTENT scenario) and you do not know how big that document might be. In cases where the document is known to be small, just using background threads is fine, such as via RxJava.

With that in mind, here is another sample app that demonstrates using ACTION_OPEN_DOCUMENT and ACTION_GET_CONTENT to work with user-provided documents. Unlike most examples in this book, though, this app has some direct usefulness, as it is a passphrase generator, using the diceware approach.

**Dice? Where?!?**

Simply put, diceware is a technique for generating a lengthy passphrase that still has
The name “diceware” comes from the canonical way of generating the passphrase: rolling five six-sided dice (the sorts of dice that you see in casinos and board games) and looking up words in a word list. The more randomly-chosen words in the passphrase, the stronger the passphrase and the more time it would take for it to be cracked by somebody.

Perhaps the most famous such passphrase is correct horse battery staple, though a four-word passphrase is probably a bit short today.

**We Want Words!**

To use the diceware approach to generate a passphrase, you need a list of words.

A traditional diceware word list contains two columns. The right-hand column is the word, and the left-hand column is the dice roll that corresponds to that word:

4244  liverwurst
4245  lizard
4246  llama
4251  luau
4252  lubricant
4253  lucidity
4254  ludicrous
4255  luggage

The canonical diceware site has a number of word lists for a variety of languages. Each of those lists has 7,776 words, which equates to $6^5$, or the number of combinations of five rolls of a six-sided die.

However, other word lists also exist. The EFF has published a few lists, aiming for more commonly-used words and eliminating ones that might cause confusion (e.g., homophones). They also have some short lists, with only 1,296 ($6^4$) words, with an emphasis on shorter words. Shorter word lists require more words in the passphrase to get the same level of security (e.g., 8 words from the short lists result in similar security as 6 words from the longer lists).

The Documents/Diceware sample application packages one of the EFF word lists in the app itself, as an asset, so the app is usable “out of the box” to generate a passphrase. However, it also has action bar items to allow you to use
ACTION_OPEN_DOCUMENT or ACTION_GET_CONTENT to use a different word list, if you wanted.

**The Results**

First, let’s take a look at what the app does, before we see how it is built.

When you run the app, you immediately get a CardView showing a randomly-generated passphrase, using the word list that is baked into the app:

![Diceware App, As Initially Launched](image)

*Figure 757: Diceware App, As Initially Launched*
Clicking the refresh action bar item will generate a fresh passphrase, while tapping the “Words” action bar item lets you choose the length of the passphrase (from 4-10 words):

![Diceware App, Showing Word Count Submenu](image)

There are three options in the action bar overflow:

- “Get Word File”, which uses ACTION_GET_CONTENT to allow you to pick an alternative word list file
- “Open Word File”, which uses ACTION_OPEN_DOCUMENT to allow you to do the same
- “Reset”, which switches you back to the built-in word list

**How We Got There**

The Diceware app consists of a single PassphraseFragment, loaded using a FragmentTransaction by the MainActivity.

**Loading Our Words**

PassphraseFragment uses two RxJava Observable objects:
CONSUMING DOCUMENTS

- One manages loading the list of words and randomly choosing a word from that list (wordsObservable)
- The other manages getting durable access to the external word file that you choose to load in (docObservable)

When the app first runs, neither of these are set up yet. In `onViewCreated()`, we confirm that we do not have a `docObservable` at the moment — if we did, that would indicate that we are still in the middle of getting durable access to some words. Normally, `docObservable` will be `null` here, and so we call a `loadWords()` method:

```java
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    passphrase=view.findViewById(R.id.passphrase);

    if (savedInstanceState!=null) {
        wordCount=savedInstanceState.getInt(STATE_WORD_COUNT);
    }

    if (docObservable!=null) {
        docSub();
    } else {
        loadWords(false, wordsObservable==null);
    }
}
```

(we will cover `docObservable`, `docSub()`, and `wordCount` later)

`loadWords()` takes two boolean parameters:

- The first is “should we forcibly reload our words, even if we already loaded them before?”
- The second is “do we want to generate a new passphrase?”

PassphraseFragment is a retained fragment. It is entirely possible that we already have our words loaded from disk, in which case we do not need to load them again (e.g., after the user rotated the screen). So, here we pass `false` for the first parameter.
However, just because the user rotated the screen does not mean that we want to generate a fresh passphrase. We only want to do that if we do not already have a passphrase, or have one being generated right now. If `wordsObservable` exists (is not `null`), then we know that a passphrase has either been displayed or is soon to be displayed, and so we can skip creating a new one. When the app is first launched, though, `wordsObservable` is `null`, and so we tell `loadWords()` to generate a passphrase.

`loadWords()` then sets up `wordsObservable`:

```java
private void loadWords(boolean forceReload, boolean regenPassphrase) {
    if (wordsObservable == null || forceReload) {
        final Application app = getActivity().getApplication();
        wordsObservable = Observable
            .defer(() -> (Observable.just(PreferenceManager
                .getDefaultSharedPreferences(app))))
            .subscribeOn(Schedulers.io())
            .map(sharedPreferences -> {
                PassphraseFragment.this.prefs = sharedPreferences;
                return sharedPreferences.getString(PREF_URI, "")
            })
            .map(s -> {
                InputStream in;
                if (s.length() == 0) {
                    in = app.getAssets().open(ASSET_FILENAME);
                } else {
                    in = app.getContentResolver().openInputStream(Uri.parse(s));
                }
                return readWords(in);
            })
            .cache()
            .observeOn(AndroidSchedulers.mainThread());
    }
    unsubWords();

    if (regenPassphrase) {
        wordsSub = wordsObservable.subscribe(this::rollDemBones, error -> {
            Toast.makeText(getActivity(), error.getMessage(), Toast.LENGTH_LONG)
                .show();
        };
    }
```
We only need to set up `wordsObservable` if it does not already exist or `forceReload` is true. In either of those cases, we:

- Use `defer()` to set up an `Observable` that starts by loading the default `SharedPreferences` for our app, as that is where we will record the `Uri` of any external word list that we are supposed to be using
- Use `subscribeOn()` to move all this I/O to a background thread
- Use `map()` to extract the `String` preference value, keyed by `PREF_URI`, that is the `Uri` for our external word list, returning the empty string if there is no such `Uri` (note: we cannot return `null` because RxJava does not like that)
- Use another `map()` to create an `InputStream` either on that external word list or the one in `assets/`, then read in the words from that stream via `readWords()`
- Use `cache()` to get RxJava to hold onto the results of all that work, so long as we have the same `wordsObservable` object
- Use `observeOn()` to arrange to observe the results on the main application thread

`readWords()` simply reads in the lines from the asset or external word list, divides each line on the whitespace between the two columns, and extracts the word from the second column:
CONSUMING DOCUMENTS

```java
return(result);
}
```

(from Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java)

loadWords() then calls unsubWords(). This will dispose() any existing subscription to wordsObservable:

```java
private void unsubWords() {
    if (wordsSub!=null && !wordsSub.isDisposed()) {
        wordsSub.dispose();
    }
}
```

(from Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java)

Then, if we need a passphrase (regenPassphrase is true), we subscribe() to the wordsObservable, routing the word list to a rollDemBones() method, and displaying a Toast and logging to Logcat in case there is some sort of error (e.g., IOException reading in the words).

rollDemBones() uses SecureRandom to pick wordCount words from the list and updates the passphrase TextView with those words:

```java
private void rollDemBones(List<String> words) {
    StringBuilder buf=new StringBuilder();
    int size=words.size();

    for (int i=0;i<wordCount;i++) {
        if (buf.length()>0) {
            buf.append(' ');
        }
        buf.append(words.get(random.nextInt(size)));
    }
    passphrase.setText(buf.toString());
}
```

(from Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java)

The net result, after all of that, is that when we first run the app, we create and subscribe to the wordsObservable, and after a brief bit of I/O, we show the initial passphrase to the user.
Getting More Words

Handling the ACTION_GET_CONTENT and ACTION_OPEN_DOCUMENT scenarios is reminiscent of the Documents/Durable sample from before.

The two action bar items (“Get Word File”, “Open Word File”) route to get() and open() methods, each of which call startActivityForResult() with the appropriate action string:

```java
@TargetApi(Build.VERSION_CODES.KITKAT)
private void open() {
    Intent i =
        new Intent()
        .setType("text/plain")
        .setAction(Intent.ACTION_OPEN_DOCUMENT)
        .addCategory(Intent.CATEGORY_OPENABLE);

    startActivityForResult(i, REQUEST_OPEN);
}

private void get() {
    Intent i =
        new Intent()
        .setType("text/plain")
        .setAction(Intent.ACTION_GET_CONTENT)
        .addCategory(Intent.CATEGORY_OPENABLE);

    startActivityForResult(i, REQUEST_GET);
}
```

(from Documents/Diceware/app/src/main/java/com/commonsware/android/diceware/PassphraseFragment.java)

In onActivityResult(), if we received a RESULT_OK response, we set up docObservable, where we:

- Use defer() and just() to “observe” the results of calling createDurableContent(), supplying it the Intent that is the result of the startActivityForResult() call
- Use subscribeOn() to move that work to a background thread
- Use cache() to cache the results for as long as we have docObservable
- Use observeOn() to observe the results on the main application thread.

createDurableContent(), along with obtainDurablePermissions(), makeLocalCopy(), and buildDocFileForUri(), does the same work that the
DurablizerService did in the Documents/Durable sample app:

- Get the persistable Uri permissions, if we can have them
- Make a local copy of the content, if we cannot

The biggest differences are that createDurableContent() saves the Uri of either the opened document (if we got permission) or the local copy in SharedPreferences, and it returns a DocumentFileCompat representing the external word list:

```java
private DocumentFileCompat createDurableContent(Intent result) throws IOException {
    Uri document = result.getData();
    ContentResolver resolver = getActivity().getContentResolver();
    boolean weHaveDurablePermission = obtainDurablePermission(resolver, document);

    if (!weHaveDurablePermission) {
        document = makeLocalCopy(getActivity(), resolver, document);
    }

    if (weHaveDurablePermission || document != null) {
        prefs.edit().putString(PREF_URI, document.toString()).commit();
        return (buildDocFileForUri(getActivity(), document));
    }

    throw new IllegalStateException("Could not get durable permission or make copy");
}

private static boolean obtainDurablePermission(ContentResolver resolver, Uri document) {
    boolean weHaveDurablePermission = false;

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
        int perms = Intent.FLAG_GRANT_READ_URI_PERMISSION
            | Intent.FLAG_GRANT_WRITE_URI_PERMISSION;

        try {
            resolver.takePersistableUriPermission(document, perms);

            for (UriPermission perm : resolver.getPersistedUriPermissions()) {
                if (perm.getUri().equals(document)) {
                    weHaveDurablePermission = true;
                }
            }
        } catch (SecurityException e) {
            // OK, we were not offered any persistable permissions
        }
    }

    return (weHaveDurablePermission);
}

private static Uri makeLocalCopy(Context ctxt, ContentResolver resolver,
```
CONSUMING DOCUMENTS

```java
Uri document)
throws IOException {
DocumentFileCompat docFile = buildDocFileForUri(ctx, document);
Uri result = null;
if (docFile.getName() != null) {
    String ext = MimeTypeMap.getSingleton().getExtensionFromMimeType(docFile.getType());
    if (ext != null) {
        ext = "\" + ext;
    }
    File f = File.createTempFile("cw", ext, ctx.getFilesDir());
    docFile.copyTo(f);
    result = Uri.fromFile(f);
} return result;
}

private static DocumentFileCompat buildDocFileForUri(Context ctx, Uri document) {
    DocumentFileCompat docFile;
    if (document.getScheme().equals(ContentResolver.SCHEME_CONTENT)) {
        docFile = DocumentFileCompat.fromSingleUri(ctx, document);
    } else {
        docFile = DocumentFileCompat.fromFile(new File(document.getPath()));
    }
    return docFile;
}
```

(onActivityResult() then calls docSub():

```java
private void docSub() {
    docSub = docObservable.subscribe(documentFile -> {
        docObservable = null;
        loadWords(true, true);
    });
}
```

Here, we subscribe to docObservable, and when the work is complete, we set
docObservable to null (indicating that we are done with it), then call
loadWords(true, true) to reload the words from our new source and generate a
new passphrase based on those words.
The net result is that tapping either of those action bar items brings up the

2658
appropriate system UI to pick a piece of content, after which we start using that content. And, since we are persisting the Uri to that external word list in SharedPreferences, we will continue using that word source for the foreseeable future.

**Other Fiddly Bits**

That “foreseeable future” may not be all that long. If the user taps the “Reset” action bar overflow item, we clear() our SharedPreferences, then call loadWords(true, true) to read in the asset’s words plus generate a passphrase based that word list:

```java
case R.id.reset:
    prefs.edit().clear().apply();
    loadWords(true, true);
    return(true);
```

(from Documents/Diceware/app/src/main/java/com.commonsware/android/diceware/PassphraseFragment.java)

The action bar itself is populated from a menu resource, one that defines a submenu for the possible wordCount values:

```xml
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item android:id="@+id/word_count"
        android:showAsAction="ifRoom"
        android:title="@string/menu_words">
    <menu>
      <group android:checkableBehavior="single">
        <item android:id="@+id/word_count_4"
              android:title="4" />
        <item android:id="@+id/word_count_5"
              android:title="5" />
        <item android:id="@+id/word_count_6"
              android:checked="true"
              android:title="6" />
        <item android:id="@+id/word_count_7"
              android:title="7" />
        <item android:id="@+id/word_count_8"
              android:title="8" />
      </group>
    </menu>
  </item>
</menu>
```
We start with the `word_count_6` item checked, and the `wordCount` field is also initialized to 6. If the user taps on any of those submenu items, we update the submenu to check the proper item, figure out the new `wordCount` (by cheating and parsing the menu title as an `Integer`), and if the user changed word count values we generate a fresh passphrase (without re-loading the word list):

```java
    case R.id.word_count_4:
    case R.id.word_count_5:
    case R.id.word_count_6:
    case R.id.word_count_7:
    case R.id.word_count_8:
    case R.id.word_count_9:
    case R.id.word_count_10:
        item.setChecked(!item.isChecked());
```
int temp=Integer.parseInt(item.getTitle().toString());

if (temp!=wordCount) {
    wordCount=temp;
    loadWords(false, true);
}
return(true);

Since that wordCount value can change, we save it as part of the saved instance state Bundle in onSaveInstanceState(), and we pull that value back out of that Bundle in onCreateView().

However, we are not putting the generated passphrase in the saved instance state Bundle ourselves, even though clearly that is being generated at runtime. Here, Diceware takes advantage of a bit of a trick. On the layout resource, the TextView that shows the passphrase has android:freezesText="true":

<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:padding="8dp">

    <android.support.v7.widget.CardView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center"
        android:padding="8dp">

        <TextView
            android:id="@+id/passphrase"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:freezesText="true"
            android:textSize="20sp"
            android:typeface="monospace"/>
    </android.support.v7.widget.CardView>
</FrameLayout>

Ordinarily, the contents of a TextView are not part of the saved instance state Bundle, because Android assumes that those values are fixed (e.g., via android:text
in the layout). In our case, we are generating the passphrase at runtime, and so android:freezeText="true" tells Android to hold onto our TextView content in the saved instance state Bundle automatically, the way that it does for EditText. Hence, with that one attribute, Android will take care of holding onto the passphrase across configuration changes for us.

Document Trees

ACTION_OPEN_DOCUMENT and ACTION_CREATE_DOCUMENT are sufficient for most apps. These roughly correspond to the “file open” and “new file” dialogs that you see in desktop operating systems.

However, there may be cases where you need the equivalent of a “choose folder” dialog, to allow the user to pick a location where you can create (or work with) several documents. For example, suppose that your app offers a report generator, taking data from the database and creating a report with tables and graphs and stuff. Some file formats, like PDF, might have the entire report in a single file — for that, use ACTION_CREATE_DOCUMENT to allow the user to choose where to put that report. Other file formats, like HTML, might require several files (e.g., the report body in HTML and embedded graphs in PNG format). For that, you really need a “folder”, into which you can create all of those individual bits of content.

For that, the Storage Access Framework offers document trees... as of Android 5.0 (API Level 21). Android 4.4's edition of the Storage Access Framework lacked this capability.

Getting a Tree

Instead of using ACTION_OPEN_DOCUMENT, you can use ACTION_OPEN_DOCUMENT_TREE. Once again, you will use startActivityForResult() to request access to the tree. In onActivityResult(), the result Intent has a Uri (getData()) that represents the tree. You should have full read/write access not only to this tree but to anything inside of it.

Another option, starting with Android 7.0, is "scoped directory access". Here, you work with StorageManager to access the device's StorageVolume list. All devices should have at least one StorageVolume, representing what we think of as external storage. Some devices may have more than that, representing mounted removable media. Given a StorageVolume, you can call createAccessIntent() to get an Intent that will ask the user permission for access to some portion of that volume, when
CONSUMING DOCUMENTS

called with startActivityForResult(). As with ACTION_OPEN_DOCUMENT_TREE, you get a Uri in onActivityResult() that you can then use to work with that tree of files.

Working in the Tree

The simplest approach for then working with the tree is to use the aforementioned DocumentFile wrapper. You can create one representing the tree by using the fromTreeUri() static method, passing in the Uri that you got from the ACTION_OPEN_DOCUMENT_TREE request.

From there, you can:

• Call listFiles() to get the immediate children of the root of this tree, getting back an array of DocumentFile objects representing those children
• Call isDirectory() to confirm that you do indeed have a tree (or, call it on a child to see if that child represents a sub-tree)
• For those existing children that are files (isFile() returns true), use getUri() to get the Uri for this child, so you can read its contents using a ContentResolver and openInputStream()
• Call createDirectory() or createFile() to add new content as an immediate child of this tree, getting a DocumentFile as a result
• For the createFile() scenario, call getUri() on the DocumentFile to get a Uri that you can use for writing out the content using ContentResolver and openOutputStream()
• and so on

Note that you can call takePersistableUriPermission() on a ContentResolver to try to have durable access to the document tree, just as you can for a Uri to an individual document.

Getting a Tree: Example

The Documents/DocumentTree sample application demonstrates how to use ACTION_OPEN_DOCUMENT_TREE and StorageManager/StorageVolume to get a Uri pointing to a directory that you can work with.

The Objective: a Preference for Storage

The sample app’s UI is a PreferenceFragment, where we have two preferences: one
to pick a document tree via ACTION_OPEN_DOCUMENT_TREE and one to pick a StorageVolume from among the available volumes. In theory, an app might include one of these for the user to pick an alternative default storage location for files, for example. However, since the StorageVolume APIs for choosing a storage volume are new to API Level 24, we will only enable that preference on compatible devices.

In each case, part of the work to get access to these locations involves startActivityForResult(), which is unusual for a preference and adds to the sample’s complexity.

What the User Sees

When the user first launches the app, the preference subtitles are “no value”, because the user has not chosen anything yet:

*Figure 759: DocumentTree Demo, As Initially Launched*
If the user taps the “Document Tree Root” preference, the UI for the Storage Access Framework appears, allowing the user to browse for a directory of interest:

*Figure 760: DocumentTree Demo, Showing “Internal Storage” via SAF*
CONSUMING DOCUMENTS

If the user chooses a location, the preference is updated with the Uri of the selected document tree:

![DocumentTree Demo](image)

*Figure 761: DocumentTree Demo, Showing Selected Document Tree Uri*
CONSUMING DOCUMENTS

If the user taps the “Storage Volume” preference, a ListPreference dialog appears, showing the available storage volumes:

![Image of DocumentTree Demo, Showing Available Storage Volume(s)](image)

*Figure 762: DocumentTree Demo, Showing Available Storage Volume(s)*

On some devices, there will only be one option (“Internal shared storage”, or what we developer call “external storage”). On other devices, if there is a piece of removable storage mounted, there will be more than one option.
CONSUMING DOCUMENTS

If the user chooses a volume, a permission confirmation dialog may appear, to confirm that the user wants to grant you access to the “Documents” directory inside of that storage volume:

![Figure 763: DocumentTree Demo, Requesting Permission](image)

*Figure 763: DocumentTree Demo, Requesting Permission*
If the user grants permission, once again the preference's subtitle will reflect the URI of the chosen location:

*Figure 764: DocumentTree Demo, Showing Selected Storage Volume Directory*
CONSUMING DOCUMENTS

On Android 5.0-6.0 devices, the app will run, but the storage volume preference is disabled:

![Figure 765: DocumentTree Demo, Running on Android 6.0](image)

The Document Tree

Of the two options, ACTION_OPEN_DOCUMENT_TREE is the most straightforward to implement: call `startActivityForResult()` and get your `Uri` in `onActivityResult()`.

But, since preferences are not set up to handle `startActivityForResult()` or receive data via `onActivityResult()`, we have a little bit of work to do.

The Preference XML

The app has a `res/raw/settings.xml` file containing our preferences:

```xml
<?xml version="1.0" encoding="utf-8"?>
  <Preference
    android:key="documentTree"
    android:title="@string/pref_doc_tree" />
  <ListPreference
```
CONSUMING DOCUMENTS

android:dialogTitle="@string/dlg_storage_volume"
android:enabled="@bool/is_nougat"
android:key="storageVolume"
android:title="@string/pref_storage_volume" />
</PreferenceScreen>

The first one is our “Document Tree Root” preference... and it is literally a Preference. This is not used all that frequently, since it cannot actually collect any preference data. In cases like this one, where we really want to handle this more like the user tapped on a generic ListView row, it is a reasonable choice.

We will explore the ListPreference for the “Storage Volume” option later in this section.

Populating the Preference

The UI is a PreferenceFragment subclass named SettingsFragment. In onCreate(), we call addPreferencesFromResource() to inflate that preference XML and populate the fragment:

```java
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    addPreferencesFromResource(R.xml.settings);

    prefDocTree=findPreference(PREF_DOC_TREE);
    prefs=prefDocTree
        .getSharedPreferences();
    prefs.registerOnSharedPreferenceChangeListener(this);
    onSharedPreferenceChanged(prefs, PREF_DOC_TREE);
    docTreeHelper=new DocumentHelper(this,
        prefDocTree);

    prefVolumes=(ListPreference)findPreference(PREF_VOLUMES);

    if (prefVolumes.isEnabled()) {
        populateVolumes();
        onSharedPreferenceChanged(prefs, PREF_STORAGE_URI);
        volumeHelper=
            new VolumeHelper(this, prefVolumes,
                PREF_STORAGE_URI, Environment.DIRECTORY_DOCUMENTS);
    }
}
```
We then do a few things to set up our “Document Tree Root” preference:

- We call `findPreference()` to get that Preference object, storing it in a `prefDocTree` field.
- We ask the Preference for the SharedPreferences that are being used, holding onto that in a field named `prefs`.
- Register the fragment itself as an `OnSharedPreferenceChangeListener` for the SharedPreferences, then immediately call `onSharedPreferenceChanged()`. That, in turn, fills in the summary of the Preference with the current Uri, if we have one:

```java
@Override
public void onSharedPreferenceChanged(SharedPreferences prefs, String key) {
    if (PREF_DOC_TREE.equals(key)) {
        prefDocTree.setSummary(prefs.getString(key, "<no value>"));
    } else if (PREF_STORAGE_URI.equals(key)) {
        prefVolumes.setSummary(prefs.getString(key, "<no value>")).replaceAll("%", "%%");
    }
}
```

- Wrap that Preference in a `DocumentHelper` object, which we will look at shortly.

We will cover the remainder of this code, pertaining to the other preference, later.

**Choosing a Tree**

We need some common code between the document-root and the storage-volume options:

- Bridging between a Preference and a hosting activity or fragment that can do the `startActivityForResult()` and `onActivityResult()` work
- Calling `takePersistableUriPermission()`
- Updating the SharedPreferences with the Uri that we receive

The `TreeUriPreferenceHelper` abstract class, along with its `DocumentHelper` and
VolumeHelper subclasses, implement this common code.

A TreeUriPreferenceHelper subclass’ constructor needs to be passed the Preference that we are “helping”, along with some implementation of the Host interface:

```java
public interface Host {
    void startActivityForHelper(Intent intent,
                                TreeUriPreferenceHelper helper);
}
```

DocumentHelper simply collects those values, passes them to TreeUriPreferenceHelper, and registers itself to be called when the user clicks on the Preference:

```java
package com.commonsware.android.documenttree;
import android.content.Intent;
import android.preference.Preference;
public class DocumentHelper extends TreeUriPreferenceHelper
                                implements Preference.OnPreferenceClickListener {
    public DocumentHelper(Host host, Preference pref) {
        super(host, pref);
        pref.setOnPreferenceClickListener(this);
    }
    @Override
    protected String getUriKey() {
        return (pref.getKey());
    }
    @Override
    public boolean onPreferenceClick(Preference preference) {
        Intent i=new Intent(Intent.ACTION_OPEN_DOCUMENT_TREE);
        host.startActivityForHelper(i, this);
        return (true);
    }
}
```

TreeUriPreferenceHelper, in turn, just holds onto the Host and Preference in host
and pref fields, respectively.

When the user clicks on the Preference, the `onPreferenceClick()` method of the `DocumentHelper` is called. There, we create an `ACTION_OPEN_DOCUMENT_TREE` Intent and call `startActivityForHelper()` on the host.

Our Host, in this case, is the `SettingsFragment`, so it has an implementation of `startActivityForHelper()`:

```java
@Override
public void startActivityForHelper(Intent intent,
                                        TreeUriPreferenceHelper helper)
{
    if (helper==docTreeHelper) {
        startActivityForResult(intent, REQUEST_DOC_TREE);
    } else if (helper==volumeHelper) {
        startActivityForResult(intent, REQUEST_STORAGE_VOLUME);
    }
}
```

It just sees which `TreeUriPreferenceHelper` we are working with, then calls `startActivityForResult()` with an appropriate request code (e.g., `REQUEST_DOC_TREE`).

Eventually, `SettingsFragment` should be called with `onActivityResult()`. If the result is `RESULT_OK`, we forward the result along to the `TreeUriPreferenceHelper`, based on the request code:

```java
@Override
public void onActivityResult(int requestCode, int resultCode, Intent data) {
    if (resultCode==Activity.RESULT_OK) {
        if (requestCode==REQUEST_DOC_TREE) {
            docTreeHelper.onActivityResult(data);
        } else if (requestCode==REQUEST_STORAGE_VOLUME) {
            volumeHelper.onActivityResult(data);
        }
    }
}
```

2674
CONSUMING DOCUMENTS
TreeUriPreferenceHelper has the common implementation of
onActivityResult(), where we call takePersistableUriPermission() (asking for
read/write access) and put the Uri into the SharedPreferences under some key:
public void onActivityResult(Intent data) {
Uri docTree=data.getData();
ContentResolver cr=pref.getContext().getContentResolver();
int perms=Intent.FLAG_GRANT_READ_URI_PERMISSION
| Intent.FLAG_GRANT_WRITE_URI_PERMISSION;
cr.takePersistableUriPermission(docTree, perms);
pref
.getSharedPreferences()
.edit()
.putString(getUriKey(), docTree.toString())
.apply();
}
(from Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/TreeUriPreferenceHelper.java)

In the case of the document-root Preference, that key is the key from the
Preference itself (getKey()). Saving the value not only persists it, but it also triggers
the SettingsFragment to be notified about the new value, causing
SettingsFragment to update the Preference summary… which is why we see the Uri
show up on the screen right after selecting it.

The Storage Volume
The StorageVolume scenario is a bit more complicated, in that we have to provide
the UI for choosing a volume — this is not provided by Android. That, plus some
interesting challenges in the StorageVolume implementation, add to our level of
effort.
The Preference XML
The settings.xml file has a ListPreference that will serve as the UI for selecting a
StorageVolume:
<ListPreference
android:dialogTitle="@string/dlg_storage_volume"
android:enabled="@bool/is_nougat"
android:key="storageVolume"

2675


Since the roster of possible volumes is dynamic, we cannot provide our ListPreference contents via string-array resources, but instead will need to do so from Java code.

Note that this preference is enabled based upon an is_nougat bool resource. That is set to true for API Level 24+ (in res/values-v24/bools.xml), false otherwise (in res/values/bools.xml).

**Populating the Preference**

Some of the work from `onCreate()` of SettingsFragment is for setting up this ListPreference:

```java
prefVolumes=(ListPreference)findPreference(PREF_VOLUMES);

if (prefVolumes.isEnabled()) {
    populateVolumes();
    onSharedPreferenceChanged(prefs, PREF_STORAGE_URI);
    volumeHelper =
        new VolumeHelper(this, prefVolumes,
                         PREF_STORAGE_URI, Environment.DIRECTORY_DOCUMENTS);
}
```

We store the ListPreference in a `prefVolumes` field, before calling a private `populateVolumes()` method to fill in the list contents. We also trigger updating its summary via a manual call to `onSharedPreferenceChanged()`, plus wrap the ListPreference in a VolumeHelper that we will explore in detail shortly. And all of this is wrapped in a check to see if the preference is enabled; if it is not, we skip this work, as it is unnecessary.

`populateVolumes()` is responsible for providing the entries and values for the ListPreference, based on the available volumes:

```java
private void populateVolumes() {
    StorageManager storage =
        (StorageManager)Activity.getSystemService(Context.STORAGE_SERVICE);
    List<StorageVolume> volumes = storage.getStorageVolumes();
}
```
We start off by getting a StorageManager system service. Here, we are using the newer version of `getSystemService()`, introduced in API Level 21, where we can pass in the Java class of the system service that we want (`StorageManager.class`). This allows Android to return an instance of the actual class, avoiding a cast.

Then, we call `getStorageVolumes()` on the StorageManager, to get the roster of available StorageVolume objects.

Since those StorageVolume objects might arrive in any order, we sort() them by their description, which is a human-readable label describing what the volume is. For example, for removable storage, it might be a combination of the manufacturer of the drive or card, plus the stated capacity of the drive or card.

Since ListPreference wants two String arrays for the entries and values, we set those up, filling them in from the description and UUIDs of the volumes. Each volume is supposed to have a UUID, but that is not guaranteed — in particular, the StorageVolume for external storage returns `null` for `getUuid()`. Since ListPreference `really` does not like null values, we substitute in a non-UUID string...
(STORAGE_FAKE_UUID, defined to be "fake") to identify it. We then give those two string arrays to the ListPreference.

Choosing a Volume

VolumeHelper, like DocumentHelper, is designed to help bridge between the preference system, the hosting fragment, and the Android APIs for getting a document tree Uri.

VolumeHelper takes two additional constructor parameters, beyond the Host and Preference:

- The key for the SharedPreferences under which the Uri will be stored. The ListPreference will store the UUID of the storage volume under its key, but once we get the Uri, we need to save it to the SharedPreferences as well, for later use.
- The directory on the storage volume to use. createAccessIntent() accepts any of the standard Environment directories — in this case, we are using DIRECTORY_DOWNLOADS

The constructor holds onto those additional parameters in fields, then registers itself to respond to when the ListPreference value changes, because the user selected a different StorageVolume in the list:

```java
package com.commonsware.android.documenttree;

import android.content.Intent;
import android.os.storage.StorageManager;
import android.os.storage.StorageVolume;
import android.preference.ListPreference;
import android.preference.Preference;
import java.util.List;

public class VolumeHelper extends TreeUriPreferenceHelper
    implements Preference.OnPreferenceChangeListener {
    private final String uriKey;
    private final String dirName;

    public VolumeHelper(Host host, ListPreference pref, String uriKey,
        String dirName) {
        super(host, pref);

        this.uriKey=uriKey;
        this.dirName=dirName;
    }
}
```
CONSUMING DOCUMENTS

```java
pref.setOnPreferenceChangeListener(this);
}

@Override
protected String getUriKey() {
    return (uriKey);
}

@Override
public boolean onPreferenceChange(Preference pref,
        Object o) {
    StorageManager storage =
        pref.getContext().getSystemService(StorageManager.class);
    List<StorageVolume> volumes = storage.getStorageVolumes();
    String uuid = o.toString();

    for (StorageVolume volume : volumes) {
        if (((volume.getUuid() == null &&
                uuid.equals(SettingsFragment.STORAGE_FAKE_UUID)) ||
                (uuid.equals(volume.getUuid())))) {
            Intent i = volume.createAccessIntent(dirName);
            host.startActivityForHelper(i, this);
            break;
        }
    }

    return(true);
}
```

(from Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/VolumeHelper.java)

When the user eventually does change the selection in the ListPreference and onPreferenceChange() is called, we get a fresh StorageManager. Unfortunately, StorageManager does not have any sort of lookup API to get a StorageVolume by UUID, so we have to iterate over the currently-available volumes and find a match, taking into account our fake UUID for the null-UUID case.

When we find a match, we call createAccessIntent() on the StorageVolume, passing in the directory name. That Intent is then given to the Host via startActivityForHelper(). That will trigger the same process as was used for DocumentHelper, eventually resulting in the Uri being saved to the SharedPreferences under the supplied key.
Potential Issues

It is unclear if more than one StorageVolume could have a null UUID. If it can, the approach of using a fake value in lieu of null will not work. Of course, if more than one StorageVolume could have a null UUID, we will have no means of identifying which StorageVolume the null UUID refers to, making long-term identification of StorageVolume objects difficult.

Scoped Directory Access Bug

The scoped directory access feature — using StorageVolume to request access to standard directories — works fairly well on Android 7.0+... with one UX flaw, tied to how the user grants you that access.

The flow of the permission dialogs resembles that of Android 6.0’s runtime permissions:

- When you first ask for access, the user can allow or deny
- If the user denied access, and you later ask for access again, the dialog now has a “Don’t ask again” checkbox
- If the user checked that checkbox and denied access again, any future attempts you make to request access will be denied immediately, without the user seeing a dialog

One problem is that we have no good way of knowing that the user has previously denied our request, let alone checked the “Don’t ask again” checkbox. With Android 6.0’s runtime permissions, we have checkSelfPermission() and shouldShowPermissionRequestRationale() for those things. We have no equivalents for scoped directory access.

However, the bigger problem is that once the user checks “Don’t ask again” and denies access, the user has no further recourse. With runtime permissions, the user can always go into the Permissions area of an app’s page in Settings and manually grant permissions. There is no equivalent of this for the scoped directory access API.

On Android 7.1, the user can use “Clear Data” to reset these dialogs, causing future dialogs to appear again even if “Don’t ask again” had been checked. Of course, “Clear Data” has somewhat broader impact than this, and the user might not appreciate wiping out all the app’s local data.
Worse, on Android 7.0, not only does “Clear Data” not fix this, but a full uninstall of the app does not fix this. Nothing short of a factory reset will allow the app to ask the user for permission and the user have an opportunity again to grant permission.

Admittedly, this is an edge case, but it is one that you should keep in mind if you are using `createAccessIntent()` and the scoped directory access API. Keep an eye on [this issue](#) to try to get some resolution to how the user is supposed to manually revert the “Don’t ask again” status.

## Android 8.0 Changes

Android 8.0 introduced some new options for consuming documents and document trees via the Storage Access Framework.

### Document Tree Traversal

The `DocumentsContract` client interface to the Storage Access Framework now has a `findDocumentPath()` method. Many developers will think that this means that they can get a filesystem path for a document `Uri` from the Framework.

That is not what this method does.

Instead, `findDocumentPath()` returns a list of document IDs representing the hierarchy of document trees leading to the specific document being requested. In other words, if the document is inside of a `goo` tree, which is inside of a `bar` tree, which is inside of a `foo` tree, and `foo` is the top of a provider's hierarchy, `findDocumentPath()` would return a List of document IDs representing `foo`, `bar`, `goo`, and the requested document.

Presumably, the idea is that this would be used by client UIs to help build a way to traverse the relevant set of document trees for a particular document.

For this to work, the corresponding `DocumentsProvider` needs to implement its own `findDocumentPath()` method.

### Web Links for Documents

`DocumentsContract` also has a `createWebLinkIntent()` method, with a corresponding implementation on `DocumentsProvider`. This is very poorly documented, but apparently the idea is that for some cloud document providers,
you can get a URL to the document, given the Storage Access Framework Uri for the
document. Presumably, this is a publicly-visible document, and the URL could be
sent to other parties (e.g., via email) for them to see the document.

Android itself does not ship with a cloud document provider. Google Play devices
may ship with Google Drive, and Drive might support this feature.

Document Settings Activity

If you implement a DocumentsProvider, you have the option of including
FLAG_SUPPORTS_SETTINGS in the details that you return for queryChildDocuments().
If you do that, and you have an activity that supports ACTION_DOCUMENT_SETTINGS,
the user may be presented with an option to visit that activity. The activity should be
given the Uri of the particular document that the user wishes to manage. A provider
might use this for offering management of metadata for the document: tags, access
rights, etc.
The Storage Access Framework gives developers access to ACTION_OPEN_DOCUMENT and related Intent actions to perform operations on a document provider.

However, what if you want to be a document provider?

To do that, you will need to create a subclass of DocumentsProvider, override some abstract methods, and perhaps put up with some really obtuse error messages.

This chapter will help you in setting up your DocumentsProvider. With luck, you will escape without encountering errors.

**Prerequisites**

This chapter assumes that you have read the preceding chapter on consuming documents, along with its prerequisites.

**Have Your Content, and Provide it Too**

Most apps will not need to implement a document provider. They might not even consume documents, let alone provide them to other apps.

However, if your app has document-style content, and that content is of a MIME type that could reasonably be manipulated by other apps, you should consider implementing a document provider to allow the user to manipulate that content using those other apps.

Historically, developers had two main approaches for content:
PROVIDING DOCUMENTS

1. Store it on internal storage
2. Store it on external storage

The internal storage route would be for content that would not normally be user-accessible, while external storage would be for user-accessible content.

In either of those cases, you will want to consider creating a document provider. In the case of internal storage, the user has no way to get to that content except through your app, and so if your app does not offer some capabilities that other apps do for that content, you limit your user by not having a document provider. In the case of external storage, while users in theory could use a file manager or something to try to get other apps to recognize the content, it will be easier for users if you provide a document provider to proactively publish this content to consuming apps.

However, bear in mind that your app does not have to store its content in either of these places. It could store the content in somebody else’s document provider, using the mechanisms discussed in the preceding chapter on consuming documents. In this case, you would not need to publish a document provider yourself, as the content is available through the same provider that your code is using.

It may also be the case that while your app is the one directly storing the content on internal or external storage, that content would not reasonably be used by other apps. Perhaps it is in some non-standard format that other apps are unlikely to support. Perhaps the files are not to be used by other apps for security reasons. In these cases, skipping the document provider is reasonable, though not exactly ideal from the user’s standpoint. In particular, it restricts them from using those files with apps that can work with any file, such as attaching them to email messages.

So, for example:

• If you are implementing a camera app, and you are not storing the photos in the standard DIRECTROY_DCIM location for photos, but you are storing the photos yourself in files consider implementing a document provider so users can get at the photos you are taking. But, if you are implementing a camera app, you might elect to allow the user to indicate some place in somebody else’s document provider where you could save the photo on their behalf.
• If you are implementing some sort of network-synced file service (e.g., Dropbox, Bittorrent Sync), or some sort of on-device version control system, consider implementing a document provider so users can manipulate the documents that you are managing on their behalf.
Key Provider Concepts

Creating a document provider is significantly more complex than is creating a document consumer. To help make sense of what is required, here are some key terms that you will need to understand.

Roots

A document provider can publish one or more “roots”. Basically, a “root” points to a tree of documents. Many providers will have just one root, but it is entirely possible for your provider to have more than one.

Documents

Documents, in turn, represent what in filesystem terms would be considered files and directories. A document can either have children (e.g., a directory) or it can have content (e.g., a file), but not both.

A root also is a document — here, “root” refers to the root of a tree of documents.

Root and Document IDs

Each root has an ID unique to your app to identify that root as being distinct from any other root. This is a string.

Each document — files and directories alike — will have a string document ID to uniquely identify that document within its root. If you have some natural identifier (e.g., a primary key in some table), feel free to use it. Otherwise, you might consider your document ID to be some path to get to the document.

And, since a root is also a document, a root will have both a root ID and a document ID.

These document IDs need to be durable. Clients, or the Storage Access Framework itself, may wind up caching these IDs. Hence, pick something that not only uniquely identifies this document, but will continue to uniquely identify the document even after the document has been modified.
Pieces of a Provider

The Documents/Provider sample application implements a document provider, one that serves documents baked into the app itself in assets/. Of course, this is a rather artificial scenario — usually, a document provider will be working with a read/write data store, like internal storage.

The Activity

A document provider app probably needs a real UI. Perhaps that UI is for broader functionality that the app provides on top of serving documents. Perhaps that UI is merely to configure the document store, such as providing account credentials for the online storage service that the document provider exposes on Android.

If nothing else, you will need a do-nothing activity for the user to run, to ensure that your app is moved out of the stopped state.

In the sample app, this is handled by MainActivity, which uses Theme.Translucent.NoDisplay to avoid a UI and just shows a Toast to indicate that the provider is now activated:

```java
package com.commonsware.android.documents.provider;

import android.app.Activity;
import android.content.res.AssetManager;
import android.os.Bundle;
import android.util.Log;
import android.widget.Toast;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;

public class MainActivity extends Activity {
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        Toast.makeText(this, R.string.activated, Toast.LENGTH_LONG).show();
        finish();
    }
}
```

(from Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/MainActivity.java)
The API Level Resources

The document provider itself comes courtesy of a subclass of DocumentsProvider. However, the DocumentsProvider class only exists on API Level 19 and higher — our subclass is useless on older devices. To ensure that our provider is only used on API Level 19 and higher, we should only enable it on API Level 19+ devices.

To that end, in res/values/bools.xml, we have a boolean resource named min19, set to false:

```xml
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <bool name="min19">false</bool>
</resources>
```

(from Documents/Provider/app/src/main/res/values/bools.xml)

In res/values-v19/bools.xml, we redefine that boolean resource to be true:

```xml
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <bool name="min19">true</bool>
</resources>
```

(from Documents/Provider/app/src/main/res/values-v19/bools.xml)

Hence, when we refer to the min19 boolean resource, we will get true or false depending upon whether we are on API Level 19 or not.

The Manifest

Since DocumentsProvider is a subclass of ContentProvider, we will need a <provider> element in the manifest pointing to our subclass of DocumentsProvider:

```xml
<provider
    android:name=".DemoDocumentsProvider"
    android:authorities="com.commonsware.android.documents.provider"
    android:enabled="@bool/min19"
    android:exported="true"
    android:grantUriPermissions="true"
    android:permission="android.permission.MANAGE_DOCUMENTS">
    <intent-filter>
        <action android:name="android.content.action.DOCUMENTS_PROVIDER" />
    </intent-filter>
</provider>
```
PROVIDING DOCUMENTS

That element:

- Uses our @bool/min19 resource from above to indicate that this component should only be enabled on API Level 19 and higher
- Is exported, but requires that applications looking to talk to our provider hold the MANAGE_DOCUMENTS permission, which can only be held by the firmware (or apps signed with the firmware's signing key)
- Sets the android:grantUriPermissions attribute to true, as that will be used by DocumentsProvider to allow third-party apps limited, conditional access to our documents
- Has your standard android:name and android:authorities attributes, as with any other <provider>

In addition, the <provider> has a nested <intent-filter> element. This may seem odd, as this used to be impossible, and it is not intuitively obvious what it would mean for a ContentProvider to have an IntentFilter. It also is not documented as being allowed on <provider>, so we have no official explanation of what this means. Most likely, the magic android.content.action.DOCUMENTS_PROVIDER filter is being used simply as a marker, to indicate to Android that this particular <provider> is part of the Storage Access Framework and implements a DocumentsProvider.

The DocumentsProvider

The real business logic of publishing documents comes from your subclass of DocumentsProvider. As this class is new to API Level 19, your build target (e.g., compileSdkVersion in build.gradle) needs to be 19 or higher.

A minimal DocumentsProvider implementation will typically need five methods, outlined below.

onCreate()

As with any ContentProvider, your DocumentsProvider can override onCreate() to perform initialization work. Technically, this is not required, but the odds are very good that you will have something that you need to initialize.

In the case of our sample DocumentsProvider — named DemoDocumentsProvider — onCreate() simply obtains access to an AssetManager instance that can be used for serving documents:
private AssetManager assets;

@Override
public boolean onCreate() {
    assets=getContext().getAssets();

    return(true);
}

queryRoots()

Your queryRoots() method needs to return information about the root(s) that your provider will provide.

However, rather than returning this in the form of some clean object model (e.g., a List of Document.Root objects or some such), the return value is a Cursor. While in principle this Cursor could come from a database, in many cases it will be a MatrixCursor, which is a Cursor interface over a two-dimensional array representing the rows and columns.

From here, you should return all presently valid roots. The “presently valid” part is because a root might exist but not be usable at the present time. For example, suppose that you are writing a DocumentsProvider that provides a document interface to an Internet-hosted storage service. In this case, you may need the user to authenticate in order to allow access to those files, such as to pass that authentication data along to the Web service to be able to retrieve directory and file data. If the user is not presently logged in, though, not only can you not talk to the Web service right now, but you do not have the ability to force the user to authenticate right now. Instead, you will have to cull the root(s) governed by those authentication credentials. This may mean that the Cursor you return has no rows, as you simply do not have anything that can be published right now.

The Cursor that you return will have one row per presently valid root. The columns will be ones defined on the DocumentsContract.Root class. Your queryRoots() method is passed a String array representing the columns requested by the Storage Access Framework. As your app may not support all of those columns, you will need to determine the intersection between the requested columns and the ones you support.

The sample app defines a SUPPORTED_ROOT_PROJECTION static data member to list
Providing Documents

the DocumentsContract.Root columns that are supported in general:

```java
private static final String[] SUPPORTED_ROOT_PROJECTION =
    new String[] {
        Root.COLUMN_ROOT_ID, Root.COLUMN_FLAGS, Root.COLUMN_TITLE,
        Root.COLUMN_DOCUMENT_ID, Root.COLUMN_ICON
    };
```

(from Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java)

And the demo provider has a private netProjection() utility method that computes the intersection between the requested columns and the supported ones:

```java
private static String[] netProjection(String[] requested, String[] supported) {
    if (requested == null) {
        return (supported);
    }

    ArrayList<String> result = new ArrayList<String>();
    for (String request : requested) {
        for (String support : supported) {
            if (request.equals(support)) {
                result.add(request);
                break;
            }
        }
    }

    return (result.toArray(new String[0]));
}
```

(from Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java)

That net projection is used in the MatrixCursor constructor, to teach it the available columns, as part of the queryRoots() implementation:

```java
@Override
public Cursor queryRoots(String[] projection)
    throws FileNotFoundException {
    String[] netProjection = netProjection(projection, SUPPORTED_ROOT_PROJECTION);
    MatrixCursor result = new MatrixCursor(netProjection);
    MatrixCursor.RowBuilder row = result.newRow();

    row.add(Root.COLUMN_ROOT_ID, ROOT_ID);
    row.add(Root.COLUMN_ICON, R.drawable.ic_launcher);
    row.add(Root.COLUMN_FLAGS, Root.FLAG_LOCAL_ONLY);
    row.add(Root.COLUMN_TITLE, getContext().getString(R.string.root));
    row.add(Root.COLUMN_DOCUMENT_ID, ROOT_DOCUMENT_ID);

    return (result);
}
```

2690
queryRoots() then adds a row to the MatrixCursor, through a
MatrixCursor.RowBuilder, containing five columns:

1. DocumentsContract.Root.COLUMN_ROOT_ID is the root ID for this root, as
described earlier in this chapter.
2. DocumentsContract.Root.COLUMN_ICON, which is a reference to a drawable
resource that may be used in Storage Access Framework UI to help visually
represent this root. In principle, this could be anything; in practice, you will
probably choose your launcher icon, as it is the icon that the user will
recognize.
3. DocumentsContract.Root.COLUMN_FLAGS, indicating which optional
capabilities this root supports. In this case, the only flag we are setting is
FLAG_LOCAL_ONLY, indicating that network I/O is not required to browse the
contents of the provider. Our sample app indicates that it is local-only, as its
documents are all packaged in assets/. A provider backed by a Web service,
though, would not include this flag, so the Storage Access Framework knows
that calls to some of the other methods (e.g., queryChildDocuments()) may
take a significant amount of time.
4. DocumentsContract.Root.COLUMN_TITLE, which is a string identifying this
root. The title and icon will tend to be included in Storage Access
Framework-supplied UIs. In this case, with only a single root, the title is
hard-coded to be a string resource. In other cases, this might be some other
human-grokkable display name (e.g., the name of some storage service
account).
5. DocumentsContract.Root.COLUMN_DOCUMENT_ID, which returns the
document ID representing the document tree for this root.

In this case, the document IDs for this DocumentsProvider are the relative paths
within assets/ of the files, starting from a root docs/ directory. So, while the root ID
could be anything, the root document ID should be consistent with the other
document ID values. In this case, the sample app uses:

```java
private static final String ROOT_ID="thisIsMyBoomstick";
private static final String ROOT_DOCUMENT_ID="docs";
```

queryChildDocuments()

As noted previously, some documents will represent a directory, while others will
represent files. For those that represent a directory, queryChildDocuments() will need to return the document information for the contents of the directory.

queryChildDocuments() is passed:

- the document ID of the directory
- the columns, defined on the DocumentsContract.Document class, that the Storage Access Framework wants
- the sort order, expressed as a SQL-style ORDER BY clause (minus the actual ORDER BY part), that you might use to help control the order in which to return the child documents (or ignore if you wish)

As with queryRoots(), we need to come up with the intersection of the columns that the requester asks for and the columns that we support. There is a static string array named SUPPORTED_DOCUMENT_PROJECTION that represents the columns that we support:

```java
private static final String[] SUPPORTED_DOCUMENT_PROJECTION=
        new String[] { Document.COLUMN_DOCUMENT_ID,
                        Document.COLUMN_SIZE,
                        Document.COLUMN_MIME_TYPE,
                        Document.COLUMN_DISPLAY_NAME,
                        Document.COLUMN_FLAGS};
```

(from Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java)

The queryChildDocuments() method then uses the same netProjection() helper method that queryRoots() did to determine the intersection:

```java
@Override
public Cursor queryChildDocuments(String parentDocId,
                                    String[] projection,
                                    String sortOrder)
        throws FileNotFoundException {
    String[] netProjection=
        netProjection(projection, SUPPORTED_DOCUMENT_PROJECTION);
    MatrixCursor result=new MatrixCursor(netProjection);

    try {
        String[] children=assets.list(parentDocId);

        for (String child : children) {
            addDocumentRow(result, child,
                            parentDocId + File.separator + child);
        }
    }
    catch (IOException e) {
```
As with queryRoots(), the return value of queryChildDocuments() is a Cursor representing the documents contained in this directory. Once again, we use a MatrixCursor to build up an in-memory Cursor, this time for all files within the assets/ directory denoted by parentDocId, using the list() method on AssetManager to find out what those files are.

The logic to populate the MatrixCursor is delegated to an addDocumentRow() private method, as we will be using it elsewhere in this DocumentsProvider implementation. addDocumentRow() creates a MatrixCursor.RowBuilder and fills in the supported columns:

```
private void addDocumentRow(MatrixCursor result, String child, String assetPath) throws IOException {
    MatrixCursor.RowBuilder row = result.newRow();
    row.add(Document.COLUMN_DOCUMENT_ID, assetPath);
    if (isDirectory(assetPath)) {
        row.add(Document.COLUMN_MIME_TYPE, Document.MIME_TYPE_DIR);
    } else {
        String ext = MimeTypeMap.getFileExtensionFromUrl(assetPath);
        row.add(Document.COLUMN_MIME_TYPE, MimeTypeMapSingleton.getInstance().getMimeTypeFromExtension(ext));
        row.add(Document.COLUMN_SIZE, getAssetLength(assetPath));
    }
    row.add(Document.COLUMN_DISPLAY_NAME, child);
    row.add(Document.COLUMN_FLAGS, 0);
}
```

Of note:

- the document ID of the child is simply its relative path within assets/
Providing Documents

- The MIME type is a special one if the child document represents a directory, or else is looked up using MimeTypeMap if the child document represents a file.
- The “display name” could be something special (e.g., the <title> of a Web page), but in this case is just the filename.

To determine if an asset path represents a directory, the isDirectory() utility method just sees if list() returns a non-empty list:

```java
private boolean isDirectory(String assetPath) throws IOException {
    return (assets.list(assetPath).length>=1);
}
```

(from Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java)

To find the size of a document — to fill in the COLUMN_SIZE column in the output — we can ask the AssetManager for a FileDescriptor on the asset, then obtain the length from that descriptor, as seen in the getAssetLength() utility method:

```java
private long getAssetLength(String assetPath) throws IOException {
    return (assets.openFd(assetPath).getLength());
}
```

(from Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java)

The net result is that, given the name of a directory in assets/, we return a Cursor with one row per child of that directory, with columns indicating details of that child.

queryDocument()

queryDocument() is similar to queryChildDocuments(). Both return a Cursor with the same sorts of columns as output. The difference: queryDocument() provides you with the document ID of a file, and you return details of that file. By contrast, queryChildDocuments() gives you the document ID of a directory, and you return the details of all documents within that directory.

This is why addDocumentRow() was implemented as a separate method, as we need the same business logic (populate a MatrixCursor row based on an asset path) from queryDocument():

```java
@Override
public Cursor queryDocument(String documentId, String[] projection)
```
In this case, the only thing different is that we need to get the bare filename, for use in the DISPLAY_NAME field. Here, we cheat a bit and use getLastPathSegment() on Uri to obtain the filename.

openDocument()

The openDocument() method behaves much like the openFile() method of a classic streaming ContentProvider: given a path, you return a ParcelFileDescriptor representing the file contents. For documents that are true files on the filesystem, you can use the static open() method on ParcelFileDescriptor. For documents that are not files on the filesystem — such as documents that are assets in the APK — you will need to set up a ParcelFileDescriptor pipe and stream the content that way.

That is what DemoDocumentsProvider does, using logic copied from the book’s streaming ContentProvider samples:
openDocument() is passed three parameters:

1. The document ID of the document to stream back
2. A file mode (r, w, or wt) indicating what sort of operations the client wants to perform on the stream
3. A CancellationSignal that we can use to find out that our streaming is being interrupted

In this case:

- openDocument() ignores the mode, because it did not return FLAG_SUPPORTS_WRITE in either queryChildDocuments() or queryDocument() to indicate that writing is an option, so the mode should always be r
- openDocument() ignores the CancellationSignal, though in reality it should pay attention to it when streaming back the content and stop streaming when requested

The TransferThread that does the actual streaming is, once again, the same as the one used earlier in this book for a streaming ContentProvider:
public void run() {
    byte[] buf=new byte[8192];
    int len;

    try {
        while ((len=in.read(buf)) >= 0) {
            out.write(buf, 0, len);
        }

        in.close();
        out.flush();
        out.close();
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(),
                "Exception transferring file", e);
    }
}
The Results

If you have both this sample app and the one from the previous chapter, then run the one from the previous chapter to bring up the Storage Access Framework UI, you will see our provider among the list of available providers:

![Storage Access Framework Picker, Showing Custom Provider](image)

*Figure 766: Storage Access Framework Picker, Showing Custom Provider*

The provider’s assets/docs/ directory contains three files, one just off the root and two in a bar/ subdirectory:

![DocumentsProvider Sample Documents](image)

*Figure 767: DocumentsProvider Sample Documents*
Hence, tapping on our provider in the Storage Access Framework picker brings up the contents of the root document:

*Figure 768: Storage Access Framework Picker, Showing Documents in Root*
Tapping on the bar/ directory brings up its contents in turn:

*Figure 769: Storage Access Framework Picker, Showing Yet More Documents*
Tapping on one of the files brings up the details for that file:

![Image](image.png)

*Figure 770: Document Consumer, Showing Details of Picked Document*

**Optional Provider Capabilities**

A DocumentsProvider can do a fair bit more than what the above sample app demonstrates. While the sample will suffice for the basics, it is reasonably likely that a production-grade DocumentsProvider will need to implement and provide some other optional capabilities, such as those described in this section.

**Other CRUD Operations**

CRUD — Create, Read, Update, and Delete — is a standard shorthand for the basic operations one can perform on data. The sample app handles the “Read” portion of CRUD, but a DocumentsProvider can support all of them if desired.

**Create**

It may be that your DocumentsProvider is only going to serve up documents that were created in your app, or were created outside of the Android device (e.g., on a
Providing Documents

Web app). If, however, you want consumers of your provider to be able to use ACTION_CREATE_DOCUMENT to create new documents in your provider, you will need to do a few things.

First, in the COLUMN_FLAGS for the relevant root(s) returned by queryRoots(), you will need to include FLAG_SUPPORTS_CREATE, defined on DocumentsContract.Root. This indicates that at least one directory within that root supports creating new documents. Without this flag, your root(s) will be shown for ACTION_OPEN_DOCUMENT requests but not ACTION_CREATE_DOCUMENT requests.

Next, in one or more directories returned as part of queryDocument() and queryChildDocuments() calls, in the COLUMN_FLAGS column, you will need to include FLAG_DIR_SUPPORTS_CREATE, defined on DocumentsContract.Documents. This indicates that this document is a directory that supports creating new documents inside of it. Otherwise, a directory will be assumed to not support creating new documents. Note that this flag is only used for documents representing directories, not documents representing files.

Finally, you will need to implement createDocument() in your DocumentsProvider. This will be called if a consumer app used ACTION_CREATE_DOCUMENT and the user chose your provider and one of your directories for the new document. You are passed in:

- the document ID of the directory
- the MIME type of the new file
- a suggested display name to use for the new file, though you can modify this if needed

Your job, in createDocument(), is to create the document and return the document ID for the newly-created document. For example, if your documents are held in internal storage, you might create a new file for the document itself plus a database row in some documents table to hold the MIME type and display name.

**Update**

For something like files, an “update” is replacing the current contents with something new. In the case of a streaming protocol like DocumentsProvider, this implies that your provider can support output as well as input.

This too requires a few changes to your provider.
PROVIDING DOCUMENTS

First, for the file(s) that can be updated, in the results for queryDocument() and queryChildDocuments(), you will need to include FLAG_SUPPORTS_WRITE in COLUMN_FLAGS, to indicate that writing to this file should work.

Then, you will need to pay attention to the mode passed into openDocument(). If the mode is w or wt, you would need to arrange to support writing the file, where your background thread reads from an InputStream on the pipe and writes the data to wherever your data is being stored.

Delete

For any documents that the consumer can delete, include FLAG_SUPPORTS_DELETE in COLUMN_FLAGS in the results for queryDocument() and queryChildDocuments().

You will also need to implement deleteDocument() in your DocumentsProvider. You are supplied the document ID to delete, and your job is to delete it.

If the document represents a directory, you may also need to delete all of its children. That really depends on how you are leveraging the “directory” construct in DocumentsProvider:

- If the “directory” is like a filesystem directory, where children have only one parent, you will want to delete the children when you delete the parent
- If the “directory” is more like a category, such as a tag, where children could have multiple parents, you will need to decide how to handle the children that would be orphaned by your deleting the last parent (delete the children? move them to some other default parent? something else?)

Change Notification

If the data served by your provider changes, it is incumbent upon you to let possible consumers know about the change. For example, if you elect to delete children when you delete their parent, you should let consumers know that those children were deleted. This is not necessary for direct operations performed by consumers (e.g., writing to a document), but is necessary for anything else.

To do that, you call notifyChange() on a ContentResolver, just as you would for changes to the data in a ContentProvider. However, notifyChange() takes a Uri as a parameter, to indicate the scope of the change. There are static utility methods on DocumentsContract that will return a Uri that you can use. Notably:
PROVIDING DOCUMENTS

- buildDocumentUri(), given your authority and a document ID, provides a Uri that points to that document
- buildChildDocumentsUri(), given your authority and a document ID, provides a Uri that represents the collection of children of that document

So, for example, if by deleting a parent you also delete the children, you would use buildChildDocumentsUri() with notifyChange() to ensure that consumers know that those children were modified. The Storage Access Framework will use methods like queryChildDocuments() to determine that the children were deleted in this case.

**Thumbnails**

By default, the Storage Access Framework will use stock icons for directories and files. You can supply your own thumbnails instead, though, if you want. To do this:

- Include FLAG_SUPPORTS_THUMBNAIL in the COLUMN_FLAGS for the affected document(s) in queryDocument() and queryChildDocuments()
- Implement openDocumentThumbnail() in your DocumentsProvider

openDocumentThumbnail() is provided the document ID of the document whose thumbnail is required, along with a Point object providing a requested size. While your thumbnail does not have to exactly match that size — for example, the aspect ratio that is requested may not match the thumbnail — it should be close.

However, the return value for openDocumentThumbnail() is an AssetFileDescriptor, which is a wrapper around a ParcelFileDescriptor. If your image exists as a file that happens to be the right size, return it by using the static open() method on ParcelFileDescriptor is fairly straightforward. If, however, you need to scale your source image to fit the desired size, implementing this via a pipe will be moderately tedious.

**Recent Documents**

If your app has its own concept of recent documents, you can expose that roster to the Storage Access Framework, which can incorporate it as part of its UI. To do this:

- Have your queryRoots() method include FLAG_SUPPORTS_RECENTS in the COLUMN_FLAGS value for the root(s) that support recent documents
- Implement queryRecentDocuments() on your DocumentsProvider, where you are given the root ID (not a document ID!) of one of your roots, and you
need to return the same sort of Cursor as you would from queryChildDocuments(), but representing the recent documents for that root

The two constraints upon the returned Cursor are:

- It should be sorted descending based on last-modified date (e.g., the COLUMN_LAST_MODIFIED column in your rows)
- It should be capped at 64 rows, though it can be less if desired

Note that you can, if you wish, have the Cursor return rows reflecting both files and directories — you are not limited to one or the other.

**Search**

If your provider has its own search capability, you can expose that to the Storage Access Framework, which in turn can make it available to users looking for a certain document. To support this:

- Have your queryRoots() method include FLAG_SUPPORTS_SEARCH in the COLUMN_FLAGS value for the root(s) that support searching
- Implement querySearchDocuments() on your DocumentsProvider, where you are given the root ID (not a document ID!) of one of your roots, and you need to return the same sort of Cursor as you would from queryChildDocuments(), but representing the results of a search

querySearchDocuments() is passed a String representing the search expression entered by the user. It is up to you to decide what that expression means. It is also up to you to determine where you are searching for that expression (filenames? file contents?).

Note that the Cursor you return should only contain documents that reflect files, not documents that point to directories.

**Other Flags**

There are a few other flags that are available to you on DocumentsContract.Document that you can use in COLUMN_FLAGS for Cursor results representing a document or collection of documents, such as the results of queryDocument() and queryChildDocuments():
PROVIDING DOCUMENTS

• If the document represents a directory, and you are supporting thumbnails, and you would like the contents of this directory to be represented in a thumbnail grid as opposed to a list, include FLAG_DIR_PREFERS_GRID

• If the document represents a directory, and you feel that users will be better served showing the documents in descending order based upon COLUMN_LAST_MODIFIED, rather than alphabetical by display name, include FLAG_DIR_PREFERS_LAST_MODIFIED
SQLite databases, by default, are stored on internal storage, accessible only to the app that creates them.

At least, that is the theory.

In practice, it is conceivable that others could get at an app’s SQLite database, and that those “others” may not have the user’s best interests at heart. Hence, if you are storing data in SQLite that should remain confidential despite extreme measures to steal the data, you may wish to consider encrypting the database.

Perhaps the simplest way to encrypt a SQLite database is to use SQLCipher. SQLCipher is a SQLite extension that encrypts and decrypts database pages as they are written and read. However, SQLite extensions need to be compiled into SQLite, and the stock Android SQLite does not have the SQLCipher extension.

SQLCipher for Android, therefore, comes in the form of a replacement implementation of SQLite that you add as an NDK library to your project. It also ships with replacement editions of the android.database.sqlite.* classes that use the SQLCipher library instead of the built-in SQLite. This way, your app can be largely oblivious to the actual database implementation, particularly if it is hidden behind a ContentProvider or similar abstraction layer.

SQLCipher for Android is a joint initiative of Zetetic (the creators of SQLCipher) and the Guardian Project (home of many privacy-enhancing projects for Android). SQLCipher for Android is open source, under the Apache License 2.0.
Prerequisites

Understanding this chapter requires that you have read the chapter on database access.

Scenarios for Encryption

So, why might you want to encrypt a database?

Some developers probably are thinking that this is a way of protecting the app's content against “those pesky rooted device users”. In practice, this is unlikely to help. As with most encryption mechanisms, SQLCipher uses an encryption key. If the app has the key, such as being hard-coded into the app itself, anyone can get the key by reverse-engineering the app.

Rather, encrypted databases are to help the user defend their data against other people seeing it when they should not. The classic example is somebody leaving their phone in the back of a taxi — if that device winds up in the hands of some group with the skills to root the device, they can get at any unencrypted content they want. While some users will handle this via the whole-disk encryption available since Android 3.0, others might not.

If the database is going anywhere other than internal storage, there is all the more reason to consider encrypting it, as then it may not even require a rooted device to access the database. Scenarios here include:

1. Databases stored on external storage
2. Databases backed up using external storage, BackupManager, or another Internet-based solution
3. Databases explicitly being shared among a user’s devices, or between a user’s device and a desktop (note that SQLCipher works on many operating systems, including desktops and iOS)

Obtaining SQLCipher

SQLCipher is available from Zetetic. As of July 2016, the current shipping version was 3.5.0. It is very important for you to use 3.5.0 or higher, as earlier versions of SQLCipher for Android will not work on Android 7.0 or higher versions of Android.
In Android Studio, to add SQLCipher for Android to your project, just add the official AAR dependency:

```java
dependencies {
    implementation 'net.zetetic:android-database-sqlcipher:3.5.0@aar'
}
```

### Using SQLCipher

If you have existing code that uses classic Android SQLite, you will need to change your import statements to pick up the SQLCipher for Android equivalents of the classes. For example, you obtain `SQLiteDatabase` now from `net.sqlcipher.database.sqlcipher`, not `android.database.sqlite`. Similarly, you obtain `SQLException` from `net.sqlcipher.database` instead of `android.database`. Unfortunately, there is no complete list of which classes need this conversion — `Cursor`, for example, does not. Try converting everything from `android.database` and `android.database.sqlite`, and leave alone those that do not exist in the SQLCipher for Android equivalent packages.

Before starting to use SQLCipher for Android, you need to call `SQLiteDatabase.loadLibs()`, supplying a suitable `Context` object as a parameter. This initializes the necessary libraries. If you are using a `ContentProvider`, just call this in `onCreate()` before actually using anything else with your database. If you are not using a `ContentProvider`, you probably will want to create a custom subclass of `Application` and make this call from that class’ `onCreate()`, and reference your custom `Application` class in the `android:name` attribute of the `<application>` element in your manifest. Either of these approaches will help ensure that the libraries are ready before you try doing anything with the database.

Finally, when calling `getReadableDatabase()` or `getWritableDatabase()` on `SQLiteDatabase`, you need to supply the encryption key to use. For the purposes of book examples, a hard-coded passphrase is sufficient. However, those can be trivially reverse-engineered, and so they offer little real-world protection. But, they keep the code simple, which is useful when examining APIs.

The [Database/ConstantsSecure-AndroidStudio](#) sample app is yet another variation of the `ConstantsBrowser` sample that we have been using for most of the database examples. From the standpoint of the `ConstantsBrowser` activity and `ConstantsFragment` UI, nothing is different. However, `DatabaseHelper` uses SQLCipher, rather than SQLite.
In the DatabaseHelper constructor, we call loadLibs() on the SQLiteDatabase class, which is a required initialization step to get the native libraries set up:

```java
public DatabaseHelper(Context context) {
    super(context, DATABASE_NAME, null, SCHEMA);
    SQLiteDatabase.loadLibs(context);
}
```

It also offers zero-argument getReadableDatabase() and getWritableDatabase() methods, akin to those offered by the regular SQLiteOpenHelper. However, the DatabaseHelper editions turn around and invoke the one-argument equivalents on the SQLCipher edition of SQLiteOpenHelper:

```java
SQLiteDatabase getReadableDatabase() {
    return super.getReadableDatabase(PASSPHRASE);
}
```

```java
SQLiteDatabase getWritableDatabase() {
    return super.getWritableDatabase(PASSPHRASE);
}
```

Here, the PASSPHRASE is just a hard-coded string:

```java
private static final String PASSPHRASE =
    "hard-coding passphrases is only for sample code;" +
    "nobody does this in production";
```

That is all the changes that are needed to use SQLCipher.

**SQLCipher Limitations**

Alas, SQLCipher for Android is not perfect.

It will add a few MB to the size of your APK file per CPU architecture. For most modern Android devices, this extra size will not be a huge issue, though it will be an impediment for older devices with less internal storage, or for apps that are getting close to the size limits imposed by the Play Store or other distribution mechanisms.
The chapter on the NDK contains a section about a technology called libhoudini that can help reduce this bloat, albeit with a significant performance penalty.

However, the size is mostly from code, and that may cause a problem for Eclipse users. Eclipse may crash with its own OutOfMemoryError during the final build process. To address that, find your eclipse.ini file (location varies by OS and installation method) and increase the -Xmx value shown on one of the lines (e.g., change it to -Xmx512m).

Other code that expects to be using native SQLite databases will require alteration to work with SQLCipher for Android databases. For example, the SQLiteAssetHelper described elsewhere in this book would need to be ported to use the SQLCipher for Android implementations of SQLiteOpenHelper, SQLiteDatabase, etc. This is not too difficult for an open source component like SQLiteAssetHelper.

**Passwords and Sessions**

Given an encrypted database, there are several ways that an attacker can try to access the data, including:

1. Use a brute-force attack via the app itself
2. Use a brute-force attack on the database directly, by copying it to some other machine
3. Obtain the password by the strategic deployment of a $5 wrench

The classic way to prevent the first approach is by having business logic that prevents lots of failed login attempts in a short period of time. This can be built into your login dialog (or the equivalent), tracking the number and times of failed logins and introducing delays, forced app exits, or something to add time and hassle for trying lots of passwords.

Since manually trying passwords is nasty, brutish, and long, many attackers would automate the process by copying the SQLCipher database to another machine (e.g., desktop) and running a brute-force attack on it directly. SQLCipher for Android has many built-in protections to help defend against this. So long as you are using a sufficiently long and complex encryption key, you should be fairly well-protected against such attacks.

Defending against wrenches is decidedly more difficult and is beyond the scope of this book.
About Those Passphrases…

Having a solid encryption algorithm, like the AES-256 used by default with SQLCipher for Android, is only half the battle. The other half is in using a high-quality passphrase, one that is unlikely to be guessed by anyone looking to break the encryption.

Upgrading to Encryption

Suppose you have an app already out on the market, and you decide that you want to add the option for encryption. It is fairly likely that the user will be miffed if they lose all their data in the process of switching to an encrypted database. Therefore, you will want to try to retain their data.

SQLCipher for Android does not support in-place encryption of database. However, it does support working with unencrypted databases and encrypted databases simultaneously, giving you the option of migration.

The approach boils down to:

- Open the unencrypted database in SQLCipher for Android, using an empty passphrase
- Use the ATTACH statement to open the encrypted database inside the same SQLCipher for Android session
- Use a supplied sqlcipher_export() function to migrate most of the data
- Copy the Android database schema version between the databases
- DETACH the encrypted database
- Close the unencrypted database (and, presumably, delete it)
- Use the encrypted database from this point forward

Since both database files will exist at one time, you will find it simplest to use separate names for them (e.g., stuff.db and stuff-encrypted.db).

To see how this works, take a look at the Database/SQLCipherPassphrase-AndroidStudio, which is a variation of the original, non-ContentProvider “constants” sample app, this time using SQLCipher for Android and supporting an upgrade from a non-encrypted database to an encrypted one.

The bulk of the logic for handling the encryption upgrade is in a static encrypt() method on our DatabaseHelper:
First, we initialize SQLCipher for Android by calling `loadLibs()` on the SQLCipher version of `SQLiteDatabase`. We could do this someplace else, but for this sample, this is as good a spot as any.

We then create `File` objects pointing at the locations of the old, unencrypted database (with a name represented by a `LEGACY_DATABASE_NAME` static data member) and the new encrypted database (`DATABASE_NAME`). To get the `File` locations of those databases, we use `getDatabasePath()`, a method on `Context`, which returns the correct location for a database file given its name.

If the encrypted database exists, there is nothing that we need to do. Similarly, if it does not exist but the unencrypted database also does not exist, there is nothing that we can do. In either of those cases, we skip over the rest of the logic; in the first case, we already did the conversion (presumably); in the latter case, this is a new installation, and our `SQLiteOpenHelper` `onCreate()` logic will handle that. But, in the case where we do not have the encrypted database but do have the unencrypted one, we can create the encrypted database from the unencrypted data, which is what the bulk of the `encrypt()` method does.

To that, we:
**Encrypted Storage**

- Use openOrCreateDatabase() to open the already-existing unencrypted database file in SQLCipher for Android, using "" as the passphrase.
- Use a rawExecSQL() method available on the SQLCipher for Android version of SQLiteDatabase to ATTACH the encrypted database, given its path, to our database session, using the supplied passphrase. This means that we can access the tables from both databases simultaneously, though we need to prefix all references to the attached database via its handle, encrypted.
- Use rawExecSQL() to execute SELECT sqlitecipher_export('encrypted'), which copies most of our data from the unencrypted database (the database we have open) into the encrypted database (the one we attached). The big thing that sqlitecipher_export() does not copy is the schema version number that Android maintains.
- Use rawExecSQL() to DETACH the attached encrypted database, as we no longer need it.
- Call getVersion() on the SQLiteDatabase representing the unencrypted database, to retrieve the schema version number that Android maintains.
- Close the unencrypted database and open the encrypted one using openOrCreateDatabase().
- Use setVersion() on SQLiteDatabase to set the schema version of the encrypted database to the value we had from the unencrypted database.
- Close the encrypted database and delete the unencrypted database file. Note that on API Level 16+, we could use the deleteDatabase() method on SQLiteDatabase to cleanly delete everything associated with SQLite.

The combination of doing all of that migrates our data from an unencrypted database to an encrypted one.

Then, we simply need to call encrypt() before we try loading our constants, from doInBackground() of our LoadCursorTask:

```java
private class LoadCursorTask extends BaseTask<Void> {
    private final Context ctxt;

    LoadCursorTask() {
        this.ctxt = getActivity().getApplicationContext();
    }

    @Override
    protected Cursor doInBackground(Void... params) {
        DatabaseHelper.encrypt(ctxt);
        return doQuery();
    }
}
```
To test this upgrade logic, you will need to:

- Run the original unencrypted version of this sample, found in the Database/Constants sample application
- Add a new constant using the unencrypted version of the app
- Run the encrypted version of the sample from this section, which shares the same package name as the original and therefore will replace it on your emulator

You will see your added constant appear along with all of the standard ones, yet if you examine /data/data/com.commonsware.android.constants/databases on your ARM emulator via DDMS, you will see that your database is now named constants-crypt.db instead of constants.db, as we have replaced the unencrypted database with an encrypted one.

### Changing Encryption Passphrases

Another thing the user might wish to do is change their passphrase. Perhaps they fear that their existing passphrase has been compromised (e.g., a narrow escape from a $5 wrench). Perhaps they rotate their passphrases as a matter of course. Perhaps they simply keep typing in their current one incorrectly and want to switch to one they think they can enter more accurately.

SQLCipher for Android supports a `rekey` `PRAGMA` that can accomplish this. Given an open encrypted database `db` — opened using the old passphrase — you can change the password to a `newPassword` string variable via:

```java
db.execSQL(String.format("PRAGMA rekey = '%s'", newPassword));
```

Note that this may take some time, as SQLCipher for Android needs to re-encrypt the entire database.

### Dealing with the Version 3.0.x Upgrade

If you are starting with SQLCipher for Android with the 3.0.x release, all is good.

If you have been using SQLCipher for Android from previous releases, but you are still in development mode, all is still good, so long as you can wipe out your old databases.
If you have apps in production using SQLCipher for Android from previous releases, you will have a small headache: the database structure has changed. SQLCipher for Android provides us with a PRAGMA `cipher_migrate` that we can run to upgrade the database in place to the new structure, once we have opened the database with our passphrase. However:

1. There is no great built-in place to put the code for calling this pragma
2. You do not want to blindly call this pragma every time you open the database, as it results in extra processing time

SQLCipher for Android, in an attempt to help with this, offers a modified version of methods like `openOrCreateDatabase()` on `SQLiteDatabase`, ones that take a `SQLiteDatabaseHook` implementation as the last parameter. This interface requires two methods:

1. `preKey()`, called after the database is opened but before the passphrase is applied
2. `postKey()`, called after the database is opened and after the passphrase is applied, but before anything else is done (e.g., standard `SQLiteOpenHelper` schema version checking)

Both methods are passed the `SQLiteDatabase` as a parameter, for you to do with as needed. So, for example, you could have a `postKey()` implementation that does the `postKey()` call only if needed:

```java
public class SQLCipherV3Hook implements SQLiteDatabaseHook {
    private static final String PREFS =
            "net.sqlcipher.database.SQLCipherV3Helper";

    public static void resetMigrationFlag(Context ctxt, String dbPath) {
        SharedPreferences prefs =
                ctxt.getSharedPreferences(PREFS, Context.MODE_PRIVATE);
        prefs.edit().putBoolean(dbPath, false).commit();
    }

    @Override
    public void preKey(SQLiteDatabase database) {
        // no-op
    }

    @Override
    public void postKey(SQLiteDatabase database) {
        SharedPreferences prefs =
                getContext().getSharedPreferences(PREFS, Context.MODE_PRIVATE);
    }
}
```
You can also pass a SQLiteDatabaseHook implementation into the SQLiteOpenHelper constructor as the fifth parameter, which will be used when SQLiteOpenHelper works with the underlying SQLiteDatabase.

**Multi-Factor Authentication**

Another way to effectively boost the strength of your security is to implement your own multi-factor authentication. In this case, the passphrase is not obtained solely through the user typing in the whole thing, but instead is synthesized from two or more sources. So, in addition to some EditText widget for entering in a portion of the passphrase, the rest could come from things like:

- A value written to an NFC tag that the user must tap
- A value encoded in a QR code that the user must scan
- A value obtained by some Bluetooth-connected device via a custom protocol

You, in code, would concatenate the pieces together, possibly using delimiters that cannot be typed in (e.g., ASCII characters below 32) to denote the sources of each segment of the passphrase. The result would be the actual passphrase you would use with SQLCipher for Android.

The objective is to make it easier for users to have more complex passphrases, while not having to type in something complex every time. Tapping an NFC tag is much faster than tapping out a passphrase on a typical phone keyboard, for example. Also, the “something you know and something you have” benefit of multi-factor authentication can help with defending against $5 wrench attacks: if the NFC tag was destroyed, and the user never knew the portion of the passphrase stored on it, the user cannot divulge it.

Of course, this adds risks, such as the NFC tag being destroyed accidentally (e.g., “my dog ate it”). This can be mitigated in some cases by some “admin” being able to reset the password or supply a new NFC tag. In that case, getting the credentials requires two kidnappings and two $5 wrenches (or the serial application of a single
Detecting Failed Logins

If you try to decrypt a database using the incorrect passphrase — whether an attempt by outsiders to use the app, or the user “fat-fingering” the passphrase and making a typo — you will get an exception:

11-19 09:17:22.700: E/SQLiteOpenHelper(1634): net.sqlcipher.database.SQLiteException: file is encrypted or is not a database

Alas, this is not a specific exception, making it a bit difficult to detect failed passphrases specifically. Your options are:

- Assume that your testing is sound and that exceptions when opening a database represent invalid passphrases, or
- Use a generic error message that hints at an invalid passphrase but leaves open the possibility of something else being wrong, or
- Read into the exception’s message looking for “file is encrypted or is not a database”, though this is fragile in the face of changes to SQLCipher for Android

SQLCipher for Android and Performance

Some developers worry about the overhead that encryption will place on the database I/O, and therefore worry that SQLCipher for Android will make their app unacceptably slow.

The impact of SQLCipher is not that bad, particularly for hardware with faster CPUs. Encryption is CPU-intensive, so faster CPUs reduce the overhead of the encryption. Also, since the disk I/O is comparable between SQLite and SQLCipher, the fact that flash memory is slow will mean that disk I/O, not decryption speed, will be the primary determinant of the speed of your queries. Similarly, disk I/O will count for more than CPU speed for the encryption needed for INSERT/UPDATE/DELETE operations.

For example, porting one relatively crude benchmark to use SQLCipher for Android showed no statistically significant performance difference from the SQLite edition on a Nexus 5 running Android 4.4.2.
To the extent that encryption adds overhead, it will tend to magnify existing problems. For example, anything that involves a “table scan” (i.e., a non-indexed lookup of database contents) will need more pages to be decrypted and, therefore, more decryption time. If your database I/O is well-tuned for SQLite, such as adding appropriate indexes, then your SQLCipher for Android overhead should be nominal.

Of course, the worse the CPU, the worse the story, and so older/cheaper devices may fare worse with SQLCipher for Android by comparison.

**Encrypted Preferences**

There are effectively three forms of data storage in Android:

- SQLite databases
- SharedPreferences
- Arbitrary files, in whatever format you want

You can encrypt SQLite via SQLCipher for Android, as seen in this chapter. You can encrypt arbitrary files as part of your data format, such as via `javax.crypto`.

What is not supported, out of the box, is a way to encrypt `SharedPreferences`.

There are two approaches for encrypting the contents of `SharedPreferences`:

1. Encrypt the container in which the `SharedPreferences` are stored
2. Encrypt each preference value as you store it in the `SharedPreferences`, and decrypt it when you read the value back out

**Encryption via Custom SharedPreferences**

`SharedPreferences` is an interface. Hence, you can create other implementations of that interface that store their data in something other than unencrypted XML files.

`CwSharedPreferences` is one such implementation. You can find it in the [cwac-prefs project on GitHub](https://github.com/cwac/cwac-prefs).

`CwSharedPreferences` handles the `SharedPreferences` and `SharedPreferences.Editor` interfaces, along with the in-memory representations of the preferences. It then delegates the work of storing the preferences to a strategy object, implementing a strategy interface (`CwSharedPreferences.StorageStrategy`).

2719
Two such strategy implementations are supplied in the project: one using ordinary SQLite, and one using SQLCipher for Android.

The basic recipe for using CWSharedPreferences is:

- Create the strategy object, such as

```java
new SQLCipherStrategy(getContext(), NAME, "atestpassword", LoadPolicy.SYNC)
```

(here, NAME is the name of the set of preferences, "atestpassword" is your passphrase, and LoadPolicy.SYNC indicates that the preferences should be loaded from disk immediately, not on a background thread)

- Create a CWSharedPreferences that employs your chosen strategy:

```java
new CWSharedPreferences(yourStrategyObjectGoesHere);
```

- Use the CWSharedPreferences as you would any other SharedPreferences implementation
- Call close() on the strategy object, to release any resources that it might hold (e.g., open database connection)

**Encryption via Custom Preference UI and Accessors**

The big drawback to the custom SharedPreferences is the fact that you cannot get the PreferenceScreen system to work with it. The preference UI is hard-wired to use the stock implementation of SharedPreferences and does not appear to support any way to substitute in some other implementation.

Hence, another approach is to keep things in standard SharedPreferences’ XML files, but encrypt text values on a preference-by-preference basis. Since the data type needs to remain the same, most likely you would restrict this to encrypting strings (e.g., EditTextPreference, ListPreference) rather than numbers, booleans, etc.

To do this, you would need to:

- Implement static methods somewhere for your encryption and decryption algorithms
- Subclass the Preference classes of interest and override methods that would deal with the raw preference data, like onDialogClosed(), to encrypt the values you persist and decrypt the values you read in, using the static
methods mentioned above

- Use your extended Preference classes in your preference XML as needed
- Use those static methods as part of reading (or writing) the preference values directly via SharedPreferences

The downsides to this approach include:

- Only certain preferences are encrypted, rather than all of them
- You lose some of the low-level encryption power of SQLCipher for Android, such as automatic hashing of passphrases, which you would have to handle yourself
- There may not be a library that supplies these extended Preference classes, forcing you to roll your own

**IOCipher**

SQLCipher for Android is also used as the backing store for **IOCipher**. IOCipher is a virtual file system (VFS) for Android, allowing you to write code that looks and works like it uses normal file I/O, yet all of the files are actually saved as BLOBs in a SQLCipher for Android database. The result is a fully-encrypted VFS, inheriting all of SQLCipher's security features, such as default AES-256 encryption. This may be easier for you to use than encrypting and decrypting files individually via javax.crypto, for example.

IOCipher is considered to be in pre-alpha state as of November 2012.
Packaging and Distributing Data

Sometimes, you not only want to ship your code and simple resources with your app, but you also want to ship other types of data, such as an initial database that your app will use when first run. This chapter will examine the means by which you can do those sorts of things.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [database access](#)
- [content provider theory](#)
- [content provider implementations](#)

Packing a Database To Go

Android's support for databases is focused on databases you create and populate entirely at runtime. Even if you want some initial data in the database, the expectation is that you would add that via Java code, such as the series of `insert()` calls we made in the `DatabaseHelper` of the various flavors of the `ConstantsBrowser` sample application.

However, that is tedious and slow for larger initial data sets, even if you make careful use of transactions to minimize the disk I/O.

What would be nice is to be able to ship a pre-populated database with your app. While Android does not offer built-in support for this, there are a few ways you can accomplish it yourself. One of the easiest, though, is to use existing third-party code
that supports this pattern, such as Jeff Gilfelt’s SQLiteAssetHelper, available via a GitHub repository.

Android Studio users can add a implementation statement to the dependencies closure in build.gradle to pull in com.readystatesoftware.sqliteasset:sqliteassethelper:... (for some version indicated by ...).

SQLiteAssetHelper replaces your existing SQLiteOpenHelper subclass with one that handles database creation and upgrading for you. Rather than you writing a lot of SQL code for each of those, you provide a pre-populated SQLite database (for creation) and a series of SQL scripts (for upgrades). SQLiteAssetHelper then does the work to set up your pre-populated database when the database is first accessed and running your SQL scripts as needed to handle schema changes. And, SQLiteAssetHelper is open source, licensed under the same Apache License 2.0 that is used for Android proper.

To examine SQLiteAssetHelper in action, let’s look at the Database/ConstantsAssets-AndroidStudio sample project. This is yet another rendition of the same app as the other flavors of ConstantsBrowser, but one where we use a pre-populated database.

Create and Pack the Database

Whereas normally you create your SQLite database at runtime from Java code in your app, you now create your SQLite database using whatever tools you like, at development time. Whether you use the command-line sqlite3 utility, the SQLite Manager extension for Firefox, or anything else, is up to you. You will need to set up all of your tables, indexes, and so forth.

Then, you need to:

1. Create an assets/databases/ directory in your project
2. Copy your database into this directory (or put it there in the first place, if you prefer)

If your minSdkVersion is less than 11, you will instead need to have a ZIP or GZIP archive containing the database. The archive should have the same name as the database file, just with the .zip or .gz extension. The reason for the ZIP compression comes from an Android 1.x/2.x limitation – assets that are compressed by the Android build tools have a file-size limitation (around 1MB). Hence, you need
to store larger files in a file format that will not be compressed by the Android build tools, and those tools will not try to compress a .zip file.

In the ConstantsAssets project, you will see an assets/databases/constants.db file, containing a copy of the SQLite database with our constants table and pre-populated values.

**Unpack the Database, With a Little Help(er)**

Your compressed database will ship with your APK. To get it into its regular position on internal storage, you use SQLiteAssetHelper. Simply create a subclass of SQLiteAssetHelper and override its constructor, supplying the same values as you would for a SQLiteOpenHelper subclass, notably the database name and schema revision number. Note that the database name that you use must match the filename of the compressed database (minus the .zip extension, if you needed that).

So, for example, our new DatabaseHelper looks like this:

```java
package com.commonsware.android.dbasset;

import android.content.Context;
import com.readystatesoftware.sqliteasset.SQLiteAssetHelper;

class DatabaseHelper extends SQLiteAssetHelper {

    static final String TITLE = "title";
    static final String VALUE = "value";
    static final String TABLE = "constants";
    private static final String DATABASE_NAME = "constants.db";

    public DatabaseHelper(Context context) {
        super(context, DATABASE_NAME, null, 1);
    }
}
```

SQLiteAssetHelper will then copy your database out of assets and set it up for conventional use, as soon as you call getReadableDatabase() or getWritableDatabase() on an instance of your SQLiteAssetHelper subclass.

**Upgrading Sans Java**

Traditionally, with SQLiteOpenHelper, to handle a revision in your schema, you
override onUpgrade() and do the upgrade work in there. With SQLiteAssetHelper, there is a built-in onUpgrade() method that uses SQL scripts in your APK to do the upgrade work instead.

These scripts will also reside in your assets/databases/ directory of your project. The name of the file will be $NAME_upgrade_$FROM-$TO.sql, where you replace $NAME with the name of your database (e.g., constants.db), $FROM with the old schema version number (e.g., 1) and $TO with the new schema version number (e.g., 2). Hence, you wind up with files like assets/databases/ constants.db_upgrade_1-2.sql. This should contain the SQL statements necessary to upgrade your schema between the versions.

SQLiteAssetHelper will chain these together as needed. Hence, to upgrade from schema version 1 to 3, you could either have a single dedicated 1->3 script, or a 1->2 script and a 2->3 script.

**Limitations**

The biggest limitation comes with disk space. Since APK files are read-only at runtime, you cannot delete the copy of the database held as an asset in your APK file once SQLiteAssetHelper has unpacked it. This means that the space taken up by your ZIP file will be taken up indefinitely. Note, though, that you could use this to your advantage, offering the user a “start over from scratch” option that deletes their existing database, so SQLiteAssetHelper will unpack a fresh original copy on the next run. Or, you could implement a SQLiteDownloadHelper that follows the SQLiteAssetHelper approach but obtains its database from the Internet instead of from assets.

In principle, SQLite could change their file format. If that ever happens, you will need to make sure that you create a SQLite database in the file format that can be used by Android, more so than what can be used by the latest SQLite standalone tools.
This chapter offers tips and techniques for working with SQLite beyond what the previous chapters in the book have covered.

**Prerequisites**

This chapter assumes that you have read the core chapters, particularly the ones on databases and Internet access.

Also, please read the chapter on advanced action bar techniques, particularly the section on SearchView, as that is used in one of the sample apps.

**Full-Text Indexing**

Standard SQL databases are great for ordinary queries. In particular, when it comes to text, SQL databases are great for finding rows where a certain column value matches a particular string. They are usually pretty good about finding when a column value matches a particular string prefix, if there is an index on that column. Things start to break down when you want to search for an occurrence of a string in a column, as this usually requires a “table scan” (i.e., iteratively examining each row to see if this matches). And getting more complex than that is often impossible, or at least rather difficult.

SQLite, in its stock form, inherits all those capabilities and limitations. However, SQLite also offers full-text indexing, where we can search our database much like how we use a search engine (e.g., “find all rows where this column has both foo and bar in it somewhere”). While a full-text index takes up additional disk space, the speed of the full-text searching is quite impressive.
For example, if you are reading this book using the Android APK edition (instead of the PDF, EPUB, or Kindle/MOBI editions), tap on the SearchView action bar item and search for FTS4. You will get a list of matches back almost instantaneously, despite the fact that you are searching a multi-megabyte book. That is because this book ships a SQLite-powered full-text index of the book’s contents, specifically to power your use of SearchView.

In this section, we will review how you can add full-text indexing to your SQLite database and how you can let the user take advantage of that index using a SearchView.

First, a Word About SQLite Versions

SQLite has evolved since Android’s initial production release in 2008.

In many cases, Android does not incorporate updates to third-party code, for backwards-compatibility reasons (e.g., Apache’s HttpClient). In the case of SQLite, newer Android versions do take on newer versions of SQLite… but the exact version of SQLite that a given version of Android uses is undocumented. Worse, some device manufacturers replace the stock SQLite for a version of Android with a different one.

This Stack Overflow answer contains a mapping of Android OS releases to SQLite versions, including various “anomalies” where manufacturers have elected to ship something else.

In many cases, the SQLite version does not matter. Core SQLite capabilities will have existed since the earliest days of Android. However, full-text indexing did not exist in the first SQLite used by Android, meaning that you will have to pay attention to your minSdkVersion and aim high enough that devices should support the full-text indexing option you choose.

Note that you could use an external SQLite implementation, one that gives you a newer SQLite engine than what might be on the device. For example, SQLCipher for Android ships its own copy of SQLite (with the SQLCipher extensions compiled in), one that is often newer than the one that is baked into the firmware of any given device.

FTS3 and FTS4

There are two full-text indexing options available in SQLite: FTS3 and FTS4. FTS4
can be much faster on certain queries, though overall the speed of the two implementations should be similar. FTS4 has two key limitations:

1. It may take a bit more disk space for its indexes.
2. It was added to SQLite 3.7.4, which was only introduced into standard Android in API Level 11.

The sample app for this section will demonstrate FTS4, as that is available on most Android devices.

Note that the Android developer documentation does not cover FTS3 or FTS4 full-text indexing. The details for the SQL syntax to support these options can be found in the SQLite documentation.

Creating a Full-Text Indexed Table

A full-text indexed table, using FTS3 or FTS4, uses SQLite’s `CREATE VIRTUAL TABLE` syntax. This indicates that you are opting into some special table-storage behavior, rather than the stock stuff.

In the `Database/FTS` sample project, the `onCreate()` method of our `SQLiteOpenHelper` subclass (`DatabaseHelper`) creates such a virtual table, using FTS4 for full-text indexing:

```java
@Override
public void onCreate(SQLiteDatabase db) {
    db.execSQL("CREATE VIRTUAL TABLE questions USING fts4(
            +"_id INTEGER PRIMARY KEY, title TEXT, 
            +"link TEXT, profileImage TEXT, creationDate INTEGER, 
            +"order=DESC);";
}
```

There are a few differences here from a typical `CREATE TABLE` statement, beyond the introduction of the `VIRTUAL` keyword:

- The `USING fts4` indicates that the virtual table is employing the FTS4 full-text indexing engine. To use FTS3, just replace `fts4` with `fts3`.
- You can have key-value pairs in the column list, separated by equals signs, to provide options for configuring the virtual table. In this case, it will provide options for configuring the FTS4 indexing behavior. In this case, we are
providing order=DESC, to indicate that the full-text index should be optimized for returning items in descending order. Note that these options only exist for FTS4, not FTS3. The full roster of available options is covered in the SQLite documentation.

This gives us a table that supports normal table operations but also has a full-text index for its columns. However, there are some limitations, notably that these tables ignore constraints. So, for example, the PRIMARY KEY constraint applied to the _id column is ignored.

### Populating a Full-Text Indexed Table

Adding content to an FTS3 or FTS4 table uses the same INSERT statements that you might use for a regular table. For example, the DatabaseHelper in the sample app has an insertQuestions() method that deletes all existing rows in the questions table, then inserts a bunch of rows based on a supplied List of Item objects:

```java
void insertQuestions(Context app, List<Item> items) {
    SQLiteDatabase db=getDb(app);

    db.beginTransaction();

    db.delete("questions", null, null);

    try {
        for (Item item : items) {
            Object[] args={ item.id, item.title, item.link,
                            item.owner.profileImage, item.creationDate};

            db.execSQL("INSERT INTO questions (_id, title, " +
                             "link, profileImage, creationDate) " +
                             "VALUES (?, ?, ?, ?, ?)",
                        args);
        }

        db.setTransactionSuccessful();
    } finally {
        db.endTransaction();
    }
}
```

(From Database/FTS/app/src/main/java/com/commonsware/android/fts/DatabaseHelper.java)

If those Item objects look familiar, that is because this app is a modified version of
the Stack Overflow questions apps profiled in the chapter on Internet access.

The reason why we are deleting everything before inserting is just to keep the sample simple. The database table will hold all of the questions pulled from the Stack Exchange API. Each time we run the app, we get the latest questions from that API. The vision was to use INSERT OR REPLACE or INSERT OR IGNORE statements to be able to merge content into the table. However, FTS3 and FTS4 tables ignore all constraints, as noted above, which prevents the conflict resolution options (e.g., OR REPLACE) from working. Hence, rather than manually sifting through to find if there is an existing row or not for a given ID value, this sample simply gets rid of all existing rows. A production-grade app would likely apply a more sophisticated algorithm.

**Querying a Full-Text Indexed Table**

While you can query a full-text indexed table using normal SELECT statements, usually the point is to apply the MATCH operator, as is seen in the loadQuestions() method from DatabaseHelper:

```java
Cursor loadQuestions(Context app, String match) {
    SQLiteDatabase db=getDb(app);

    if (TextUtils.isEmpty(match)) {
        return(db.rawQuery("SELECT * FROM questions ORDER BY creationDate DESC", null));
    }

    String[] args={ match };

    return(db.rawQuery("SELECT * FROM questions WHERE title "
                        +"MATCH ? ORDER BY creationDate DESC", args));
}
```

The MATCH operator supports a wide range of query structures, including:

- Keyword matches (e.g., Android)
- Prefix matches (e.g., SQL*)
- Phrase matches (e.g., "open source")
- NEAR, AND, OR, and NOT operators (e.g., sqlite AND database)

The result is the same sort of Cursor that you would get from a regular SELECT
statement against a non-full-text-indexed table.

**Some Notes About the Rest of the Sample App**

As noted previously, this sample app is a revised version of the Stack Overflow questions list from the chapter on Internet access. It is specifically derived from the Picasso version of the sample. However, this version is designed to allow the user to full-text search the downloaded question data (e.g., title), above and beyond just seeing the list of latest questions.

This, in turn, requires a few more changes than those outlined so far. The following sections outline some of the highlights.

**Adding a ModelFragment**

The original sample had a very simple data model: a list of questions retrieved via Retrofit. Hence, the sample did not include much in the way of model management.

The FTS sample needs a database, which implies more local disk I/O that we are responsible for, which in turn leads us in the direction of implementing a model fragment (ModelFragment), much as the tutorials and a few other samples do:

```java
package com.commonsware.android.fts;

import android.app.Activity;
import android.content.Context;
import android.database.Cursor;
import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.util.Log;
import org.greenrobot.eventbus.EventBus;
import org.greenrobot.eventbus.Subscribe;
import org.greenrobot.eventbus.ThreadMode;
import retrofit2.Retrofit;
import retrofit2.converter.gson.GsonConverterFactory;

public class ModelFragment extends Fragment {
  private Context app=null;

  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setRetainInstance(true);
  }

  @Override
  public void onAttach(Activity host) {
    super.onAttach(host);
  }
}
```
EventBus.getDefault().register(this);

if (app == null) {
    app = host.getApplicationContext();
    new FetchQuestionsThread().start();
}

@Override
public void onDetach() {
    EventBus.getDefault().unregister(this);
    super.onDetach();
}

@Subscribe(threadMode = ThreadMode.BACKGROUND)
public void onSearchRequested(SearchRequestedEvent event) {
    try {
        Cursor results = DatabaseHelper.getInstance(app).loadQuestions(app, event.match);
        EventBus.getDefault().postSticky(new ModelLoadedEvent(results));
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(),
                "Exception searching database", e);
    }
}

class FetchQuestionsThread extends Thread {
    @Override
    public void run() {
        Retrofit retrofit =
                new Retrofit.Builder()
                        .baseUrl("https://api.stackexchange.com")
                        .addConverterFactory(GsonConverterFactory.create())
                        .build();
        StackOverflowInterface so =
                retrofit.create(StackOverflowInterface.class);

        try {
            SOQuestions questions = so.questions("android").execute().body();
            DatabaseHelper
                    .getInstance(app)
                    .insertQuestions(app, questions.items);
        }
        catch (Exception e) {
            Log.e(getClass().getSimpleName(),
                   "Exception populating database", e);
        }

        try {
            Cursor results = DatabaseHelper.getInstance(app).loadQuestions(app, null);
            EventBus.getDefault().postSticky(new ModelLoadedEvent(results));
        }
        catch (Exception e) {
            Log.e(getClass().getSimpleName(),
                   "Exception populating database", e);
        }
    }
}
In `onCreate()`, we mark this fragment as retained, as that is key to the model fragment pattern, so the fragment retains the model data across configuration changes.

In `onAttach()`, we register for the greenrobot EventBus, plus kick off a `FetchQuestionsThread` if we have not done so already (i.e., this is the first `onAttach()` call we have received). `onDetach()` unregisters us from the event bus.

`FetchQuestionsThread`, in turn, uses Retrofit to download the questions from Stack Overflow, then uses `DatabaseHelper` to insert the questions into the FTS-enabled database table, then uses the `DatabaseHelper` again to retrieve all existing questions in the form of a `Cursor`, which it wraps in a `ModelLoadedEvent` and posts to the `EventBus`. This time, though, it posts it as a sticky event.

That sticky event is consumed by a revised version of the `QuestionsFragment`, in its `onModelLoaded()` method:

```java
@Subscribe(sticky = true, threadMode = ThreadMode.MAIN)
public void onModelLoaded(ModelLoadedEvent event) {
    ((SimpleCursorAdapter)getListAdapter()).changeCursor(event.model);

    if (sv != null) {
        sv.setEnabled(true);
    }
}
```

But because this is a sticky event, we will get this event both when it is raised (because the data is loaded) and any time thereafter when the fragment registers with the `EventBus`. This allows `QuestionsFragment` to not be retained, as it will get back the bulk of its model data automatically from greenrobot's `EventBus`.

`QuestionsFragment` also is modified from the Picasso sample to deal with the fact that its model data is now a `Cursor`, so it uses `SimpleCursorAdapter` to populate the list. To handle loading avatar images from the URLs, `QuestionsFragment` adds a `QuestionBinder` implementation of `ViewBinder` to the `SimpleCursorAdapter`, where `QuestionBinder` handles the Picasso logic from before:
private class QuestionBinder implements SimpleCursorAdapter.ViewBinder {
    int size;

    QuestionBinder() {
        size = getActivity().getResources().getDimensionPixelSize(R.dimen.icon);
    }

    @Override
    public boolean setViewValue(View view, Cursor cursor, int columnIndex) {
        switch (view.getId()) {
            case R.id.title:
                ((TextView)view).setText(Html.fromHtml(cursor.getString(columnIndex)));
                return(true);
            case R.id.icon:
                Picasso.with(getActivity()).load(cursor.getString(columnIndex))
                        .resize(size, size).centerCrop()
                        .placeholder(R.drawable.owner_placeholder)
                        .error(R.drawable.owner_error).into((ImageView)view);
                return(true);
            default:
                return(false);
        }
    }
}

The main activity (MainActivity) sets up the ModelFragment in onCreate(), at least when one does not already exist due to a configuration change:

```java
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
        getSupportFragmentManager().beginTransaction()
            .add(android.R.id.content, new QuestionsFragment()).commit();
    }

    model = (ModelFragment) getSupportFragmentManager().findFragmentByTag(MODEL);

    if (model == null) {
        model = new ModelFragment();
        getSupportFragmentManager().beginTransaction().add(model, MODEL).commit();
    }
}
```
Adding a SearchView

As is covered in the chapter on advanced action bar techniques, a SearchView can be used to provide the standard “magnifying glass” search icon in the action bar. When tapped, the action bar item expands into a field where the user can type something, which our code can then receive and use to update the UI. In the SearchView sample from the action bar chapter, we saw using a SearchView for filtering. This time, we will use a SearchView for searching.

For a search, we need to know when the user is done typing, which is usually done by the user clicking a submit button. Hence, our code to configure the SearchView (a configureSearchView() method in QuestionsFragment) calls setSubmitButtonEnabled(true):

```java
private void configureSearchView(Menu menu) {
    MenuItem search = menu.findItem(R.id.search);

    search.setOnActionExpandListener(this);
    sv = (SearchView) search.getActionView();
    sv.setOnQueryTextListener(this);
    sv.setSubmitButtonEnabled(true);
    sv.setIconifiedByDefault(true);

    if (initialQuery != null) {
        sv.setIconified(false);
        search.expandActionView();
        sv.setQuery(initialQuery, true);
    }
}
```

This, in turn, means that we need to pay attention to onQueryTextSubmit() in our SearchView.OnQueryTextListener implementation. That interface is implemented on QuestionsFragment itself, and delegates its work to a doSearch() method:

```java
@Override
public boolean onQueryTextSubmit(String query) {
    doSearch(query);

    return(true);
}
```

(from Database/FTS/app/src/main/java/com/commonsware/android/fts/QuestionsFragment.java)
That method, in turn, confirms that the search is different than the last one we did (so we do not waste time running the search again), disables the SearchView, and posts a SearchRequestedEvent on the EventBus with the user’s search string:

```java
private void doSearch(String match) {
    if (!match.equals(lastQuery)) {
        lastQuery = match;
        if (sv != null) {
            sv.setEnabled(false);
        }
        EventBus.getDefault().post(new SearchRequestedEvent(match));
    }
}
```

That event is picked up by onSearchRequested() on ModelFragment. The @Subscribe(threadMode = ThreadMode.BACKGROUND) annotation means that the event will be delivered to us on an EventBus-supplied background thread, so we can perform database I/O. In it, we call loadQuestions() on the DatabaseHelper to perform the search, and post another sticky ModelLoadedEvent to update the UI with the search results and re-enable the SearchView:

```java
@Subscribe(threadMode = ThreadMode.BACKGROUND)
public void onSearchRequested(SearchRequestedEvent event) {
    try {
        Cursor results = DatabaseHelper.getInstance(app).loadQuestions(app, event.match);
        EventBus.getDefault().postSticky(new ModelLoadedEvent(results));
    } catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception searching database", e);
    }
}
```

When the user clears the SearchView, such as by pressing the BACK button a few times, the onMenuItemActionCollapse() method of QuestionsFragment calls a clearSearch() method:

```java
@Override
public boolean onMenuItemActionCollapse(MenuItem item) {
    clearSearch();
}
```
That `clearSearch()` method simply posts another `SearchRequestedEvent`, this time to load a fresh roster of all questions:

```java
private void clearSearch() {
    if (lastQuery!=null) {
        lastQuery=null;

        sv.setEnabled(false);
        EventBus.getDefault().post(new SearchRequestedEvent(null));
    }
}
```

(from `Database/FTS/app/src/main/java/com/commonsware/android/fts/QuestionsFragment.java`)
The Results

When you run the app, you are initially presented with the list of questions pulled from the Stack Exchange API:

*Figure 771: FTS Demo, As Initially Launched*
Tapping on the `SearchView` opens it up, as normal, though this time with the “submit” button (the rightward-pointing arrowhead):

![Figure 772: FTS Demo, with Open SearchView](image-url)

*Figure 772: FTS Demo, with Open SearchView*
Typing in a search, then tapping the “submit” button, will reload the list with those questions that match the search criteria in the question title:

Figure 773: FTS Demo, Showing Basic Search

Figure 774: FTS Demo, Showing Boolean Search
Using the BACK button to get out of the SearchView reloads the full list of questions.

**Getting Snippets**

Usually, the content that is being indexed is a lot longer than Stack Overflow question titles. For example, it might be chapters in a book on Android application development. In that case, it would be useful to not only find out what chapters match the search expression, but what the prose is around the search expression, to help the user determine which search results are likely to be useful.

The APK edition of this book stores each paragraph and bullet as a separate entry in a SQLite database in an FTS3-enabled table. The query used when the reader types in a search expression in the app’s SearchView is:

```
SELECT ROWID as _id, file, node, snippet(booksearch) AS snippet FROM booksearch WHERE prose MATCH ?
```

Here, file and node are used to identify where this passage came from within the book, so when the user taps on a search result in the list, the book reader can jump to that particular location.
The snippet() auxiliary function will return, as the name suggests, a snippet of the indexed text, with the search match highlighted. It takes the name of the table booksearch as a mandatory parameter. It also supports optional parameters for what to bracket the search match with (defaults to `<b>` and `</b>`) and what to use for an ellipsis for extended prose segments (defaults to `[b>...</b>`). In the case of this query, the default formatting of the result is used. The resulting text can then be fed into Html.fromHtml() to generate the text for the ListView row, showing the search match within the snippet highlighted in bold:

![Figure 775: This Book’s Reader App, Showing Search Results](image)

The app also shows the name of the chapter in the lower-right corner of each row, to help provide larger context for where this snippet comes from.
Data Backup

Backing up your PC used to be essential. To some extent, it still is, but as more and more stuff moves to “the cloud”, local machine backups become less and less important.

Backing up mobile devices historically has been an afterthought, as a lot of what people use these devices for are gateways to Internet-hosted content and services. However, as more and more stuff becomes local to the device — for disconnected operation, for example — the greater the need for backing up that local data.

Android does not have a full-device backup as part of the OS. It does have some hooks that Google advertises as being “backup”, but IT professionals would not consider Google’s definition to match their own for “backup”. And, what hooks there are exist at the level of an app, not the device, providing opportunity — and requirements — for developers to tailor what gets backed up and, to a lesser extent, how it gets backed up.

This chapter will explore the steps to back up your app’s data, with and without Google’s assistance.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on file access and Internet access.

Having read the chapters on SSL and SQLCipher for Android are not required but may prove to be useful background for some of the side topics in this chapter.
First, Some Terminology

One key concept when it comes to backups is what, exactly, we are backing up. The general rule is that you focus your backup regimen on the “system of record”. This is the one and only system that has the master copy of the data. While it may be one “system”, that “system” may be rather complex (e.g., cluster of database servers). However, anything else outside of that system — such as clients for those servers — are not part of the system of record. While they may have some data that is also held by the system of record, that data is considered to be a cached local copy; the system of record has the “real” copy of the data.

Differing Definitions of “Backup”

The problem is that we toss around the term “backup” as though there is a universal canonical definition for that term. Hence, what Google will tell users is “backup” will not necessarily line up with what an IT department will consider “backup” to mean.

What Google Thinks “Backup” Means

Google’s focus is on the cloud. Therefore, their focus is on apps using data resident in the cloud, with some servers forming the system of record. Google (presumably) does some sort of backup for their own systems of record, for their own Internet-based services, and Google assumes that other firms are doing the same.

The side-effect of this definition, though, is that Google does not view an app as having much in the way of local data that needs to be backed up. Cached data can always be reloaded from the system of record, after all. What Google expects needs to be backed up will be local preferences and perhaps authentication or authorization credentials for working with the system of record. This dataset is small and does not necessarily change all that often.

Because the dataset does not change that often, Google only really cares about restoring that data in case of a total device replacement. In other words, if your phone gets run over by a bakery truck, and you wind up replacing that phone with another Android phone, Google is interested in making sure that your old phone’s apps get restored along with the old phone’s last backup of the tiny dataset. After that, you are on your own. In particular, because the dataset does not change that often and does not have much in the way of critical data, Google is not concerned with allowing users to restore app data from backup for any reason other than
replacing the device outright. In other words, Google is only concerned with disaster recovery.

Google does not offer any configurability for where backups themselves are stored. Whatever Google backs up, Google stores where Google wants. Terms of service and related agreements give Google — at least in Google's eyes — the right to do pretty much anything they want with that data. While they will tout the fact that Android 6.0+ backups are stored in an encrypted fashion, they fail to note that Google — not the developer, not the user – holds the encryption keys. Thus, the security offered by this encryption is nominal, perhaps slowing down somebody who breaks into Google's network, but otherwise not preventing anyone from accessing the data.

Also, there is a 25MB data cap on the size of the backup, so if your app might have data in excess of that, you need to handle backups yourself.

Finally, the author of this book cannot get Google's backup system to work on production hardware, as will be explained a bit more later in this chapter.

What IT Thinks “Backup” Means

Apps may well be the system of record for the data that they work with. There is no requirement that all apps be front-ends for some server, any more than there is a requirement that all desktop OS apps be front-ends for some server. There may be plenty of business or technical reasons why an app will be the system of record for its data, either all of the time or in between specific sync operations with some central data store.

As a result, an IT department will recognize that apps need a much more robust backup and restoration service, one that takes into account conventional IT backup concepts.

Most IT-grade backup regimens have the notion of “backup aging”. Rather than Google's approach of considering only one backup to be relevant, an IT department will maintain a series of backups (e.g., 14 days of nightly backups, plus 3 months of weekly backups, plus 5 years of monthly backups), to be able to handle data that might be lost, but where that loss is not detected for some time.

Most IT-grade backups regimens allow data to be restored, in part or completely, at any point, not just in case a device is stepped on by an elephant or otherwise destroyed. Disaster recovery is a *scenario* of a backup regimen, not the sole objective.
IT departments also tend to be very concerned about where their business data goes. The idea that the data should be available, unencrypted, to arbitrary third parties would be an anathema. Business data should be backed up on by IT-supplied technology on IT-supplied backup media, employing whatever security the IT department thinks is necessary.

Suffice it to say, Google's approach to “backup” does not align well with what an IT department will want.

What Your Legal Counsel Thinks “Backup” Means

Legal counsel, at some point, should be brought into the discussion of backups, as, for better or worse, there are legal risks involved in backups.

Particularly with Google-style, send-the-data-to-a-third-party backups, you need to ensure that this will not get you in legal trouble. From European Union privacy laws to HIPAA in the US, there are plenty of laws that prohibit the careless distribution of data.

Beyond that, legal counsel will be worried about “the Ashley Madison scenario”. A firm’s IT department will be responsible for ensuring that their servers are not hacked into. However, once you start passing data to third parties, now you are at risk of those servers getting hacked into. Legal counsel can advise you on what your legal exposure is, in terms of potential lawsuits from people whose data might get leaked by these sorts of attacks.

Implementing IT-Style Backup

So, if we want to add backup and restore capability to our app, what is needed? To explore that, we will use the Backup/BackupClient sample project as an illustration. This is a clone of a sample that originally appeared in the chapter on files. We have a three-tab ViewPager, with a large EditText widget in each tab. The three tabs differ in where they persist their data:

- `getFilesDir()`
- `getExternalFilesDir()`
- `DIRECTORY_DOCUMENTS` — the user’s Documents/ directory on API Level 19+ devices

This revised sample adds backup-and-restore functionality to this app.
The app also has one other change: it stores the most-recently-visited tab in SharedPreferences. To that end, MainActivity has a PrefsLoadThread static inner class that asynchronously loads the SharedPreferences, then delivers them via greenrobot’s EventBus:

```java
private static class PrefsLoadThread extends Thread {
    private final Context ctxt;

    PrefsLoadThread(Context ctxt) {
        this.ctxt=ctxt.getApplicationContext();
    }

    @Override
    public void run() {
        SharedPreferences prefs=
            PreferenceManager.getDefaultSharedPreferences(ctxt);
        PrefsLoadedEvent event=new PrefsLoadedEvent(prefs);

        EventBus.getDefault().post(event);
    }
}
```

MainActivity picks up this event in onPrefsLoaded(), an EventBus method that takes PrefsLoadedEvent as a parameter and updates the current page of the ViewPager (named pager):

```java
@Subscribe(threadMode = ThreadMode.MAIN)
public void onPrefsLoaded(PrefsLoadedEvent event) {
    this.prefs=eventprefs;

    int lastVisited=prefs.getInt(PREF_LAST_VISITED, -1);

    if (lastVisited>-1) {
        pager.setCurrentItem(lastVisited);
    }
}
```

The PrefsLoadThread is kicked off in onStart(), and the PREF_LAST_VISITED value is saved in onStop(), along with the registration and unregistration from the event bus:
The net effect is that we retain the last-visited tab across invocations of MainActivity. This forms part of the data that we would like to back up.

**Choosing the Backup Scope**

The first question is: what exactly are we backing up? Files? Databases? SharedPreferences? Stuff that is out in common areas, like top-level directories on external storage (e.g., DIRECTORY_DOCUMENTS) or the ContactsContract ContentProvider?

Typically, an individual app will focus on backing up only that app's data, which would exclude the common areas from consideration. That does not mean that you can't back up common data, but it makes restoration a bit more challenging, as you do not want to overwrite changes to that data that the user made from another app.

In BackupClient, we are backing up:

- the contents of `getFilesDir()`, which will hold onto one of our tabs' contents
DATA BACKUP

- the contents of `getExternalFilesDir()`, which will hold onto another of our tabs' contents
- some of the contents of the directory that holds the `SharedPreferences` for the app, which will pick up the preference value we are using for the last-visited tab

Notably, we are not backing up the file out on shared storage (the “Public” tab, set to store its data in `Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOCUMENTS)`). Hence, whatever is in that tab will be left alone when we restore the data from the backup.

Choosing a Backup Trigger

The next question is: when are we backing up the data?

There are any number of possibilities:

- A push message, such as through `GCM`, could request that the app back up its data
- Time-based triggers, using `AlarmManager` or `JobScheduler`, could be used to periodically make backups
- You could offer backups on demand, such as through an action bar item

The automated options (push message, `AlarmManager`, `JobScheduler`) are great, so users do not forget to make a backup. On the other hand, there is the risk that the user is using the app at the time the automated backup is supposed to happen, which means you will need some additional logic to ensure that you postpone that backup until a quieter time. It is difficult to back up data that is actively in use.

The `BackupClient` sample will settle for a simple manual trigger, via a “Backup” action bar item in the main activity. We also have a “Restore” action bar item, to request to restore the data from a backup. So, `MainActivity` will load in a menu resource that contains these two options:

```xml
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/backup"
    android:icon="@drawable/ic_backup_white_24dp"
    android:title="@string/menu_backup"/>
</menu>
```
It uses a pair of icons culled from [Google's material design icon set](https://material.io/iconsets/).

That resource is inflated in `onCreateOptionsMenu()`. If the user chooses the “Backup” option, we start a `BackupService` to do the work:

```java
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
    return (super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.backup) {
        BackupService.enqueueWork(this);
        return(true);
    } else if (item.getItemId()==R.id.restore) {
        startActivity(new Intent(this, RestoreRosterActivity.class));
        return(true);
    }
    return(super.onOptionsItemSelected(item));
}
```

We will get into the restore scenario a bit later in this chapter.

### Generating the Dataset

Next, we need to actually collect the data to be backed up and package it in some form to send to a server to serve as the backup dataset.

There are any number of ways to package this sort of data, but a ZIP file seems like a likely candidate:
It is fairly easy to work with on Android
It is fairly easy to work with on servers that might need to unpack the data
It is fairly easy to examine using desktop tools, for development, diagnostics, etc.

It is the job of the BackupService to create a ZIP file of our desired data, then send that ZIP file to a backup server.

BackupService itself is a JobIntentService, as this sort of work is a nice “fire-and-forget” sort of request, where we no longer need the service once the work is done.

In `onHandleWork()`, we orchestrate the major steps in this process:

```java
@override
public void onHandleWork(@NonNull Intent i) {
    try {
        File backup = buildBackup();

        uploadBackup(backup);
        backup.delete();

        EventBus.getDefault().post(new BackupCompletedEvent());
    } catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception creating ZIP file", e);
        EventBus.getDefault().post(new BackupFailedEvent());
    }
}
```

We:

• Call a `buildBackup()` method that creates our backup dataset
• Call an `uploadBackup()` method to send the dataset to some backup server
• Delete the local backup when that is done, as we no longer need it
• Raise events on an event bus for the UI layer's use, for when a backup succeeds or fails

Those events can then trigger UI responses. In the case of this trivial sample app, they just result in Toast messages to the user:
A production-grade app would do something more sophisticated, particularly for error messages, given that a Toast is ephemeral, and so the user might not see it.

buildBackup() is responsible for creating a file that contains our desired dataset and returning the File object pointing to that file:

```java
private File buildBackup() throws IOException {
    File zipFile = new File(getCacheDir(), BACKUP_FILENAME);
    if (zipFile.exists()) {
        zipFile.delete();
    }
    FileOutputStream fos = new FileOutputStream(zipFile);
    ZipOutputStream zos = new ZipOutputStream(fos);
    zipDir(ZIP_PREFIX_FILES, getFilesDir(), zos);
    zipDir(ZIP_PREFIX_PREFS, getSharedPrefsDir(), zos);
    zipDir(ZIP_PREFIX_EXTERNAL, getExternalFilesDir(null), zos);
    zos.flush();
    fos.getFD().sync();
    zos.close();
    return(zipFile);
}
```

We put the backup ZIP file in internal storage cache (getCacheDir()), as that is not something that we are backing up, and therefore we do not need to worry about somehow trying to back up the backup file itself.
We then call `zipDir()` three times, one for each directory of data to be backed up. Two of the three locations have SDK-supplied methods to get the `File` object pointing at those directories: `getFilesDir()` and `getExternalFilesDir()`. Unfortunately, the SDK does not provide any direct method that returns a `File` pointing at the directory for `SharedPreferences`. So, we have to hack one ourselves, in the form of `getSharedPrefsDir()`:

```java
static File getSharedPrefsDir(Context ctxt) {
    return new File(new File(ctxt.getApplicationInfo().dataDir),
                    "shared_prefs");
}
```

`getApplicationInfo()` returns the `ApplicationInfo` object describing our app. That has a `dataDir` field that points to all of our internal storage (whereas `getFilesDir()` points to a subdirectory off of `dataDir`). The `SharedPreferences` are stored in XML files in a `shared_prefs/` directory off of the location pointed to by the `dataDir` field. This is not an ideal solution, as in theory the `SharedPreferences` storage location could move. However, this code should work for all API levels from 1 through 23, and therefore it is reasonably likely that it will hold up over time.

`zipDir()` not only takes the `File` of data to be backed up and a `ZipOutputStream` representing where to package the data, but it also takes a path prefix. ZIP files do not really have a directory structure; that structure is faked based on path-style names associated with each entry. The prefix is added to each of those names, giving the effect of putting each directory’s contents into a separate “directory” within the ZIP archive. Those three prefixes are defined as simple `String` constants:

```java
static final String ZIP_PREFIX_FILES="files/";
static final String ZIP_PREFIX_PREFS="shared_prefs/";
static final String ZIP_PREFIX_EXTERNAL="external/";
```

`zipDir()` itself (mostly) is a typical recursive put-the-files-in-the-archive method:

```java
private void zipDir(String basePath, File dir,
                    ZipOutputStreamzos) throws IOException {
    byte[]buf=newbyte[16384];

    if (dir.listFiles()!=null) {
        for (File=file:dir.listFiles()) {
            if (file.isDirectory()) {
```
The one wrinkle is that we filter out files with a particular name, denoted by the BACKUP_PREFS_FILENAME constant:

```java
private static final String BACKUP_PREFS_FILENAME =
  "com.commonsware.android.backup.BackupService.xml";
```

We will explore what this file is, and why we are not backing it up, later in this chapter.

This backup approach has its flaws, in the interests of keeping the example simple:

- The UI layer is not saving all in-flight data before doing the backup. Hence, any changes in the current tab, since we moved to that tab, are not saved to disk or backed up. And, since we only save what the current tab is in onStop(), that too has not been adjusted since our activity moved to the foreground, and so it may be out of date. A production-grade app will need to decide what data that has not been saved through ordinary means should be saved prior to a manual backup, assuming that the app has a manual
backup option in the first place.

- The UI layer is not preventing the user from changing data that is being backed up while the backup is happening. In this sample app, the data to be backed up is small enough that it will probably happen quickly enough to not be a problem. A production-grade app, though, should take steps to prevent data entry (though perhaps not navigation through the app) while the backup is going on. Any such steps, though, need to take into account the possibility that the backup may fail — we do not want a failed backup to block the user from working in the app for hours.

Transmitting the Dataset

Given the data to be backed up in a nice convenient package, we need to get that dataset off the device and someplace safe, where we can later download and restore it if needed. There are any number of possible solutions here, including many existing public Web services (Dropbox, Amazon’s AWS S3, Google Drive, etc.). If you are only worried about manual backups, you could even consider using ACTION_SEND to send the dataset as an email attachment, though size and content limitations on email attachments may make this impractical for many users.

BackupService works with some implementation of a particular REST-style API for backing up and restoring the data. This API is fairly lightweight, light enough that it can be implemented in ~70 lines of Ruby code, as will be seen [later in this chapter](#). You could implement the same sort of API in any number of Web frameworks.

For backing up data, there are two REST operations that we need to perform:

- We need to create a new backup entry, via an HTTP POST request to /api/backups on the backup server
- We need to upload the dataset itself, via an HTTP PUT request to /api/backups/.../dataset on the backup server, where the ... is a backup ID that we get from the response to the original POST request

To implement the client side, BackupService employs the OkHttp library profiled in the [chapter on Internet access](#). Specifically, `uploadBackup()` does both of the HTTP requests necessary to back up the data, given the `File` pointing to the ZIP archive that is our dataset:

```java
private void uploadBackup(File backup) throws IOException {
    Request request = new Request.Builder()
        .url(URL_CREATE_BACKUP)
```
DATA BACKUP
.post(RequestBody.create(JSON, "{}"))
.build();
Response response=OKHTTP_CLIENT.newCall(request).execute();
if (response.code()==201) {
String backupURL=response.header("Location");
request=new
new Request.Builder()
.url(backupURL+RESOURCE_DATASET)
.put(RequestBody.create(ZIP, backup))
.build();
response=OKHTTP_CLIENT.newCall(request).execute();
if (response.code()==201) {
String datasetURL=response.header("Location");
SharedPreferences prefs=
getSharedPreferences(getClass().getName(),
Context.MODE_PRIVATE);
prefs
.edit()
.putString(PREF_LAST_BACKUP_DATASET, datasetURL)
.commit();
}
else {
Log.e(getClass().getSimpleName(),
"Unsuccessful request to upload backup");
}
}
else {
Log.e(getClass().getSimpleName(),
"Unsuccessful request to create backup");
}
}
(from Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupService.java)

We create an OkHttp Request.Builder representing our POST request. The URL is
defined as a constant, URL_CREATE_BACKUP:
private static final String URL_CREATE_BACKUP=
BuildConfig.URL_SERVER+"/api/backups";
(from Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupService.java)

This, in turn, is built up from the fixed REST endpoint path (/api/backups), with
the rest of the URL coming from BuildConfig.URL_SERVER. This is defined out in
2758


our build.gradle file, allowing us to have different backup server locations based upon build types (or, in principle, product flavors):

```java
buildTypes {
    debug {
        buildConfigField "String", "URL_SERVER", '"http://10.0.2.2:4567"'
    }

    release {
        buildConfigField "String", "URL_SERVER", '"http://10.0.2.2:4567"'
    }
}
```

Here, they happen to both point to the same value at the moment, the IP address that, on an Android emulator, represents localhost of your development machine. However, you could easily change the release build type to point to some production instance of a backup server.

The body of the POST request is a JSON object containing whatever we want, in case we need to provide some sort of identifiers with the backup for server-side use or analysis. In this case, we are passing an empty JSON object ({})

```java
private static final MediaType JSON =
    MediaType.parse("application/json; charset=utf-8");
```

We then use an instance of an OkHttpClient object to perform the request, getting the Response synchronously (since we are already on a background thread). If multiple components in your app will all be using OkHttp, the recommendation is to use a singleton instance of OkHttpClient, here defined on BackupService itself:

```java
static final OkHttpClient OKHTTP_CLIENT =
    new OkHttpClient();
```

The REST protocol to the backup server is that a 201 response code (“Created”) means that our backup metadata has been saved and an ID has been generated for our backup. The Location header in the response contains a REST URL pointing to the backup itself (/api/backups/... for some value of ...). We then use that to generate the URL for the dataset (/api/backups/.../dataset), and perform a PUT request for the dataset, using the ZIP MediaType defined as yet another constant:
Once again, a 201 response indicates that our resource was created, and the Location header provides the URL for the backup dataset. We stuff that URL in a SharedPreferences object unique to BackupService, under a PREF_LAST_BACKUP_DATASET key. We will use that — at least, in theory — if we are restored from a Google disaster recovery process. We will explore that more later in the chapter.

If we get an unexpected response from the server, the sample app logs a message to Logcat and otherwise quietly fails. A production-grade app would handle these scenarios better, including informing the user about the problem.

Of course, a production-grade backup implementation might want more than what we have here, such as better security. For apps being publicly distributed through the Play Store or similar channels, you may want to offer multiple ways of saving off the backup, through some common API with multiple implementations. That way, users can choose whether to back up data via a private server or a public one (e.g., Amazon S3) or some other means that you offer.

**Initiating a Restore**

Unfortunately, on occasion, the user may have a need to restore the app's data from a backup.

There are three primary possible triggers for this work to be done:

- The user could ask for data to be restored manually, through some option in the app's UI, such as an action bar item
- The request to restore the data could be pushed to the device, such as through GCM, perhaps in response to an IT department staff member initiating a remote restore
- The user could have gotten a new device, and if the user had chosen automatic disaster recovery “backups” on their old device, they could have our app and its data automatically restored onto the new device

There is also the question of *which* backup to restore. Frequently, the user will want the most recent backup, but that is not always the case. The user might realize that the data has been wrong for days and needs to restore an earlier backup than the
most recent one.

To that end, the BackupClient demo app will allow the user to manually request that data be restored, via a “Restore” action bar item. We will fetch a list of available backups from the backup server, so the user can choose what backup to restore from.

The “Restore” action bar item in MainActivity simply launches a RestoreRosterActivity, to allow the user to choose the backup to restore. That activity merely sets up a dynamic fragment, RestoreRosterFragment, in onCreate():

```java
package com.commonsware.android.backup;

import android.os.Bundle;
import android.support.v4.app.FragmentActivity;

public class RestoreRosterActivity extends FragmentActivity {

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
            getSupportFragmentManager().beginTransaction().add(android.R.id.content, new RestoreRosterFragment()).commit();
        }
    }
}
```

(from Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreRosterActivity.java)

RestoreRosterFragment has fairly basic implementations of the onCreate(), onStart(), and onStop() lifecycle methods, to mark the fragment as being a retained fragment, plus to register and unregister from the event bus:

```java
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);
}

@Override
public void onStart() {
    super.onStart();
}
```
RestoreRosterFragment is a ListFragment, so the ListView will be set up automatically in the inherited implementation of onCreateView(). In onViewCreated(), we can kick off a REST request to pull down the list of backups from the backup server. This client assumes that the REST server has an /api/ backups endpoint that will return a JSON roster of the available backups, so we can use OkHttp to perform the GET request for that data:

```java
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    Request request = new Request.Builder()
        .url(URL_BACKUPS)
        .build();

    BackupService.OKHTTP_CLIENT.newCall(request).enqueue(this);
}
```

Here, we use the same OkHttpClient instance as BackupService uses — since this is a static data member that is automatically initialized, it does not matter whether or not we have used BackupService already in this process. The endpoint URL is found in the URL_BACKUPS constant:

```java
private static final String URL_BACKUPS =
    BuildConfig.URL_SERVER+"/api/backups";
```

Since this is being driven by the UI, and we are calling OkHttp from the main application thread, we use enqueue() instead of execute(), to schedule the request
to be performed on a background thread supplied and managed by OkHttp. RestoreRosterFragment implements the required Callback interface needed by enqueue(). That interface, in turn, requires two methods. One is onFailure(), to be called if there is a problem in executing the HTTP request. Here, we just inform the user about the problem in a Toast, though a production-grade app would do something more sophisticated:

```java
@Override
public void onFailure(Request request, IOException e) {
    Toast.makeText(getActivity(), R.string.msg_roster_failure,
                      Toast.LENGTH_LONG).show();
    Log.e(getClass().getSimpleName(),
          "Exception retrieving backup roster", e);
}
```

The more important method is onResponse(), called when we get a valid-looking response from the server:

```java
@Override
public void onResponse(Response response) throws IOException {
    Gson gson=
        new GsonBuilder()
            .setDateFormat("yyyy-MM-dd'T'HH:mm:ssZZZZZ")
            .create();

    Type listType=
        new TypeToken<List<BackupMetadata>>(){}.getType();

    EventBus.getDefault()
       .post(
          gson.fromJson(response.body().charStream(), listType));
}
```

This sample could use Retrofit for performing this REST-style GET request, in which case Retrofit would work with OkHttp and Google's Gson to parse our response. In this case, we are using OkHttp directly, and so we need to arrange to have Gson parse the response.

To that end, we:

- Create a Gson instance through a GsonBuilder, teaching it that the JSON data to be mapped to Date objects in our results have a particular serialized
DATA BACKUP

- Create a Type object wrapping our expected response: a List of BackupMetadata objects
- Get the JSON from the response (response.body().charStream), and pass that to the Gson object for parsing

And, since onResponse() is called on a background thread, we use the event bus to deliver that List of BackupMetadata objects to the fragment itself, so we can pick up that event on the main application thread.

The JSON we get back will be a JSON array containing a list of JSON objects, with each of those objects being mapped to a BackupMetadata instance by Gson:

```java
package com.commonsware.android.backup;

import java.util.Date;

public class BackupMetadata {
  Date timestamp;
  String dataset;

  @Override
  public String toString() {
    return (timestamp.toString());
  }
}
```

(from Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupMetadata.java)

RestoreRosterFragment then has an onEventMainThread() method, to pick up the List of BackupMetadata, to wrap that in an ArrayAdapter and put those results in the fragment’s ListView:

```java
@Subscribe(threadMode = ThreadMode.MAIN)
public void onEventMainThread(List<BackupMetadata> roster) {
  adapter=new ArrayAdapter<BackupMetadata>(getActivity(),
    android.R.layout.simple_list_item_1, roster);

  setListAdapter(adapter);
}
```
Starting the Restore Activity

When the user clicks on an available backup in the ListView, `onListItemClick()` gets called:

```java
@Override
public void onListItemClick(ListView l, View v, int position, long id) {
    String url = BuildConfig.URL_SERVER + adapter.getItem(position).dataset;
    Intent i = new Intent(getActivity(), RestoreProgressActivity.class)
        .setData(Uri.parse(url))
        .addFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
                  Intent.FLAG_ACTIVITY_CLEAR_TASK |
                  Intent.FLAG_ACTIVITY_EXCLUDE_FROM_RECENTS);
    startActivity(i);
}
```
The BackupMetadata has a relative URL to the backup's dataset, so we combine that with BuildConfig.URL_SERVER to get a fully-qualified URL. Then, we start up a RestoreProgressActivity, which will be responsible for kicking off the restore and showing some form of progress indicator along the way.

The tricky part with restoring your app’s data is that you cannot have any app components running that rely upon that data, as the data will be changing out from underneath those components. In our case, we need to get rid of our MainActivity.

To do that, we attach a few flags to the Intent used to start up the RestoreProgressActivity:

- FLAG_ACTIVITY_NEW_TASK
- FLAG_ACTIVITY_CLEAR_TASK
- FLAG_ACTIVITY_EXCLUDE_FROM_RECENTS

These will get rid of all of our previous activities (including the currently-active RestoreRosterActivity) and will prevent the RestoreProgressActivity from showing up in the overview screen.

RestoreProgressActivity has a simple layout with a large centered Progressbar:

```xml
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <ProgressBar
        style="@android:style/Widget.ProgressBar.Large"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center"/>
</FrameLayout>
```

(from Backup/BackupClient/app/src/main/res/layout/progress.xml)

In onCreate() of RestoreProgressActivity, in addition to showing that Progressbar, we kick off a RestoreService to actually download and restore the backup. We are passed the URL to the backup dataset in the Intent used to start RestoreProgressActivity, and we just pass that same URL along (as a Uri) to the service:

```java
@override
```

```java
DATA BACKUP
```

2766
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.progress);

    if (savedInstanceState == null) {
        RestoreService.enqueueWork(this);
    }
}

(from Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreProgressActivity.java)

However, we only do that if we are not being recreated after a configuration change, so this only happens on the first invocation of the activity.

RestoreProgressActivity also registers for events on the event bus, using the typical onStop()/onStart() pattern:

@override
protected void.onStart() {
    super.onStart();

    EventBus.getDefault().register(this);
}

@override
protected void onStop() {
    EventBus.getDefault().unregister(this);

    super.onStop();
}

(from Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreProgressActivity.java)

**Downloading and Restoring the Dataset**

Meanwhile, over in RestoreService, we download and unpack the dataset:

package com.commonsware.android.backup;

import android.content.Context;
import android.content.Intent;
import android.support.annotation.NonNull;
import android.support.v4.app.JobIntentService;
import android.util.Log;
import com.squareup.okhttp.Request;
import com.squareup.okhttp.Response;
import org.greenrobot.eventbus.EventBus;
import java.io.File;
import okio.BufferedSink;
import okio.Okio;

public class RestoreService extends JobIntentService {
  private static final int UNIQUE_JOB_ID = 1337;

  static void enqueueWork(Context ctxt) {
    enqueueWork(ctxt, RestoreService.class, UNIQUE_JOB_ID,
                new Intent(ctxt, RestoreService.class));
  }

  @Override
  public void onHandleWork(@NonNull Intent i) {
    Request request = new Request.Builder()
        .url(i.getData().toString())
        .build();

    try {
      Response response = BackupService.OKHTTP_CLIENT.newCall(request).execute();
      File toRestore = new File(getCacheDir(), "backup.zip");

      if (toRestore.exists()) {
        toRestore.delete();
      }

      BufferedSink sink = Okio.buffer(Okio.sink(toRestore));
      sink.writeAll(response.body().source());
      sink.close();

      ZipUtils.unzip(toRestore, getFilesDir(),
                     BackupService.ZIP_PREFIX_FILES);
      ZipUtils.unzip(toRestore,
                     BackupService.getSharedPrefsDir(this),
                     BackupService.ZIP_PREFIX_PREFS);
      ZipUtils.unzip(toRestore, getExternalFilesDir(null),
                     BackupService.ZIP_PREFIX_EXTERNAL);

      EventBus.getDefault().post(new RestoreCompletedEvent());
    }
    catch (Exception e) {
      Log.e(getClass().getSimpleName(),
            "Exception restoring backup", e);
      EventBus.getDefault().post(new RestoreFailedEvent());
    }
}
The URL for the dataset is coming in via the Intent passed into `onHandleIntent()`. We use that to build the OkHttp Request, then do a synchronous call via `execute()` to get the `Response`.

Previous uses of OkHttp in this chapter focused on REST responses, where we could either just use Location headers or pass the text of the response over to Gson. Here, we are expecting a ZIP file, and possibly a large one. The right way to get that written to disk (so we can unpack it) is to stream the data down and write that data out to disk, rather than attempting to read everything into memory first.

To that end, we take advantage of the fact that OkHttp itself is built atop Square’s **Okio library**, which offers a nice Java API for handling streams, based on sinks and sources. The recipe for streaming an HTTP response to disk involves:

- Creating a sink for the destination file (in this case, a `backup.zip` file placed in `getCacheDir()`)  
- Wrapping that in a `BufferedSink`  
- Telling the sink to write everything from the `source()` we get from OkHttp representing the ZIP data  
- Closing the sink

At that point, we need to unpack the dataset into the places we got the data from in the first place when we backed it up:

- `getFilesDir()`  
- the directory for `SharedPreferences`  
- `getExternalFilesDir()`

To that end, we use a slightly modified version of the `ZipUtils` class first referenced in the tutorials. The one used in the tutorials comes from the CWAC-Security
library. However, that ZipUtils class does not handle two things that we need here:

- Unpacking a subset of the files, from one virtual directory within the ZIP archive
- Restoring them to an already-existing directory without deleting and recreating that directory.

The BackupClient project has its own modified version of ZipUtils that handles those cases. Beyond that, the unzip() method is the same as before, taking:

- The ZIP file to unpack
- The filesystem directory where the unpacked files should go
- The virtual directory within the ZIP archive that we want (as opposed to the entire contents)

When that is done, we post a RestoreCompletedEvent. If there is some problem, we post a RestoreFailedEvent, in addition to logging details to Logcat.

RestoreProgressActivity listens for both of those events:

```java
@Subscribe(threadMode = ThreadMode.MAIN)
public void onCompleted(RestoreService.RestoreCompletedEvent event) {
    startActivity(new Intent(this, MainActivity.class));
    finish();
}

@Subscribe(threadMode = ThreadMode.MAIN)
public void onFailed(RestoreService.RestoreFailedEvent event) {
    Toast.makeText(this, R.string.msg_restore_failed, Toast.LENGTH_LONG).show();
    finish();
}
```

(from Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreProgressActivity.java)

In the success case, we can now start up a fresh MainActivity (since the original was destroyed as part of launching RestoreProgressActivity), and it can read the restored data.

In the failure case... we are really screwed. We may have partially restored the data, but perhaps not all of it, and there is no telling what state the data is in. A production-grade app would handle this by:

---

2770
DATA BACKUP

- Moving all of the existing data to a safe location on the device
- Attempting to restore the data
- If there is an unhandled exception in the restoration process, deleting the partially-restored data and moving the original data back into position

This would reduce the odds of some catastrophic problem wiping out the app. In this sample, though, we just show a Toast, `finish()` the activity (thereby exiting the app, as we have no other active activities), and hoping the user uninstalls and reinstall the app, or just uninstalls the app, or something.

Trying This Yourself… With a Little Help from Ol’ Blue Eyes

Everything discussed so far assumes the existence of some REST-style Web server that we can interact with for backups. As it so happens, the BackupClient project has a crude implementation of such a server, in the form of a Ruby script using the Sinatra gem:

```ruby
require 'fileutils'
require 'time'
require 'sinatra'
require 'json'

BACKUP_ROOT = '/tmp/backups'

get '/' do
  'Hello world!
end

get '/api/backups' do
  result = []

  if File.exist?(BACKUP_ROOT)
    Dir.foreach(BACKUP_ROOT) do |item|
      next if item == '.' or item == '..'

      subdir = File.join(BACKUP_ROOT, item)

      if File.directory?(subdir)
        f = File.join(subdir, "metadata.json")

        if File.exist?(f)
          metadata = JSON.load(open(f))
          metadata['dataset'] = '/api/backups/#{item}/dataset'
        end
      end
      result << metadata
  end
```
DATA BACKUP

end
end
end
result.sort_by!{|metadata| metadata['timestamp']}
result.reverse!

JSON.pretty_generate(result)
end

post '/api/backups' do
  id=SecureRandom.uuid
  dir=File.join(BACKUP_ROOT, id)
  FileUtils.mkdir_p(dir)
  f=File.join(dir, "metadata.json")
  metadata={'timestamp'=>Time.new.xmlschema}
  File.open(f, 'w') { |io| io.write(JSON.generate(metadata))}

  redirect to('/api/backups/'+id), 201
end

put '/api/backups/:id/dataset' do
  dir=File.join(BACKUP_ROOT, params[:id])

  if File.exist?(dir)
    f=File.join(dir, "backup.zip")
    File.open(f, 'w') { |io| io.write(request.body.read)}

    redirect to("/api/backups/#{params[:id]}/dataset"), 201
  else
    status 404
  end
end

get '/api/backups/:id/dataset' do
  dir=File.join(BACKUP_ROOT, params[:id])
  f=File.join(dir, "backup.zip")

  if File.exist?(f)
    send_file f
  else
    status 404
  end
end

(from Backup/BackupClient/server.rb)
If you have familiarity with Ruby, you can:

- install the sinatra and json gems in your environment
- run the script (ruby server.rb)

That will give you a server, listening to localhost:4567... which happens to be what the BackupClient Android app is looking to talk to, if that app is running on an emulator. If you want to test with an actual Android device, the -o switch lets you specify the IP address to listen to, and -p lets you change up the port number if you wish.

**The Google Backup Bootstrap**

Once you get your real backup system going, then, if you wish, you can play around with Google's disaster recovery bootstrap. By opting into what Google terms "backup", you can have some of your data automatically backed up, then restored when the user replaces their device.

**What to Bootstrap?**

The biggest decision that you will need to make is what should be included in Google's bootstrap backup and what should not.

The primary considerations are privacy and security. Any data included in the bootstrap is visible to other parties. If that data is not encrypted with a user-supplied passphrase, other parties will be able to do what they want with the data, without much recourse.

One option, therefore, is to opt out of these bootstrap backups entirely, and handle disaster recovery like any other restore process.

Another is to only include some identifying information in the bootstrap backup, to help expedite the restore process, but without really compromising security much. In the context of the BackupClient sample shown earlier in this chapter, if the backup server was adequately secured, including a dataset URL in the bootstrap backup would not be much of a problem. Having the URL itself is probably not that useful, and if only authorized users can download datasets from those URLs, attackers would not gain anything from peeking at the bootstrap. BackupClient itself has very little security, to keep the sample (reasonably) simple, but you can imagine requiring user accounts or similar means to try to lock down access to the
DATA BACKUP

backup server.

The far other end of the spectrum is to allow Android to backup “the whole shootin’ match” (i.e., everything), on the grounds that the data you have is not especially private.

You and your qualified legal counsel will need to make this decision before deciding what to do for implementing the bootstrap backup itself.

Bootstrap Backup on Android 6.0+

Android has had a backup API since Android 2.2. However, not only did developers have to opt into the backups, but they had to write special code to assist in those backups. As such, that API was not used that much.

Android 6.0 has gone the other direction, with opt-out backups of all likely data, if your targetSdkVersion is 23 or higher. Specifically:

• Your app’s internal storage (getFilesDir(), SharedPreferences, getDatabaseDir(), etc.) gets backed up, with the exception of getCacheDir() and getNoBackupFilesDir() (the latter introduced in API Level 21)
• getExternalFilesDir() is backed up, but not other locations on external storage

Backups occur approximately once per day, if the device is idle, charging, and on WiFi.

Configuring the Backup

If what you want to back up is different than what Android 6.0+ will back up by default, you can add manifest entries to better control what is and is not backed up.

To opt out entirely, add android:allowBackup="false" to your <application> element in the manifest:

```xml
<application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme"
    tools:replace="android:allowBackup">
```
Here, the tools:replace ensures that no library attempts to override your allowBackup value.

Conversely, if you want to participate in the bootstrap backup, but you want to change the roster of what gets backed up, use the android:fullBackupContent attribute on the <application> element. This needs to point to an XML resource that describes what it is that you do and do not want backed up.

The BackupClient sample has this configured. The <application> element points to a res/xml/backup_rules.xml resource:

```xml
<application
    android:fullBackupContent="@xml/backup_rules"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.Apptheme">
    <activity
        android:name=".MainActivity"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>
            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
    <activity android:name=".RestoreRosterActivity"/>
    <activity android:name=".RestoreProgressActivity"/>
    <service android:name=".BackupService"
             android:permission="android.permission.BIND_JOB_SERVICE"/>
    <service android:name=".RestoreService"
             android:permission="android.permission.BIND_JOB_SERVICE"/>
</application>
```

(from Backup/BackupClient/app/src/main/AndroidManifest.xml)

That XML resource can contain <include> and <exclude> elements, inside of a root <full-backup-content> element. The rules are:

- If there are no <include> elements — only <exclude> elements – then all
the files that get backed up by default will get backed up, except those blocked by those `<exclude>` elements.

- If there are one or more `<include>` elements (perhaps along with `<exclude>` elements), then *none* of the files that get backed up by default will be backed up. Instead, only the files listed in the `<include>` elements (and not blocked by any `<exclude>` elements) will be backed up.

The `BackupClient` sample has two `<include>` elements, in effect saying that only what is cited in these elements should be backed up:

```xml
<?xml version="1.0" encoding="utf-8"?>
<full-backup-content>
  <include>
    <domain>sharedpref</domain>
    <path>com.commonsware.android.backup_preferences.xml</path>
  </include>
  <include>
    <domain>sharedpref</domain>
    <path>com.commonsware.android.backup.BackupService.xml</path>
  </include>
</full-backup-content>
```

(from `Backup/BackupClient/app/src/main/res/xml/backup_rules.xml`)

The `<include>` and `<exclude>` elements must have a `domain` attribute and a `path` attribute. These combine to indicate what is being included or excluded.

The `domain` attribute indicates one of five locations relative to your app:

- `root` points to all of your internal storage
- `file` points to the subset of your internal storage used for ordinary files (i.e., `getFilesDir()`)
- `database` points to the subset of your internal storage used for databases (i.e., `getDatabasePath()`)
- `sharedpref` points to the subset of your internal storage used for `SharedPreferences`
- `external` points to the location used by `getExternalFilesDir(null)`

The `path` attribute then provides a relative path, from the base location indicated by `domain`, for the item to be included or excluded.

Hence, the `BackupClient` backup rules say to include two `SharedPreferences` files. One is written to by `BackupService` on every backup, holding a single value, keyed by `lastBackupDataset`, with the URL to the last backup dataset. The other is the default `SharedPreferences`, used for the last-visited tab by the UI. Because these
SharedPreferences files are included in the bootstrap backup, they should be restored in case the user replaces the device. However, they are the only things that is supposed to be backed up — everything else in the app should be left alone.

Note that the documentation does not state clearly if the path attribute is required. It is possible that the path attribute is optional, where if it is missing, it means you want to include or exclude everything in the cited domain.

Testing the Backup and Restore Steps

In theory, to test your backup configuration, you can run three commands on the command line:

```
adb shell setprop log.tag.BackupXmlParserLogging VERBOSE
adb shell bmgr run
adb shell bmgr fullbackup ...
```

where ... is the application ID of the app to be backed up. For the sample app, that is com.commonsware.android.backup.

(the above assumes that you have adb in your PATH)

You can then manually initiate a restore operation via:

```
adb shell bmgr restore ...
```

for the same value of ... Presumably, you would do this after modifying or clearing the backed-up data, so you can confirm that the data was restored properly.

For the purposes of conducting lightweight experiments with the auto-backup facility, you do not need to mess around with the entire backup system outlined earlier in this chapter. That backs up the actual content; the auto-backup facility is backing up SharedPreferences, and that happens whether or not we are also backing up the content.

So, for example, you could do the following:

- Run the sample app and switch to some tab other than the default, then press BACK to exit the app and save your last-visited tab in SharedPreferences
- Execute the following at the command line of your developer machine, to examine the contents of the SharedPreferences:
DATA BACKUP

adb shell run-as com.commonsware.android.backup
"cat /data/data/com.commonsware.android.backup/shared_prefs/com.commonsware.android.backup_preferences.xml"

(NOTE: the above should be all on one line; it is split here across three lines due to the length of the command)

You should see something like:

```xml
<?xml version='1.0' encoding='utf-8' standalone='yes' ?>
<map>
  <int name="lastVisited" value="2" />
</map>
```

The value will be the index of whatever tab you were on when you exited the activity.

- Run the commands shown earlier to back up those SharedPreferences:

  ```
  adb shell setprop log.tag.BackupXmlParserLogging VERBOSE
  adb shell bmgr run
  adb shell bmgr fullbackup com.commonsware.android.backup
  ```

You should see output in Logcat indicating that the backup was taken:

```
14936-14936/? D/AndroidRuntime: Calling main entry com.android.commands.bmgr.Bmgr
800-2345/? D/BackupManagerService: fullTransportBackup()
800-14960/? I/PFTBT: Initiating full-data transport backup of ...
800-14961/? D/BackupManagerService: Binding to full backup agent : ...
800-14961/? D/BackupManagerService: awaiting agent for ApplicationInfo(...) 
800-810/? D/BackupManagerService: agentConnected pkg=com.commonsware...
800-14961/? I/BackupManagerService: got agent
android.app.IBackupAgent$Stub$Proxy@e17804c
800-14961/? I/BackupRestoreController: Getting widget state for user: 0
800-14962/? I/file_backup_helper: Name: apps/com.commonsware.android...
800-14962/? D/BackupManagerService: Calling doFullBackup() on com.commonsware... 
9380-9391/com.commonsware.android.backup I/file_backup_helper: Name: ...
800-14960/? I/PFTBT: Transport suggested backoff=0
800-14960/? I/PFTBT: Full backup completed.
9380-9380/? I/Process: Sending signal. PID: 9380 SIG: 9
800-2345/? D/BackupManagerService: Done with full transport backup.
```

(NOTE: the lines have been truncated due to length)

- Run the app again and switch to another tab, then press BACK to exit the
DATA BACKUP

- Run the run-as command again to examine the contents of the current SharedPreferences, and see that it contains your newly-chosen tab.
- Execute adb shell bmgr restore com.commonsware.android.backup from the command line to restore the SharedPreferences from your backup. You should get additional lines in Logcat showing that the restoration took place:

```log
16814-16814/? D/AndroidRuntime: Calling main entry com.android.commands.bmgr.Bmgr
```
DATA BACKUP

Run the `run-as` command again to examine the contents of the current SharedPreferences, and see that it contains your original tab.

• Uninstall your application, then try the `run-as` again, which will give you an error indicating that the file was not found.

• Re-run the app from the IDE. Then, run the `run-as` command again, to see that your file was restored without manually having to restore it.

Bootstrap Backup on Android 2.2-5.1

Prior to Android 6.0, Android had a “backup service”, inaugurated in Android 2.2. As with the Android 6.0 approach, the original backup service was mostly for disaster recovery.

Unlike with Android 6.0’s approach, you needed to opt into having these backups. Partly, this opt-in was accomplished via code, as you had to extend a BackupAgentHelper and register it in your manifest as the android:backupAgent, via the `<application>` element. The BackupAgentHelper subclass would indicate what should be backed up, by instantiating one or more BackupHelper objects (e.g., FileBackupHelper), configuring them to back up certain items, then registering them with the BackupAgentHelper via an addHelper() method.

Partly, though, the opt-in was accomplished via registering for an API key. This process was never integrated into the rest of the Play Services architecture, which now has a standardized approach for registering for various API keys and agreeing to the terms of service for each.

Instead, you would need to visit an obscure Web page, agree to the terms of service, provide information about your app (notably the application ID), get the API key, and add it to your manifest via a `<meta-data>` element.

However, those terms of service contain some interesting clauses, ones that may give your legal counsel some concern, such as:

• “the form and nature” of the backup service “may change from time to time without prior notice to you”
• “Google may stop... providing the Service (or any features within the Service) to you or to users generally at Google's sole discretion, without prior notice to you”
• You “agree to use the Service only for purposes that are permitted by... any applicable law... in the relevant jurisdictions (including any laws regarding the export of data or software to and from the United States or other relevant countries)” without ever disclosing what those “relevant countries” are
• You agree to not “sell... access to the Service”, which would seem to preclude its use by paid apps or apps using in-app purchases to upgrade to some “pro” edition that enabled backups
• “you are responsible for maintaining the security... of the Backup Service Key(s)”, despite the fact that these have to be published in the manifest and therefore are readable by anyone
• “you will not transmit any Content through the Service that is copyrighted, protected by trade secret or otherwise subject to third party proprietary rights”, despite the fact that developers have no means of validating these rights for user-supplied content
• “Google may need to change these Terms from time to time... Once the modified Terms are posted, the changes will become effective immediately, and you are deemed to have accepted the modified Terms if you continue to use the Service”, despite the fact that developers have no means of finding out exactly when the terms change or somehow instantaneously preventing installed copies of their apps from using the service

Beyond this, there are no statements about where the data is actually backed up, other than opening it up to just about anyone that Google wishes to characterize as “Subsidiaries and Affiliates”.

Please discuss these terms with legal counsel before registering for this service and integrating it within your app.

Additional documentation about this form of backup, should you choose to pursue it, can be found online.

**Boosting Backup Security**

Backups, in effect, are intentional data leaks. You want something other than the device to have access to your app's data. Hence, it is important to take reasonable steps to ensure that those backups are secure, secure enough that nobody is going to
be able to exploit them for uses that go against the user’s wishes. Rest assured that people will try to exploit backups and will succeed if your security is insufficient.

**Securing Access to the Dataset**

The backup dataset that you transfer off the device needs to be secure from attack. Unauthorized people should not be able to get at the dataset.

For a backup system like the one outlined in this chapter, the big thing to secure is access to the dataset via its URL. If anyone who gets the URL can download the dataset, now all an attacker needs to do is determine how to get that URL, such as by exploiting flaws in Google’s bootstrap backup. Or, for that matter, Google staff could get at the URL, at least in principle.

In this case, the URL alone must be insufficient. It would need to be combined with other information from the user, such as some sort of site authentication, where that other information is not retained.

If you are holding onto backup datasets yourself, on your own servers, you will also need to ensure that only authorized staff can get at those datasets and that such access is highly visible. Otherwise, you are at risk of an insider attack, whether through so-called “social engineering” or just good old-fashioned extortion.

**Securing Transmission of the Dataset**

Another way that an attacker could get at the dataset is to copy the data in motion, as it is sent from your app to the backup server. Make sure that you are using suitable security here:

- HTTPS with certificate pinning
- Corporate VPN
- etc.

Bear in mind that users may wind up making a backup from any sort of network, ranging from your office network to the free WiFi at a local coffee shop. In principle, you could detect this and refuse to back up the data when you do not recognize the network. However, this reduces the value of the backup system, as the user might not be able to make a manual backup at some point when they need it (e.g., on business travel).
Encrypting the Dataset

The ultimate in protection for the user is to have the data be encrypted by a user-supplied passphrase. Then, even you cannot access the data without the user’s assistance. There are ways of addressing this, perhaps involving brute force attacks or other sorts of brute force attacks. However, it certainly slows attackers down.

The simplest way to have encrypted backups — from the standpoint of the person writing the backup code — is to encrypt the data itself. For example, you do not necessarily need to re-encrypt a SQLCipher for Android database as part of a backup dataset, as it is already encrypted. Note, though, that having encrypted data at rest does not mean you can skip encrypting the data in motion, as it is sent to your backup server. While attackers would not be able to read the backed-up data readily, they could replace the backed-up data sent over the unencrypted communications channel and perhaps cause problems that way.

If, however, you are not in position to encrypt the data at rest within your app, you may wish to consider asking the user for a passphrase and using that to encrypt the backup dataset. Note that this passphrase requirement largely eliminates the ability for you to do unattended automated backups, as you either do not have the passphrase then (and so cannot encrypt the backups) or you are saving the passphrase (and so have just made it trivial for somebody to get it and decrypt the data).

Alternative Approaches

Backing up local data is essential where the device is the system of record, to be able to deal with catastrophe (e.g., the user accidentally uninstalls the app).

That being said, there are a few ways of dealing with backing up local data that might not necessarily seem to the user as though it is a backup process.

Data Versioning

Beyond the accidental wiping of data, such as through an erroneous install, a backup can also help recover from more fine-grained errors, like accidentally deleting a bit of data (e.g., a row or set of rows from database tables).

One way to address that is to use some sort of data versioning approach. Many software developers are familiar with this in the form of source code version control,
such as git. Here, you never really “delete” anything forever. Instead, you delete (or change) things in your working copy of the data, with the versioning system tracking changes to the data, so you can roll back to some earlier version if the need arises.

This is not limited to source code or similar sorts of documents. One simple example of versioning that has been used for decades is to not actually delete database rows, but instead set some is_deleted column to a known value. Then, when you query the database, you filter out the “deleted” rows by excluding from the query those rows where is_deleted is set to that specific value. Recovering those deleted rows is then a matter of showing all the deleted ones to the user and clearing is_deleted for the ones to be restored.

Obviously, this gets much more complicated once you get into foreign key constraints (i.e., how can you restore X if it depends on Y that was also deleted?). And it is not a full replacement for a backup-and-restore system, since anything that damages or deletes the entire database cannot be recovered via this sort of versioning. But, if you are looking to implement a robust disk-based “undo” facility for users, just bear in mind that it also helps out for some sorts of cases where you might ordinarily think of restoring from a backup.

Import and Export

Another feature that you can add that has some relationship to data backups is data import and export. Whatever is exported can be backed up by the user by some other means; if the master copy of the app’s data gets damaged, you might be able to recover from that damage via importing a previous export.

Of course, import and export are also used for data exchange with foreign systems (e.g., exporting tabular data in a format that can be read in by a desktop spreadsheet program). Also, traditionally, import and export are tasks that are manually requested by users. However, you might consider giving the user an option of performing an automatic export as a replacement for, or adjunct to, some other form of regular backup.

Data Synchronization

The ultimate solution for not having to mess with a robust device-based backup system is to not have the device be the system of record. Instead, some server is the system of record, with the device holding what amounts to a persistent cache of some of that data:
DATA BACKUP

- Data that you retrieved previously, so you do not necessarily have to keep downloading the same data from the server
- Data that the user has modified that you are planning on sending to the server at some time in the future (e.g., during the nightly sync, or when the Internet is available again).
Trail: Security
The traditional approach to securing HTTP operations is by means of SSL. Android supports SSL, much as ordinary Java does. Most of the time, you can just allow Android to do its thing with respect to SSL, and you will be fine. However, there may be times when you have to play a more direct role in SSL communications, to handle arbitrary SSL-encrypted endpoints, or to help ensure that your app is not the victim of a man-in-the-middle attack.

This chapter will explore various SSL scenarios and how to address them.

**Prerequisites**

Understanding this chapter requires that you have read the core chapters of this book, particularly the chapter on Internet access.

**Basic SSL Operation**

Generally speaking, SSL “just works”, for ordinary sites with ordinary certificates.

If you use an https: URL with HttpUrlConnection or WebView, SSL handshaking will happen automatically, and assuming the certificates check out OK, you will get your result, just as if you had requested an http: URL.

However, originally, requesting a download via DownloadManager with an https: scheme would result in java.lang.IllegalArgumentException: Can only download HTTP URIs. As of Android 4.0, SSL is supported. Hence, you need to be careful about making SSL requests via DownloadManager if your minSdkVersion is less than 14.
SSL

For example, the Retrofit and Picasso sample apps from the chapter on Internet access both use https://api.stackexchange.com for their service endpoint. As a result, those requests — for the API JSON, at least — will go over SSL. You would need to log the URLs used for the image avatars to see whether StackExchange gives you https URLs or not.

Problems in Paradise

Ideally, SSL just works.

In practice, it often does, but depending on your app and your situation, you may encounter issues, such as:

- You want to test using SSL, but your test server does not have a domain name, let alone a SSL certificate, and so you need to try using a self-signed certificate
- Your IT department chose an obscure certificate authority for obtaining the SSL certificate used by your production server, and older Android devices do not recognize that certificate authority
- You are worried about MITM (“man-in-the-middle” or “Martian-in-the-middle”) attacks, and you hear all these scary things about certificate authorities being hacked, and so you want to try to ensure that only valid certificates are honored by your app

And so on.

Here are some more details about some common SSL problems.

Self-Signed Certificate

SSL certificates used for public Web sites are usually backed by a “root certificate authority” that is well-known. That is not always the case.

One case is when the certificate is “self-signed”, meaning that it was generated by somebody without involving a certificate authority. If you have shipped a production Android app, you created a self-signed certificate when you created your production key store. And you have been using a system-generated self-signed certificate throughout your development, known as the “debug signing key”.

Self-signed certificates are rarely used on public-facing Web sites, as Web browsers
are taught to warn users when such certificates are encountered. However, self-signed certificates might be used on internal servers, particularly test servers and other non-production environments.

There are even some benefits for using a self-signed certificate for production servers, if those servers will be talking only to your own apps and not arbitrary Web browsers.

**Wildcard Certificate**

Some certificates are difficult to validate because they use wildcards.

For example, Amazon S3 is a file storage and serving “cloud” solution from Amazon.com. They allow you to define “buckets” containing “objects”, where each object then has its own URL. That URL is based on the name of the bucket and the name of the object. One option is for you to have the domain name of the URL be based on the name of the bucket, leaving the path to be solely the name of the object. This works, even with SSL, but Amazon needed to use a “wildcard SSL certificate”, one that matches *.s3.amazonaws.com, not just a single domain name. By default, this will fail on Android, as Android's stock TrustManager will not validate wildcards for multiple domain name segments (e.g., http://misc.commonsware.com.s3.amazonaws.com/foo.txt). You will get an exception akin to:

```
javax.net.ssl.SSLHandshakeException: java.security.cert.CertificateException: No subject alternative DNS name matching misc.commonsware.com.s3.amazonaws.com found
```

**Custom Certificate Authority**

Some larger organizations have set up their own certificate authority. Sometimes, they aspire to become a recognized root certificate authority, but have not been adopted by many browsers. Sometimes, they simply want to have more structure than a pure self-signed certificate but do not necessarily want to have all certificates go through a root certificate authority, perhaps due to expense.

In these cases, Android will reject the SSL certificate, for the same reason it rejects self-signed ones: it cannot validate the certificate chain all the way back to a known root certificate authority. But, with a little work, you can enable Android to support these as well.
Man in the Middle Attacks

Man-in-the-middle (MITM) attacks are a common way of trying to intercept SSL encrypted communications. The “man” in the “middle” might be a proxy server, a different Web site you wind up communicating with via DNS poisoning, etc. The objective of the “man” is to pretend to be the actual Web site or Web service you are trying to communicate with. If your app “falls for it”, your app will open an encrypted channel to the attacker, not your site, and the attacker will have access to the unencrypted data you send over that channel.

Unfortunately, Android apps have a long history of being victims of man-in-the-middle attacks.

“Why Eve and Mallory Love Android: An Analysis of Android SSL (In)Security”, an analysis of possible man-in-the-middle attacks on Android, is depressing. One in six surveyed apps explicitly ignored SSL certificate validation issues, mostly by means of do-nothing TrustManager implementations as noted above. Out of a selected 100 apps, 41 could be successfully attacked using man-in-the-middle techniques, yielding a treasure trove of credit card information, account credentials for all the major social networks, and so forth.

Their paper outlines a few ways in which apps can screw up SSL management — the following sections outline some of them.

Disabling SSL Certificate Validation

As mentioned above, if you disable SSL certificate validation, by implementing and using a do-nothing TrustManager, you are wide open for man-in-the-middle attacks. A simple transparent proxy server can pretend to be the real endpoint — apps ignoring SSL validation entirely will trust that the transparent proxy is the real endpoint and, therefore, perform SSL key exchange with the proxy rather than the real site. The proxy, as a result, gets access to everything the app sends.

Ignoring Domain Names

A related flaw is when you disable hostname verification. The “common name” (CN) of the SSL certificate should reflect the domain name being requested. Requesting https://www.foo.com/something and receiving an SSL certificate for xkcdhatguy.com would be indicative of a mis-configured Web server at best and a man-in-the-middle attack at worst.
By default, this is checked, and if there is no match, you will get errors like:

```
javax.net.ssl.SSLException: hostname in certificate didn't match: <...>
```

where the ... is replaced by whatever domain name you were requesting.

But some developers disable this check. Perhaps during development they were accessing the server using a private IP address, and they were getting SSLExceptions when trying to access that server. It is very important to allow Android to check the hostname for you, which is the default behavior.

**Hacked CAs**

The truly scary issue is when the problem stems from the CA itself.

Comodo, TURKTRUST, and other certificate authorities have been hacked, where nefarious parties gained the ability to create arbitrary certificates backed by the CA. For example, in the TURKTRUST case, Google found that somebody had created a *.google.com certificate that had TURKTRUST as the root CA. Any browser — or Android app — that implicitly trusted TURKTRUST-issued certificates would believe that this certificate was genuine. This is the ultimate in man-in-the-middle attacks, as code that is ordinarily fairly well-written will believe the CA and therefore happily communicate with the attacker.

Even well-intentioned certificate authorities sometimes make mistakes. StartSSL offered a tool called StartEncrypt to make it easy to request and install certificates on a Web server. However, they made mistakes in the Web service API used by that tool to communicate back to StartSSL's servers. Attackers could create SSL certificates for a wide range of existing domains, including google.com, facebook.com, and other widely-used domains. Those fraudulent certificates could have been used to implement MITM attacks.

**Introducing Network Security Configuration**

You can use a “network security configuration” to help address those issues. This comes in the form of an XML resource, which you teach Android to use for your network connections. That resource tailors what you do and do not want to accept for SSL connections, such as “yes, I want to accept this self-signed certificate, at least for debug builds of the app” and “yes, I am willing to accept this additional certificate authority”.

---

2793
This XML resource will have a `<network-security-config>` root element. That in turn will contain:

- Zero or one `<base-config>` elements, defining global rules
- Zero, one, or several `<domain-config>` elements, defining rules to apply to a specific domain name or set of domain names
- Zero or one `<debug-overrides>` elements, defining global rules that will be applied only for debug builds of your app

### The Native Android 7.0 Version

On Android 7.0 and higher, you can direct Android to apply your network security configuration by having an `android:networkSecurityConfig` attribute on the `<application>` element in your manifest:

```xml
<application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:networkSecurityConfig="@xml/net_security_config">
    // other stuff here
</application>
```

The name of the XML resource does not matter, so long as your `android:networkSecurityConfig` attribute points to it.

On Android 7.0 and higher, your network security configuration will be applied automatically for all network connections, without any Java configuration.

### The CWAC-NetSecurity Backport

At the time of this writing, Google has not released an official backport of the network security configuration subsystem.

The author of this book converted that subsystem into a library – CWAC-NetSecurity — that serves as a backport, working back to API Level 17 (Android 4.2). It does not support every feature of the native implementation, and it requires a bit of Java code to arrange to use your network security configuration for HTTP requests. However, you can use the same XML resource structure. As with many backports, the vision is that you would use the backport until such time as your `minSdkVersion` rises to 24 or higher, at which point you can just use the native implementation.
The CWAC-NetSecurity library also offers a TrustManagerBuilder and related classes to make it easier for developers to integrate the network security configuration backport, particularly for OkHttp3 and HttpURLConnection.

The artifact for this library is distributed via the CWAC repository, so you will need to configure that in your module's build.gradle file, along with your implementation statement:

```gradle
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    implementation 'com.commonsware.cwac:netsecurity:0.0.1'
    implementation 'com.squareup.okhttp3:okhttp:3.4.0'
}
```

If you are using this library with OkHttp3, you also need to have a implementation statement for a compatible OkHttp3 artifact, as shown above.

If you are using HttpURLConnection, or tying this code into some other HTTP client stack, you can skip the OkHttp3 dependency.

Next, add in this `<meta-data>` element to your manifest, as a child of the `<application>` element:

```xml
<meta-data
    android:name="android.security.net.config"
    android:resource="@xml/net_security_config" />
```

The value for android:resource should be the same XML resource that you used in the android:networkSecurityConfig attribute in the `<application>` element for the native network security configuration support on Android 7.0.

Then, in your code where you want to set up your network communications, create a TrustManagerBuilder and teach it to load the configuration from the manifest:

```java
TrustManagerBuilder tmbl =
        new TrustManagerBuilder().withManifestConfig(ctx);
```

(where ctx is some Context)
SSL

If you are using OkHttp3, create your basic OkHttpClient.Builder, then call:

OkHttp3Integrator.applyTo(tmb, okb);

(where tmb is the TrustManagerBuilder from before, and okb is your OkHttpClient.Builder)

At this point, you can create your OkHttpClient from the Builder and start using it.

If you are using HttpURLConnection, you can call applyTo() on the TrustManagerBuilder itself, passing in the HttpURLConnection. Afterwards, you can start using the HttpURLConnection to make your HTTP request:

```java
URL url = new URL(i.getData().toString);
HttpURLConnection c = (HttpURLConnection)url.openConnection();
TrustManagerBuilder tmb =
    new TrustManagerBuilder().withManifestConfig(this);
tmb.applyTo(c);
```

(from Internet/CA/app/src/main/java/com/commonsware/android/downloader/Downloader.java)

In either case, on Android 7.0+ devices, withManifestConfig() will not use the backport. Instead, the platform-native implementation of the network security configuration subsystem will be used. On Android 4.2-6.0 devices, the backport will be used.

SSL Problems and Network Security Configuration

With all that as prologue, let’s examine how the network security configuration subsystem — native or backport — can address some of the SSL issues outlined earlier in this chapter.

The sample code for these scenarios comes from the Internet/CA sample application. This application is based on some of the samples from the chapter on notifications, that use HttpURLConnection to download a PDF from the CommonsWare site.

Pinning the Certificate Authority

Your app may only communicate with one server, such as an employee-only server
for your organization. To help limit the risk of possible MITM attacks, you might want to lock down your app, to only work with certificates coming from your chosen certificate authority for this server. That way, in addition to the other logistical problems facing attackers, they would need to get a forged SSL certificate from your certificate provider, instead of a forged SSL certificate from any certificate provider.

To make this work, first, you will need a PEM or DER file representing the root certificate for the certificate authority. Usually, the certificate authority will publish one of these on its Web site. You will need to put that file in res/raw/ of your project, under a suitable resource name. For this scenario, in the sample app, there are two raw resources of note: addtrustexternalcaroot.pem and verisign_class3.pem, for Comodo and Verisign, respectively.

Next, you will need to create your network security configuration. As noted above, this is an XML resource, in res/xml/, that describes what changes you wish to make to the mix of supported certificate authorities. In the sample app, one such resource is res/xml/network_comodo.xml:

```xml
<?xml version="1.0" encoding="utf-8"?>
<network-security-config>
  <domain-config>
    <domain includeSubdomains="false" usesCleartextTraffic="false">wares.commonsware.com</domain>
    <trust-anchors>
      <certificates src="@raw/addtrustexternalcaroot" />
    </trust-anchors>
  </domain-config>
</network-security-config>
```

(From Internet/CA/app/src/main/res/xml/network_comodo.xml)

As mentioned previously, the root element is <network-security-config>. In there, you can have one or more <domain-config> elements, describing the rules that you wish to apply to certain domains being used by your app.

A <domain-config> element will have one or more <domain> elements, listing domains that this particular configuration controls. Here, we have just one, for wares.commonsware.com. The includeSubdomains attribute indicates whether this rule applies to subdomains of the base domain, such as foo.wares.commonsware.com.

A <domain-config> element can have a <trust-anchors> element, listing what certificates to use to validate SSL connections made to this domain. Those certificates are identified by <certificate> elements, usually pointing to raw resources that are the PEM or DER files for those certificate authorities. In this case, we point to the addtrustexternalcaroot resource.
SSL
To teach Android that you have this network security configuration that you wish to
apply, you will need add an android:networkSecurityConfig attribute (for the
native Android 7.0 code) and perhaps a <meta-data> element to the <application>
element of your manifest (for the CWAC-NetSecurity backport):
<application
android:icon="@drawable/ic_launcher"
android:label="@string/app_name"
android:networkSecurityConfig="@xml/${networkSecurityConfig}">
>
<activity
android:name="DownloaderDemo"
android:label="@string/app_name">
>
<intent-filter>
<action android:name="android.intent.action.MAIN" />
<category android:name="android.intent.category.LAUNCHER" />
</intent-filter>
</activity>
<service
android:name="Downloader"
android:permission="android.permission.BIND_JOB_SERVICE" />
<provider
android:name="LegacyCompatFileProvider"
android:authorities="${applicationId}.provider"
android:exported="false"
android:grantUriPermissions="true">
>
<meta-data
android:name="android.support.FILE_PROVIDER_PATHS"
android:resource="@xml/provider_paths" />
</provider>
<meta-data
android:name="android.security.net.config"
android:resource="@xml/${networkSecurityConfig}" />
</application>
(from Internet/CA/app/src/main/AndroidManifest.xml)

In this case, the resource value used in both places is not a simple XML resource
name, like @xml/network_comodo, though that will be what most apps will use. This
sample application has different product flavors for applying different network
security configurations, configured in build.gradle. Those product flavors use
manifestPlaceholders to indicate which XML resource to apply for that flavor:

2798


apply plugin: 'com.android.application'

            buildConfigField "String", "URL", WARES
        }
        pin {
            dimension "default"
            resValue "string", "app_name", "Cert Pin Demo"
            applicationId "com.commonsware.android.downloader.ca.pin"
            manifestPlaceholders =
                [networkSecurityConfig: 'network_pin']
            buildConfigField "String", "URL", WARES
        }
    }
}
The CommonsWare Warescription Web site, at the time of this writing, uses an SSL certificate backed by Comodo. Running the comodoDebug build variant should successfully download the PDF file, as the SSL certificate will be validated properly. However, running the verisignDebug build variant will fail the SSL validation and crash:
If you have multiple certificate authorities that you wish to support, you can have multiple `<certificate>` elements, or a `<certificate>` element pointing to a file with multiple PEM or DER entries.

**Unusual Certificate Authorities**

Perhaps your organization runs its own certificate authority (e.g., for internal servers). Or perhaps your organization is using a regular certificate authority, but one that is too new to be recognized by Android. You could cover the unexpected certificate authority by using the `<certificate>` elements shown above.

But, what happens if you want to support something custom and regular certificate authorities as well?

In that case, there is a special `<certificate>` element that you can add:

```<certificates src="system"/>```
The value system, instead of a reference to a raw resource, indicates that the default system set of certificate authorities should be considered to be valid.

The systemDebug build variant uses a different network security configuration:

```xml
<?xml version="1.0" encoding="utf-8"?>
<network-security-config>
  <domain-config>
    <domain includeSubdomains="false" usesCleartextTraffic="false">wares.commonsware.com</domain>
    <trust-anchors>
      <certificates src="/raw/verisign_class3" />
      <certificates src="system" />
    </trust-anchors>
  </domain-config>
</network-security-config>
```

(from Internet/CA/app/src/main/res/xml/network_verisign_system.xml)

Here, first, we pull in Verisign's root certificate. If that were all we had (as you can see in the network_verisign.xml resource file), an attempt to download something from wares.commonsware.com would fail, as that site uses a Comodo certificate, not a Verisign one. However, we also have the system set of certificate authorities. Since Comodo is a major certificate authority, it is included in Android's default set, and so our download should succeed.

**Pinning the Certificate**

Perhaps even supporting any CA's certificates will be too much of a risk for you and your users. For example, perhaps your site's certificate is from a certificate authority that has issued fraudulent credentials in the past, and so you fear that your users might still be at risk of a MITM attack.

You can *really* narrow things down by pinning your app to your specific certificate. Then, only that one certificate will be accepted, not others that might be issued, for your domain, by your certificate authority, either through social engineering, nation-state duress, or whatever.

To do this, you will use a `<pin-set>` element, instead of a `<certificate>` element, in your network security configuration, as seen in the network_pin resource:

```xml
<?xml version="1.0" encoding="utf-8"?>
<network-security-config>
  <domain-config>
    <domain includeSubdomains="false" usesCleartextTraffic="false">wares.commonsware.com</domain>
    <pin-set expiration="2020-05-01">
      <pin digest="SHA-256">sF1A3ez70l81aUjLwU6KiAMoYoPNFQDyueJH+4YDwoppo</pin>
    </pin-set>
  </domain-config>
</network-security-config>
```
The `<pin-set>` element can include one or more `<pin>` elements, each of which has a digest attribute and a value. The digest value has to be SHA-256 at the present time, though perhaps other hash algorithms will be supported in the future. The value of the `<pin>` element is the base64-encoded SHA-256 hash of the SubjectPublicKeyInfo field of the X509 certificate of the server.

To generate that value, you will need to use a tool like openssl. Given a PEM file named `server.crt`, you can generate the hash for that server using the following command:

```
openssl x509 -in server.crt -pubkey -noout | openssl pkey -pubin -outform der | openssl dgst -sha256 -binary | openssl enc -base64
```

(NOTE: this should appear all on one line but will be word-wrapped to the size of the book page)

The `<pin-set>` element can also have an `expiration` attribute, with a date in `yyyy-MM-dd` format. Prior to this date, the SSL certificate of the server must match one of the pins. On or after this date, the pins are ignored. For example, you might choose a date that is a bit before the date when the SSL certificate itself will expire. This has the benefit of allowing the app to work even if you fail to update the app and supply a new pin for a new SSL certificate, or if you do update that app but the user does not install the update in time. On the other hand, manually altering the device date and time can bypass your pin.

This behavior — pin expiration allowing formerly-blocked access — is a bit unusual. Typically, with security, we “fail closed”, meaning that once something has expired, no access is allowed. Instead, `<pin-set>` specifically “fails open”, meaning that once it expires, security is weakened. In this case, Google elected to focus on utility over security.

**Self-Signed Certificates**

As Moxie Marlinspike points out, one way to avoid having your app be the victim of a man-in-the-middle attack due to a hijacked certificate authority is to simply *not use a certificate authority.*

Certificate authorities are designed for use by general-purpose clients (e.g., Web
browsers) hitting general-purpose servers (e.g., Web servers). In the case where you control both the client and the server, you don’t need a certificate authority. You merely need to have a self-signed certificate that both ends know about.

This works well if the Web server is solely functioning as a Web service to deliver data to your Android app, or perhaps other native apps on other platforms for which you can also support self-signed certificates. Depending upon your server’s capabilities, you might be able to arrange to have the same server-side application logic be available both from a self-signed certificate on one domain (for use with apps) and from a CA-rooted certificate for another domain (for use with Web browsers).

However, it is very possible that the staff who manage the servers will reject the notion of using a self-signed certificate, perhaps in an effort to minimize the complexity of supporting multiple SSL paths (for browsers and apps). Or, you may not control the server well enough to go with a self-signed certificate, such as if you are using a cloud computing provider.

However, if self-signed certificates are an option for you, the network security configuration code makes them simple to integrate.

You can use the PEM or DER file from your self-signed certificate much as you would one from a certificate authority: put in res/raw/ and set up your network security configuration XML to match:

```xml
<?xml version="1.0" encoding="utf-8"?>
<network-security-config>
  <domain-config includeSubdomains="false" usesCleartextTraffic="false">
    <domain>scrap.commonsware.com</domain>
  </domain-config>
  <trust-anchors>
    <certificates src="@raw/example"/>
  </trust-anchors>
</network-security-config>
```

This is from the selfSigned product flavor. Note that it will not work on your development machine, as you do not have a Web server with a self-signed SSL certificate at scrap.commonsware.com. However, this shows the basic setup, as being the same as before.

[This site](#) has instructions for setting up a self-signed certificate. The CRT file that is created (e.g., example.crt) is what you would put in your app.
Self-Signed Certificates for Debug Builds

If you are only using a self-signed certificate for debuggable builds (e.g., debug build type), you can use the `<debug-overrides>` XML element in your network security configuration. This adds your self-signed certificates to the roster of trust anchors, but only for debuggable builds. For non-debuggable builds (e.g., release build type), your self-signed SSL certificate will be ignored.

You can see this in the `network_override.xml` resource:

```xml
<?xml version="1.0" encoding="utf-8"?>
<network-security-config>
  <debug-overrides>
    <trust-anchors>
      <certificates src="@raw/example"/>
    </trust-anchors>
  </debug-overrides>
</network-security-config>
```

(from Internet/CA/app/src/main/res/xml/network_override.xml)

This is for the override product flavor which, like selfSigned, will not work for you, as you will not have a Web server using that SSL certificate.

Blocking Cleartext Traffic

For a domain, or perhaps for everything in your app, you might want to ensure that you always are using SSL... even to the point of being willing to crash your app if you are not using SSL. While this is an extreme measure, some apps have those sorts of security requirements.

The network security configuration subsystem supports a `cleartextTrafficPermitted` attribute on `<base-config>` and `<domain-config>`:

```xml
<base-config cleartextTrafficPermitted="false">
  <trust-anchors>
    <certificates src="system"/>
  </trust-anchors>
</base-config>
```

If set to false, this means that you want to block all “cleartext” (non-SSL) traffic for the scope of that element.
The native implementation of network security configuration supports this flag for most Internet communications. Notably, WebView does not support it.

The CWAC-NetSecurity backport, if you are using the OkHttp3 integration, attempts to honor this, by checking the scheme for requests. If you make an http request, but you have cleartextTrafficPermitted="false" for the appropriate scope (e.g., for the domain in the URL), the request is rejected. However, this is not quite as strong as the native implementation, and it certainly does not affect anything other than the OkHttp3 integration.

On Android 6.0, you have another option of enabling this same sort of check. You also have a way to have StrictMode validate cleartext traffic on Android 6.0+.

Supporting User-Added Certificates

The native Android 7.0+ network security configuration subsystem not only allows you to use [certificates src="system" /] to say “we also allow any standard certificate authorities here”, but also [certificates src="user" /]. This indicates that certificate authorities added by the user, through Settings, should be honored as well. By default, for apps with targetSdkVersion set to 24 or higher, user-added certificates are ignored unless [certificates src="user" /] is included in a network security configuration.

Such user-added certificate authorities are a bit controversial in Android app development. On the one hand, they allow users to add support for unrecognized authorities, in case Android is slow to adopt them, and without apps having to do anything. On the other hand, those user-added certificate authorities are global in scope, rather than being tied to specific domains.

Note that this feature is not available in the CWAC-NetSecurity backport. [certificates src="user" /] is ignored. User-added certificate authorities are lumped in with the system-defined certificate authorities, so if you have [certificates src="system" /], you will get certificate authorities from both sources.

Other SSL Strengthening Techniques

Not everything that one can do to improve SSL security is covered by either the native network security configuration implementation or the CWAC-NetSecurity backport. Here are some other possibilities to consider.
Certificate Memorizing

If your app needs to connect to arbitrary SSL servers — perhaps ones configured by the user (e.g., email client) or are intrinsic to the app’s usage (e.g., URLs in a Web browser) — detecting man-in-the-middle attacks boils down to proper SSL certificate validation... and praying for no hacked CA certificates.

However, one way to incrementally improve security is to use certificate memorizing. With this technique, each time you see a certificate that you have not seen before, or perhaps a different certificate for a site visited previously, you ask the user to confirm that it is OK to proceed.

The idea here is that even if we cannot tell, absolutely, whether a given certificate is genuine or from an attacker, we can detect differences in certificates over time. So, if the user has been seeing certificate A, and now all of a sudden receives certificate B instead, there are two main possibilities:

1. The HTTPS server changed certificates for legitimate reasons
2. An attacker is providing an alternative certificate

So, what we do is check certificates against a roster that the user has approved before. If the newly-received certificate is not in that roster, we fail the HTTPS request, but raise a custom exception so that your code can detect this case and ask the user for approval to proceed.

Technically savvy users may be able to deduce whether the certificate is indeed genuine; slightly less-savvy users might simply contact the site to see if this is expected behavior. The downside is that technically unsophisticated users might be baffled by the question of whether or not they should accept the certificate and may take their confusion out on you, the developer of the app that is asking the question.

There is a standalone implementation of a MemorizingTrustManager that you could consider using. It has been around for a few years, with a slow-but-steady set of updates.

However, that library handles asking the user for acceptance of the certificates for you, rather than raising some event that your app can handle itself. In order to tailor the UI, you would need to modify the library itself.

Moreover, the library attempts to handle this UI while your SSL request is in process, by blocking the background thread upon which you are making the HTTPS request.
A side-effect of this is that MemorizingTrustManager has some fairly unpleasant code for trying to block this thread while interacting with the user on the main application thread. And, if the user takes too long, your request to the server may time out anyway.

Requiring Encryption, Android 6.0 Style

Android 6.0 supports an usesCleartextTraffic attribute on the <application> element in the manifest. This works like the cleartextTrafficPermitted option in the network security configuration subsystem. If this is set to false, you are saying that your app not only should be using SSL for everything, but that you expressly want to crash the app in case you wind up not using SSL.

If you try to perform plain HTTP requests on Android 6.0 with usesCleartextTraffic set to false, you will crash when you attempt to download the file, with a stack trace akin to:

```
06-19 08:03:46.325    6420-6478/com.commonsware.android.downloader E/com.commonsware.android.downloader.Downloader: Exception in download
        java.net.UnknownServiceException: CLEARTEXT communication not supported: []
            at com.android.okhttp.Connection.connect(Connection.java:149)
            at com.android.okhttp.Connection.connectAndSetOwner(Connection.java:185)
            .
            .
```

What is really going on “under the covers” is that this attribute sets a flag that HTTP client APIs can check, electing to fail a request if the flag says that SSL is required and the request’s URL does not have the https scheme. Android’s built-in HTTP clients should support this flag, but third-party HTTP stacks that manage their own socket connections may not. Also note that WebView does not honor usesCleartextTraffic.

Watching for Encryption

The downside of usesCleartextTraffic is that it is “all or nothing” and always terminates your process. The same thing holds true for using cleartextTrafficPermitted with the network security configuration in the <base-config> element. That is wonderful in situations where SSL is crucial. It is less wonderful if your app crashes in production in situations where SSL would be a really good idea but is unavailable for whatever reason.
StrictMode on API Level 23+ devices supports a way to be warned if your app performs unencrypted network operations, via a detectCleartextNetwork() method on StrictMode.VmPolicy.Builder. You can configure this, and suitable penalties, alongside the rest of your StrictMode setup. This can include doing different things for debug versus release builds, for example. So, in a debug build, you might choose penaltyDeath() to crash the process, while in a release build, you settle for penaltyLog() or something else less drastic.

If you are using a build server, you could set it up to watch for StrictMode Logcat messages coming from your test suite to find out about these accesses.

**Advanced Uses of CWAC-NetSecurity**

Adding a couple of lines of Java code, along with the dependency, is all that you need to use CWAC-NetSecurity to gain the benefits of the backport of the network security configuration subsystem. However, CWAC-NetSecurity offers a few more features that may be of use to you.

**Using Alternative Network Security Configuration XML**

withManifestConfig() on TrustManagerBuilder uses the resource that you declare in your manifest as the network security configuration to apply. However, that is fairly inflexible, as you can only define this in the manifest once. Also, withManifestConfig() performs the version check to only apply the backport on pre-7.0 devices.

You can also use withConfig(), where you provide a Context and the resource ID of the XML resource to use for the network security configuration. This is useful for cases where:

- You want to always use the backport, for consistent behavior across OS versions
- You want to use different configurations in different settings for the same APK

For example, the test suites use withConfig(), as otherwise we would need dozens of separate manifests.
Using the Backport Directly

You do not have to use `TrustManagerBuilder` to use the network security configuration backport. If you wish to use it directly:

- Create an instance of `ApplicationConfig`, passing in a `ConfigSource` implementation that indicates where the configuration should be pulled from. Two likely `ConfigSource` implementations are `ManifestConfigSource` (to use the one defined in the manifest) and `XmlConfigSource` (to use one defined in an arbitrary XML resource).
- Call `getTrustManager()` on the `ApplicationConfig` to get a `TrustManager` that will implement the requested configuration.
- Add that `TrustManager` to your HTTP client via whatever API that client offers for such things. In many cases, that will be by configuring an `SSLContext` to use the `TrustManager`, then using the `SSLContext` (or an `SSLSocketFactory` created by the `SSLContext`) with your HTTP client.

Integrating with Other HTTP Client Libraries

If you want to integrate `TrustManagerBuilder` and the network security configuration backport with some other HTTP client API, start by reviewing the `OkHttp3Integrator` class in the `netsecurity-okhttp3` library. This will give you an idea of what is required and how easy it will be to replicate this class for your particular HTTP client API.

Adding the TrustManager

Calling `build()` on the `TrustManagerBuilder` gives you a `CompositeTrustManager`, set up to implement your desired network security configuration. You will need to add that to your HTTP client by one means or another. If `size()` on the `CompositeTrustManager` returns 0, though, you can skip it, as it means that there are no rules to be applied (e.g., you used `withManifestConfig()`, and your app is running on an Android 7.0+ device).

So, you might have code that looks like this, where `tmb` is a configured `TrustManagerBuilder`:

```java
CompositeTrustManager trustManager = tmb.build();
if (trustManager.size() > 0) {
    SSLContext ssl = SSLContext.getInstance("TLS");
...}
```
// SSL

Example:

```java
X509Interceptor interceptor = new X509Interceptor(trustManager, tm);

ssl.init(null, new TrustManager[]{trustManager}, null);

// apply the SSLContext or ssl.getSocketFactory() to your HTTP client
```

**Handling Cleartext**

You can call `isCleartextTrafficPermitted()` on the `CompositeTrustManager` to determine if cleartext traffic should be supported. This takes the domain name of the Web server you are going to be communicating with and returns a simple boolean. If `isCleartextTrafficPermitted()` returns `false`, you will need to examine the scheme of the URL and accept or reject the HTTP operation accordingly.

If you fail to do this, then cleartext traffic will be allowed in all cases, akin to the stock `HttpURLConnection` integration.

**Handling Redirects**

If your HTTP client automatically traverses server-side redirects (making the HTTP request for the redirected-to URL), you will need to handle the cleartext check and the `setHost()` call on every step of the redirection, not just your initial request. In the case of OkHttp3, this is accomplished via their interceptor framework.

**Debugging Certificate Chains**

You can call `withCertChainListener()` on `TrustManagerBuilder`, providing an implementation of `CertChainListener`. Your listener will be called with `onChain()` each time a certificate chain is encountered. In `onChain()`, you can inspect the certificates, dump their contents to Logcat, or whatever you wish to do.

This is designed for use in development. For example, when writing the `demo/` app, the author used a `CertChainListener` to log what HTTP requests were being made, what domains those were for, and what root certificates are being used. This in turn led to creating the network security configuration that matched.

However, logging certificate chains on a production device may result in security issues. Please only use `CertChainListener` in debug builds.
NetCipher

The Guardian Project has released an Android library project called NetCipher — formerly known as OnionKit — designed to help boost Internet security for Android applications.

In particular, NetCipher helps your application integrate with Orbot, a Tor proxy. Tor ("The Onion Router") is designed to help with anonymity, having your Internet requests go through a series of Tor routers before actually connecting to your targeted server through some Tor endpoint. Tor is used for everything from mitigating Web site tracking to helping dissidents bypass national firewalls.

NetCipher helps your app:

- Detect if Orbot is installed, and help the user install it if it is not
- Detect if Orbot is running, and help you start it if it is not
- Make HTTP requests by means of Orbot instead of directly over the Internet

There is a dedicated chapter on NetCipher, if you have interest in this technology.
NetCipher is a library from the Guardian Project to improve the privacy and security of HTTP network communications. In particular, it makes it easier for your app to integrate with Orbot, an Android proxy server that forwards HTTP requests via Tor.

This chapter covers:

- An introduction to Tor, Orbot, and NetCipher
- An explanation of how to use a fairly simple API layered atop NetCipher to add its functionality to your app

Prerequisites

This chapter assumes that you have read the core chapters of the book, particularly the one on Internet access. Having read the chapter on SSL is also a very good idea.

Network Security’s Got Onions

Maintaining privacy and security on the Internet, in the face of so-called “advanced persistent threats”, is a continuous challenge facing many people, particularly those under threats from hostile forces, ranging from organized crime syndicates to your average rampaging warlord. Tor was created to help deal with this sort of problem; Orbot was created to extend Tor to Android.

A Quick Primer on Tor

Originally named The Onion Router, Tor was created by researchers in the US Naval Research Laboratory back in the mid-1990’s, with an eye towards protecting US
intelligence communications. In 2006, the technology spun out into an independent non-profit organization, which has continued to improve upon the core Tor software and expand the reach of Tor. Through packages like the Tor Browser Bundle, it is fairly easy for at-risk people to start using Tor to help shroud their communications.

Without getting into the full technical details of Tor — which are well beyond the scope of this chapter — Tor basically works by routing a request through a series of relay servers, through a process known as onion routing. Requests are secured through layers of encryption, to keep any two connected relays from knowing the full details of the communications. Some relays serve as “exit nodes”, for requests being made of ordinary Web servers. Certain servers — Tor hidden services — are only reachable through Tor; requests made of these servers never leave the Tor network.

Of course, technology like Tor is agnostic in terms of its users and usages, and there have been plenty of examples of people using Tor for illicit purposes, such as the Silk Road. This has a tendency to obscure Tor’s benefits to people who need to remain somewhat hidden online, whether from stalkers or other harassers or from the security forces of dictatorships.

**Introducing Orbot**

The entry path into Tor is usually via some sort of proxy server, that a regular Internet client can connect to. Orbot is one such proxy server, that runs on Android. Apps can use Orbot’s HTTP or SOCKS proxies to route requests; those requests will then wind up traversing the Tor network to the end site, whether that site is on the public Internet (reached from a Tor exit node) or a Tor hidden service.

By default, Orbot is limited to localhost use, meaning that it does not have open ports that can be reached from other devices on the local WiFi LAN segment (or some subnet of the mobile carrier, if not on WiFi). For an Android app on the same device, this is not a problem, and it in fact simplifies things a fair bit, as there is no guesswork as to what the IP address should be for the proxy. As we will see, though, finding out exactly how to connect to Orbot is a bit tricky, though with some helper code it is not too bad.

**What NetCipher Provides**

While we know that Orbot will be listening on localhost, we do not necessarily know the port that it is using for its HTTP proxy. Partly, that is because the user
might configure it manually. Partly, that is because there are occasional conflicts with Orbot’s default port.

Hence, NetCipher contains some code that will help you find out:

- Is Orbot installed? (and, if not, help get it installed)
- Is Orbot running? (and, if not, help get it running)
- What port is used for the HTTP proxy?

The NetCipher HTTP Integration APIs

NetCipher offers two levels of API for integration. This chapter focuses on the newer of those, a suite that offers simple plug-and-play integration with popular HTTP client APIs: HttpURLConnection, OkHttp, Volley, and Apache’s HttpClient. This focus stems from two main reasons:

- These integration APIs are much simpler to use
- The author of this book wrote those APIs, and so is biased as to how simple they are to use

The Internet/HTTPStacks sample application demonstrates all four of the HTTP integration APIs. Each of the four is based on the Stack Overflow sample app from the chapter on Internet access, with NetCipher integration added in.

There are a few simple steps for adding in NetCipher integration: choosing your HTTP stack, adding the dependencies, setting up OrbotHelper, and then using a secure connection.

Choose an HTTP Stack

As noted above, NetCipher offers integration APIs for four major HTTP client implementations (a.k.a., “HTTP stacks”):

- HttpURLConnection
- OkHttp3
- Apache’s independent HttpClient package
- Volley

HttpURLConnection support is part of the core NetCipher library (info.guardianproject.netcipher:netcipher), as HttpURLConnection is part of
standard Java and Android. The other three HTTP stacks have separate libraries:

<table>
<thead>
<tr>
<th>HTTP Stack</th>
<th>NetCipher Artifact</th>
</tr>
</thead>
<tbody>
<tr>
<td>OkHttp3</td>
<td>info.guardianproject.netcipher:netcipher-okhttp3</td>
</tr>
<tr>
<td>HttpClient</td>
<td>info.guardianproject.netcipher:netcipher-httpclient</td>
</tr>
<tr>
<td>Volley</td>
<td>info.guardianproject.netcipher:netcipher-volley</td>
</tr>
</tbody>
</table>

**Add the Dependencies**

Unfortunately, some packaging issues with the 2.0.0-alpha1 edition of NetCipher, adding the dependencies is more complicated than it needs to be. Your project needs to have dependencies on:

- info.guardianproject.netcipher:netcipher:2.0.0-alpha1, for the core of NetCipher
- the NetCipher artifact specifically for your HTTP stack, if you are using something other than HttpURLConnection
- the artifact for the HTTP client API itself
- any other artifacts that your project needs for other reasons

So, for example, the okhttp3 module in the HTTPStacks project is a sample app that uses OkHttp 3.x for its HTTP client API. It needs three artifacts in its dependencies closure to pull in OkHttp and NetCipher’s support for OkHttp:

```
compile 'info.guardianproject.netcipher:netcipher:2.0.0-alpha1'
compile 'info.guardianproject.netcipher:netcipher-okhttp3:2.0.0-alpha1'
compile 'com.squareup.okhttp3:okhttp:3.8.0'
```

(from Internet/HTTPStacks/okhttp3/build.gradle)

Volley integration has been tested with com.android.volley:volley:1.0.0, while the HttpClient integration work with the cz.msebera.android:httpclient:4.4.1.2 independent repackaging of Apache HttpClient for Android.

**Set up OrbotHelper**

OrbotHelper is a singleton that manages a lot of the asynchronous communication between your app and Orbot. It is designed to be initialized fairly early on in your
NETCIPHER
app’s lifecycle. One likely candidate is to have a custom Application subclass, where
you override onCreate() and set up OrbotHelper.
All of the sample apps do this in a custom SampleApplication class:
package com.commonsware.android.http;
import android.app.Application
android.app.Application;
import com.squareup.leakcanary.LeakCanary
com.squareup.leakcanary.LeakCanary;
import info.guardianproject.netcipher.proxy.OrbotHelper
info.guardianproject.netcipher.proxy.OrbotHelper;
public class SampleApplication extends Application {
@Override
public void onCreate() {
super
super.onCreate();
LeakCanary.install(this
this);
OrbotHelper.get(this
this).init();
}
}
(from Internet/HTTPStacks/okhttp3/src/main/java/com/commonsware/android/http/SampleApplication.java)

This custom Application also sets up LeakCanary.
SampleApplication is then tied into the app
<application> element in the manifest:

via the android:name attribute on the

<application
android:name=".SampleApplication"
android:allowBackup="true"
android:icon="@drawable/ic_launcher"
android:label="@string/app_name"
android:theme="@style/Theme.Apptheme">
>
(from Internet/HTTPStacks/okhttp3/src/main/AndroidManifest.xml)

Choose and Create a Builder
Each module defines a corresponding builder class that can be used to configure
NetCipher for use with that stack, with names based on the classes used with those
HTTP stacks:

2817


You will need an instance of your chosen builder class. The simplest way to do that is to call the `forMaxSecurity()` static method on the builder class. `forMaxSecurity()` takes a `Context` as a parameter, though it only holds onto the Application singleton internally, so any `Context` is safe. `forMaxSecurity()` returns a builder configured for the best protection that NetCipher can offer.

### Get a Connection

Then, call `build()` on the builder object. It will take a `StrongBuilder.Callback` object as a parameter, typed for whatever HTTP stack you chose. So, for example, if you went with `StrongConnectionBuilder`, your callback will be a `StrongBuilder.Callback<HttpURLConnection>`.  

<table>
<thead>
<tr>
<th>HTTP Stack</th>
<th>Builder Class</th>
<th>Connection Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>HttpURLConnection</td>
<td>StrongConnectionBuilder</td>
<td>HttpURLConnection</td>
</tr>
<tr>
<td>OkHttpClient</td>
<td>StrongHttpClientBuilder</td>
<td>OkHttpClient</td>
</tr>
<tr>
<td>HttpClient</td>
<td>StrongHttpClientBuilder</td>
<td>HttpClient</td>
</tr>
<tr>
<td>Volley</td>
<td>StrongVolleyQueueBuilder</td>
<td>RequestQueue</td>
</tr>
</tbody>
</table>

You will need to implement four methods on that `Callback`:

- `onConnected()` will be passed an instance of your connection class (e.g., an `HttpURLConnection` instance), ready for your use, configured to hook into NetCipher
- `onConnectionException()` will be passed an `IOException`, if one of those occurs while trying to set up your connection
NetCipher

- `onTimeout()` will be called if Orbot is not installed or we could not connect to it within 30 seconds
- `onInvalid()` will be called if the Tor connection is established but is deemed to be compromised (more on this later)

Seeing the Builder in Action

Each of the four modules in the sample app (`hurl`, `httpclient`, `okhttp3`, and `volley`) have a similar `MainActivity` implementation, one that populates a `ListView` with the latest Stack Overflow Android questions. The difference in which HTTP stack the sample uses.

For example, the `okhttp3` module, in `onCreate()` of its `MainActivity`, uses `StrongOkHttpClientBuilder`:

```java
@override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  try {
    StrongOkHttpClientBuilder
      .forMaxSecurity(this)
      .withTorValidation()
      .build(this);
  } catch (Exception e) {
    Toast.makeText(this, R.string.msg_crash, Toast.LENGTH_LONG).show();
    Log.e(getClass().getSimpleName(), "Exception loading SO questions", e);
    finish();
  }
}
```

(from `Internet/HTTPStacks/okhttp3/src/main/java/com/commonsware/android/http/MainActivity.java`)

Here, we use `forMaxSecurity()` to create the `StrongOkHttpClientBuilder`, then configure it further with `withTorValidation()`. This requests that we do a test HTTP request to a Tor status URL to confirm that our request has indeed gone over Tor.

Note that `StrongConnectionBuilder` — for use with `HttpURLConnection` — also requires that you call `connectTo()`, before `build()`, to indicate the specific URL for
which you want an HttpURLConnection. This is unique among the builders. These sorts of per-builder differences are discussed later in this chapter.

build() is passed this, referencing MainActivity itself, which is implementing the StrongBuilder.Callback interface:

```java
public class MainActivity extends AppCompatActivity implements
    StrongBuilder.Callback<OkHttpClient> {

    // (from Internet/HTTPStacks/okhttp3/src/main/java/com/commonsware/android/http/MainActivity.java)

    That Callback is tied to the particular type of connection we are creating. We are using OkHttp3 and StrongOkHttpClientBuilder, so we are creating an OkHttpClient connection.

    Our onConnected() method for that Callback gets the OkHttpClient and makes an HTTP request using it:

    @Override
    public void onConnected(final OkHttpClient client) {
        new Thread() {
            @Override
            public void run() {
                try {
                    Request request = new Request.Builder().url(SO_URL).build();
                    Response response = client.newCall(request).execute();

                    final SOQuestions result = new Gson().fromJson(response.body().charStream(), SOQuestions.class);

                    runOnUiThread(new Runnable() {
                        @Override
                        public void run() {
                            setListAdapter(new ItemsAdapter(result.items));
                        }
                    });
                } catch (IOException e) {
                  onConnectionException(e);
                }
            }
        }.start();
    }

    // (from Internet/HTTPStacks/okhttp3/src/main/java/com/commonsware/android/http/MainActivity.java)

    SO_URL, passed into url(), is a Web service request URL from the Stack Exchange API, looking for Stack Overflow questions tagged with the android tag:

    String SO_URL = "https://api.stackexchange.com/2.1/questions?"
Note that `onConnected()` will be called on the main application thread, so you will need to get your connection over to whatever background thread will be doing your work. In this case, we create a background thread right here to retrieve the JSON, parse it, and use `runOnUiThread()` to update the `ListActivity` with an `ItemsAdapter` to show the parsed Stack Overflow questions:

```java
class ItemsAdapter extends ArrayAdapter<Item> {
    ItemsAdapter(List<Item> items) {
        super(MainActivity.this, android.R.layout.simple_list_item_1, items);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View row = super.getView(position, convertView, parent);
        TextView title = (TextView)row.findViewById(android.R.id.text1);
        title.setText(Html.fromHtml(getItem(position).title));
        return(row);
    }
}
```

The other three methods that we need to implement for our `Callback` are for error conditions: `onConnectionException()`, `onTimeout()`, and `onInvalid()`:

```java
@Override
public void onConnectionException(Exception e) {
    Log.e(getClass().getSimpleName(), "Exception loading SO questions", e);
    runOnUiThread(new Runnable() {
        @Override
        public void run() {
            Toast.makeText(MainActivity.this, R.string.msg_crash, Toast.LENGTH_LONG).show();
            finish();
        }
    });
}
```
Other than initializing OrbotHelper, setting up the builder, and implementing StrongBuilder.Callback somewhere to handle the results, the rest of the code is tied to application logic, not NetCipher itself.

**The Rest of the Builder API**

The API shown above for getting a NetCipher-secured connection via your favorite HTTP stack is designed for ease of use. However, as shown, it is not very flexible.

The rest of the builder API offers that flexibility, at the cost of some additional code.
Common Configuration Methods

The **StrongBuilder** interface defines the common public API for all four of the builder classes:

```java
package info.guardianproject.netcipher.client;

import android.content.Intent;
import java.io.IOException;
import java.security.KeyManagementException;
import java.security.KeyStore;
import java.security.KeyStoreException;
import java.security.NoSuchAlgorithmException;
import java.security.UnrecoverableKeyException;
import java.security.cert.CertificateException;
import javax.net.ssl.TrustManager;

public interface StrongBuilder<T extends StrongBuilder, C> {
    /**
     * Callback to get a connection handed to you for use, already set up for NetCipher.
     *
     * @param <C> the type of connection created by this builder
     */
    interface Callback<C> {
        /**
         * Called when the NetCipher-enhanced connection is ready for use.
         *
         * @param connection the connection
         */
```
void onConnected(C connection);

/**
 * Called if we tried to connect through to Orbot but failed
 * for some reason
 *
 * @param e the reason
 */
void onConnectionException(Exception e);

/**
 * Called if our attempt to get a status from Orbot failed
 * after a defined period of time. See statusTimeout() on
 * OrbotInitializer.
 */
void onTimeout();

/**
 * Called if you requested validation that we are connecting
 * through Tor, and while we were able to connect to Orbot, that
 * validation failed.
 */
void onInvalid();

}  

/**
 * Call this to configure the Tor proxy from the results
 * returned by Orbot, using the best available proxy
 * (SOCKS if possible, else HTTP)
 *
 * @return the builder
 */
T withBestProxy();

/**
 * @return true if this builder supports HTTP proxies, false
 * otherwise
 */
boolean supportsHttpProxy();

/**
 * Call this to configure the Tor proxy from the results
 * returned by Orbot, using the HTTP proxy.
 *
 * @return the builder
 */
T withHttpProxy();
/**
 * @return true if this builder supports SOCKS proxies, false
 * otherwise
 */
 boolean supportsSocksProxy();

/**
 * Call this to configure the Tor proxy from the results
 * returned by Orbot, using the SOCKS proxy.
 *
 * @return the builder
 */
 T withSocksProxy();

/**
 * Applies your own custom TrustManagers, such as for
 * replacing the stock keystore support with a custom
 * keystore.
 *
 * @param trustManagers the TrustManagers to use
 * @return the builder
 */
 T withTrustManagers(TrustManager[] trustManagers)
 throws NoSuchAlgorithmException, KeyManagementException;

/**
 * Call this if you want a weaker set of supported ciphers,
 * because you are running into compatibility problems with
 * some server due to a cipher mismatch. The better solution
 * is to fix the server.
 *
 * @return the builder
 */
 T withWeakCiphers();

/**
 * Call this if you want the builder to confirm that we are
 * communicating over Tor, by reaching out to a Tor test
 * server and confirming our connection status. By default,
 * this is skipped. Adding this check adds security, but it
 * has the chance of false negatives (e.g., we cannot reach
 * that Tor server for some reason).
 *
 * @return the builder
 */
 T withTorValidation();

/**

NETCIPHER

```java
* Builds a connection, applying the configuration already
  * specified in the builder.
  *
  * @param status status Intent from OrbotInitializer
  * @return the connection
  * @throws IOException
  */
C build(Intent status) throws Exception;

/**
 * Asynchronous version of build(), one that uses OrbotInitializer
 * internally to get the status and checks the validity of the Tor
 * connection (if requested). Note that your callback methods may
 * be invoked on any thread; do not assume that they will be called
 * on any particular thread.
 * *
 * @param callback Callback to get a connection handed to you
 *                 for use, already set up for NetCipher
 */
void build(Callback<? super C> callback);
```

withTorValidation(), build(), and the Callback nested interface were covered earlier in this chapter, but the others offer finer-grained configuration options.

Five of the methods are tied into choosing what proxy protocol should be used with Orbot.

forMaxSecurity(), under the covers, uses withBestProxy(), which chooses the best proxy for the situation. Right now, the implementation chooses the SOCKS proxy where that is supported, falling back to the HTTP proxy where it is not.

The supportsHttpProxy() and supportsSocksProxy() methods indicate whether a given builder supports these proxy types.

The withHttpProxy() and withSocksProxy() methods tell the builder that you want to use that specific proxy. Use these with care, making sure that the proxy you want is supported. withBestProxy() is a far better choice overall.

withWeakCiphers() expands the roster of SSL ciphers that NetCipher allows the HTTPS connection to use. Normally, NetCipher tries to avoid ciphers with known security issues. However, that may cause problems with some servers, if NetCipher and the server cannot negotiate a common cipher. withWeakCiphers() allows NetCipher to use more ciphers, to perhaps overcome the negotiation problem, with
the cost of possibly weaker security.

withTrustManagers() allows you to replace the TrustManager implementation that NetCipher would use by default with a different one, perhaps one that supports certificate pinning or other SSL strengthening techniques.

Differences Between the Stacks

While each of the builders supports the StrongBuilder API, there are some differences between the implementations.

**StrongConnectionBuilder**

Before calling build(), you need to call connectTo() to supply the URL (as a String or URL) that you want to connect to. The other builders give you objects that you can reuse across many requests (e.g., OkHttp3’s OkHttpClient), but that is not possible with HttpURLConnection.

The hurl module’s MainActivity does just that:

```java
@override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    try {
        StrongConnectionBuilder
            .forMaxSecurity(this)
            .withTorValidation()
            .connectTo(SO_URL)
            .build(this);
    } catch (Exception e) {
        Toast.makeText(this, R.string.msg_crash, Toast.LENGTH_LONG)
            .show();
        Log.e(getClass().getSimpleName(), "Exception loading SO questions", e);
        finish();
    }
}
```

(from Internet/HTTPStacks/hurl/src/main/java/com/commonsware/android/http/MainActivity.java)

The onConnected() method then just uses the fully-configured HttpURLConnection
To help make this a bit easier, StrongConnectionBuilder supports the copy constructor. You can create a master StrongConnectionBuilder with your base configuration, then make a copy, call connectTo() on the copy, then call build() on the copy, throwing away the copy when you are done.

**StrongHttpClientBuilder**

The builder for Apache's independent packaging of HttpClient for Android extends Apache's own HttpClientBuilder. As a result, you can call all the normal HttpClientBuilder methods in addition to calling the StrongBuilder methods. The
noteworthy exception is that the standard zero-parameter build() offered by 
HttpClientBuilder is not supported.

The httpclient module's MainActivity does not need any HttpClient-specific 
configuration:

```java
@override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    try {
        StrongHttpClientBuilder
            .forMaxSecurity(this)
            .withTorValidation()
            .build(this);
    } catch (Exception e) {
        Toast.makeText(this, R.string.msg_crash, Toast.LENGTH_LONG)
            .show();
        Log.e(getClass().getSimpleName(),
            "Exception loading SO questions", e);
        finish();
    }
}
```

(from Internet/HTTPStacks/httpclient/src/main/java/com/commonsware/android/http/MainActivity.java)

The onConnected() method then just uses the configured HttpClient object:

```java
@override
public void onConnected(final HttpClient client) {
    new Thread() {
        @Override
        public void run() {
            try {
               HttpGet get=newHttpGet(SO_URL);
                String json=client.execute(get, new BasicResponseHandler());

                final SOQuestions result=
                    new Gson().fromJson(new StringReader(json),
                        SOQuestions.class);

                runOnUiThread(new Runnable() {
                    @Override
                    public void run() {
                        setListAdapter(new ItemsAdapter(result.items));
                    }
                });
            }
        }
    };
}
```
StrongVolleyQueueBuilder

This builder class adheres to the StrongBuilder API without any changes, making its use fairly straightforward:

```java
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    try {
        StrongVolleyQueueBuilder
            .forMaxSecurity(this)
            .withTorValidation()
            .build(this);
    } catch (Exception e) {
        Toast.makeText(this, R.string.msg_crash, Toast.LENGTH_LONG)
            .show();
        Log.e(getClass().getSimpleName(),
            "Exception loading SO questions", e);
        finish();
    }
}
```

The onConnected() method then just uses the configured RequestQueue object:

```java
@Override
public void onConnected(final RequestQueue rq) {
    new Thread() {
        @Override
        public void run() {
            final StringRequest stringRequest=...
new StringRequest(StringRequest.Method.GET, SO_URL, 
new Response.Listener<String>() {
    @Override
    public void onResponse(String response) {
        final SOQuestions result =
            new Gson().fromJson(new StringReader(response), 
            SOQuestions.class);

        runOnUiThread(new Runnable() {
            @Override
            public void run() {
                setListAdapter(new ItemsAdapter(result.items));
            }
        });
    }
},
new Response.ErrorListener() {
    @Override
    public void onErrorResponse(VolleyError error) {
        Log.e(getClass().getSimpleName(),
            "Exception making Volley request", error);
    }
});

rq.add(stringRequest);
}).start();

(from Internet/HTTPStacks/volley/src/main/java/com/commonsware/android/http/MainActivity.java)

**StrongOkHttpClientBuilder**

Note that OkHttp3 **does not support SOCKS proxies**. Hence, supportsSocksProxy() returns false, causing withBestProxy() to fall back to the HTTP proxy. This is handled for you automatically.
This chapter is a catch-all for various Android capabilities related to network I/O and the Internet, beyond what is covered elsewhere in the book.

(yes, this chapter could have a more exciting rationale for existing, but the author is subject to “Truth in Advertising” laws...)

**Prerequisites**

Readers of this chapter should have read the core chapters of the book.

**Downloading Files**

Android 2.3 introduced a `DownloadManager` designed to handle a lot of the complexities of downloading larger files, such as:

1. Determining whether the user is on WiFi or mobile data, and if so, whether the download should occur
2. Handling when the user, previously on WiFi, moves out of range of the access point and “fails over” to mobile data
3. Ensuring the device stays awake while the download proceeds

`DownloadManager` itself is less complicated than the alternative of writing all of that stuff yourself. However, it does present a few challenges. In this section, we will examine the [Internet/Download](#) sample project, one that uses `DownloadManager`. 
The Permissions

To use DownloadManager, you will need to hold the INTERNET permission. You will also need the WRITE_EXTERNAL_STORAGE permission, as DownloadManager can only download to external storage. Note that you need to hold WRITE_EXTERNAL_STORAGE even if you are trying to have DownloadManager write to some location where that permission might not be needed (e.g., getExternalFilesDir() on an Android 4.4+ device). DownloadManager is requiring you to hold that permission, more so than the Android framework, and DownloadManager requires that permission for all API levels at the present time.

For example, here is the manifest for the Internet/Download application, where we request these two permissions:

```xml
<?xml version="1.0" encoding="utf-8"?>
<manifest
    package="com.commonsware.android.downmgr"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens>
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true" />

    <uses-permission android:name="android.permission.INTERNET" />
    <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />

    <application>
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@style/AppTheme">
        <activity>
            android:name="com.commonsware.android.downmgr.DownloadDemo"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN" />

                <category android:name="android.intent.category.LAUNCHER" />
            </intent-filter>
        </activity>
    </application>
</manifest>
```
WRITE_EXTERNAL_STORAGE is a dangerous permission. With a targetSdkVersion of 23 or higher, we need to handle that in our app. This app uses the same AbstractPermissionActivity seen in the chapter on permissions, so we can request WRITE_EXTERNAL_STORAGE from the user on the first run of our app from the DownloadDemo activity:

```java
package com.commonsware.android.downmgr;

import android.Manifest;
import android.app.Activity;
import android.app.DownloadManager;
import android.content.Intent;
import android.os.Bundle;
import android.os.StrictMode;
import android.widget.Toast;

public class DownloadDemo extends AbstractPermissionActivity {
    @Override
    protected String[] getDesiredPermissions() {
        return new String[] {Manifest.permission.WRITE_EXTERNAL_STORAGE};
    }

    @Override
    protected void onPermissionDenied() {
        Toast.makeText(this, R.string.msg_sorry, Toast.LENGTH_LONG).show();
        finish();
    }

    @Override
    public void onReady(Bundle savedInstanceState) {
        StrictMode.setThreadPolicy(new StrictMode.ThreadPolicy.Builder()
            .detectNetwork()
            .penaltyDeath()
            .build());

        if (getSupportFragmentManager().findFragmentById(android.R.id.content)==null) {
            getSupportFragmentManager().beginTransaction()
                .add(android.R.id.content,
                     new DownloadFragment()).commit();
        }
    }

    public void viewLog() {
        startActivity(new Intent(DownloadManager.ACTION_VIEW_DOWNLOADS));
    }
}
```

That activity then goes on to display a DownloadFragment, where most of our code resides.
The Layout

Our sample application has a simple layout, consisting of three buttons:

1. One to kick off a download
2. One to query the status of a download
3. One to display a system-supplied activity containing the roster of downloaded files

```xml
<?xml version="1.0" encoding="utf-8"?><LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent">
  <Button
    android:id="@+id/start"
    android:text="@string/start_download"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_weight="1"
  />
  <Button
    android:id="@+id/query"
    android:text="@string/query_status"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_weight="1"
    android:enabled="false"
  />
  <Button
    android:id="@+id/view"
    android:text="@string/view_log"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_weight="1"
  />
</LinearLayout>
```

Requesting the Download

To kick off a download, we first need to get access to the DownloadManager. This is a so-called “system service”. You can call getSystemService() on any activity (or other...
Context), provide it the identifier of the system service you want, and receive the system service object back. However, since `getSystemService()` supports a wide range of these objects, you need to cast it to the proper type for the service you requested.

So, for example, here is the `onCreateView()` method of the `DownloadFragment`, in which we get the `DownloadManager`:

```java
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup parent, Bundle savedInstanceState) {
    mgr = (DownloadManager) getActivity().getSystemService(Context.DOWNLOAD_SERVICE);
    View result = inflater.inflate(R.layout.main, parent, false);
    query = result.findViewById(R.id.query);
    query.setOnClickListener(this);
    start = result.findViewById(R.id.start);
    start.setOnClickListener(this);
    result.findViewById(R.id.view).setOnClickListener(this);
    return result;
}
```

Most of these managers have no `close()` or `release()` or `goAwayPlease()` sort of methods — you can just use them and let garbage collection take care of cleaning them up.

Given the manager, we can now call an `enqueue()` method to request a download. The name is relevant — do not assume that your download will begin immediately, though often times it will. The `enqueue()` method takes a `DownloadManager.Request` object as a parameter. The `Request` object uses the builder pattern, in that most methods return the `Request` itself, so you can chain a series of calls together with less typing.

For example, the top-most button in our layout is tied to a `startDownload()` method in `DownloadFragment`, shown below:

```java
private void startDownload(View v) {
    Uri uri = Uri.parse("https://commonsware.com/misc/test.mp4");
    Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS).mkdirs();
    DownloadManager.Request req = new DownloadManager.Request(uri);
```
We are downloading a sample MP4 file, and we want to download it to the external storage area. To do the latter, we are using `getExternalStoragePublicDirectory()` on `Environment`, which gives us a directory suitable for storing a certain class of content. In this case, we are going to store the download in the `Environment.DIRECTORY_DOWNLOADS`, though we could just as easily have chosen `Environment.DIRECTORY_MOVIES`, since we are downloading a video clip. Note that the `File` object returned by `getExternalStoragePublicDirectory()` may point to a not-yet-created directory, which is why we call `mkdirs()` on it, to ensure the directory exists.

We then create the `DownloadManager.Request` object, with the following attributes:

1. We are downloading the specific URL we want, courtesy of the `Uri` supplied to the `Request` constructor
2. We are willing to use either mobile data or WiFi for the download (`setAllowedNetworkTypes()`, but we do not want the download to incur roaming charges (`setAllowedOverRoaming()`) 
3. We want the file downloaded as `test.mp4` in the downloads area on the external storage (`setDestinationInExternalPublicDir()`) 

We also provide a name (`setTitle()`) and description (`setDescription()`) which are used as part of the notification drawer entry for this download. The user will see these when they slide down the drawer while the download is progressing.

The `enqueue()` method returns an ID of this download, which we hold onto for use in querying the download status.

**Keeping Track of Download Status**

If the user presses the Query Status button, we want to find out the details of how
the download is progressing. To do that, we can call query() on the DownloadManager. The query() method takes a DownloadManager.Query object, describing what download(s) you are interested in. In our case, we use the value we got from the enqueue() method when the user requested the download:

```java
private void queryStatus(View v) {
    Cursor c =
        mgr.query(new DownloadManager.Query().setFilterById(lastDownload));

    if (c == null) {
        Toast.makeText(getActivity(), R.string.download_not_found,
            Toast.LENGTH_LONG).show();
    } else {
        c.moveToFirst();

        Log.d(getClass().getName(),
            "COLUMN_ID: " + c.getLong(c.getColumnIndex(DownloadManager.COLUMN_ID)));
        Log.d(getClass().getName(),
            "COLUMN_BYTES_DOWNLOADED_SO_FAR: " + c.getLong(c.getColumnIndex(DownloadManager.COLUMN_BYTES_DOWNLOADED_SO_FAR)));
        Log.d(getClass().getName(),
            "COLUMN_LAST_MODIFIED_TIMESTAMP: " + c.getLong(c.getColumnIndex(DownloadManager.COLUMN_LAST_MODIFIED_TIMESTAMP)));
        Log.d(getClass().getName(),
            "COLUMN_LOCAL_URI: " + c.getString(c.getColumnIndex(DownloadManager.COLUMN_LOCAL_URI)));
        Log.d(getClass().getName(),
            "COLUMN_STATUS: " + c.getInt(c.getColumnIndex(DownloadManager.COLUMN_STATUS)));
        Log.d(getClass().getName(),
            "COLUMN_REASON: " + c.getInt(c.getColumnIndex(DownloadManager.COLUMN_REASON)));

        Toast.makeText(getActivity(), statusMessage(c), Toast.LENGTH_LONG)
            .show();

        c.close();
    }
}
```

(from Internet/Download/app/src/main/java/com/commonsware/android/downmgr/DownloadFragment.java)

The query() method returns a Cursor, containing a series of columns representing the details about our download. There is a series of constants on the DownloadManager class outlining what is possible. In our case, we retrieve (and dump to Logcat):

1. The ID of the download (COLUMN_ID)
2. The amount of data that has been downloaded to date (COLUMN_BYTES_DOWNLOADED_SO_FAR)
3. What the last-modified timestamp is on the download
4. Where the file is being saved to locally (COLUMN_LOCAL_URI)
5. What the actual status is (COLUMN_STATUS)
6. What the reason is for that status (COLUMN_REASON)

Note that COLUMN_LOCAL_URI may be unavailable, if the user has deleted the downloaded file between when the download completed and the time you try to access the column.

There are a number of possible status codes (e.g., STATUS_FAILED, STATUS_SUCCESSFUL, STATUS_RUNNING). Some, like STATUS_FAILED, may have an accompanying reason to provide more details.

Note that you really should close this Cursor when you are done with it. StrictMode, for example, will complain if you do not.

**Download Broadcasts**

To find out about the results of the download, we need to register a BroadcastReceiver, to watch for two actions used by DownloadManager:

1. ACTION_DOWNLOAD_COMPLETE, to let us know when the download is done
2. ACTION_NOTIFICATION_CLICKED, to let us know if the user taps on the Notification displayed on the user's device related to our download

So, in onResume() of our fragment, we register a single BroadcastReceiver for both of those events:

```java
@Override
public void onResume() {
    super.onResume();

    IntentFilter f =
        new IntentFilter(DownloadManager.ACTION_DOWNLOAD_COMPLETE);

    f.addAction(DownloadManager.ACTION_NOTIFICATION_CLICKED);

    getActivity().registerReceiver(onEvent, f);
}
```

That BroadcastReceiver is unregistered in onPause():
@Override
public void onPause() {
    getActivity().unregisterReceiver(onEvent);
    super.onPause();
}

The BroadcastReceiver implementation examines the action string of the incoming Intent (via a call to `getAction()`) and either displays a Toast (for `ACTION_NOTIFICATION_CLICKED`) or enables the start-download Button:

```java
public void onReceive(Context ctxt, Intent i) {
    if (DownloadManager.ACTION_NOTIFICATION_CLICKED.equals(i.getAction())) {
        Toast.makeText(ctxt, R.string.hi, Toast.LENGTH_LONG).show();
    } else {
        start.setEnabled(true);
    }
}
```

(from Internet/Download/app/src/main/java/com/commonsware/android/downmgr/DownloadFragment.java)
What the User Sees

The user, upon launching the application, sees our three pretty buttons:

*Figure 777: The Download Demo Sample, As Initially Launched*
Clicking the first disables the button while the download is going on, and a download icon appears in the status bar (though it is a bit difficult to see, given the poor contrast between Android's icon and Android's status bar):

Figure 778: The Download Demo Sample, Downloading
Sliding down the notification drawer shows the user the progress in the form of a ProgressBar widget:

Figure 779: The DownloadManager Notification

Tapping on the entry in the notification drawer returns control to our original activity, where they see a Toast, raised by our BroadcastReceiver.
If they tap the middle button during the download, a different Toast will appear indicating that the download is in progress:

![Figure 780: The Download Demo, Showing Download Status](image)

Additional details are also dumped to Logcat:

```
12-10 08:45:01.289: DEBUG/com.commonsware.android.download.DownloadDemo(372):
    COLUMN_ID: 12
12-10 08:45:01.289: DEBUG/com.commonsware.android.download.DownloadDemo(372):
    COLUMN_BYTES_DOWNLOADED_SO_FAR: 615400
12-10 08:45:01.289: DEBUG/com.commonsware.android.download.DownloadDemo(372):
    COLUMN_LAST_MODIFIED_TIMESTAMP: 1291988696232
12-10 08:45:01.289: DEBUG/com.commonsware.android.download.DownloadDemo(372):
    COLUMN_LOCAL_URI: file:///mnt/sdcard/Download/test.mp4
12-10 08:45:01.299: DEBUG/com.commonsware.android.download.DownloadDemo(372):
    COLUMN_STATUS: 2
12-10 08:45:01.299: DEBUG/com.commonsware.android.download.DownloadDemo(372):
    COLUMN_REASON: 0
```

Once the download is complete, tapping the middle button will indicate that the download is, indeed, complete, and final information about the download is emitted to Logcat:

```
```

2845
Tapping the bottom button brings up the activity displaying all downloads, including both successes and failures:

![Downloads Activity]

*Figure 781: The DownloadManager Results*

And, of course, the file is downloaded.

**Limitations**

While DownloadManager nowadays supports HTTPS (SSL) URLs, that was not the case when it was introduced back in Android 2.3. You will want to test any HTTPS URLs you intend to use with DownloadManager if you are supporting older versions of Android.
MICROSOFT NETWORK TOPICS

If you display the list of all downloads, and your download is among them, it is a really good idea to make sure that some activity (perhaps one of yours) is able to respond to an ACTION_VIEW Intent on that download’s MIME type. Otherwise, when the user taps on the entry in the list, they will get a Toast indicating that there is nothing available to view the download. This may confuse users. Alternatively, use setVisibleInDownloadsUi() on your request, passing in false, to suppress it from this list.

Also, starting with Android 5.0, the Downloads app that provides the core implementation of DownloadManager keeps track of when other apps get uninstalled. At that point, the Downloads app deletes the files downloaded by DownloadManager on behalf of that app. This includes files stored in common locations (e.g., DIRECTORY_DOWNLOADS) that would ordinarily survive an uninstall. For example, if you run the Internet/Download sample app on an Android 5.0+ device, then uninstall the app, the downloaded file vanishes from the Downloads app. If you elect to use DownloadManager, you should either:

- Download the file to a temporary spot, then move it to a long-term location yourself, or
- Advise the user that the file will be deleted if the user uninstalls your app, suggesting that the user might want to make a safe copy of the file

Data Saver

Android has had a per-app “data saver” mode for some time, with an eye towards reducing bandwidth consumption when the device is using a known metered data plan. Android 7.0+ extended this to a device-wide setting.

Apps can be in one of three states as a result:

- The device is normal
- The device is in data-saver mode
- The device is in data-saver mode, but your app is whitelisted by the user

The idea is that if the device is in normal mode, you can do what you want. If the device is in data-saver mode, you should restrict your bandwidth, even if the user whitelists you. Apps that are not whitelisted have no network access while in the background.

To that end, ConnectivityManager has three things for you.
First, isActiveNetworkMetered() will return true if the device is on a metered data connection, false otherwise. This has been around for years (API Level 16+), but has not been all that popular, apparently.

Second, Android 7.0 has a getRestrictBackgroundStatus() method on ConnectivityManager. This returns an int that resolves to one of three values:

- RESTRICT_BACKGROUND_STATUS_DISABLED
- RESTRICT_BACKGROUND_STATUS_ENABLED
- RESTRICT_BACKGROUND_STATUS_WHITELISTED

If isActiveNetworkMetered() is true, and getRestrictBackgroundStatus() returns RESTRICT_BACKGROUND_STATUS_ENABLED, any attempts to use the network may fail, and so your app should plan accordingly.

If you want to try to react in real-time to changes in the data-saver configuration, you can register a receiver for ACTION_RESTRICT_BACKGROUND_CHANGED (defined on ConnectivityManager). This will be broadcast for any change in data-saver settings, which means that your app's state may not have changed. You will need to call getRestrictBackgroundStatus() to find out your current state. Also note that this broadcast is only sent to receivers registered dynamically, via registerReceiver(). You cannot register for this broadcast in the manifest.

To try to get on the whitelist, you might be tempted to try using ACTION_IGNORE_BACKGROUND_DATA_RESTRICTIONS_SETTINGS to lead the user to add your app to the Data Saver whitelist, so you have normal background network access. However, bear in mind that Google has a similar feature for the battery saver whitelist... and trying to use that action got apps banned from the Play Store. At the moment, there is no similar language around the use of the data saver whitelist... but, then again, they did not tell you they were going to ban you for asking to be on the battery saver whitelist until after Android 6.0 shipped.
Trail: Media
Whether it comes in the form of simple beeps or in the form of symphonies (or gangster rap or whatever), Android applications often need to play audio. A few things in Android can play audio automatically, such as a Notification. However, once you get past those, you are on your own.

Fortunately for you, Android offers support for audio playback, and we will examine some of the options in this chapter.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Get Your Media On

In Android, you have a few different places you can pull media clips from — one of these will hopefully fit your needs:

- You can package audio clips as raw resources (res/raw/ in your project), so they are bundled with your application. The benefit is that you're guaranteed the clips will be there; the downside is that they cannot be replaced without upgrading the application.
- You can package audio clips as assets (assets/ in your project) and reference them via file:///android_asset/ URLs in a Uri. The benefit over raw resources is that this location works with APIs that expect Uri parameters instead of resource IDs. The downside — assets are only replaceable when the application is upgraded — remains. On the whole, the audio APIs tend
to favor raw resources over assets.
• You can download and store media in internal storage, external storage, or possibly on removable storage.
• You can, in some cases, stream media off the Internet, bypassing any local storage.

MediaPlayer for Audio

If you want to play back music, particularly material in MP3 format, you will want to use the `MediaPlayer` class. With it, you can feed it an audio clip, start/stop/pause playback, and get notified on key events, such as when the clip is ready to be played or is done playing.

You have three ways to set up a `MediaPlayer` and tell it what audio clip to play:

• If the clip is a raw resource, use `MediaPlayer.create()` and provide the resource ID of the clip.
• If you have a `Uri` to the clip, use the `Uri`-flavored version of `MediaPlayer.create()`.
• If you have a string path to the clip, just create a `MediaPlayer` using the default constructor, then call `setDataSource()` with the path to the clip. However, in this case, you also need to call `prepare()` or `prepareAsync()`. Both will set up the clip to be ready to play, such as fetching the first few seconds off the file or stream. The `prepare()` method is synchronous; as soon as it returns, the clip is ready to play. The `prepareAsync()` method is asynchronous.

Once the clip is prepared, `start()` begins playback, `pause()` pauses playback (with `start()` picking up playback where `pause()` paused), and `stop()` ends playback. One caveat: you cannot simply call `start()` again on the `MediaPlayer` once you have called `stop()` — we'll cover a workaround a bit later in this section.

To see this in action, take a look at the `Media/Audio` sample project. It contains a single activity — `MainActivity` — that offers playback of a Creative Commons-licensed audio clip, stored as an Ogg Vorbis file as a raw resource (`R.raw.clip`).

In `onCreate()`, we use the static `create()` factory method on `MediaPlayer` to set up a `MediaPlayer` for our audio clip:

```java
@override
public void onCreate(Bundle state) {
```
super.onCreate(state);

try {
    mp=MediaPlayer.create(this, R.raw.clip);
    mp.setOnCompletionListener(this);
} catch (Exception e) {
    goBlooey(e);
}

(from Media/Audio/app/src/main/java/com/commonsware/android/audio/MainActivity.java)

We also register the activity itself as the OnCompletionListener, to find out if the audio clip is played through to the end.

Under the covers, create() not only creates an instance of MediaPlayer and sets up the data source, but it also calls prepare(), so the MediaPlayer is ready for use once create() returns. However, this also means that there might be an exception, such as providing an invalid resource ID (e.g., one pointing to a Photoshop file instead of an audio file). goBlooey() simply logs the exception and shows a Toast as a crude form of error handling:

private void goBlooey(Exception e) {
    Log.e(getClass().getSimpleName(), getString(R.string.msg_error), e);
    Toast.makeText(this, R.string.msg_error.toast, Toast.LENGTH_LONG).show();
}

(from Media/Audio/app/src/main/java/com/commonsware/android/audio/MainActivity.java)

Our UI is purely a set of action bar items:

<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:id="@+id/play"
          android:icon="@drawable/ic_play_arrow"
          android:showAsAction="ifRoom"
          android:title="@string/menu_play" />
    <item android:id="@+id/pause"
          android:icon="@drawable/ic_pause"
          android:showAsAction="ifRoom" />
</menu>
Note that only the play action bar item is visible at the outset. We will toggle the visibility of the action bar items based on the status of the playback of the clip.

We populate the action bar in `onCreateOptionsMenu()`, also retrieving the three `MenuItem` objects for our three action bar items:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
    play = menu.findItem(R.id.play);
    pause = menu.findItem(R.id.pause);
    stop = menu.findItem(R.id.stop);

    return (super.onCreateOptionsMenu(menu));
}
```

`onOptionsItemSelected()` merely delegates the three action items to three similarly-named methods: `play()`, `pause()`, and `stop()`:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.play:
            play();
            return (true);

        case R.id.pause:
            pause();
            return (true);

        case R.id.stop:
            stop();
            return (true);
    }
    return (false);
}
```
The `play()` method calls `start()` to cause the MediaPlayer to begin playing back the audio clip. It also toggles the visibility of the action bar items, so the pause and stop ones are now visible:

```java
private void play() {
    mp.start();

    play.setVisible(false);
    pause.setVisible(true);
    stop.setVisible(true);
}
```

`play()` is asynchronous, as the audio clip plays back on another system-supplied thread. We are not tying up the main application thread by playing back this clip.

`pause()` is similar: it calls `pause()` to cause the MediaPlayer to pause playback of the audio clip. It also toggles the visibility of the action bar items, so the play and stop ones are now visible:

```java
private void pause() {
    mp.pause();

    play.setVisible(true);
    pause.setVisible(false);
    stop.setVisible(true);
}
```

Where things get a bit complicated is in the `stop()` method. There, we not only want to stop playback, but also set up the MediaPlayer to be able to play back from the beginning of the clip:

```java
private void stop() {
    mp.stop();
    pause.setVisible(false);
    stop.setVisible(false);
}
```
Stopping the playback is merely a matter of calling `stop()` on the `MediaPlayer`. After that, we hide all the action bar items.

To reset the `MediaPlayer` to play the clip again, you need to re-prepare the player, via `prepare()` or `prepareAsync()`. You also need to call `seekTo(0)`. `seekTo()` positions playback at a certain number of milliseconds from the beginning of the audio, so `seekTo(0)` repositions the player back to the beginning.

However, if we try doing this work right away, we get odd results, owing to the asynchronous nature of the media playback. We need to let the `stop()` complete its work before we `prepare()` and `seekTo()`. Unfortunately, there is no listener interface for the stop-completed event. So, we fake it, delaying the “rewind” of the clip by 100 milliseconds.

Also, once the `MediaPlayer` is ready again, we enable the play action bar item, allowing playback to commence from start, if the user wants.

Finally, in `onDestroy()`, we `stop()` the `MediaPlayer` if it returns `true` from `isPlaying()`, so the playback does not continue after the activity is destroyed:
Other Ways to Make Noise

While MediaPlayer is the primary audio playback option, particularly for content along the lines of MP3 files, there are other alternatives if you are looking to build other sorts of applications, notably games and custom forms of streaming audio.

SoundPool

The SoundPool class's claim to fame is the ability to overlay multiple sounds, and do so in a prioritized fashion, so your application can just ask for sounds to be played and SoundPool deals with each sound starting, stopping, and blending while playing.

This may make more sense with an example.

Suppose you are creating a first-person shooter. Such a game may have several sounds going on at any one time:

1. The sound of the wind whistling amongst the trees on the battlefield
2. The sound of the surf crashing against the beach in the landing zone
3. The sound of booted feet crunching on the sand
4. The sound of the character's own panting as the character runs on the beach
5. The sound of orders being barked by a sergeant positioned behind the character
6. The sound of machine gun fire aimed at the character and the character's squad mates
7. The sound of explosions from the gun batteries of the battleship providing suppression fire

And so on.

In principle, SoundPool can blend all of those together into a single audio stream for output. Your game might set up the wind and surf as constant background sounds, toggle the feet and panting on and off based on the character's movement, randomly add the barked orders, and tie the gunfire based on actual game play.

In reality, your average smartphone will lack the CPU power to handle all of that audio without harming the frame rate of the game. So, to keep the frame rate up,
you tell SoundPool to play at most two streams at once. This means that when nothing else is happening in the game, you will hear the wind and surf, but during the actual battle, those sounds get dropped out — the user might never even miss them — so the game speed remains good.

**AudioTrack**

The lowest-level Java API for playing back audio is AudioTrack. It has two main roles:

1. Its primary role is to support streaming audio, where the streams come in some format other than what MediaPlayer handles. While MediaPlayer can handle RTSP, for example, it does not offer SIP. If you want to create a SIP client (perhaps for a VOIP or Web conferencing application), you will need to convert the incoming data stream to PCM format, then hand the stream off to an AudioTrack instance for playback.

2. It can also be used for “static” (versus streamed) bits of sound that you have pre-decoded to PCM format and want to play back with as little latency as possible. For example, you might use this for a game for in-game sounds (beeps, bullets, or “boing”s). By pre-decoding the data to PCM and caching that result, then using AudioTrack for playback, you will use the least amount of overhead, minimizing CPU impact on game play and on battery life.

**ToneGenerator**

If you want your phone to sound like... well... a phone, you can use ToneGenerator to have it play back dual-tone multi-frequency (DTMF) tones. In other words, you can simulate the sounds played by a regular “touch-tone” phone in response to button presses. This is used by the Android dialer, for example, to play back the tones when users dial the phone using the on-screen keypad, as an audio reinforcement.

Note that these will play through the phone's earpiece, speaker, or attached headset. They do not play through the outbound call stream. In principle, you might be able to get ToneGenerator to play tones through the speaker loud enough to be picked up by the microphone, but this probably is not a recommended practice.

You can create a ToneGenerator through its constructor. This takes two parameters:

- the audio stream associated with this audio
- the volume level to apply to the audio
The stream indication helps with muting; if the user has muted this particular stream, then ToneGenerator will wind up not generating a tone.

Then, when you need a beep, you can call startTone(), with the identifier of one of the many DTMF tones listed on the ToneGenerator class:

```
beeper.startTone(ToneGenerator.TONE_PROP_NACK);
```

Many of the tones have a fixed duration. In that case, startTone() will play that tone to completion, or until you call stopTone() to interrupt it.

Some tones will repeat indefinitely. There is a second startTone() variant that takes a duration in milliseconds that you can use to automatically stop the tone after a particular period of time. Or, you can use stopTone() to stop the one.
Audio Recording

Most Android devices have microphones. On such devices, it might be nice to get audio input from those microphones, whether to record locally, process locally (e.g., speech recognition), or to stream out over the Internet (e.g., voice over IP).

Not surprisingly, Android has some capabilities in this area. Also, not surprisingly, there are multiple APIs, with varying mixes of power and complexity, to allow you to capture microphone input. In this chapter, we will examine `MediaRecorder` for recording audio files and `AudioRecord` for raw microphone input.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having read the chapter on audio playback is probably also a good idea. And, for the section on playing back local streams, you will want to have read up on content providers, particularly the chapter on provider patterns.

Recording by Intent

Just as the easiest way to take a picture with the camera is to use the device's built-in camera app, the easiest way to record some audio is to use a built-in activity for it. And, as with using the built-in camera app, the built-in audio recording activity has some significant limitations.

Requesting the built-in audio recording activity is a matter of calling `startActivityForResult()` for a `MediaStore.Audio.Media.RECORD_SOUND_ACTION` action. You can see this in the `Media/SoundRecordIntent` sample project, specifically the `MainActivity`:
package com.commonsware.android.soundrecord;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.provider.MediaStore;
import android.widget.Toast;

public class MainActivity extends Activity {
  private static final int REQUEST_ID=1337;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    Intent i=new Intent(MediaStore.Audio.Media.RECORD_SOUND_ACTION);

    startActivityForResult(i, REQUEST_ID);
  }

  @Override
  protected void onActivityResult(int requestCode, int resultCode, Intent data) {
    if (requestCode == REQUEST_ID && resultCode == RESULT_OK) {
      Toast.makeText(this, "Recording finished!", Toast.LENGTH_LONG).show();
    }

    finish();
  }
}

(from Media/SoundRecordIntent/app/src/main/java/com/commonsware/android/soundrecord/MainActivity.java)
As with a few other sample apps in this book, the Media/SoundRecordIntent uses a Theme.Translucent.NoTitleBar activity, avoiding its own UI. Instead, in onCreate(), we immediately call startActivityForResult() for MediaStore.Audio.Media.RECORD_SOUND_ACTION. That will bring up a recording activity:

If the user records some audio via the “record” ImageButton (one with the circle icon) and the “stop” ImageButton (one with the square icon), you will get control back in onActivityResult(), where you are passed an Intent whose Uri (via getData()) will point to this audio recording in the MediaStore.

However:

- You have no control over where the file is stored or what it is named. It appears that, by default, these files are dumped unceremoniously in the root of external storage.
- You have no control over anything about the way the audio is recorded, such as codecs or bitrates. For example, it appears that, by default, the files are recorded in AMR format.
- ACTION_VIEW may not be able to play back this audio (leastways, it failed to
in testing on a few devices). Whether that is due to codecs, the way the data is put in MediaStore, or the limits of the default audio player on Android, is unclear.

Hence, in many cases, while this works, it may not work well enough — or controlled enough — to meet your needs. In that case, you will want to handle the recording yourself, as will be described in the next couple of sections.

**Recording to Files**

If your objective is to record a voice note, a presentation, or something along those lines, then MediaRecorder is probably the class that you want. It will let you specify what sort of media you wish to record, in what format, and to what location. It then handles the actual act of recording.

To illustrate this, let us review the Media/AudioRecording sample project.

Our activity’s layout consists of a single ToggleButton widget named record:

```xml
<ToggleButton
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/record"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:textAppearance="?android:attr/textAppearanceLarge"/>
```

(from Media/AudioRecording/app/src/main/res/layout/activity_main.xml)

Our project is set up to record the output to the Environment.DIRECTORY_DOWNLOADS location on external storage. And, if we have a targetSdkVersion of 23 or higher (which we do), we need runtime permissions. We also need runtime permissions for RECORD_AUDIO, since, well, we are recording audio. So our manifest requests both of those permissions:

```xml
<manifest
    xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonsware.android.audiorecord"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>
```

---

2864
**AUDIO RECORDING**

<uses-permission android:name="android.permission.RECORD_AUDIO"/>
<uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE"/>

<uses-feature
    android:name="android.hardware.microphone"
    android:required="true"/>

<application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.Apptheme">
    <activity
        android:name=".MainActivity"
        android:label="@string/title_activity_main">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>
            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>
</manifest>

(from Media/AudioRecording/app/src/main/AndroidManifest.xml)

And, following in the pattern demonstrated in the chapter on permissions, we use AbstractPermissionsActivity to handle all the details of obtaining our runtime. Our launcher activity — MainActivity — inherits from AbstractPermissionsActivity, which requests our permissions when the app starts up. MainActivity simply inherits the necessary methods. Two of these, getDesiredPermissions() and onPermissionDenied(), are specifically for the permission logic:

```java
@Override
protected String[] getDesiredPermissions() {
    return new String[]{RECORD_AUDIO, WRITE_EXTERNAL_STORAGE};
}

@Override
protected void onPermissionDenied() {
    Toast.makeText(this, R.string.msg_sorry, Toast.LENGTH_LONG).show();
    finish();
}
```
onReady() serves as our onCreate() replacement, and it will be invoked when we have our runtime permissions. There, we load the layout and set the activity itself up as the OnCheckedChangedListener, to find out when the user toggles the button:

```java
@Override
public void onReady(Bundle savedInstanceState) {
    setContentView(R.layout.activity_main);

    ((ToggleButton)findViewById(R.id.record)).setOnCheckedChangeListener(this);
}
```

Also, in onStart(), we initialize a MediaRecorder, setting the activity up as being the one to handle info and error events about the recording. Similarly, we release() the MediaRecorder in onStop(), to reduce our overhead when we are not in the foreground:

```java
@Override
public void onStart() {
    super.onStart();

    recorder=new MediaRecorder();
    recorder.setOnErrorListener(this);
    recorder.setOnInfoListener(this);
}

@Override
public void onStop() {
    recorder.release();
    recorder=null;

    super.onStop();
}
```

Most of the work occurs in onCheckedChanged(), where we get control when the user toggles the button. If we are now checked, we begin recording; if not, we stop the previous recording:

```java
@Override
public void onCheckedChanged(CompoundButton buttonView, boolean isChecked) {
    if (isChecked) {
```
To record audio, we:

- Create a `File` object representing where the recording should be stored, in this case using `Environment.getExternalStoragePublicDirectory()` to find a location on external storage
- Tell the `MediaRecorder` that we wish to record from the microphone, through a call to `setAudioSource()`, that we wish to record a 3GP file via a call to `setOutputFormat()`, and that we wish to record the results to our
AUDIO RECORDING

File via a call to `setOutputFile()`

- If we are running on Android 2.3.3 or higher, we can also configure our encoder to be AAC via `setAudioEncoder()` and set our requested bitrate to 160Kbps via `setAudioEncodingBitRate()` — otherwise, we use `setAudioEncoder()` to request AMR narrowband
- Indicate how many audio channels we want via `setAudioChannels()`, such as 2 to attempt to record in stereo
- Kick off the actual recording via calls to `prepare()` (to set up the output file) and `record()`

Stopping the recording, when the user toggles off the button, is merely a matter of calling `stop()` on the `MediaRecorder`, then using `MediaScannerConnection` to get the resulting file indexed by the `MediaStore`, so it shows up for desktop users, media apps, etc.

Because we told the `MediaRecorder` that our activity was our `OnErrorListener` and `OnInfoListener`, we have to implement those interfaces on the activity and implement their required methods (`onError()` and `onInfo()`, respectively). In the normal course of events, neither of these should be triggered. If they are, we are passed an int value (typically named `what`) that indicates what happened:

```java
@Override
public void onInfo(MediaRecorder mr, int what, int extra) {
    String msg = getString(R.string.strange);

    switch (what) {
        case MediaRecorder.MEDIA_RECORDER_INFO_MAX_DURATION_REACHED:
            msg = getString(R.string.max_duration);
            break;

        case MediaRecorder.MEDIA_RECORDER_INFO_MAX_FILESIZE_REACHED:
            msg = getString(R.string.max_size);
            break;
    }

    Toast.makeText(this, msg, Toast.LENGTH_LONG).show();
}

@Override
public void onError(MediaRecorder mr, int what, int extra) {
    Toast.makeText(this, R.string.strange, Toast.LENGTH_LONG).show();
}
```

(from Media/AudioRecording/app/src/main/java/com/commonsware/android/audiorecord/MainActivity.java)
Here, we just raise a Toast in either case, with either a generic message or a specific message for the cases where the maximum time duration or the maximum file size for our recording has been reached.

The results are that we get a recording on external storage (typically in a Downloads directory) after we toggle the button on, record some audio, then toggle the button off.

MediaRecorder is rather fussy about the order of method calls for its configuration. For example, you must call setAudioEncoder() after the call to setOutputFormat().

Also, the available codecs and file types are rather limited. Notably, Android lacks the ability to record to MP3 format, perhaps due to patent licensing issues.

## Recording to Streams

The nice thing about recording to files is that Android handles all of the actual file I/O for us. The downside is that because Android handles all of the actual file I/O for us, it can only write files that are accessible to it and our process, meaning external storage. This may not be suitable in all cases, such as wanting to record to some form of private encrypted storage.

The good news is that Android does support recording to streams, in the form of a pipe created by ParcelFileDescriptor and createPipe(). This follows the same basic pattern that we saw in the chapter on content provider patterns, where we served a stream via a pipe. However, as you will see, there are some limits on how well we can do this.

To demonstrate and explain, let us examine the Media/AudioRecordStream sample project. This is nearly a complete clone of the previous sample, so we will only focus on the changes in this section.

The author would like to thank Lucio Maciel for his assistance in getting this example to work.

### Setting Up the Stream

The biggest change, by far, is in our setOutputFile() call. Before, we supplied a path to external storage. Now, we supply the write end of a pipe:
Our `getStreamFd()` method looks a lot like the `openFile()` method of our pipe-providing provider:

```java
private FileDescriptor getStreamFd() {
    ParcelFileDescriptor[] pipe = null;

    try {
        pipe = ParcelFileDescriptor.createPipe();

        new TransferThread(new AutoCloseInputStream(pipe[0]),
            new FileOutputStream(getOutputFile())).start();
    } catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception opening pipe", e);
    }

    return (pipe[1].getFileDescriptor());
}
```

We create our pipe with `createPipe()`, spawn a `TransferThread` to copy the recording from an `InputStream` to a `FileOutputStream`, and return the write end of the pipe. However, `setOutputFile()` on `MediaRecorder` takes the actual integer file descriptor, not a `ParcelFileDescriptor`, so we use `getFileDescriptor()` to retrieve the file descriptor and return that.

Our `TransferThread` is similar to the one from the content provider sample, except that we pass over a `FileOutputStream`, so we can not only `flush()` but also `sync()` when we are done writing:

```java
static class TransferThread extends Thread {
    InputStream in;
    FileOutputStream out;

    TransferThread(InputStream in, FileOutputStream out) {
        this.in = in;
        this.out = out;
    }

    @Override
    public void run() {
```
Changes in Recording Configuration

The biggest limitation of a pipe's stream is that it is purely a stream. You cannot rewind re-read earlier bits of data. In other words, the stream is not seekable.

That is a problem with MediaRecorder in some configurations. For example, a 3GP file contains a header with information about the overall file, information that MediaRecorder does not know until the recording is complete. In the case of a file, MediaRecorder can simply rewind and update the header with the final data when everything is done. However, that is not possible with a pipe-based stream.

However, some configurations will work, notably “raw” ones that just have the recorded audio, with no type of header. That is what we use in this sample.

Specifically, we now write to a .amr file:

```java
private static final String BASENAME="recording-stream.amr";
```

We also set our output format to RAW_AMR, and our encoder to AMR_NB:
This combination works. Other combinations might also work. But our approach of writing the 3GP file, as in the file-based example, will not work.

**Raw Audio Input**

Just as AudioTrack allows you to play audio supplied as raw 8- or 16-bit PCM input, AudioRecord allows you to record audio from the microphone, supplied to you in PCM format. It is then up to you to actually do something with the raw byte PCM data, including converting it to some other format and container as needed.

Note that you need the RECORD_AUDIO permission to work with AudioRecord, just as you need it to work with MediaRecorder.

**Requesting the Microphone**

As noted in the opening paragraph of this chapter, most Android devices have microphones. The key word there is *most*. Not all Android devices will have microphones, as only some tablets (and fewer Android TV devices) will support microphone input.

As with most of this optional hardware, the solution is to use `<uses-feature>`. In that case, you would request the android.hardware.microphone feature, with android:required="false" if you felt that you do not absolutely need a microphone. In that case, you would use hasSystemFeature() on PackageManager to determine at runtime if you do indeed have a microphone.

Note that the RECORD_AUDIO permission implies that you need a microphone. Hence, even if you skip the `<uses-feature>` element, your app will still only ship to devices that have a microphone. If the microphone is optional, be sure to include android:required="false", so your app will be available to devices that lack a microphone.
Video Playback

Just as Android supports audio playback, it also supports video playback of local and streaming content. Unlike audio playback – which supports a mix of high-level and low-level APIs – video playback offers a purely high-level interface, in the form of the same MediaPlayer class you used for audio playback. To keep things a bit simpler, though, Android does offer a VideoView widget you can drop in an activity or fragment to play back video.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, along with the chapter on audio playback.

Moving Pictures

Video clips get their own widget, the VideoView. Put it in a layout, feed it an MP4 video clip, and you get playback!

For example, take a look at this layout, from the Media/Video sample project:

```xml
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <VideoView
        android:id="@+id/video"
        android:layout_width="match_parent"
        android:layout_height="match_parent" />
</LinearLayout>
```
The layout is simply a full-screen video player. Whether it will use the full screen will be dependent on the video clip, its aspect ratio, and whether you have the device (or emulator) in portrait or landscape mode.

Wiring up the Java is almost as simple:

```java
package com.commonsware.android.video;

import java.io.File;
import android.Manifest;
import android.app.Activity;
import android.graphics.PixelFormat;
import android.os.Bundle;
import android.os.Environment;
import android.widget.MediaController;
import android.widget.Toast;
import android.widget.VideoView;

public class VideoDemo extends AbstractPermissionActivity {
    private VideoView video;
    private MediaController ctrl;

    @Override
    protected String[] getDesiredPermissions() {
        return new String[] {Manifest.permission.WRITE_EXTERNAL_STORAGE};
    }

    @Override
    protected void onPermissionDenied() {
        Toast.makeText(this, R.string.msg_sorry, Toast.LENGTH_LONG).show();
        finish();
    }

    @Override
    public void onReady(Bundle state) {
        getWindow().setFormat(PixelFormat.TRANSLUCENT);
        setContentView(R.layout.main);

        File clip=new File(Environment.getExternalStorageDirectory(),
            "test.mp4");
    }
}
```
We use the AbstractPermissionActivity profiled earlier in the book, as we need READ_EXTERNAL_STORAGE rights to be able to read a test.mp4 video from the root of external storage.

Beyond that, we:

1. Confirm that our video file exists on external storage
2. Tell the VideoView which file to play
3. Create a MediaController pop-up panel and cross-connect it to the VideoView
4. Give the VideoView the focus and start playback

The biggest trick with VideoView is getting a video clip onto the device. While VideoView does support some streaming video, the requirements on the MP4 file are fairly stringent. If you want to be able to play a wider array of video clips, you need to have them on the device, preferably on an SD card.
The crude VideoDemo class assumes there is an MP4 file named test.mp4 in the root of external storage on your device or emulator. Once there, the Java code shown above will give you a working video player:

![VideoDemo](image)

*Figure 783: VideoDemo, Showing a Creative Commons-Licensed Video*
Tapping on the video will pop up the playback controls:

![Video Playback Controls](image)

*Figure 784: VideoDemo, Showing Media Controls*

The video will scale based on space as well:
Using the Camera via 3rd-Party Apps

Most Android devices will have a camera, since they are fairly commonplace on mobile devices these days. You, as an Android developer, can take advantage of the camera, for everything from snapping tourist photos to scanning barcodes. If you wish to let other apps do the “heavy lifting” for you, working with the camera can be fairly straightforward. If you want more control, you can work with the camera directly, though this control comes with greater complexity.

You can also record videos using the camera. Once again, you have the option of either using a third-party activity, or doing it yourself.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the material on implicit Intents. You also need to read the chapters on the ContentProvider component, particularly the coverage of FileProvider.

Being Specific About Features

If your app needs a camera — by any of the means cited in this chapter – you should include a <uses-feature> element in the manifest indicating your requirements. However, you need to be fairly specific about your requirements here.

For example, the Nexus 7 (2012) has a camera... but only a front-facing camera. This facilitates apps like video chat. However, the android.hardware.camera implies that you need a high-resolution rear-facing camera. Hence, to work with the Nexus 7's camera, you need to:
USING THE CAMERA VIA 3RD-PARTY APPS

- Require the CAMERA permission (if you are using the Camera directly)
- Not require the android.hardware.camera feature (android:required="false")
- Optionally require the android.hardware.camera.front feature (if your app definitely needs a front-facing camera)

At runtime, you would use hasSystemFeature() on PackageManager, or interrogate the Camera class for available cameras, to determine what you have access to.

Note that if you want to record audio when recording videos, you should also consider the android.hardware.microphone feature.

Still Photos: Letting the Camera App Do It

The easiest way to take a picture is to not take the picture yourself, but let somebody else do it. The most common implementation of this approach is to use an ACTION_IMAGE_CAPTURE Intent to bring up the user’s default camera application, and let it take a picture on your behalf.

In theory, this is fairly simple:

- You call startActivityForResult() on an ACTION_IMAGE_CAPTURE Intent
- You either get a thumbnail photo back or — if you provided EXTRA_OUTPUT as an extra on the ACTION_IMAGE_CAPTURE Intent — a full-sized photo should be written to where you designated in EXTRA_OUTPUT

In practice, this gets complicated, in part because Android 7.0 is trying to get rid of file schemes on Uri values. As a result, EXTRA_OUTPUT cannot point to a file. Instead, it has to point to a ContentProvider, such as FileProvider.

To see this in use, take a look at the Camera/FileProvider sample project. This app will use system-supplied activities to take a picture, then view the result, without actually implementing any of its own UI.

Setting the Theme

Of course, we still need an activity, so our code can be launched by the user. We just set it up with Theme.Translucent.NoTitleBar, so no UI will be created for it:

```
<activity
    android:name=".MainActivity"
```
**USING THE CAMERA VIA 3RD-PARTY APPS**

```xml
<activity
    android:label="@string/app_name"
    android:theme="@android:style/Theme.Translucent.NoTitleBar">
    <intent-filter>
        <action android:name="android.intent.action.MAIN" />
        <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
</activity>
```

(from Camera/FileProvider/app/src/main/AndroidManifest.xml)

**Requesting the Feature**

Since our app is useless without a camera, we have the `<uses-feature>` element in the manifest stating that we need some sort of camera:

```xml
<uses-feature android:name="android.hardware.camera.any" />
```

(from Camera/FileProvider/app/src/main/AndroidManifest.xml)

This will prevent our app from being installed on a device that lacks a camera.

**Adding the FileProvider**

As noted earlier, Android 7.0 has a ban on file: Uri values, if your targetSdkVersion is 24 or higher. In particular, you cannot use a file: Uri in an Intent, whether as the “data” aspect of the Intent or as the value of an extra.

The proper way to implement this is to use a ContentProvider, such as a FileProvider, as is covered in [one of the chapters on providers](#). This is a fair bit more complicated, and not all camera apps will work well with a content: Uri, but our options are limited.

Our res/xml/provider_paths.xml metadata for the FileProvider indicate that we want to serve up the contents of the photos/ directory inside of getFilesDir(), with a Uri segment of /p/ mapping to that location:

```xml
<?xml version="1.0" encoding="utf-8"?>
<paths>
    <files-path
        name="p"
        path="photos" />
</paths>
```

(from Camera/FileProvider/app/src/main/res/xml/provider_paths.xml)
Using the Camera via 3rd-Party Apps

Our manifest now has a `<provider>` element for our FileProvider subclass, named LegacyCompatFileProvider:

```xml
<provider
    android:name="LegacyCompatFileProvider"
    android:authorities="${applicationId}.provider"
    android:exported="false"
    android:grantUriPermissions="true">
    <meta-data
        android:name="android.support.FILE_PROVIDER_PATHS"
        android:resource="@xml/provider_paths" />
</provider>
```

That element:

- Provides a pointer to that metadata resource, to configure FileProvider
- Uses the applicationId of this app as the basis of our authorities value, using a manifest placeholder
- Blocks access to third parties (android:exported="false") except where we explicitly grant permission in our Java code (android:grantUriPermissions="true")

LegacyCompatFileProvider is the same implementation as from the original discussion of FileProvider, using LegacyCompatCursorWrapper to help increase the odds that clients of this ContentProvider will behave properly:

```java
package com.commonsware.android.camcon;

import android.database.Cursor;
import android.net.Uri;
import android.support.v4.content.FileProvider;
import com.commonsware.cwac.provider.LegacyCompatCursorWrapper;

public class LegacyCompatFileProvider extends FileProvider {
    @Override
    public Cursor query(Uri uri, String[] projection, String selection, String[] selectionArgs, String sortOrder) {
        return new LegacyCompatCursorWrapper(super.query(uri, projection, selection, selectionArgs, sortOrder));
    }
}
```

Now we can start the work of taking pictures.
Taking a Picture

At this point, we can start using the provider, to give us a Uri that we can use with EXTRA_OUTPUT and an ACTION_IMAGE_CAPTURE Intent.

Our onCreate() method spends a lot of lines to eventually make that startActivityForResult() call:

```java
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (savedInstanceState==null) {
        output=new File(new File(getFilesDir(), PHOTOS), FILENAME);

        if (output.exists()) {
            output.delete();
        } else {
            output.getParentFile().mkdirs();
        }
    }

    Intent i=new Intent(MediaStore.ACTION_IMAGE_CAPTURE);
    Uri outputUri=FileProvider.getUriForFile(this, AUTHORITY, output);

    i.putExtra(MediaStore.EXTRA_OUTPUT, outputUri);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.LOLLIPOP) {
        i.addFlags(Intent.FLAG_GRANT_WRITE_URI_PERMISSION);
    } else if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.JELLY_BEAN) {
        ClipData clip=
            ClipData.newUri(getContentResolver(), "A photo", outputUri);

        i.setClipData(clip);
        i.addFlags(Intent.FLAG_GRANT_WRITE_URI_PERMISSION);
    } else {
        List<ResolveInfo> resInfoList=
            PackageManager().queryIntentActivities(i, PackageManager.MATCH_DEFAULT_ONLY);

        for (ResolveInfo resolveInfo : resInfoList) {
            String packageName = resolveInfo.activityInfo.packageName;
            grantUriPermission(packageName, outputUri,
                Intent.FLAG_GRANT_WRITE_URI_PERMISSION);
        }
    }
```
When we are first run, our savedInstanceState Bundle will be null. If it is not null, we know that we are coming back from some prior invocation of this activity, and so we do not need to call startActivityForResult() to take a picture.

First, we need a File pointing to where we want the photo to be stored. We create a directory inside of getFilesDir() (named photos via the PHOTOS constant), and in there identify a file (named CameraContentDemo.jpeg via the FILENAME constant).

Then, we create the ACTION_IMAGE_CAPTURE Intent, use FileProvider.getUriForFile() to get a Uri pointing to our desired File, then put that Uri in the EXTRA_OUTPUT extra of the Intent.

Now, though, we have to grant permissions to be able to write to that Uri.

If we are on Android 5.0+, calling addFlags(FLAG_GRANT_WRITE_URI_PERMISSION) not only affects the “data” aspect of the Intent, but also EXTRA_OUTPUT, due to a bit of a hack that Google added to the Intent class. So, that scenario is simple. The problem comes in with Android 4.4 and older devices, where addFlags(FLAG_GRANT_WRITE_URI_PERMISSION) does not affect Uri values passed in extras.

For Android 4.2 through 4.4, we can use a trick: while flags skip over Intent extras, flags do apply to a ClipData that you attach to the Intent via setClipData(). Even though the camera app will never use this ClipData, by wrapping our Uri in a ClipData and attaching that to the Intent, our addFlags(FLAG_GRANT_WRITE_URI_PERMISSION) will affect that Uri. The fact that the
camera app gets the Uri from EXTRA_OUTPUT, instead of from the ClipData, makes no difference.

For Android 4.1 and older devices, though, there is no means for us to simply indicate on the Intent itself that it is fine for the app handling our request to write to our Uri. Instead, we:

- Find all activities that support ACTION_IMAGE_CAPTURE, using PackageManager and queryIntentActivities()
- Iterate over all of them and call grantUriPermission(), inherited from Context, to allow the app to read and write from our Uri

This allows our Intent to succeed for any camera app... at least those that properly handle content: Uri values.

Finally, after all of that, we can call startActivityForResult(). However, in case the user does not have a camera app, we wrap that call in a try/catch block, watching for an ActivityNotFoundException.

**Saving the State**

In order to be able to save the File across configuration changes, we stuff it in the saved instance state Bundle in onSaveInstanceState():

```java
@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putSerializable(EXTRA_FILENAME, output);
}
```

(from Camera/FileProvider/app/src/main/java/commonsware/android/camcon/MainActivity.java)

This is what allows us to pull that value back out in onReady().

**Viewing the Photo**

Our onActivityResult() method then uses the same File, creating an ACTION_VIEW Intent, pointing at our output Uri, granting read permission on that Uri, indicating the MIME type is image/jpeg, and starting up an activity for that.

```java
@Override
protected void onActivityResult(int requestCode, int resultCode,
```
**USING THE CAMERA VIA 3RD-PARTY APPS**

```java
Intent data) {
    if (requestCode == CONTENT_REQUEST) {
        if (resultCode == RESULT_OK) {
            Intent i = new Intent(Intent.ACTION_VIEW);
            Uri outputUri = FileProvider.getUriForFile(this, AUTHORITY, output);

            i.setDataAndType(outputUri, "image/jpeg");
            i.addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);

            try {
                startActivity(i);
            }
            catch (ActivityNotFoundException e) {
                Toast.makeText(this, R.string.msg_no_viewer, Toast.LENGTH_LONG).show();
            }

            finish();
        }
    }
}
```

(from Camera/FileProvider/app/src/main/java/com/commonsware/android/camcon/MainActivity.java)

We do not have to fuss with the grantUriPermissions() loop, as addFlags() has always granted permission to the “data” aspect of the Intent (our Uri).

We wrap the startActivity() call in another try/catch block, watching for ActivityNotFoundException. Not all devices will have an image viewing app that supports a content Uri. For example, stock Android 5.1 (e.g., on a Nexus 4) will not have such an image viewer.

**The Caveats**

There are several downsides to this approach.

First, you have no control over the camera app itself. You do not even really know what app it is. You cannot dictate certain features that you would like (e.g., resolution, color effects). You simply blindly ask for a photo and get the result.

Also, since you do not know what the camera app is or behaves like, you cannot document that portion of your application's flow very well. You can say things like “at this point, you can take a picture using your chosen camera app”, but that is about as specific as you can get.

As noted above, it is possible that your app's process will be terminated while your app is not in the foreground, because the user is taking a picture using the third-party camera app. Whether or not this happens depends on how much system RAM the camera app uses and what else is all going on with the device. But, it does
happen. Your app should be able to cope with such things, just as we are doing with
the saved instance state Bundle. However, many developers do not expect their
process to be replaced between a call to startActivityForResult() and the
corresponding onActivityResult() callback.

Not every camera app will support a content Uri for the EXTRA_OUTPUT value. In fact,
Google's own camera app did not do this until the summer of 2016. With
ACTION_VIEW, since the content Uri is in the “data” facet of the Intent, the <intent-
filter> elements in the manifest will ensure that our Intent only goes to an activity
that advertises support for content. However, there is no equivalent of this for Uri
values in extras. And so we will launch the camera app, which then may crash
because it does not like our Uri, and our app does not really find out about the
problem, other than not getting RESULT_OK in onActivityResult().

Finally, some camera apps misbehave, returning odd results, such as a thumbnail-
sized image rather than a max-resolution image. There is little you can do about
this.

Permissions and Third-Party Camera Apps

The sample app shown above does not request any permissions — there are no
<uses-permission> elements in the manifest. While there is a CAMERA permission to
use the camera, we do not need it. The camera app that we are starting needs it.

However, you might need the CAMERA permission elsewhere in your app. For
example, you might be embedding some third-party scanning library, where it will
use the camera directly in your app.

In this case, on Android 6.0+, for apps with a targetSdkVersion of 23 or higher, even
though ACTION_IMAGE_CAPTURE itself does not normally need the CAMERA permission,
you cannot use ACTION_IMAGE_CAPTURE if the user has not granted the CAMERA
permission at runtime.

In other words:
A Matter of Orientation

When you take a picture using an Android device — whether using ACTION_IMAGE_CAPTURE or working with the camera APIs directly, you may find that your picture turns out strange. For example, you might take a picture in portrait mode, then find that some image viewers will show you a portrait picture, while others show you a landscape picture with its contents rotated.

That is due to the way Android camera hardware encodes the JPEG images that it takes. The orientation that you take the picture in may not be the orientation of the result.

EXIF Tags

JPEG images can have EXIF tags. These represent metadata about the image itself. For example, if you hear that an image has been “geotagged”, that means that the image has EXIF tags that contain the latitude and longitude of where the picture was taken.

These tags are contained in the JPEG file but are in a separate section from the actual image data itself. Tools can read in the EXIF tags and use them for additional information for the user (e.g., an image viewer with an integrated map to show where the picture was taken).

<table>
<thead>
<tr>
<th>If you do this...</th>
<th>...can you use ACTION_IMAGE_CAPTURE?</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you do not request the CAMERA permission</td>
<td>Yes</td>
</tr>
<tr>
<td>If you request the CAMERA permission, and your targetSdkVersion is below 23</td>
<td>Yes</td>
</tr>
<tr>
<td>If you request the CAMERA permission, and the user grants the runtime permission</td>
<td>Yes</td>
</tr>
<tr>
<td>If you request the CAMERA permission, and you have not yet asked the user for the runtime permission</td>
<td>No</td>
</tr>
<tr>
<td>If you request the CAMERA permission, and the user <strong>denies</strong> the runtime permission</td>
<td>No</td>
</tr>
</tbody>
</table>
EXIF Tags and Camera Images

One EXIF tag is the “orientation” tag. In effect, this tag is a message from whatever created the image (e.g., camera hardware) to whatever is showing the camera image, saying “could you please rotate this image for me? #kthxbye”.

In other words, the camera hardware is being lazy.

A lot of camera hardware is designed to take landscape images, particularly when using a rear-facing camera, as that is the traditional way that cameras were held by default, going back decades. In an ideal world, if the user took a portrait photo, the camera hardware would take a portrait picture. Or, at least, the camera hardware would take a landscape picture, but then rotate the image to be portrait before delivering the JPEG to whatever app requested the image.

Some camera hardware does just that.

However, other camera hardware leaves the image as a landscape image, regardless of how the device was held when the image was taken. Instead, the camera hardware will set the orientation tag to indicate how image viewers should rotate the image, to reflect what the image really should look like.

EXIF Tags and Android

Of course, this would not be a problem if all image viewers paid attention to the orientation tag. However, many do not, particularly on Android... because BitmapFactory ignores all EXIF tags. As a result, you get the unmodified image, instead of one rotated as the camera hardware requested.

And so, if you blindly load the image, it will show up without taking the orientation tag into account.

If you want to take the orientation tag into account, you need to find out the value of that tag. BitmapFactory will not help you here. However, ExifInterface can... though which ExifInterface you use is important.

android.media.ExifInterface that Android used for years has security flaws. Android 7.0+ devices should all ship with a patched version. Some Android 6.0 devices might get a patch. Everything else will go unpatched, and if your app uses android.media.ExifInterface, your app may expose the user to security risks.
Fortunately, alternative ExifInterface implementations exist, that not only avoid the security flaw, but also support InputStream as well as File. That is only available on android.media.ExifInterface starting with Android 7.0; older versions only supported a File, which is awkward in modern Android development.

The simplest solution for most developers would be to use the exifinterface artifact from the Android Support Library

```java
dependencies {
    implementation 'com.android.support:exifinterface:25.1.0'
}
```

This has the same API as does the Android 7.0+ edition of ExifInterface, including InputStream support.

However, for whatever reason, the API that Google has elected to expose through both of their supplied ExifInterface classes pales in comparison to the EXIF classes that they have elsewhere, such as the AOSP editions of the camera and gallery apps. A version of this code is available as an artifact published by Alessandro Crugnola and is demonstrated in the next section. If your EXIF needs are fairly limited, using the Google-supplied ExifInterface classes is simple. But even for something as seemingly simple as rotating an image, you need a more robust EXIF API.

**You Spin (Photos) Right Round**

The [Camera/EXIFRotater](https://github.com/azr/smartcam) sample project contains three images in assets/,, culled from [this GitHub repository](https://github.com/azr/smartcam) that supplements [this article on the problems with EXIF orientation handling](https://github.com/azr/smartcam). Specifically, we have images with orientation tag values of 3, 6, and 8, which are the most common ones that you will encounter.
The objective of this app is to show one of those images in its original form and rotated in accordance with the EXIF orientation tag:

![EXIF Rotater Sample App, with Original and Rotated Images](image)

However, there are two product flavors in this project, reflecting two different ways of getting that visual output: rotating the `ImageView` and rotating the image itself. These are controlled via a `ROTATE_BITMAP` value added to `BuildConfig`:

```java
productFlavors {
    image {
        dimension "default"
        buildConfigField "boolean", "ROTATE_BITMAP", "false"
    }
    matrix {
        dimension "default"
        buildConfigField "boolean", "ROTATE_BITMAP", "true"
    }
}
```

(from Camera/EXIFRotater/app/build.gradle)

The `MainActivity` kicks off an ImageLoadThread in `onCreate()`. That thread is responsible for loading (and, if appropriate, rotating) the image. When that is done,
the thread will post an ImageLoadedEvent to an event bus (using greenrobot's EventBus) to have the UI display the image (and, if needed, rotate a copy of it):

```java
private static class ImageLoadThread extends Thread {
    private final Context ctxt;
    ImageLoadThread(Context ctxt) {
        this.ctxt=ctxt.getApplicationContext();
    }

    @Override
    public void run() {
        AssetManager assets=ctxt.getAssets();

        try {
            InputStream is=assets.open(ASSET_NAME);
            ExifInterface exif=new ExifInterface();

            exif.readExif(is, ExifInterface.Options.OPTION_ALL);

            ExifTag tag=exif.getTag(ExifInterface.TAG_ORIENTATION);
            int orientation=(tag==null ? -1 : tag.getValueAsInt(-1));

            if (orientation==8 || orientation==3 || orientation==6) {
                is=assets.open(ASSET_NAME);

                Bitmap original=BitmapFactory.decodeStream(is);
                Bitmap rotated=null;

                if (BuildConfig.ROTATE_BITMAP) {
                    rotated=rotateViaMatrix(original, orientation);

                    exif.setTagValue(ExifInterface.TAG_ORIENTATION, 1);
                    exif.removeCompressedThumbnail();

                    File output=
                        new File(ctxt.getExternalFilesDir(null), "rotated.jpg");

                    exif.writeExif(rotated, output.getAbsolutePath(), 100);

                    MediaScannerConnection.scanFile(ctxt,
                        new String[]{output.getAbsolutePath()}, null, null);
                }

                EventBus
                    .getDefault()
                    .postSticky(new ImageLoadedEvent(original, rotated, orientation));
            }
        }
    }
```
We first get an InputStream on the particular image from assets/ that we are to show (hard-coded as the ASSET_NAME constant).

We then create an ExifInterface, using the richer implementation from the aforementioned artifact. This ExifInterface has a few versions of readExif(), including one that can take our InputStream as input. We can then get the orientation tag value via calls to getTag() (to get an ExifTag for TAG_ORIENTATION), then getValueAsInt(). The latter method retrieves an integer tag value, with a supplied default value if the tag exists but does not have an integer value.

However, it is also possible that the tag does not exist. In fact, many JPEG images will lack this header, implying that the image is already in the correct orientation. So, we use the ternary operator and the default value to getValueAsInt() to get either the actual orientation tag numeric value or –1 if, for any reason, we cannot get that value.

If the orientation is 3, 6, or 8, we will want to show the image. So, we use BitmapFactory to load the image, via decodeStream(). If ROTATE_BITMAP is true, we do five things:

1. We rotate the Bitmap itself using a Matrix, in the rotateViaMatrix() method:

```java
static private Bitmap rotateViaMatrix(Bitmap original, int orientation) {
    Matrix matrix = new Matrix();
    matrix.setRotate(degreesForRotation(orientation));
    return (Bitmap) Bitmap.createBitmap(original, 0, 0, original.getWidth(), original.getHeight(), matrix, true));
}
```

(from Camera/EXIFRotater/app/src/main/java/com/commonsware/android/exif/MainActivity.java)
1. We set the orientation tag to normal (1), reflecting the fact that we have oriented the image properly.
2. We remove any thumbnail from our EXIF metadata read from the original image.
3. We write the revised EXIF data and the rotated Bitmap to a file on external storage, so we have a JPEG showing the rotated results yet including all of the original EXIF tags (excluding the orientation tag and thumbnail).
4. We tell MediaScannerConnection to scan this newly-created file, so it shows up in file managers, both on-device and on-desktop.

If `ROTATE_BITMAP` is false, we instead handle the rotation in our `onImageLoaded()` method that is called when the `ImageLoadedEvent` is posted:

```java
@Subscribe(sticky=true, threadMode=ThreadMode.MAIN)
public void onImageLoaded(ImageLoadedEvent event) {
    original.setImageBitmap(event.original);

    if (BuildConfig.ROTATE_BITMAP) {
        oriented.setImageBitmap(event.rotated);
    } else {
        oriented.setImageBitmap(event.original);
        oriented.setRotation(degreesForRotation(event.orientation));
    }
}
```

Rather than show the rotated image in the lower `ImageView`, we show the original image, then rotate the `ImageView`.

Which of these two approaches — rotate the `ImageView` or rotate the image — is appropriate for you depends on your app. If all you need to do is show the image properly to the user, rotating the `ImageView` should be less memory-intensive. If, on the other hand, you need to save the corrected image somewhere for later use, you will need to rotate the image itself to make that correction.

**And Then, There Are the Bugs**

Some devices have buggy firmware, where they do not rotate the image themselves *nor* set the orientation tag in the image. Instead, they just ignore the whole issue. For these devices, we have no way of distinguishing between “images that need to be rotated, but we do not know the orientation” and “images that are fine and do not
need to be rotated”.

Your best option is to let the user manually request that the image be rotated (e.g., action bar “rotate” item).

**Scanning with ZXing**

If your objective is to scan a barcode, it is *much* simpler for you to integrate Barcode Scanner into your app than to roll it yourself.

**Barcode Scanner** – one of the most popular Android apps of all time — can scan a wide range of 1D and 2D barcode types. They offer an integration library that you can add to your app to initiate a scan and get the results. The library will even lead the user to the Play Store to install Barcode Scanner if they do not already have the app.

One limitation is that while the ZXing team (the authors and maintainers of Barcode Scanner) make the integration library available, they only do so in *source form*.

That sample project — **Camera/ZXing** – has a UI dominated by a “Scan!” button. Clicking the button invokes a `doScan()` method in our sample activity:

This passes control to Barcode Scanner by means of the integration JAR and the `IntentIntegrator` class. `initiateScan()` will validate that Barcode Scanner is installed, then will start up the camera and scan for a barcode.

Once Barcode Scanner detects a barcode and decodes it, the activity invoked by `initiateScan()` finishes, and control returns to you in `onActivityResult()` (as the Barcode Scanner scanning activity was invoked via `startActivityForResult()`). There, you can once again use `IntentIntegrator` to find out details of the scan, notably the type of barcode and the encoded contents:

```java
public void onActivityResult(int request, int result, Intent i) {
    IntentResult scan = IntentIntegrator.parseActivityResult(request,
                                                    result,
                                                    i);

    if (scan!=null) {
        format.setText(scan.getFormatName());
        contents.setText(scan.getContents());
    }
}
```
To use IntentIntegrator and IntentResult, the sample project has two modules: the app/ module for the app, and a zxing/ module containing those two classes (and a rump AndroidManifest.xml to make the build tools happy). The app/ module depends upon the zxing module via a implementation project(':zxing') dependency directive.

Some notes:

- Barcode Scanner's scanning activity only works in landscape
- Even though you are not using the camera directly yourself, you should consider including the <uses-feature> element declaring that you need a camera, if your app cannot function without barcodes
- If you wish to add Barcode Scanner logic directly to your app, and avoid the dependency on the third-party APK, that is possible, but the process for doing it is not well documented or supported

Videos: Letting the Camera App Do It

Just as ACTION_IMAGE_CAPTURE can be used to have a third-party app supply you with still images, there is an ACTION_VIDEO_CAPTURE on MediaStore that can be used as an Intent action for asking a third-party app capture a video for you. As with ACTION_IMAGE_CAPTURE, you use startActivityForResult() with ACTION_VIDEO_CAPTURE to find out when the video has been recorded.

There are two extras of note for ACTION_VIDEO_CAPTURE:

- MediaStore.EXTRA_OUTPUT, which indicates where the video should be written, and
- MediaStore.EXTRA_VIDEO_QUALITY, which should be an integer, either 0 for low quality/low size videos or 1 for high quality

If you elect to skip EXTRA_OUTPUT, the video will be written to the default directory for videos on the device (typically a "Movies" directory in the root of external storage), and the Uri you receive on the Intent in onActivityResult() will point to this file.

The impacts of skipping EXTRA_VIDEO_QUALITY are undocumented.
The Media/VideoRecordIntent sample project is a near-clone of the Camera/FileProvider sample from earlier in this chapter. Instead of requesting a third-party app take a still image, though, this sample requests that a third-party app record a video:

```java
package com.commonsware.android.videorecord;

import android.app.Activity;
import android.content.Intent;
import android.content.pm.PackageManager;
import android.content.pm.ResolveInfo;
import android.net.Uri;
import android.os.Build;
import android.os.Bundle;
import android.provider.MediaStore;
import android.support.v4.content.FileProvider;
import java.io.File;
import java.util.List;

public class MainActivity extends Activity {

    // Other variables...

    private void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (savedInstanceState==null) {
            output=new File(new File(getFilesDir(), VIDEOS), FILENAME);

            if (output.exists()) {
                output.delete();
            } else {
                output.getParentFile().mkdirs();
            }
        } else {
            output=(File)savedInstanceState.getSerializable(EXTRA_FILENAME);
        }
    }
}
```
outputUri = FileProvider.getUriForFile(this, AUTHORITY, output);

if (savedInstanceState == null) {
    Intent i = new Intent(MediaStore.ACTION_VIDEO_CAPTURE);

    i.putExtra(MediaStore.EXTRA_OUTPUT, outputUri);
    i.putExtra(MediaStore.EXTRA_VIDEO_QUALITY, 1);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
        i.addFlags(Intent.FLAG_GRANT_WRITE_URI_PERMISSION |
                    Intent.FLAG_GRANT_READ_URI_PERMISSION);
    } else {
        List<ResolveInfo> resInfoList =
            PackageManager().queryIntentActivities(i, PackageManager.MATCH_DEFAULT_ONLY);

        for (ResolveInfo resolveInfo : resInfoList) {
            String packageName = resolveInfo.activityInfo.packageName;

            grantUriPermission(packageName, outputUri,
                               Intent.FLAG_GRANT_WRITE_URI_PERMISSION |
                               Intent.FLAG_GRANT_READ_URI_PERMISSION);
        }
    }

    startActivityForResult(i, REQUEST_ID);
}

@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putSerializable(EXTRA_FILENAME, output);
}

@Override
protected void onActivityResult(int requestCode, int resultCode, Intent data) {
    if (requestCode == REQUEST_ID && resultCode == RESULT_OK) {
        Intent view =
            new Intent(Intent.ACTION_VIEW)
                .setDataAndType(outputUri, "video/mp4")
                .addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);

        startActivity(view);
    }
onCreate() of MainActivity starts by setting up a File object pointing to a sample.mp4 file in internal storage. If the file already exists, onCreate() deletes it; otherwise it ensures that the directory already exists. We then go through much of the same headache that we did in the ACTION_IMAGE_CAPTURE scenario, creating a Uri for our FileProvider that points to our designated File, ensures that the video-recording app has read/write access to our Uri, before finally calling startActivityForResult().

The call to startActivityForResult() will trigger the third-party app to record the video. When control returns to MainActivity, onActivityResult() creates an ACTION_VIEW Intent for the same Uri, then calls startActivity() to request that some app play back the video.

And, as before, we hold onto the File object via the saved instance state Bundle, and we only record the video if there is no such saved instance state Bundle, in case there is a configuration change causing our activity to be destroyed and recreated.

There is only one problem: this app is less likely to work on your device that did the ACTION_IMAGE_CAPTURE sample.

Camera apps need to be able to support content Uri values for EXTRA_OUTPUT for both still images and video. However, Google did not support this in their own camera app, decreasing the likelihood that anyone else supports it.

You can elect to use a file Uri, pointing to a location on external storage. However, that will require you to keep your targetSdkVersion at 23 or lower, as once you go above that, file Uri values are banned in Intent objects on Android 7.0.

**Using a Camera Library**

Relying upon third-party applications for taking pictures does introduce some challenges:

- Not all camera apps are created equal. Some implement ACTION_IMAGE_CAPTURE and ACTION_VIDEO_CAPTURE well... and others do not.
Some might only ever give you a thumbnail, or some might not support all valid Uri values for writing out the output, and so on.

- Even within “valid” output, there can be variances. One common variation is how portrait images are handled. Some camera apps will write out an image that is actually in portrait mode. Some camera apps will write out an image that is set up for landscape, but with an “EXIF header” in the JPEG data that tells image viewers to rotate the image to portrait. Unfortunately, not everything honors those headers, such as Android’s own BitmapFactory.

- If the camera app uses a lot of system RAM, your app may be kicked out of RAM while the user is taking a picture. This should not be a problem, as your app’s process is eligible to be terminated at any point when you are not in the foreground. However, it is a bit unexpected to think that taking a picture may cause you to have to switch to a fresh process.

The alternative to relying upon a third-party app is to implement camera functionality within your own app. For that, you have three major options:

1. Use the android.hardware.Camera API, added to Android way back in API Level 1, but marked as deprecated in API Level 21
2. Use the android.hardware.camera2 API, added to Android in API Level 21 as a replacement for android.hardware.Camera, but therefore is only useful on its own if your minSdkVersion is 21 or higher
3. Use some third-party library that wraps around one or both of those APIs

Using the native camera APIs is possible but difficult. However, there are a few libraries that simplify the process. Here, we will look at two of them: CameraKit-Android and Fotoapparat.

**CameraKit-Android**

Debuting in 2017, CameraKit-Android is an MIT-licensed library, making it convenient for both open source and proprietary development. It offers a fair bit of flexibility in a simple API. It supports both taking photos and recording videos. However:

- The library was handed off from previous maintainers to a new team, leaving many outstanding issues in limbo
- The documentation is incorrect for several features

The Camera/CameraKit sample project demonstrates using CameraKit-Android. It has a two-button UI in its MainActivity, where one button will trigger taking a...
Using the Camera via 3rd-Party Apps

picture, while the other button triggers recording a video.

Adding the Dependency

CameraKit-Android is published as the com.wonderkiln:camerakit-core artifact on JCenter. However:

- The library depends upon appcompat-v7, despite not using classes from there
- The library depends upon Google Play Services, though only for one particular method

Hence, the sample app uses Gradle to exclude those two transitive dependencies and instead depend upon support-compat, since the sample app it not using appcompat-v7 itself:

dependencies {
    implementation 'com.github.clans:fab:1.6.4'
    implementation 'com.githang:com-phillipcalvin-iconbutton:1.0.1@aar'
    implementation 'com.android.support:support-compat:27.0.2'
    implementation('com.wonderkiln:camerakit-core:0.13.1') {
        exclude group: 'com.android.support', module: 'appcompat-v7'
        exclude group: 'com.google.android.gms', module: 'play-services-vision'
    }
}

(from Camera/CameraKit/app/build.gradle)

The other two dependencies are for:

- An implementation of a floating action button (FAB), profiled in the chapter on the Design Support Library
- An icon button library, for use by the MainActivity

Adding the Preview Display

The actual photo- or video-taking activity is CameraActivity. It uses a camera.xml layout resource, which in our case contains a custom CameraView from CameraKit-Android, along with a FAB:

<?xml version="1.0" encoding="utf-8">
CameraKit-Android puts most of its configuration on its CameraView, whether via custom attributes or via corresponding getter/setter methods on the Java class. In this case, we are using the ckFlash attribute, indicating that we want flash mode to be enabled.

Other available attributes include:

- ckFacing, to indicate if you want the rear-facing (default) or front-facing camera
- ckFocus, to indicate what focus mode you want (defaults to continuous focus)
- ckJpegQuality, to indicate the quality factor to use when saving a photo as JPEG (defaults to 100, indicating maximum quality/maximum size)
- ckVideoQuality, to indicate the resolution of the video to capture, or to choose the highest-available or lowest-available resolution (defaults to a maximum of 480p, or 640x480)
- ckZoom, indicating that we want a pinch-to-zoom implementation, so pinch gestures control the camera’s zoom level
Permissions

If you do not request runtime permissions, CameraKit-Android will do that for you as part of displaying that CameraView. In the case of this sample app, MainActivity extends the AbstractPermissionActivity seen elsewhere in this book, and it requests three permissions:

- CAMERA, for using the camera
- WRITE_EXTERNAL_STORAGE, as this is where videos are recorded by default
- RECORD_AUDIO, needed for recording videos, as they also capture audio off of a microphone

Integrating with the Lifecycle

MainActivity invokes CameraActivity by means of two static methods on CameraActivity: takePhoto() and recordVideo(). These simply start up CameraActivity with EXTRA_IS_PHOTO indicating which mode the camera should use:

```java
public static void takePhoto(Activity requester, int requestCode) {
    Intent i = new Intent(requester, CameraActivity.class)
        .putExtra(EXTRA_IS_PHOTO, true);

    requester.startActivityForResult(i, requestCode);
}

public static void recordVideo(Activity requester, int requestCode) {
    Intent i = new Intent(requester, CameraActivity.class)
        .putExtra(EXTRA_IS_PHOTO, false);

    requester.startActivityForResult(i, requestCode);
}
```

(from Camera/CameraKit/app/src/main/java/com/commonsware/android/camera/CameraActivity.java)

In onCreate(), we load up our layout and retrieve the CameraView, holding onto it in a camera field:

```java
@Override
protected void onCreate(@Nullable Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.camera);

    isPhoto = getIntent().getBooleanExtra(EXTRA_IS_PHOTO, true);
}
```
In addition, we:

- Set up the FAB with the proper icon and action, depending upon whether we are taking a picture or recording a video
- Add a listener to the CameraView, as will be discussed shortly

We need to forward onPause() and onResume() events from the hosting activity or
Taking a Picture

Taking a picture with CameraKit-Android is merely a matter of calling captureImage():

```java
private void takePhoto() {
    camera.captureImage();
    fab.setEnabled(false);
}
```

When the picture is taken, the CameraKitEventListenerAdapter instance that we registered via addCameraKitListener() on the CameraView will be called with onImage(). We are handed a CameraKitImage object, which has getBitmap() and getJpeg() methods to give us the photo in memory. The latter is the original data off of the camera; the former returns a Bitmap created from that JPEG. Note that for a high-resolution image, you may not be able to create the Bitmap without running out of memory. In a real app, we would do something with the photo, such as saving it to disk on a background thread.

Recording a Video

To start recording a video, call start(); to stop recording a video, call stopVideo():

```java
private void recordVideo() {
    if (isRecording) {
        camera.stopVideo();
        finish();
    } else {
        fab.setColorNormalResId(R.color.recording);
        fab.setImageResource(R.drawable.ic_stop_black_24dp);
        isRecording=true;
        camera.start();
    }
}
```

When the video is taken, our listener will be called with onVideo(), where we are
given a CameraKitVideo object. That has a getFile() method, which contains a File object pointing to wherever the library elected to save the video. By default, this will be in your app’s getExternalFilesDir() location, so if your minSdkVersion is 19 or higher, you will not need the WRITE_EXTERNAL_STORAGE permission. A production app would do something with this file.

**Fotoapparat**

Also debuting in 2017, the Apache-licensed Fotoapparat has a similar flow to CameraKit-Android: add a custom View for the preview and call methods to take pictures. However:

- Fotoapparat puts most of the configuration on a Fotoapparat object
- The Fotoapparat API offers a few more features than does CameraKit-Android’s API, though with a somewhat funky fluent API
- As of January 2019, Fotoapparat only supports taking photos, not recording videos

The Camera/Fotoapparat sample project is a clone of the CameraKit-Android sample, with Fotoapparat as the camera library. Since Fotoapparat does not support recording videos, the code related to that was removed, and its button in the UI is disabled.

**Adding the Dependency**

The io.fotoapparat:fotoapparat:2.5.0 dependency used in this project supports the Android Support Library:

```kotlin
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.github.clans:fab:1.6.4'
    implementation 'com.githang:com-phillipcalvin-iconbutton:1.0.1@aar'
    implementation 'com.android.support:support-compat:28.0.0'
    implementation 'io.fotoapparat:fotoapparat:2.5.0'
}

android {
    compileSdkVersion 28

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 28
    }
}
```
Starting with 2.6.0, Fotoapparat has moved to using AndroidX dependencies.

Also note that Fotoapparat nowadays is implemented in Kotlin. A side effect of this is that you will wind up pulling in the Kotlin runtime library, even if your app otherwise is implemented in Java, not Kotlin.

Permissions

Fotoapparat will merge in the `<uses-permission>` element for the CAMERA permission to your manifest, but it does not attempt to request that permission at runtime. Apps using Fotoapparat have to handle that themselves, before attempting to use the camera.

The sample app uses the same `AbstractPermissionsActivity` as before, albeit only with the CAMERA permission, since that is the only one needed here.

Adding the Preview Display

Fotoapparat has its own `CameraView`. However, whereas CameraKit-Android puts its configuration on the `CameraView`, Fotoapparat does not. As a result, other than sizing and positioning the `CameraView` where you want it, little else is needed:
Configuring the Fotoapparat

However, what we remove from the layout goes into Java code. Specifically, Fotoapparat has a Fotoapparat class. We need to build an instance of a Fotoapparat and connect it to the CameraView.

CameraActivity handles this in onCreate():

```java
@override
protected void onCreate(@Nullable Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.camera);

    CameraView camera = findViewById(R.id.camera);

    fab = findViewById(R.id.fab);
    fab.setOnClickListener(view -> takePhoto());

    fotoapparat = Fotoapparat
        .with(this)
        .into(camera)
        .previewScaleType(ScaleType.CenterCrop)
        .photoResolution(ResolutionSelectorsKt.highestResolution())
        .lensPosition(LensPositionSelectorsKt.back())
        .focusMode(SelectorsKt.firstAvailable(
            FocusModeSelectorsKt.continuousFocusPicture(),
            FocusModeSelectorsKt.autoFocus(), FocusModeSelectorsKt.fixed()))
        .flash(SelectorsKt.firstAvailable(FlashSelectorsKt.autoRedEye(),
            FlashSelectorsKt.autoFlash()))
        .build();
}
```
The Fotoapparat API is designed for significant use of statically imported methods. This is akin to how libraries like JUnit and Espresso work, reducing the visual clutter of the main Java code at the cost of a bunch of additional import statements. In Fotoapparat’s case, these methods are actually Kotlin global functions, which Kotlin/JVM maps to static methods on generates classes based on the Kotlin filename.

Fotoapparat is also significantly more configurable than is CameraKit-Android. There are many more options, and more complex options, for controlling how the camera is used.

So, in onCreate(), we:

- Create a FotoapparatBuilder via with(), which takes a Context
- Tie it to the CameraView via into()
- Indicate that we want the camera preview to fill the available space, at the cost of cropping portions that do not match our CameraView aspect ratio, via previewScaleType(ScaleType.CenterCrop)
- Indicate that we want to take the highest resolution photo possible, via photoResolution(ResolutionSelectorsKt.highestResolution())
- Indicate that we want the rear-facing camera via lensPosition(LensPositionSelectorsKt.back())
- Request either continuous focus, auto-focus, or fixed focus, whichever one is available, via the focusMode() call
- Request either auto-redeye or auto flash, whichever one is available, via the flash() call

Then, we build() the Fotoapparat from the FotoapparatBuilder.

Methods like photoResolution(), focusMode(), and flashMode() take a “selector” object. Sometimes, that might be a specific setting (e.g., highestResolution() for photoResolution()). Sometimes, that might be more of a “functor” object, one that makes a decision of other selectors to use based upon availability (e.g., firstAvailable()). This leads to a very expressive API, at the cost of a fairly convoluted set of objects and methods — writing an API like this can get complicated rather quickly.

**Integrating with the Lifecycle**

As with CameraKit-Android, we need to forward lifecycle events along to the
Using the Camera via 3rd-Party Apps

Fotoapparat object. In this case, though, we need to forward onStart() and onStop(), not onPause() and onResume:

```java
@Override
protected void onStart() {
    super.onStart();
    fotoapparat.start();
}

@Override
protected void onStop() {
    fotoapparat.stop();
    super.onStop();
}
```

(from Camera/Fotoapparat/app/src/main/java/com/commonsware/android/camera/CameraActivity.java)

Taking a Picture

The Fotoapparat object has a takePicture() method which, as you might expect, takes a picture. It gives you back a PhotoResult object, which you can use to work with the resulting photo. In the sample app, we call toBitmap() on it, then use whenAvailable() to get a callback when the image is ready. This gives us a BitmapPhoto object, from which we can get the JPEG bytes, akin to the CameraKit-Android example:

```java
private void takePhoto() {
    fab.setEnabled(false);

    PhotoResult result = fotoapparat.takePicture();

    result.toBitmap().whenAvailable(bitmapPhoto -> {
        // TODO: do something with picture

        setResult(RESULT_OK);
        finish();

        return Unit.INSTANCE;
    });
}
```

(note: the return Unit.INSTANCE; in the lambda expression is there because this really is a Kotlin-defined function set to return Unit, so in Java we have to explicitly
have the return to specify the object to return)

If, however, your objective is to save the photo to a file, simply call `saveToFile()` on the `PhotoResult` object. This will asynchronously write your JPEG to the supplied `File` location, and it returns a `PendingResult`, as `toBitmap()` does, for you to attach a callback to find out when the save operation is complete.

**Directly Working with the Camera**

Of course, you can bypass these third-party apps and libraries, electing instead to work directly with the camera if you so choose. This is very painful, as will be illustrated in the next chapter.
Letting third-party apps take the pictures and videos for you is all well and good, but there will be times where you need more control than that. It is possible for you to work directly with the device cameras. However, doing is exceptionally complicated.

Part of that complexity is because Android presently has three separate APIs for working with the camera:

- `android.hardware.Camera` for taking still photos
- `android.hardware.camera2` for taking still photos on Android 5.0+ devices
- `MediaRecorder` for recording videos

This chapter will attempt to outline the basic steps for using these APIs.

**Prerequisites**

This chapter assumes that you have read the previous chapter covering Intent-based uses of the camera and the chapter on audio recording.

**Notes About the Code Snippets**

The code snippets shown in this chapter are here purely to illustrate how to call certain APIs. They are not from any particular sample project, as a sample project small enough to fit in a book would be riddled with bugs and limitations.

**A Tale of Two APIs**

As noted in the introduction to this chapter, there are three APIs for working with
the camera. One — MediaRecorder — is focused purely on recording videos. It relies on you using one of the other two APIs for setting up the camera preview, so the user can see what will be recorded. Those other two APIs exist for taking still photos, where one (android.hardware.camera2) is substantially newer.

**android.hardware.Camera**

The original camera API is based around the android.hardware.Camera class.

(NOTE: there is another Camera class, in android.graphics, that is not directly related to taking pictures)

Instances of this class represent an open camera, where you call methods on the Camera to do things like take pictures. You also work extensively with a Camera.Parameters object, where you can determine a number of key characteristics about the camera (e.g., what the available resolutions are for pictures) and set up the particular results that you want.

This API works on all Android devices.

**android.hardware.camera2**

The original camera API worked, albeit with some difficulty. However, it was fairly limited, as it was designed primarily around the smartphone camera capabilities of 2005-2010. Nowadays, device manufacturers have access to much more powerful camera modules from chipset manufacturers like Qualcomm. Android needed a more powerful API to accommodate the current hardware, and a more flexible API to be able to adjust to changes over time.

Hence, Android 5.0 brought a new API, based on a series of classes in the android.hardware.camera2 package. On the plus side, these offer much greater capability. They are also designed with asynchronous work in mind, off-loading slow or complex operations onto background threads for you. However, on the whole, the API is more complicated, much less documented, and substantially different than the original API.

It is also only available on Android 5.0 devices. If your minSdkVersion is 21 or higher, that is not a problem. If, however, you are aiming to support older devices than that, you have two choices:

1. Stick with the original API for all devices
2. Use the original API for older devices and the newer API for newer devices

The latter might allow you to offer more features to users of those newer devices, but it does roughly double the work required to implement camera logic in your app.

**MediaRecorder**

MediaRecorder is responsible for both audio recording and video recording. MediaRecorder has a fairly limited API, one that has not changed substantially since 2011. However, if you use it carefully, it works. It works in tandem with either camera API — you use the camera APIs to show the user what will be recorded, and you use MediaRecorder to actually do the recording.

However, MediaRecorder has a number of issues, such as a fair bit of delay between when you ask it to begin recording and when it actually begins recording. This makes it a poor choice for fast-twitch video recording purposes. Some apps, notably Vine, have elected to skip using MediaRecorder. Instead, they use the regular camera APIs. These APIs, among other things, give you access to the preview frames that are used to show the user what is visible through the camera lens. With a fair amount of work, you can stitch those together into a video. Needless to say, this is a beyond-advanced topic that is well outside the scope of this book.

**The APIs That You (Probably) Can’t Use**

The aforementioned APIs are all part of the Android SDK. For camera apps that ship with devices, those apps are not limited to these APIs. Device manufacturers are welcome to create apps that use internal proprietary APIs for their devices.

Hence, when it comes to determining what is and is not possible through the camera APIs, it is important to compare to other third-party camera apps, more so than manufacturer-supplied apps. Manufacturers can “cheat”; you cannot.

**Performing Basic Camera Operations**

Cameras have some key functionality:

- Showing a preview to the user, so the user can see in real time what the camera lens sees, so the user can frame a picture
- Take a still picture
- Record a video
In the following sections, we will outline what is required to perform these operations using the various APIs.

Permissions

First, you need permission to use the camera. That way, when end users install your application, they will be notified that you intend to use the camera, so they can determine if they deem that appropriate for your application.

You simply need the `CAMERA` permission in your `AndroidManifest.xml` file, along with whatever other permissions your application logic might require.

If you plan to record video, using `MediaRecorder`, you will also want to request the `RECORD_AUDIO` permission.

And, if you were planning on storing pictures or videos out on external storage, you probably need the `WRITE_EXTERNAL_STORAGE` permission. The exception would be if your `minSdkVersion` is 19 or higher and you are only storing those files in locations that are automatically read/write for your app, such as `getExternalFilesDir()` or `getExternalCacheDir()`.

Note that all three of these permissions (`CAMERA`, `RECORD_AUDIO`, and `WRITE_EXTERNAL_STORAGE`) are part of the Android 6.0 runtime permission system. If your app has a `targetSdkVersion` of 23 or higher, you will need to request those permissions at runtime. If your app has a lower `targetSdkVersion`, while you will not have to do anything special for your app, bear in mind that the user can still revoke your access to those capabilities, and so you may find lots of devices that claim to support a camera but just do not seem to have any cameras available when you try to use one.

Features

Your manifest also should contain one or more `<uses-feature>` elements, declaring what you need in terms of camera hardware. By default, asking for the `CAMERA` permission indicates that you need a camera. More specifically, asking for the `CAMERA` permission indicates that you need an auto-focus camera.

The following sections outline some common scenarios and how to handle them.
A Camera is Optional

If you would like a camera, but having one is not essential for the use of your app, put the following `<uses-feature>` element in your manifest:

```xml
<uses-feature android:name="android.hardware.camera" android:required="false" />
```

This indicates that you would like a camera, but it is not required. This reverses the default established by the `CAMERA` permission.

A Camera is Required

Technically, you would not need any `<uses-feature>` element in your manifest to indicate that you need a camera, as the `CAMERA` permission would handle that for you. However, it is good form to explicitly declare it anyway:

```xml
<uses-feature android:name="android.hardware.camera" android:required="true" />
```

Not only does that make your manifest more self-documenting, but it also helps protect you in case the default behavior of the `CAMERA` permission changes.

Other Camera Features

There are three other camera features that you could consider having `<uses-feature>` elements for:

1. `android.hardware.camera.autofocus`, to indicate whether or not the device needs a camera with auto-focus capability.
2. `android.hardware.camera.flash`, to indicate whether or not the device must support a camera flash.
3. `android.hardware.camera.front`, to indicate whether or not the app needs a front-facing camera specifically (the `android.hardware.camera` requests a rear-facing camera).

Of these, the only one you should definitely include in your app is `android.hardware.camera.autofocus`, once again because of the default effects of requesting the `CAMERA` permission. In particular, if you do not absolutely need auto-focus capabilities, you can use `android:required="false"` to reverse the `CAMERA` default requirement.
Finding Out What Cameras Exist

Some devices will have just a rear-facing camera. Some will have just a front-facing camera. Some will have both cameras. Some will have no cameras. And, in theory at least, some could have yet more camera options.

At some point, you are likely to need to find out what cameras exist on the device that you are running on. Perhaps you need a particular camera (e.g., a front-facing camera for your “selfie”-focused app). Or, perhaps you want to allow your users to switch between cameras on the fly.

android.hardware.Camera

The simplest way to choose a camera is to not choose at all, and arrange to open the default camera. That default camera is the first rear-facing camera on the device. However, devices that have no rear-facing cameras effectively have no default camera, and so going with the default is rarely the correct choice. Instead, you should iterate over the available cameras, to find the one that you want.

To find out how many cameras there are for the current device, you can call the static getNumberOfCameras() method on the Camera class.

To find out details about a particular camera, you can call the static getCameraInfo() method on Camera. This takes two parameters:

- the ID of the camera to open, which will be a number from 0 to the number of available camera minus 1
- a Camera.CameraInfo object, into which getCameraInfo() will pour details about the camera

The most notable field on Camera.CameraInfo is facing, which tells you if this is a rear-facing (Camera.CameraInfo.CAMERA_FACING_BACK) or front-facing (Camera.CameraInfo.CAMERA_FACING_FRONT) camera.

For example, the following code snippet could be used to identify the first front-facing camera:

```java
int chosen=-1;
int count=Camera.getNumberOfCameras();
Camera.CameraInfo info=new Camera.CameraInfo();
```
for (int cameraId=0; cameraId < count; cameraId++) {
    Camera.getCameraInfo(cameraId, info);
    if (info.facing==Camera.CameraInfo.CAMERA_FACING_FRONT) {
        chosen=cameraId;
        break;
    }
}

If chosen remains at a value of -1, you know that there is no front-facing camera available to you, and you would need to decide how you wish to proceed, if you really wanted such a camera.

**android.hardware.camera2**

With the original camera API, your main entry point is the Camera class. With the Android 5.0+ camera API, your main entry point is a CameraManager. This is another system service, one you can retrieve by calling getSystemService() on a Context, asking for the CAMERA_SERVICE:

    CameraManager mgr =
        (CameraManager)ctxt.getSystemService(Context.CAMERA_SERVICE);

You will notice here that we are specifically calling getSystemService() on the Application context. That is because there is a bug in Android 5.0 where CameraManager leaks the Context that creates it. This bug has been fixed in Android 5.1. However, to be safe, you are better off retrieving this system service via the singleton Application object, as there is no risk of a memory leak (singletons are “pre-leaked”, as it were).

Given a CameraManager, you can call getCameraIdList() to get a list of camera IDs. These are strings, not integers as they were with the original camera API.

To learn more about the camera, you can ask the CameraManager to give you a CameraCharacteristics object for a given camera ID. The CameraCharacteristics object has all sorts of information about the camera, including what direction it is facing. CameraCharacteristics behaves a lot like a HashMap, in that you use get() and a key to retrieve a value, such as CameraCharacteristics.LENS_FACING to determine the camera's facing direction.
WORKING DIRECTLY WITH THE CAMERA

So, the code snippet for the first front-facing camera using a CameraManager named mgr, would be something like:

```java
String chosen = null;
for (String cameraId : mgr.getCameraIdList()) {
    CameraCharacteristics cc = mgr.getCameraCharacteristics(cameraId);
    if (cc.get(CameraCharacteristics.LENS_FACING) == CameraCharacteristics.LENS_FACING_FRONT) {
        chosen = cameraId;
        break;
    }
}
```

Here, a value of null would indicate that there is no available front-facing camera.

Opening and Closing a Camera

Once you decide which camera you wish to use, you will eventually need to “open” it. This gives your app access to that camera, and blocks other app's access while you have it open. You need to open a camera before you can use that camera to take pictures, record video, etc.

Eventually, when you are done with the camera, you should close it, to allow other apps to have access to the camera again. If you fail to close it, until your process is terminated, the camera is inaccessible.

android.hardware.Camera

Old code samples would open the camera by calling a zero-parameter static open() method on the Camera class. This opens the default camera, and as noted above, this is rarely a good idea. However, it is your only option on API Level 8 and below, if you are still supporting such devices, as those devices only supported a single camera.

Instead, if you have the ID of the camera that you wish to open, call the one-parameter static open() method, passing in the ID of the camera.

Both flavors of open() return an instance of Camera, which you can hold onto in your activity or fragment that is working with the camera.

While you have access to this camera, no other process can. Hence, it is important to
release the camera when you are no longer needing it. To release the camera, call
release() on your Camera instance, after which it is no longer safe to use the
camera. A common pattern is to open() the camera in onStart() or onResume() and
release() it in onPause() or onStop(), so you tie up the camera only while you are
in the foreground.

android.hardware.camera2

Opening and closing a camera is a lot more complicated with the Android 5.0+
camera API.

Partly, that complexity seems to be due to a threading limitation with
CameraManager — while we want to do long tasks related to the camera on
background threads, CameraManager itself is not free-threaded when it comes to
opening and closing cameras. Hence, we need to use some form of thread
synchronization to make sure that we are not trying to open and close cameras
simultaneously.

Partly, that complexity is that the way that CameraManager deals with background
operations is via a Handler tied to a HandlerThread. HandlerThread, as the name
suggests, is a Thread which has all the associated bits to support a Handler. The
main application thread itself is a HandlerThread (or, close enough), but we
specifically want to use a background thread, so we do not tie up the main
application thread. So, we need to create and manage our own HandlerThread and
Handler.

So, the first thing you will need to do is set up a HandlerThread, such as in a data
member of some class:

```java
final private HandlerThread handlerThread=new HandlerThread(NAME,
                      android.os.Process.THREAD_PRIORITY_BACKGROUND);
```

Here, NAME is some string to identify this thread (used in places like the list of
running threads in DDMS). The second parameter is the thread priority; in general,
you want your own HandlerThread instances to have background priority.

Creating the HandlerThread instance does not actually start the thread, any more
than creating a Thread object starts the thread. Instead, you need to call start()
when you want the thread to begin working its message loop. Any time after this
point, it is safe to create a Handler for that HandlerThread, by getting theLooper
from the HandlerThread and passing it to the Handler constructor:
handlerThread.start();
handler = new Handler(handlerThread.getLooper());

(You might wonder why a class named HandlerThread, designed to work with a Handler, lacks any methods to give you such a Handler. Lots of people wonder this, so you are not alone.)

Next, to actually open the camera, you will need to call openCamera() on your CameraManager, supplying:

- the ID of the camera that you wish to open
- a CameraDevice.StateCallback instance
- the Handler that you created for your HandlerThread

But, we want to make sure that we are not trying to open or close another camera while all of this is going on, so we need to use some sort of Java thread synchronization for that, such as a Semaphore:

```java
final private Semaphore lock = new Semaphore(1);
```

Then, we can consider opening the camera, once we obtain the lock:

```java
if (!lock.tryAcquire(2500, TimeUnit.MILLISECONDS)) {
    throw new RuntimeException("Time out waiting to lock camera opening.");
}

mgr.openCamera(cameraId, new DeviceCallback(), handler);
```

You will notice that we do not release the lock here, as we need to keep the lock until the camera has completed opening.

CameraDevice.StateCallback is an abstract class, so we usually have to create some dedicated subclass for it. There are three abstract methods that we will need to implement: onOpened(), onError(), and onDisconnected(). Plus, we will typically want to implement onCloseed(), even though there is a default implementation of this callback.

onOpened() will be called when the camera is open and is ours to use. We are passed a CameraDevice object representing our open camera, and it is our job to hold onto this device while we have the camera open. The big thing that we need to do in onOpened() is release that lock that we obtained when we tried opening the camera. This is also a fine time to consider starting to show camera previews to the user, and
we will see how to do that in upcoming sections of the book.

**onError()** will be called if there is some serious error when trying to open or use the camera. We are passed an error code to indicate what sort of problem we encountered. It could be that the camera is already in use (ERROR_CAMERA_IN_USE), or that while the camera exists, we do not have access to it due to device policy (ERROR_CAMERA_DISABLED), or that there was a general problem with this specific camera (ERROR_CAMERA_DEVICE) or with the overall camera engine (ERROR_CAMERA_SERVICE).

**onDisconnected()** will be called if we no longer can use the camera, for reasons other than our closing it ourselves. We are supposed to close the **CameraDevice**, if we have one, as the camera is no longer usable.

To close the camera, whether in response to **onDisconnected()** or because you are simply done with the camera, call **close()** on the **CameraDevice**, inside of the **lock**:

```java
try {
    lock.acquire();
    cameraDevice.close();
    cameraDevice=null;
}finally {
    lock.release();
}
```

Note that **close()** is a synchronous call, and so we can **release()** our lock in a **finally** block.

Our **CameraDevice.StateCallback** will be called with **onClosed()**, to let us know that the close operation has completed.

### Setting Up a Preview Surface

The camera preview is basically a stream of images, taken by the camera, usually at less than full resolution. Mostly, that stream is to be presented to the user on the screen, to help them “see what the camera sees”, so they can line up the right picture.

For presenting the preview stream to the user, there are two typical solutions: **SurfaceView** and **TextureView**.
SurfaceView for the Camera

SurfaceView is used as a raw canvas for displaying all sorts of graphics outside of the realm of your ordinary widgets. In this case, Android knows how to display a live look at what the camera sees on a SurfaceView, to serve as a preview pane. A SurfaceView is also used for video playback, and a variation of SurfaceView called GLSurfaceView is used for OpenGL animations.

That being said, SurfaceView is a subclass of View, and so it can be added to your UI the same as any other widget:

- Include it in a layout
- Return it as the View from onCreateView() of a Fragment
- Instantiate it in Java and add it to some container via addView()
- Etc.

If your app will support API Level 10 and older, you will want to call getSurfaceHolder().getType(SurfaceHolder.SURFACE_TYPE_PUSH_BUFFERS) on the SurfaceView. A “push buffers” SurfaceView is one designed to have images pushed to the surface, usually from video playback or camera previews. A SurfaceHolder is a quasi-controller object for the SurfaceView — most interactions with the SurfaceView come by way of the SurfaceHolder. This bit of configuration is not needed on API Level 11 and higher, as Android handles it for us automatically as the SurfaceView is put to use.

TextureView for the Camera

SurfaceView, however, has some limitations. This is mostly tied back to the way it works, by “punching a hole” in the UI to allow some lower-level component (like the camera) to render stuff into it. While there is a transparent layer on top of this “hole”, for use in alpha-compositing in any overlapping widgets, the SurfaceView content is not rendered as part of the normal view hierarchy. The net effect is that you cannot readily move, animate, or otherwise transform a SurfaceView.

TextureView was added in API Level 14 and works for camera previews as of API Level 15. TextureView serves much the same role as does SurfaceView, for showing camera previews, playing videos, or rendering OpenGL scenes. However, TextureView behaves as a regular View and so therefore can be animated and such without issue.

However, the cost is in performance. TextureView relies upon the GPU to do more
work, and therefore TextureView is a bit less performant than is a SurfaceView. Most camera apps will not show a difference.

**Showing the Previews**

To show previews, you need to create your surface (SurfaceView or TextureView) and have it be part of your UI. Then, you can teach your opened camera to show previews on that surface.

`android.hardware.Camera`

The biggest thing that we need to do in the original camera API to configure the preview is determine what size of preview images should be used. Devices cannot support arbitrary-sized previews. Instead, we need to ask the camera what preview sizes it supports, choose one, then configure the camera to use that specific preview size.

To do any of this, we need the `Camera.Parameters` associated with our chosen and open `Camera`. `Camera.Parameters` serves two roles:

- It tells us what is possible, in terms of camera capabilities, above and beyond the limited information reported by `Camera.Info`
- It is where we stipulate what behavior we want, by updating the parameters and associating the updated parameters with the `Camera`

Getting the `Camera.Parameters` object from a `Camera` is a simple matter of calling `getParameters()`.

To find out what the valid preview sizes are, we can call `getSupportedPreviewSizes()` on the `Camera.Parameters` object. This will return a List of `Camera.Size` objects, with each `Camera.Size` holding a width and a height as integers.

Choosing a preview size is a bit of an art form. Too big of a preview size is wasteful from a performance standpoint. Too small of a preview size results in a grainy preview. And, as will be seen later in this chapter, the difference in aspect ratio between your surface and your preview size will need to be taken into account. We will explore choosing preview sizes a bit more later in this chapter. For the moment, assume that we have sifted through the available preview sizes and have chosen something suitable. Whatever size you choose, you can pass to `setPreviewSize()` on the `Camera.Parameters`. 
Then, you can call `setParameters()` on the Camera, passing in your modified `Camera.Parameters` object, to affect this change.

You will wind up with a block of code resembling:

```java
Camera.Parameters parameters = camera.getParameters();
Camera.Size previewSize = chooseSomePreviewSize(parameters.getSupportedPreviewSizes());
parameters.setPreviewSize(previewSize.width, previewSize.height);
camera.setParameters(parameters);
```

(where `chooseSomePreviewSize()` is a method of your own design)

Given that, in principle, there are just three more steps:

1. Attach your preview surface to the Camera by calling `setPreviewDisplay()` (if you are using a `SurfaceView`) or `setPreviewTexture()` (if you are using a `SurfaceTexture`)
2. Show the preview on-screen by calling `startPreview()` on the Camera
3. Stop showing the preview by calling `stopPreview()` on the Camera

However, timing is important.

You also cannot call `setPreviewDisplay()` or `startPreview()` before your preview surface is ready. To know when that is, you will need to register a listener with your surface:

- You can register a `SurfaceHolder.Callback` with the `SurfaceHolder` of your `SurfaceView` by calling `addCallback()` on the `SurfaceHolder`. Your `SurfaceHolder.Callback` will be called with `surfaceChanged()` when the surface is ready for use, at which point it is safe to call `setPreviewDisplay()` and `startPreview()`.
- You can register a `TextureView.SurfaceTextureListener` with your `TextureView` by means of the `setSurfaceTextureListener()` call. Your `TextureView.SurfaceTextureListener` will be called with `onSurfaceTextureAvailable()` at the point in time when it is safe to call `setPreviewTexture()` and `startPreview()`.

You also need to stop the preview before you `release()` the Camera. And, as we will see later in this chapter, you also need to restart your preview after taking a photo.
Once the camera is opened — even right from within the `onOpened()` method of your `CameraDevice.StateCallback` — you can request to have preview frames be pushed to your desired preview surface.

First, strangely enough, you are going to need to choose the resolution of the picture that you wish to take. You might think that this would be delayed until a later point, such as when we actually go to take a picture, but the API seems to want it right away.

To find out the possible resolutions, you need to request a `StreamConfigurationMap` from the `CameraCharacteristics`:

```java
CameraCharacteristics cc = mgr.getCameraCharacteristics(cameraId);
StreamConfigurationMap map = cc.get(CameraCharacteristics.SCALER_STREAM_CONFIGURATION_MAP);
```

(where `cameraId` is the ID of the camera that you are working with)

From there, you can get an array of `Size` objects via a call to `getOutputSizes()`. Curiously, `getOutputSizes()` takes a Java class object, identifying the use case for the frames to be generated by the camera. So, passing `SurfaceTexture.class` would give you preview frame resolutions, but passing `ImageFormat.JPEG` would give you picture resolutions (at least, for images to be encoded in JPEG format).

So, you can get your roster of available picture sizes via:

```java
CameraCharacteristics cc = mgr.getCameraCharacteristics(cameraId);
StreamConfigurationMap map = cc.get(CameraCharacteristics.SCALER_STREAM_CONFIGURATION_MAP);
Size[] rawSizes = map.getOutputSizes(ImageFormat.JPEG);
```

From there, you will need to choose a size. This process can be a bit interesting; some notes about it appear [later in this chapter](#). But, for example, you might choose the size that is the highest resolution, as determined by the total area (width times height).

Next, you are going to need to set up an `ImageReader`. Typically this is done via the `newInstance()` factory method, which takes four parameters:

- The width and height of the desired resolution of the `picture` that you wish
to later take with the camera

- The image format to use (e.g., `PixelFormat.JPEG`) for those pictures
- How many simultaneous frames will be needed (typical value: 2)

```java
ImageReader reader = ImageReader.newInstance(pictureSize.getWidth(),
                                               pictureSize.getHeight(), pictureFormat, 2);
```

Then, you need a `Surface` associated with your preview surface. For example, you can call `getSurfaceTexture()` on a `TextureView` to get a `SurfaceTexture`, then pass it to the `Surface` constructor to get the associated `Surface` object.

Next, you can call `createCaptureSession()` on the `CameraDevice` representing the opened camera. This takes three parameters:

- An `ArrayList` of `Surface` objects, for every places that the camera driver needs to route frames towards. Typically, you will have two elements in this list: the `Surface` for your preview surface and the `Surface` that you get from your `ImageReader` by calling `getSurface()` on it.
- A `CameraCaptureSession.StateCallback` instance, to be notified about state changes in the frame-capturing process
- The `Handler` tied to your `HandlerThread`

```java
cameraDevice.createCaptureSession(Arrays.asList(surface, reader.getSurface()),
                                   new PreviewCaptureSession(), handler);
```

(Where `PreviewCaptureSession` is some subclass of `CameraCaptureSession.StateCallback`)

That actually does not begin the previews. Instead, it configures the camera to indicate that it is possible to do previews.

To continue the work for getting the previews rolling, in the `onConfigured()` callback method on your `CameraCaptureSession.StateCallback`, you can create a `CaptureRequest.Builder` that you can use for configuring the camera to capture preview frames. You get one of those by calling `createCaptureRequest()` on the `CameraDevice`, passing in an `int` indicating the general type of request that you are creating, such as `TEMPLATE_PREVIEW` for preview frames:

```java
CaptureRequest.Builder b =
cameraDevice.createCaptureRequest(CameraDevice.TEMPLATE_PREVIEW);
```
You then call `addTarget()` on the Builder, supplying the Surface onto which the captured frames will be written. For previews, that target is the Surface associated with your preview surface.

You can also call `set()` on the Builder to configure various options that you would like for the camera, such as auto-focus modes, flash modes, and the like. The code snippet shown below demonstrates setting up “continuous picture” auto-focus mode and having the auto-exposure mode engage the flash as needed.

Eventually, you ask the `CaptureRequest.Builder` to `build()` you a `CaptureRequest`, and you pass that to `setRepeatingRequest()` on the `CameraCaptureSession` that is passed into `onConfigure()` of your `CameraCaptureSession.StateCallback`:

```java
@Override
public void onConfigured(CameraCaptureSession session) {
    try {
        CaptureRequest.Builder b =
            cameraDevice.createCaptureRequest(CameraDevice.TEMPLATE_PREVIEW);

        b.addTarget(surface);
        b.set(CaptureRequest.CONTROL_AF_MODE,
              CaptureRequest.CONTROL_AF_MODE_CONTINUOUS_PICTURE);
        b.set(CaptureRequest.CONTROL_AE_MODE,
              CaptureRequest.CONTROL_AE_MODE_ON_AUTO_FLASH);

        // other Builder configuration goes here
        CaptureRequest previewRequest = b.build();

        session.setRepeatingRequest(previewRequest, null, handler);
    } catch (CameraAccessException e) {
        // do something
    } catch (IllegalStateException e) {
        // do something
    }
}
```

`setRepeatingRequest()` takes three parameters:

- the `CaptureRequest` created by the Builder
- an optional `CameraCaptureSession.CaptureCallback` object to be notified about frame captures
- the `Handler` associated with your `HandlerThread`
Note that you will want to hold onto the `CaptureRequest.Builder` that you created here, as you will want it again when it comes time to take a picture.

When you go to `close()` the `CameraDevice`, before you do so, you must also close up the previews. You do this by calling `close()` on the `CameraCaptureSession` and `close()` on your `ImageReader`.

**Taking a Picture**

At some point, you will want to take a picture. Typically, this is based on user input, though it would not have to be. Taking a picture not only involves telling the camera to capture a picture (typically at a different resolution than the previews), but also to arrange to get that written out to disk somewhere as a JPEG file.

`android.hardware.Camera`

Taking a photo with a `Camera` is a matter of calling `takePicture()` on the `Camera` object. There are two flavors of `takePicture()`, for which three parameters are in common:

- a `Camera.ShutterCallback`, which will be called the moment the picture is taken, so that you can customize the “shutter” sound
- two `Camera.PictureCallback` objects, for raw (uncompressed) and JPEG photo data, where relatively few devices support raw images using the original camera API

The four-parameter version of `takePicture()` also takes a third `Camera.PictureCallback`, to be called when “a scaled, fully processed postview image is available”. This explanation probably means something to somebody, but the author of this book has no idea what it means.

You cannot call `takePicture()` until after `startPreview()` has been called to set up a preview pane. `takePicture()` will automatically stop the preview. At some point, if you want to be able to take another photo, you will need to call `startPreview()` again. Note, though, that you cannot call `startPreview()` until after the final compressed photo has been delivered to your `Camera.PictureCallback` object.

Before you call `takePicture()`, you are going to want to adjust the `Camera.Parameters` to configure how the photo should be taken. The primary setting to adjust is the size of the picture to take. Just as you ask `Camera.Parameters` for available preview sizes and choose one, you can call...
getSupportedPictureSizes(), which returns a List of Camera.Size objects. You can then choose a size and pass its width and height to setPictureSize() on the Camera.Parameters. Other things to potentially adjust include:

- flash mode (getSupportedFlashModes() and setFlashMode())
- focus mode (getSupportedFocusModes() and setFocusMode())
- white balance (getSupportedWhiteBalance() and setWhiteBalance())
- geo-tagging (setGpsLatitude(), setGpsLongitude(), setGpsAltitude(), etc.)
- JPEG image quality (setJpegQuality())
- and so on

Note that calling setParameters() multiple times seems to lead to camera instability. Ideally, you collect all your desired settings from the user up front, then call setParameters() once when you set up your preview size. If you need to change parameters, you may wish to consider closing and re-opening the camera.

The Camera.PictureCallback will be called with onPictureTaken() and will be handed a byte array representing the picture. Typically, you will supply a PictureCallback for JPEG images, and so the byte array will represent the photo encoded in JPEG. At this point, you can hand that byte array off to a background thread to write it to disk, upload it to some server, or whatever else you planned to do with the picture.

Note that one thing you cannot readily do with the picture is hand it to another activity. There is a 1MB limit on the size of an Intent used with startActivity(), and usually the JPEG will be bigger than that. Hence, you cannot readily pass the picture via an Intent extra to another activity. If at all possible, use fragments or something else to keep all your relevant bits of UI together in a single activity, rather than try to get the images from activity to activity.

android.hardware.camera2

First, you should attach an ImageReader.OnImageAvailableListener instance to your ImageReader, using setOnImageAvailableListener(). ImageReader.OnImageAvailableListener is an interface; you will be called with onImageAvailable() when a new image is delivered to the ImageReader. We will come back to that onImageAvailable() method after quite a bit of additional coding.

Next, given the CaptureRequest.Builder you created when you set up the previews,
you need to adjust the builder to lock the auto-focus (assuming that auto-focus is enabled):

```java
b.set(CaptureRequest.CONTROL_AF_TRIGGER,
      CameraMetadata.CONTROL_AF_TRIGGER_START);
```

At that point, you can build() a fresh CaptureRequest and call setRepeatingRequest() on the CameraCaptureSession, to change the previews to switch to a locked focus:

```java
captureSession.setRepeatingRequest(b.build(),
                                   new RequestCaptureTransaction(),
                                   handler);
```

Here, RequestCaptureTransaction is a subclass of CameraCaptureSession.CaptureCallback, so you can be notified of how the auto-focus locking is proceeding. You wind up having to implement a fairly convoluted state machine to eventually find out it is time to take a picture… or possibly to ask for a “precapture trigger” to start on the auto-exposure system:

```java
private class RequestCaptureTransaction extends CameraCaptureSession.CaptureCallback {
    private final Session s;
    boolean isWaitingForFocus=true;
    boolean isWaitingForPrecapture=false;
    boolean haveWeStartedCapture=false;

    RequestCaptureTransaction(CameraSession session) {
        this.s=(Session)session;
    }

    @Override
    public void onCaptureProgressed(CameraCaptureSession session,
                                        CaptureRequest request, CaptureResult partialResult) {
        capture(partialResult);
    }

    @Override
    public void onCaptureFailed(CameraCaptureSession session, CaptureRequest request,
                                   CaptureFailure failure) {
        // TODO: raise event
    }

    @Override
    public void onCaptureCompleted(CameraCaptureSession session, CaptureRequest
request, TotalCaptureResult result) {
    capture(result);
}

private void capture(CaptureResult result) {
    if (isWaitingForFocus) {
        isWaitingForFocus=false;
        int autoFocusState=result.get(CaptureResult.CONTROL_AF_STATE);
        if (CaptureResult.CONTROL_AF_STATE_FOCUSED_LOCKED == autoFocusState ||
            CaptureResult.CONTROL_AF_STATE_NOT_FOCUSED_LOCKED == autoFocusState) {
            Integer state=result.get(CaptureResult.CONTROL_AF_STATE);
            if (state == null ||
                state == CaptureResult.CONTROL_AF_STATE_CONVERGED) {
                isWaitingForPrecapture=false;
                haveWeStartedCapture=true;
                capture(s);
            } else {
                isWaitingForPrecapture=true;
                precapture();
            }
        }
    } else if (isWaitingForPrecapture) {
        Integer state=result.get(CaptureResult.CONTROL_AF_STATE);
        if (state == null ||
            state == CaptureResult.CONTROL_AF_STATE_PRECAPTURE ||
            state == CaptureRequest.CONTROL_AF_STATE_FLASH_REQUIRED) {
            isWaitingForPrecapture=false;
        }
    } else if (!haveWeStartedCapture) {
        Integer state=result.get(CaptureResult.CONTROL_AF_STATE);
        if (state == null ||
            state != CaptureResult.CONTROL_AF_STATE_PRECAPTURE) {
            haveWeStartedCapture=true;
            capture();
        }
    }
}

private void precapture() {
    try {

    }

}
The author of this book wishes he understood what all this stuff is for.

But, eventually, it will be time to take the picture, represented by the `capture()` method in the above code dump. Here, we create a new `CaptureRequest.Builder`, this time using `TEMPLATE_STILL_CAPTURE` to indicate that we are trying to take a picture. We set up our target (via `addTarget()`) to be the `Surface` from the `ImageReader`. We re-establish our desired auto-focus and auto-exposure modes. Then, we stop the previews, by calling `stopRepeating()` on the `CameraCaptureSession`, undoing the prior `setRepeatingRequest()` call where we asked for previews. Then, we call `capture()` on the `CameraCaptureSession`, requesting a single-frame capture rather than a repeating request. This, like `setRepeatingRequest()`, takes our `CaptureRequest` from the `Builder`, a `CameraCaptureSession.CaptureCallback` to find out the results of the capture work, and our `Handler`.

```java
private void capture() {
  try {
    CaptureRequest.Builder captureBuilder =
        cameraDevice.createCaptureRequest(CameraDevice.TEMPLATE_STILL_CAPTURE);

    captureBuilder.addTarget(reader.getSurface());
    captureBuilder.set(CaptureRequest.CONTROL_AF_MODE,
                       CaptureRequest.CONTROL_AF_MODE_CONTINUOUS_PICTURE);
    captureBuilder.set(CaptureRequest.CONTROL_AE_MODE,
                       CaptureRequest.CONTROL_AE_MODE_ON_AUTO_FLASH);

    captureSession.stopRepeating();
    captureSession.capture(captureBuilder.build(),
                           new CapturePictureTransaction(), null);
  } catch (Exception e) {
    // do something
  }
}
```
WORKING DIRECTLY WITH THE CAMERA

The primary job of this CameraCaptureSession.CaptureCallback is to restart the previews, in onCaptureCompleted(). First, we use the preview edition of the CaptureRequest.Builder to undo some of the changes made during the camera capture process. Then, given the original preview CaptureRequest, we call setRepeatingRequest() again, to get the previews showing once more:

```java
@Override
public void onCaptureCompleted(CameraCaptureSession session, CaptureRequest request, TotalCaptureResult result) {
    try {
        b.set(CaptureRequest.CONTROL_AF_TRIGGER,
                CameraMetadata.CONTROL_AF_TRIGGER_CANCEL);
        b.set(CaptureRequest.CONTROL_AE_MODE,
                CaptureRequest.CONTROL_AE_MODE_ON_AUTO_FLASH);
        s.captureSession.capture(b.build(), null, handler);
        s.captureSession.setRepeatingRequest(previewRequest, null, handler);
    }
    catch (CameraAccessException e) {
        // do something
    }
    catch (IllegalStateException e) {
        // do something
    }
}
```

As part of all of this work, your onImageAvailable() method on your ImageReader.OnImageAvailableListener will be called when the picture is ready. The recipe for getting your JPEG image looks like this:

```java
@override
public void onImageAvailable(ImageReader imageReader) {
    Image image=imageReader.acquireNextImage();
    ByteBuffer buffer=image.getPlanes()[0].getBuffer();
    byte[] bytes=new byte[buffer.remaining()];
    buffer.get(bytes);
    image.close();
    // do something with the byte[] of JPEG data
}
```

Here, you are subject to the same sorts of limitations as were described in the section on taking pictures with the original camera API. Notably, that byte array may be large, too large to put into an Intent extra and pass to another activity.
Recoding a Video

Traditional Android video recording is handled via MediaRecorder. This means that we need to hand control over the camera from the regular camera API that we are using to MediaRecorder, record the video, and then return control back to the camera API (e.g., for previews).

MediaRecorder itself then has its own API for configuring the recorder, starting the recording, and stopping the recording.

android.hardware.Camera

To retain the camera access for your app, but allow MediaRecorder to take over the camera, call stopPreview(), then unlock(), on the Camera object:

```java
camera.stopPreview();
camera.unlock();
```

When the recording is complete, you reverse the process, by calling reconnect() and startPreview():

```java
camera.reconnect();
camera.startPreview();
```

In between the unlock() and reconnect() calls is when you use the MediaRecorder API.

android.hardware.camera2

This particular combination (video recording with the Android 5.0+ camera API) will be covered in a future edition of this chapter.

Using MediaRecorder

Creating a MediaRecorder instance is simple enough: just use the zero-argument constructor.

You then need to tell it what camera to use. With the original camera API, that is a matter of calling setCamera() on the MediaRecorder, passing in your Camera object.
Next, call `setAudioSource()` and `setVideoSource()` to indicate where the audio and video to be recorded are coming from. The typical value to use for the audio source is `CAMCORDER`. For the original camera API, you will need to use `CAMERA` as the video source:

```java
recorder.setAudioSource(MediaRecorder.AudioSource.CAMCORDER);
recorder.setVideoSource(MediaRecorder.VideoSource.CAMERA);
```

Next, you need to configure how the video should be recorded, in terms of things like resolution. The typical approach using the original camera API is to use `setProfile()`, passing in a CamcorderProfile to the `MediaRecorder`. You can find out what profiles are supported by calling methods like `hasProfile()` on `CamcorderProfile`. There are some fairly generic profiles, like `QUALITY_HIGH` and `QUALITY_LOW`, and some fairly specific profiles, like `QUALITY_2160P` for 2K video. Not all devices will support all profiles, based on Android version and camera driver capabilities. So, you will need to be responsive to varying cameras and gracefully degrade from the profile you want to a profile that you can get. For example, the following code snippet tries `QUALITY_HIGH`, falls back to `QUALITY_LOW` if `QUALITY_HIGH` is not available, and bails out if neither of those profiles exist:

```java
boolean canGoHigh = CamcorderProfile.hasProfile(cameraId, CamcorderProfile.QUALITY_HIGH);
boolean canGoLow = CamcorderProfile.hasProfile(cameraId, CamcorderProfile.QUALITY_LOW);

if (canGoHigh) {
    recorder.setProfile(CamcorderProfile.get(cameraId, CamcorderProfile.QUALITY_HIGH));
} else if (canGoLow) {
    recorder.setProfile(CamcorderProfile.get(cameraId, CamcorderProfile.QUALITY_LOW));
} else {
    throw new IllegalStateException(
        "cannot find valid CamcorderProfile";
    )
}
```

Here, `cameraId` is the int identifying your open camera.

Then, you can configure:
**WORKING DIRECTLY WITH THE CAMERA**

- the file path to which the resulting video should be written
- the maximum file size you want, after which recording will automatically stop (optional)
- the maximum duration that you want, after which recording will automatically stop (optional)
- a hint for what orientation the video should be recorded in (optional)

```java
recorder.setOutputFile(new File(getExternalFilesDir(null), FILENAME).getAbsolutePath());
recorder.setMaxFileSize(5000000); // ~5MB max
recorder.setMaxDuration(10000); // ~10 seconds max
recorder.setOrientationHint(90); // rotate output 90 degrees
```

Optionally, you can call `setInfoListener()` and `setErrorListener()`, supplying objects that will be invoked when certain events occur. Notably, if you use `setMaxFileSize()` or `setMaxDuration()`, the `OnInfoListener` object will be notified when recording automatically stops due to reaching one of those limits.

You then call `prepare()`, followed by `start()`, and your video recording will commence:

```java
recorder.prepare();
recorder.start();
```

When it comes time to stop the recording manually (e.g., user taps a “stop” button), just call `stop()`, then `release()`, on the `MediaRecorder`.

### Configuring the Still Camera

In general, when using the camera classes in Android, you get reasonable defaults for things like focus mode and flash mode. However, what might be reasonable defaults may not be what the user wants in any given circumstance. Other bits of configuration, like zoom, cannot really be defaulted (other than to “no zoom”).

For these, you will need to provide some sort of UI to allow the user to request settings, then apply them as part of your camera implementation. Here, we will focus on applying the configuration.

(and, yes, that was a pun)
**Focus Mode**

Frequently, a user will want simple autofocus behavior, where the camera attempts to focus on the content centered within the preview. However, in some situations, the user may want autofocus to be disabled, turning the camera into a fixed-focus camera. And there are some specialty focus modes that may be available to you as well, depending upon device and camera API.

Here is how you can set up the camera to use one of those focus modes, for each of the camera APIs.

**android.hardware.Camera**

The `Camera.Parameters` object has a `getSupportedFocusModes()` method. This returns a `List` of `String` objects, where each value corresponds to a focus mode that is available on this camera (front-facing, rear-facing) on this device. The possible strings are defined as constants on `Camera.Parameters`:

- `FOCUS_MODE_AUTO`
- `FOCUS_MODE_CONTINUOUS_PICTURE`
- `FOCUS_MODE_CONTINUOUS_VIDEO`
- `FOCUS_MODE_EDOF` ("extended depth of field")
- `FOCUS_MODE_FIXED`
- `FOCUS_MODE_INFINITY`
- `FOCUS_MODE_MACRO`

In truth, few devices support all of these. However, every device will support at least one; `getSupportedFocusModes()` is guaranteed to not return `null` and not return an empty `List`.

To choose a focus mode, call `setFocusMode()` on the `Camera.Parameters`, supplying the string of the desired mode. And, of course, you will eventually need to call `setParameters()` on the `Camera`, supplying your modified `Camera.Parameters`.

**android.hardware.camera2**

Similarly, you can get a list of supported auto-focus modes by calling `get(CameraCharacteristics.CONTROL_AF_AVAILABLE_MODES)` on a `CameraCharacteristics` object tied to your chosen camera. This returns an array of `int` values, instead of a `List` of strings. The possible values are defined as constants.
on CameraMetadata:

- CONTROL_AF_MODE_AUTO
- CONTROL_AF_MODE_CONTINUOUS_PICTURE
- CONTROL_AF_MODE_CONTINUOUS_VIDEO
- CONTROL_AF_MODE_EDOF ("extended depth of field")
- CONTROL_AF_MODE_MACRO
- CONTROL_AF_MODE_OFF

After the user chooses a value, you will need to call
set(CaptureRequest.CONTROL_AF_MODE, ...) on your CaptureRequest.Builder, where ... is the int of the desired focus mode. Note that you will need to do this both for the CaptureRequest.Builder for preview frames and for the CaptureRequest.Builder used when you take an actual picture. If the user is changing this value while you are already showing the preview, you will need to update the preview behavior, by calling build() on the Builder to create the CameraRequest, then calling setRepeatingRequest() to override your previous CameraRequest with the new one with the new focus mode. As a result, you tend to want to hang onto your CameraRequest.Builder for previews, so you can make these sorts of incremental changes in behavior, without having to create a fresh Builder from scratch with all of the desired settings.

**Flash Mode**

Typically, users want flash when they need flash, due to insufficient ambient lighting. However, once again, they may want specific flash modes instead (definitely flash, definitely not flash, etc.).

As with focus modes, you can ask the camera APIs what flash modes are available for a given camera. In this case, though, there is no guarantee of any flash mode configurability, since not all cameras have flash (and Android considers “off” and “flash does not exist” to be different things). And, once the user has chosen a flash mode, you can configure the camera APIs to use that particular mode.
